R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	-	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
20	CNRAM	0	R	finish interrupt observation Image Recognition Hierarchy (CNRAM)
19 to 16	-	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
15	DSP1	0	R	finish interrupt observation Image Recognition Hierarchy (DSP1)
14	DSP0	0	R	finish interrupt observation Image Recognition Hierarchy (DSP0)
13 to 4	-	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
3	CNN	0	R	finish interrupt observation Image Recognition Hierarchy (IMP CNN)
2 to 0	-	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.

(30) Power-On Self Test Clock Frequency Control Register (POSTCKCR)

POSTCKCR is a 32-bit readable/writable register. This register controls the Power-On Self Test clock (POSTφ).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	CKSTP	-	-	DIV[5:0]					
Initial value:	0	0	0	0	0	0	0	~MD25	0	0	0	0	1	0	1	1
R/W:	R	R	R	R	R	R	R	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	-	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
8	CKSTP	~MD25	R/W	Clock Stop 0: Supplies POSTφ clock 1: Stops POSTφ clock
7 to 6	-	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
5 to 0	DIV[5:0]	00 1011	R/W	Division Ratio These bits set the frequency division ratio of POSTφ clock. 00 1011 : 66.66MHz Others : Setting prohibited

This register is not used for Runtime Test.

(31) Power-On Self Test 2 Clock Frequency Control Register (POST2CKCR)

POST2CKCR is a 32-bit readable/writable register. This register controls the Power-On Self Test clock (POST2φ).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	CKSTP	-	-	DIV[5:0]					
Initial value:	0	0	0	0	0	0	0	~MD25	0	0	0	0	0	1	0	1
R/W:	R	R	R	R	R	R	R	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	-	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
8	CKSTP	~MD25	R/W	Clock Stop 0: Supplies POST2φ clock 1: Stops POST2φ clock
7 to 6	-	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
5 to 0	DIV[5:0]	00 0101	R/W	Division Ratio These bits set the frequency division ratio of POST2φ clock. 00 0101 : 133.33MHz Others : Setting prohibited

This register is for the Cortex-A76 Hierarchy.
This register is also used for Runtime Test.

(32) Power-On Self Test 4 Clock Frequency Control Register (POST4CKCR)

POST4CKCR is a 32-bit readable/writable register. This register controls the Power-On Self Test clock (POST4φ).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	CKSTP	-	-	DIV[5:0]					
Initial value:	0	0	0	0	0	0	0	~MD25	0	0	0	0	1	0	1	1
R/W:	R	R	R	R	R	R	R	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	-	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
8	CKSTP	~MD25	R/W	Clock Stop 0: Supplies POST4φ clock 1: Stops POST4φ clock
7 to 6	-	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
5 to 0	DIV[5:0]	00 1011	R/W	Division Ratio These bits set the frequency division ratio of POST4φ clock. 00 0101 : 133.33MHz 00 1011 : 66.66MHz Others : Setting prohibited

This register is for the Vision IP hierarchy.
This register is also used for Runtime Test.

171.2.2.2 Runtime Test for AP-System Core

(A) Overview

To do Runtime Test for AP-System Core, using APMU and AP-System Core is necessary.

(B) Related Registers

To do Runtime Test for AP-System Core, the following registers of APMU have to be used. For more details of each register, refer to Section 10.

Table 171.10 Register Configuration of Runtime Test for AP-System Core

Register Name	Abbreviation
Power Control Register for Cluster 0	PWRCTRLCL0
Safety Control Register for Cluster 0	SAFECTRLCL0
Power Control Register for Core z	PWRCTRLCz
Safety Control Register for Core z	SAFECTRLCz

z=[0-3]

(C) Hardware Description

When Cortex-A76 CPU core's Runtime Test is done, a power mode of Cortex-A76 CPU core goes to Pseudo OFF mode from ON mode. At that time, L1/L2 cache in Cortex-A76 CPU core is flushed automatically. So, program code for cache flush operation is not necessary. In other words, cache flush operation cannot be skipped.

When Cortex-A76 CPU cluster's Runtime Test is done, a power mode of Cortex-A76 CPU cluster goes to Pseudo OFF mode or MEM_RET mode. These two power modes can be selected by user before Runtime Test is started. If a power mode of Cortex-A76 CPU cluster goes to Pseudo OFF mode, L3 cache in Cortex-A76 CPU cluster is flushed automatically. If a power mode of Cortex-A76 CPU cluster goes to MEM_RET mode, L3 cache in Cortex-A76 CPU cluster is preserved.

171.2.2.3 Self-Check for Field-BIST

Figure 171.3 shows the Self-Check section of Field-BIST judgement circuit.
The judgement circuit compares SISR and expected SISR value and notifies error.

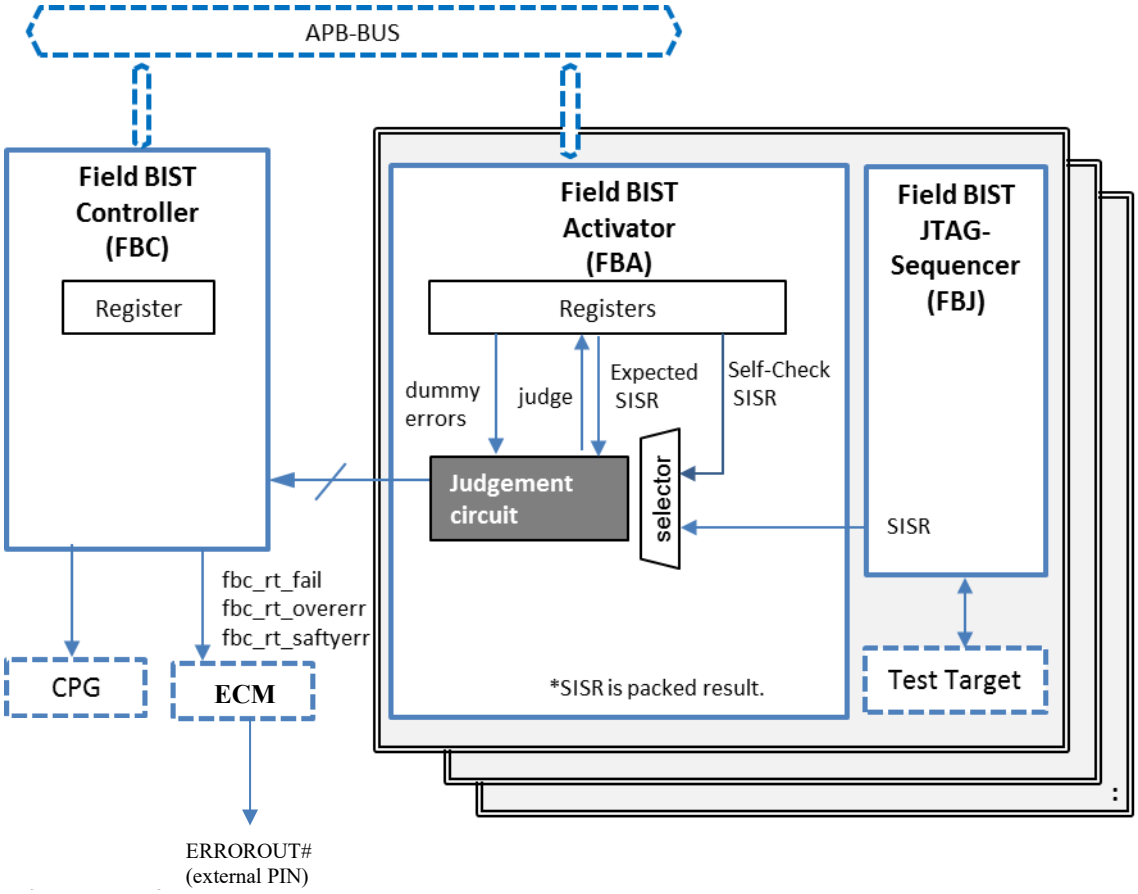

Figure 171.3 Overview of Field-BIST judgement circuit

Field BIST Self-Check Handling Process.

(1) Write an arbitrary value to SISR1 bit of RTTSISR1 register and decide Expected SISR.
(2) Write the inverted bit in REVERS bits of SLFRVS register to determine the Self-Check SISR value.
Self-Check SISR is an exclusive OR of SISR1 bits and REVERS bits.
In case REVERS bits is ALL 0, it is Pass expectation.
In cases where REVERS bits is other than ALL 0, it is Fail expectation.
(3) Self-check is executed when SLFE bit of RTTEX register writes B'1 and KCD bits writes H'F1.
(4) When STS bits of SLFRST register is B'11, the value of STR bit is valid for Self-Check result.
In the case where the SLFR bit of RTTEX register is B'1, SCNT bits returns to H'1.
In the case where the SLFR bit of RTTEX register is B'0, SCNT bits is counted up.
In the case where Self-Check is Fail, an error interrupt of fbc_rt_fail is asserted.
(5) Write ALL 0 to RTTEX register and end Self-Check.
De-assert error interrupt of fbc_rt_fail.

171.2.2.4 Error injection

Confirm the fault of the error interrupt for FieldBIST.

Field BIST Error injection Handling Process.

(1) Error injection is executed by writing 1B'1 to each bit of ERRSET register.
In the case where DSF bit is B'1, fbc_rt_fail of error interrupt is asserted.
In the case where DST is B'1, fbc_rt_overerr of error interrupt is asserted.
In the case where DSB is B'1, fbc_rt_safetyerr of error interrupt is asserted.

(2) Write ALL 0 to ERRSET and finish Error injection.
De-assert each error interrupt.

200. Electrical Characteristics

200.1 Absolute Maximum Ratings

Table 200.1 Absolute Maximum Ratings

Item	Value	Unit	Remarks
Power supply voltage (3.3 V) (VDDQ33, VDDQ18_33_SDHI, VDDQ18_33_I2C, VDDQ18_33_SPI)	-0.3 to +3.84	V	
Power supply voltage (2.5 V) (VDDQ18_25_AVB <for AVB pins>)	-0.3 to +2.9	V	
Power supply voltage (1.8 V) (VDDQ18, VDDQ18_PCIEn (n = 0), VDDQ18_CSIn (n=0,1), VDDQ18_DSIn (n=0,1) VDDQ18_25_AVB <for AVB pins>, VDDQ18_33_SDHI, VDDQ18_33_I2C, VDDQ18_33_SPI, VDD18_OCO, VDD18_OTP, VDD18_TRNG, VDD18_CPGPLLn (n=1 to 7))	-0.3 to +2.34	V	
Power supply voltage (0.6V) (VDDQVA_DDRn (n=0,1))	-0.3 to +0.96	V	LPDDR4X
Power supply voltage (1.1 V) (VDDQX_DDRn (n=0,1))	-0.3 to +1.32	V	LPDDR4X
Power supply voltage (0.5V) (VDDQVA_DDRn (n=0,1))	-0.3 to +0.96	V	LPDDR5
Power supply voltage (1.05 V) (VDDQX_DDRn (n=0,1))	-0.3 to +1.32	V	LPDDR5
Power supply voltage (0.75 V) (VDD VDD_PCIEn (n=0), VDD_CSIn (n=0,1), VDD_DSIn (n=0,1), VDD_DSIPLLn (n=0,1), VDD_DDRPLLn (n=01))	-0.3 to +1.05	V	
Input voltage (3.3-V I/O)	-0.3 to VDDQ33 + 0.3	V	
Input voltage (3.3-V I/O [SDHI])	-0.3 to VDDQ18_33_SDHI + 0.3	V	
Input voltage (3.3-V I/O [I2C])	-0.3 to VDDQ18_33_I2C + 0.3	V	
Input voltage (3.3-V I/O [SPI])	-0.3 to VDDQ18_33_SPI + 0.3	V	
Input voltage (2.5-V I/O [ETH]<AVB>)	-0.3 to VDDQ18_25_AVB + 0.3	V	
Input voltage (1.8-V I/O) [SDHI])	-0.3 to VDDQ18_33_SDHI + 0.3	V	
Input voltage (1.8-V I/O) [I2C])	-0.3 to VDDQ18_33_I2C + 0.3	V	
Input voltage (1.8-V I/O) [SPI])	-0.3 to VDDQ18_33_SPI + 0.3	V	
Input voltage (1.8-V I/O)	-0.3 to VDDQ18 + 0.3	V	

Item	Value	Unit	Remarks
Input voltage (1.8-V I/O [PCIEn (n = 0)])	-0.4 to VDDQ18_PCIEn + 0.3 (n = 0)	V	
Input voltage (1.2-V I/O [CSIn (n=0,1)])	-0.15 to 1.45 (n = 0,1)	V	
Input voltage (1.2-V I/O [DSI n (n=0,1)])	-0.15 to 1.45 (n = 0,1)	V	
Input voltage (0.6-V I/O [VDDQVA_DDRn (n=0,1)])	-0.3 to VDDQVA_DDRn + 0.3 (n=0,1)	V	LPDDR4X
Input voltage (1.1-V I/O [VDDQX_DDRn (n=0,1)])	-0.3 to 1.32	V	LPDDR4X
Input voltage (0.5-V I/O [VDDQVA_DDRn (n=0,1)])	-0.3 to VDDQVA_DDRn + 0.3 (n=0,1)	V	LPDDR5
Input voltage (1.05-V I/O [VDDQX_DDRn (n=0,1)])	-0.3 to 1.32	V	LPDDR5
Output voltage (3.3-V I/O)	-0.3 to VDDQ33 + 0.3	V	
Output voltage (3.3-V I/O [SDHI])	-0.3 to VDDQ18_33_SDHI + 0.3	V	
Output voltage (3.3-V I/O [I2C])	-0.3 to VDDQ18_33_I2C + 0.3	V	
Output voltage (3.3-V I/O [SPI])	-0.3 to VDDQ18_33_SPI + 0.3	V	
Output voltage (2.5-V I/O [ETH]<AVB>)	-0.3 to VDDQ18_25_AVB + 0.3	V	
Output voltage (1.8-V I/O) [SDHI])	-0.3 to VDDQ18_33_SDHI + 0.3	V	
Output voltage (1.8-V I/O) [I2C])	-0.3 to VDDQ18_33_I2C + 0.3	V	
Output voltage (1.8-V I/O) [SPI])	-0.3 to VDDQ18_33_SPI + 0.3	V	
Output voltage (1.8-V I/O)	-0.3 to VDDQ18 + 0.3	V	
Output voltage (1.8-V I/O [PCIEn (n = 0)])	-0.3 to VDDQ18_PCIEn + 0.3 (n = 0)	V	
Output voltage (1.2-V I/O [DSIn (n = 0 to 1)])	-0.15 to 1.45 (n = 0 to 1)	V	
Output voltage (0.6-V I/O [VDDQVA_DDRn (n=0,1)])	-0.3 to VDDQVA_DDRn + 0.3 (n=0,1)	V	LPDDR4X
Output voltage (1.1-V I/O [VDDQX_DDRn (n=0,1)])	-0.3 to 1.32	V	LPDDR4X
Output voltage (0.5-V I/O [VDDQVA_DDRn (n=0,1)])	-0.3 to VDDQVA_DDRn + 0.3 (n=0,1)	V	LPDDR5
Output voltage (1.05-V I/O [VDDQX_DDRn (n=0,1)])	-0.3 to 1.32	V	LPDDR5
Operating temperature	-40 to +125	°C	Tj (junction)
Storage temperature	-55 to +125	°C	Ta (ambient)

Notes: Permanent damage to the LSI may result if absolute maximum ratings are exceeded. In normal operation, this LSI shall be used within the specifications described in the following descriptions. If this LSI is not used within the specifications, the reliability of this LSI may lower.

Voltages are referenced at GND = VSS = AVSS = 0 V.

200.2 Power Supply

Table 200.2 Power Supply

Item	Symbol	Voltage			Unit	Remarks
		Min.	Typ.	Max.		
Power supply (DC+AC)	VDD_AVS0	0.710	0.765	0.825	V	From the power estimation, the lowest limit of the supply voltage at the SOC ball terminal is narrowed regarding the IR drop.
	VDD_AVS1	0.700	0.755	0.815		
	VDD_AVS2	0.675	0.730	0.790		
Power supply (DC)	VDD_dc_AVS0	0.740	0.765	0.795	V	Based on the power estimation, this product requires Feedback control using the PMIC remote sense signal. This is the recommended DC setting value for PMIC. Long-term reliability is guaranteed at the maximum voltage of VDD_dc_AVS0 (0.795V).
	VDD_dc_AVS1	0.730	0.755	0.785		
	VDD_dc_AVS2	0.705	0.730	0.760		
Power supply (AC)	VDD_ac	-0.03	—	0.03	V	The AC fluctuation due to the load fluctuation.
Power supply (3.3-V I/O)	VDDQ33	3.1	3.3	3.5	V	VDDQ33 for power supply and VSS for ground
Power supply (2.5-V I/O [ETH]<AVB>)	VDDQ18_25_AVB	2.4	2.5	2.6	V	VDDQ18_25_AVB for power supply and VSS for ground
Power supply (1.8-V I/O [ETH]<AVB>)	VDDQ18_25_AVB	1.7	1.8	1.9	V	VDDQ18_25_AVB for power supply and VSS for ground
Power supply (1.8-V I/O [SDHI])	VDDQ18_33_SDHI	1.7	1.8	1.9	V	VDDQ18_33_SDHI for power supply and VSS for ground
Power supply (3.3-V I/O [SDHI])	VDDQ18_33_SDHI	3.1	3.3	3.5	V	VDDQ18_33_SDHI for power supply and VSS for ground
Power supply (1.8-V I/O [I2C])	VDDQ18_33_I2C	1.7	1.8	1.9	V	VDDQ18_33_I2C for power supply and VSS for ground
Power supply (3.3-V I/O [I2C])	VDDQ18_33_I2C	3.1	3.3	3.5	V	VDDQ18_33_I2C for power supply and VSS for ground
Power supply (1.8-V I/O [SPI])	VDDQ18_33_SPI	1.7	1.8	1.9	V	VDDQ18_33_SPI for power supply and VSS for ground
Power supply (3.3-V I/O [SPI])	VDDQ18_33_SPI	3.1	3.3	3.5	V	VDDQ18_33_SPI for power supply and VSS for ground
Power supply (1.8-V I/O [OCO])	VDD18_OCO	1.7	1.8	1.9	V	VDD18_OCO for power supply and VSS for ground
Power supply (1.8-V I/O [OTP])	VDD18_OTP	1.7	1.8	1.9	V	VDD18_OTP for power supply and VSS for ground
Power supply (1.8-V I/O [TRNG])	VDD18_TRNG	1.7	1.8	1.9	V	VDD18_TRNG for power supply and VSS for ground
Power supply (1.8-V I/O [CPGPLL])	VDD18_CPGPLLn (n=1 to 7)	1.7	1.8	1.9	V	VDD18_CPGPLLn (n=1 to 7) for power supply and VSS for ground
Power supply (1.8-V I/O [VDDQ18])	VDDQ18	1.7	1.8	1.9	V	VDDQ18 for power supply and VSS for ground
Power supply (1.8-V I/O [PCIE])	VDDQ18_PCIEn (n = 0)	1.7	1.8	1.9	V	VDDQ18_PCIEn (n = 0) for power supply and VSS for ground

Item	Symbol	Voltage			Unit	Remarks
		Min.	Typ.	Max.		
Power supply (1.2-V I/O [CSI])	VDDQ18_CSIn (n = 0 to 1)	1.7	1.8	1.9	V	VDDQ18_CSI n (n = 0 to 1) for power supply and VSS for ground
Power supply (1.2-V I/O [DSI])	VDDQ18_DSIn (n = 0 to 1)	1.7	1.8	1.9	V	VDDQ18_DSI n (n = 0 to 1) for power supply and VSS for ground

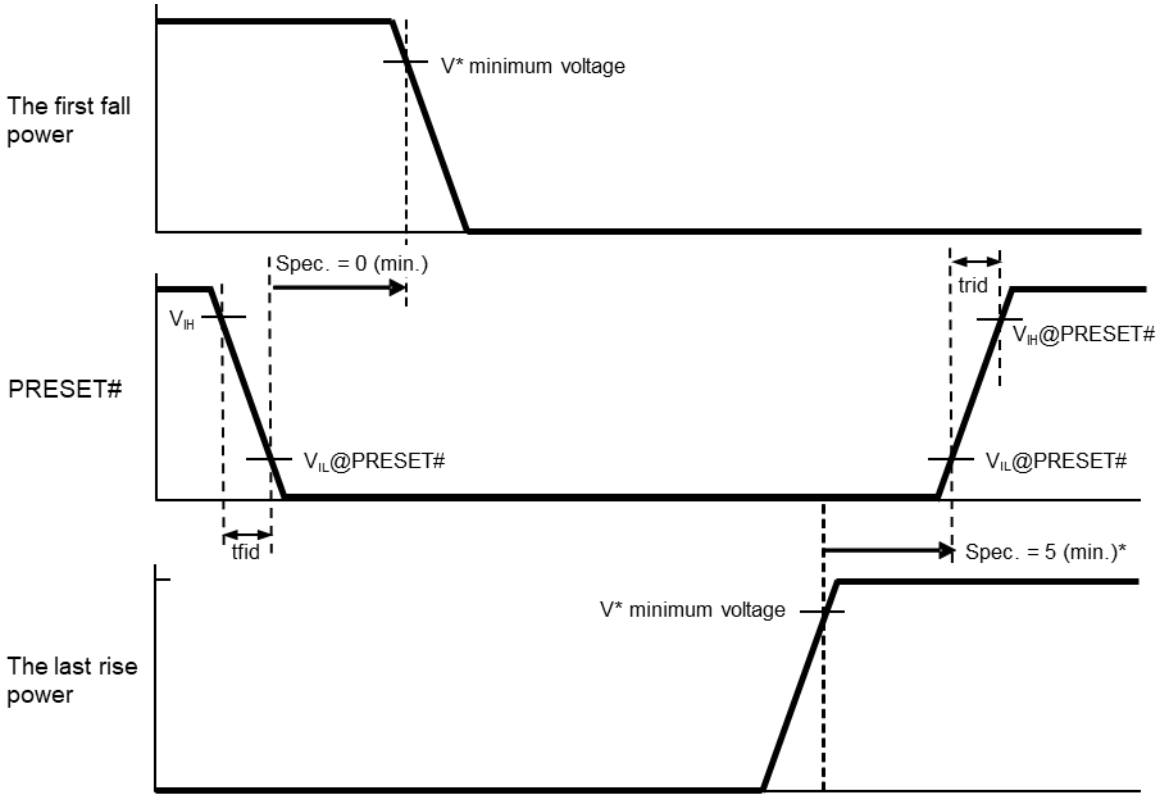
Power supply (0.75-V I/O [DSIPLL])	VDD_DSIPLLn (n=0,1)	*1	*1	*1	V	VDD_DSIPLLn (n=0,1) for power supply and VSS for ground
Power supply (0.75-V I/O [DDRPLL])	VDD_DDRPLL01	*1	*1	*1	V	VDD_DDRPLL01 for power supply and VSS for ground

Notes:*1...Refer to VDD_dc_AVSn(n=0 to 2)

200.3 Sequence of Turning On/Off Power Supplies

(1) PRESET# VS. Power

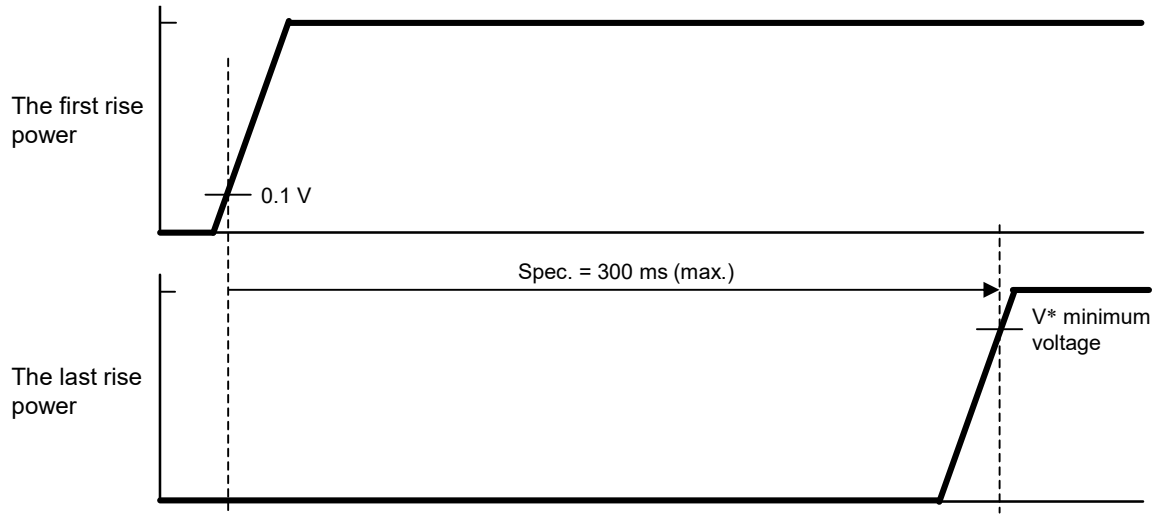


*PRESET# negate timing is defined by "tOSC + T". For details, see chapter 200.6.1 Clock and Reset Timings

Table 200.3 PRESET# Input Timing

Item	Symbol	Min.	Typ.	Max.	Unit	Remarks
PRESET# Input fall time	tfid	—	—	4	us	—
PRESET# Input rise time	trid	—	—	4	us	—

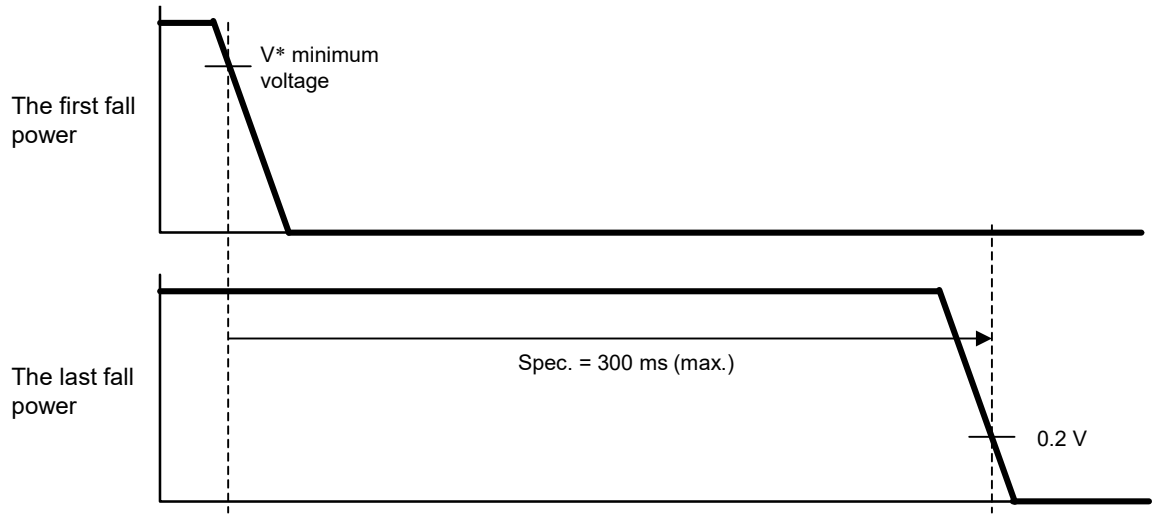
(2) Period for Power Rise



For all V*, power off state must be 0 V (GND), power rising must be started from 0 V, and end to 0 V respectively. (excluding DDR-SDRAM power-supply backup state)
Period from 0 V to 0.1V at power-on and from 0.2 V to 0 V at power-off should be shorten as much as possible.

*) Please also refer to the Power-on/off sequence of DDR-SDRAM datasheet.

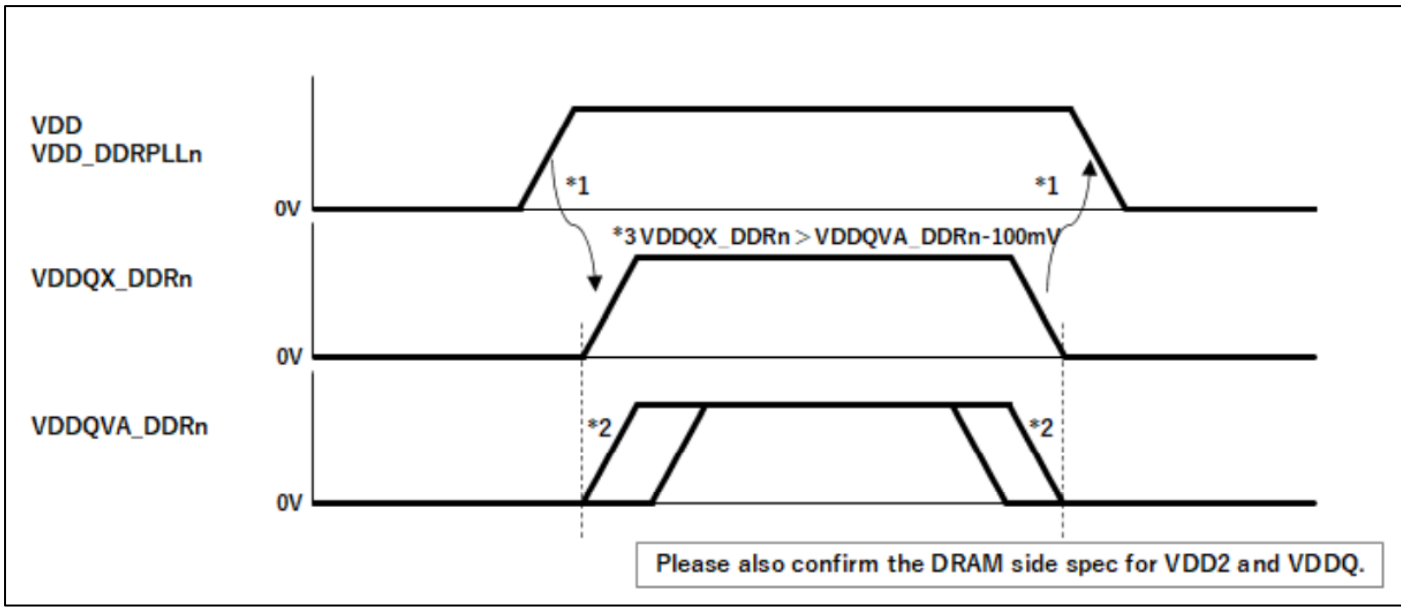
(3) Period for Power Fall



For all V*, power off state must be 0 V (GND), power rising must be started from 0 V, and end to 0 V respectively. (excluding DDR-SDRAM power-supply backup state)
Period from 0 V to 0.1V at power-on and from 0.2 V to 0 V at power-off should be shorten as much as possible.

*) Please also refer to the Power-on/off sequence of DDR-SDRAM datasheet.

(4) VDD and VDD_DDRPLLn vs VDDQX_DDRn vs VDDQVA_DDRn (n=0,1)



*1:VDD power-on must be earlier than VDDQX_DDRn, and VDD power-off must be later than VDDQX_DDRn. (n=0,1)
*2:VDDQX_DDRn power-on must be earlier than VDDQVA_DDRn, and VDDQX_DDRn power-off must be later than VDDQVA_DDRn. (n=0,1)
*3:VDDQX_DDRn must be greater than VDDQVA_DDRn-100mV. (n=0,1)

200.4 Output Voltage Characteristics

(1) V/xDrive strength Table

Table 200.4 Drive strength and setting register(3.3V IO, 2.5/1.8V IO, 3.3/1.8V IO)

Drive Strength	Drive Capacitance	Resister bit		
		DRV3	DRV2	DRV1
2	2/8	0	0	1
3	3/8	0	1	0
4	4/8	0	1	1
5	5/8	1	0	0
6	6/8	1	0	1
7	7/8	1	1	0
8	8/8	1	1	1

(2) V/xDrive strength Table

Table 200.5 Drive strength and setting register(1.8V IO)

Drive Strength	Drive Capacitance	Resister bit	
		DRV2	DRV1
1	1/4	0	0
2	2/4	0	1
3	3/4	1	0
4	4/4	1	1

Conditions: **See 200.7.1 AC Characteristic Measurement Condition**

200.5 DC Characteristics

200.5.1 Supply Current

Table 200.6 Supply Current

Item		Symbol	Power Min.	Typ.	Max.	Unit	Remarks
Supply current (Internal)		IDD	—	—	23520	mA	VDD = VDD_dc(Max)

Item	Symbol	Min.	Typ.	Max.	Unit	Measurement conditions	Remarks
Input high voltage	VIH	0.65*VDDQ18_33_SPI	—	VDDQ18_33_SPI + 0.3	V	VDDQ18_33_SPI = 1.7 V to 1.9 V, VSS = 0 V	—
Input low voltage	VIL	VSS - 0.3	—	0.35*VDDQ18_33_SPI	V	VDDQ18_33_SPI = 1.7 V to 1.9 V, VSS = 0 V	—
Output high voltage	VOH	VDDQ18_33_SPI - 0.45	—	—	V	VDDQ18_33_SPI = 1.7 V to 1.9 V, VSS = 0 V	IOH = -2 mA
Output low voltage	VOL	—	—	0.45	V	VDDQ18_33_SPI = 1.7 V to 1.9 V, VSS = 0 V	IOL = 2 mA
Pin capacitance	CL	—	—	10	pF	VDDQ18_33_SPI = 1.7 V to 1.9 V, VSS = 0 V	—
Input leakage current	ILI	—	—	10	µA	VDDQ18_33_SPI = 1.7 V to 1.9 V, VSS = 0 V Without pull-up or pull-down resistor	—
Output leakage current	ILO	—	—	10	µA	VDDQ18_33_SPI = 1.7 V to 1.9 V, VSS = 0 V Without pull-up or pull-down resistor	Hi-Z output

Table 200.18 Output leakage current by V/xDrive strength (1.8-V I/O [SPI])

Symbol	Min	Typ	Max	Unit	Measurement condition	Remarks
IOL/IOH	7.2	—	—	mA	VDDQ18_33_SPI = 1.7V to 1.9V, VSS = 0V without pull-up or pull-down, VOL = 0.45V VOH = VDDQ18_33_SPI – 0.45V	V/xDrive = 2/8
	12.2	—	—	mA		V/xDrive = 3/8
	13.1	—	—	mA		V/xDrive = 4/8
	14.7	—	—	mA		V/xDrive = 5/8
	15.3	—	—	mA		V/xDrive = 6/8
	17.0	—	—	mA		V/xDrive = 7/8
	18.1	—	—	mA		V/xDrive = 8/8

200.5.8 DC Characteristics (1.8-V I/O)

Table 200.19 DC Characteristics (1.8-V I/O)

Item	Symbol	Min.	Typ.	Max.	Unit	Measurement conditions	Remarks
Schmitt input high voltage	VT+	—	—	0.7*VDDQ18	V	VDDQ18 = 1.7 V to 1.9 V, VSS = 0 V	PRESET#, BSMODE, NMI pins
Schmitt input low voltage	VT-	0.3*VDDQ18	—	—	V		
Hysteresis voltage	ΔVT	0.1*VDDQ18	—	—	V		
Input high voltage	VIH	0.8*VDDQ18	—	VDDQ18 + 0.3	V		EXTAL pins Case of MD9=0 (Inputs an external clock to the EXTAL pin)
Input low voltage	VIL	-0.3	—	0.2*VDDQ18	V		
Input high voltage	VIH	0.7*VDDQ18	—	VDDQ18 + 0.3	V		
Input low voltage	VIL	-0.3	—	0.3*VDDQ18	V		Other pins
Output high voltage (1.8-V HyperFlash)	VOH	0.7*VDDQ18	—	VDDQ18 + 0.3	V		IOH = -3.1mA RPC* pins, QSPI* pins
Output low voltage (1.8-V HyperFlash)	VOL	-0.3	—	0.45	V		IOL = 3.1mA RPC* pins, QSPI* pins
Output high voltage (Other pins)	VOH	0.7*VDDQ18	—	VDDQ18 + 0.3	V		IOH = -4mA
Output low voltage (Other pins)	VOL	-0.3	—	0.45	V		IOL = 4mA
Pin capacitance	CL	—	—	10	pF		
Input leakage current	ILI	—	—	10	μA	VDDQ18 = 1.7 V to 1.9 V, VSS = 0 V Without pull-up or pull-down resistor	All input pins
Output leakage current	ILO	—	—	10	μA	VDDQ18 = 1.7 V to 1.9 V, VSS = 0 V Without pull-up or pull-down resistor	Hi-Z output
Pull-up current	IPU	-20	—	-65	μA	VI = 0V With pull-up resistor (50 kohm(Typ.))	
		10	—	33	μA	VI = VDDQ18 (1.7 to 1.9 V) With pull-down resistor (100 kohm(Typ.))	PRESET# pin
Pull-down current	IPD	20	—	65	μA	VI = VDDQ18 (1.7 to 1.9 V) With pull-down resistor (50 kohm(Typ.))	Other pins

Table 200.20 Output leakage current by V/xDrive strength (1.8-V I/O)

Symbol	Min	Typ	Max	Unit	Measurement condition	Remarks
IOL/IOH	4.0	—	—	mA	VDDQ18 = 1.7V to 1.9V, VSS = 0V without pull-up or pull-down, VOL = 0.45V VOH = VDDQ18 – 0.45V	V/xDrive = 1/4
	6.6	—	—	mA		V/xDrive = 2/4
	9.1	—	—	mA		V/xDrive = 3/4
	11.5	—	—	mA		V/xDrive = 4/4

Table 200.21 Output leakage current by V/xDrive strength (1.8-V I/O [HyperFlash])

Symbol	Min	Typ	Max	Unit	Measurement condition	Remarks
IOL/IOH	3.1	—	—	mA	VDDQ18 = 1.7V to 1.9V, VSS = 0V without pull-up or pull-down, VOL = 0.45V VOH = VDDQ18 – 0.45V	V/xDrive = 1/4
	4.5	—	—	mA		V/xDrive = 2/4
	5.5	—	—	mA		V/xDrive = 3/4
	6.2	—	—	mA		V/xDrive = 4/4

200.5.9 DC Characteristics (I2C open-drain 1.8-V I/O, 3.3-V I/O)

Table 200.22 DC Characteristics (I2C open-drain 1.8-V I/O, 3.3-V I/O)

Item	Symbol	Min.	Typ.	Max.	Unit	Measurement conditions	Remarks
External pull-up voltage	VPU18	1.7	1.8	1.9	V	VDDQ18_33_I2C = 1.7 to 1.9 V	
Input high voltage	VIH	VPU18 × 0.7	—	VPU18 + 0.3	V	VDDQ18_33_I2C = 1.7 to 1.9 V	
Input low voltage	VIL	-0.3	—	VPU18 × 0.3	V	VDDQ18_33_I2C = 1.7 to 1.9 V	
Output low voltage	VOL	—	—	VPU18 × 0.2	V	VDDQ18_33_I2C = 1.7 to 1.9 V	IOL= 2mA
Output low current	IOL	3	—	—	mA	VDDQ18_33_I2C = 1.7 to 1.9 V	VOL= 0.4V
External pull-up voltage	VPU33	3.1	3.3	3.5	V	VDDQ18_33_I2C = 3.1 to 3.5 V	
Input high voltage	VIH	VPU33 × 0.625	—	VPU33 + 0.3	V	VDDQ18_33_I2C = 3.1 to 3.5 V	
Input low voltage	VIL	-0.3	—	VPU33 × 0.25	V	VDDQ18_33_I2C = 3.1 to 3.5 V	
Output low voltage	VOL	—	—	0.4	V	VDDQ18_33_I2C = 3.1 to 3.5 V	IOL= 3mA
Output low current	IOL	3	—	—	mA	VDDQ18_33_I2C = 3.1 to 3.5 V	VOL= 0.4V

200.5.10 DC Characteristics (PCIe)

Table 200.23 DC Characteristics (PCIe)

Test Item	Symbol	Min.	Typ.	Max.	Unit	Remarks
DC Differential TX Impedance	ZTX-DIFF-DC	—	—	120	Ω	—
DC Input Impedance (2.5 & 5 GT/s)	ZRX-DC	40	—	60	Ω	—
DC Input Impedance (8 & 16 GT/s)	ZRX-DC	—	—	—	Ω	Not specified

200.5.11 DC Characteristics (1.8-V I/O [ETH]<AVB>)

Table 200.24 DC Characteristics (1.8-V I/O [ETH]<AVB>)

Item	Symbol	Min.	Typ.	Max.	Unit	Measurement conditions	Remarks
Input high voltage	VIH	VDDQ18_25_AVB - 0.45	—	VDDQ18_25_AVB + 0.3	V	VDDQ18_25_AVB = 1.7 V to 1.9 V, VSS = 0 V	—
Input low voltage	VIL	VSS - 0.3	—	0.58	V	VDDQ18_25_AVB = 1.7 V to 1.9 V, VSS = 0 V	—
Output high voltage	VOH	1.4	—	—	V	VDDQ18_25_AVB = 1.7 V to 1.9 V, VSS = 0 V	IOH = -2 mA
Output low voltage	VOL	—	—	0.45	V	VDDQ18_25_AVB = 1.7 V to 1.9 V, VSS = 0 V	IOL = 2 mA
Pin capacitance	CL	—	—	10	pF	VDDQ18_25_AVB = 1.7 V to 1.9 V, VSS = 0 V	—

Pin capacitance	CL	—	—	10	pF	—	All pins
Input leakage current	ILI	—	—	1	µA	VDDQ_VIN01, VDDQ = 3.0 to 3.6 V	All input pins
Output leakage current	ILO	—	—	1	µA	Without pull-up or pull-down resistor	Hi-Z output

200.5.14 DC Characteristics (1.2-V I/O [CSI2])

Table 200.29 DC Characteristics (1.2-V I/O [CSI2])

The description in this section is compliant with the following MIPI standard: 'MIPI D-PHY specification Version 1.2'.

Item	Symbol	Min.	Typ.	Max.	Unit	Measurement condition	Remarks
Input signal voltage range	V_{PIN}	-50	—	1350	mV		
Input leakage current	I_{LEAK}	-10	—	10	uA	$V_{GNDSH(min)} \leq V_{PIN} \leq V_{GNDSH(max)} + V_{PIN(absmax)}$ Lane module in LP receive mode	
Ground shift	V_{GNDSH}	-50	—	50	mV		
Transient pin voltage level	$V_{PIN(absmax)}$	-0.15	—	1.45	V		
Input common mode voltage	$V_{CMRX(DC)}$	70	—	330	mV		HS Receiver
Differential input high threshold	V_{IDTH}	—	—	40	mV		HS Receiver
Differential input low threshold	V_{IDTL}	-40	—	—	mV		HS Receiver
Single-ended input high voltage	V_{IHHS}	—	—	460	mV		HS Receiver
Single-ended input low voltage	V_{ILHS}	-40	—	—	mV		HS Receiver
Differential input impedance	Z_{ID}	80	—	125	Ω		HS Receiver
Input low voltage	V_{IL}	—	—	550	mV		LP Receiver
Input high voltage	V_{IH}	740	—	—	mV		LP Receiver
Input hysteresis	V_{HYST}	25	—	—	mV		LP Receiver

200.5.15 DC Characteristics (1.2-V I/O [DSI])

Table 200.30 DC Characteristics (1.2-V I/O [DSI])

The description in this section is compliant with the following MIPI standard: 'MIPI D-PHY specification Version 1.2'.

Item	Symbol	Min.	Typ.	Max.	Unit	Measurement condition	Remarks
Input signal voltage range	V_{PIN}	-50	—	1350	mV		
Input leakage current	I_{LEAK}	-10	—	10	uA	$V_{GNDSH(min)} \leq V_{PIN} \leq V_{GNDSH(max)} + V_{PIN(absmax)}$ Lane module in LP receive mode	
Ground shift	V_{GNDSH}	-50	—	50	mV		
transient pin voltage level	$V_{PIN(absmax)}$	-0.15	—	1.45	V		
Maximum transient time above $V_{PIN(max)}$ or below $V_{PIN(min)}$	$T_{VPIN(absmax)}$	—	—	20	ns		
HS transmit common-mode voltage	V_{CMTX}	150		250	mV	80 Ω ≤ RL ≤ 125 Ω	HS Transmitter
HS Transmit differential voltage	$\|V_{OD}\|$	140		270	mV	80 Ω ≤ RL ≤ 125 Ω	HS Transmitter
HS output high voltage	V_{OHHS}			360	mV	80 Ω ≤ RL ≤ 125 Ω	HS Transmitter
Single ended output impedance	Z_{OS}	40		62.5	Ω		HS Transmitter
Output high voltage	V_{OH}	0.95	—	1.3	V		LP Transmitter
Output low voltage	V_{OL}	-50	—	50	mV		LP Transmitter
Output impedance	Z_{OLP}	110	—	—	Ω		LP Transmitter
Input low voltage	V_{IL}	—	—	550	mV		LP Receiver
Input high voltage	V_{IH}	740	—	—	mV		LP Receiver
Input hysteresis	V_{HYST}	25	—	—	mV		LP Receiver

200.5.16 Reserved

200.5.17 DC Characteristics (0.6-V I/O [LPDDR4X])

Table 200.31 DC Characteristics (0.6-V I/O [LPDDR4X])

Item	Symbol	Min.	Typ.	Max.	Unit	Measurement conditions	Remarks
Input high voltage (MDQ pin)	VIH	VREF + 0.06	—	—	V	VDDQVA_DDRn = 0.57 to 0.65 V (*1) VDDQX_DDRn = 1.06 to 1.17 V (*1)	MDQ, MDMI and MWCK pins
Input low voltage (MDQ pin)	VIL	—	—	VREF – 0.06	V	VREF= VDDQVA_DDRn*(1/4) (*1)	
Input high voltage	VIH	0.8 × VDDQVA_DDRn (*1)	—	—	V	VDDQVA_DDRn = 0.57 to 0.65 V (*1) VDDQX_DDRn = 1.06 to 1.17 V (*1)	MBKUP pin
Input low voltage	VIL	—	—	0.2 × VDDQVA_DDRn (*1)	V		
DC differential input high voltage	VIHD	0.09	—	—	V	MWCK = H, VDDQVA_DDRn = 0.57 to 0.65 V (*1) VDDQX_DDRn = 1.06 to 1.17 V (*1)	MWCK pins
DC differential input low voltage	VILD	—	—	-0.09	V	MWCK = L, VDDQVA_DDRn = 0.57 to 0.65 V (*1) VDDQX_DDRn = 1.06 to 1.17 V (*1)	
High Hi-Z leak current	IOZH	—	—	200	µA	VDDQVA_DDRn = 0.57 to 0.65 V (*1) VDDQX_DDRn = 1.06 to 1.17 V (*1)	All pins(*2)
Low Hi-Z leak current	IOZL	-200	—	—	µA		
Pin capacitance	CL	—	—	15	pF	—	All pins(*2)

Note: *1 : n = 0,1
*2 : Except power supply pins.

200.5.18 DC Characteristics (0.5-V I/O [LPDDR5])

Table 200.32 DC Characteristics (0.5-V I/O [LPDDR5])

Item	Symbol	Min.	Typ.	Max.	Unit	Measurement conditions	Remarks
Input high voltage (MDQ pin)	VIH	VREF + 0.05	—	—	V	VDDQVA_DDRn = 0.47 to 0.57 V (*1) VDDQX_DDRn = 1.01 to 1.12 V (*1)	MDQ, MDMI and MRDQS pins
Input low voltage (MDQ pin)	VIL	—	—	VREF – 0.05	V	VREF= VDDQVA_DDRn*(1/4) (*1)	
Input high voltage	VIH	0.8 × VDDQVA_DDRn (*1)	—	—	V	VDDQVA_DDRn = 0.47 to 0.57 V (*1) VDDQX_DDRn = 1.01 to 1.12 V (*1)	MBKUP pin
Input low voltage	VIL	—	—	0.2 × VDDQVA_DDRn (*1)	V		
DC differential input high voltage	VIHD	0.09	—	—	V	MRDQS = H, VDDQVA_DDRn = 0.47 to 0.57 V (*1) VDDQX_DDRn = 1.01 to 1.12 V (*1)	MRDQS pins
DC differential input low voltage	VILD	—	—	-0.09	V	MRDQS = L, VDDQVA_DDRn = 0.47 to 0.57 V (*1) VDDQX_DDRn = 1.01 to 1.12 V (*1)	
High Hi-Z leak current	IOZH	—	—	200	µA	VDDQVA_DDRn = 0.47 to 0.57 V (*1) VDDQX_DDRn = 1.01 to 1.12 V (*1)	All pins(*2)
Low Hi-Z leak current	IOZL	-200	—	—	µA		
Pin capacitance	CL	—	—	15	pF	—	All pins(*2)

Note: *1 : n = 0,1
*2 : Except power supply pins.

200.5.19 LPDDR4X Interface ODT Characteristics

Table 200.33 LPDDR4X Interface ODT Characteristics

Item	Symbol	Min.	Typ.	Max.	Unit	Measurement conditions	Remarks
ODT resistance (40 Ω)	RTT40	33.6	—	47.7	Ω	VDDQVA_DDRn = 0.57 to 0.65 V (n=0,1)	—

200.5.20 LPDDR5 Interface ODT Characteristics

Table 200.34 LPDDR5 Interface ODT Characteristics

Item	Symbol	Min.	Typ.	Max.	Unit	Measurement conditions	Remarks
ODT resistance (40 Ω)	RTT40	33.6	—	47.7	Ω	VDDQVA_DDRn = 0.47 to 0.57 V (n=0,1)	—

200.5.21 Overload Condition (Injection Current)

The overload condition describes the behavior in case of current injection to the port pins.

Table 200.35 Overload Current

Conditions: See 200.7.1 AC Characteristic Measurement Condition

Parameter	Item	Symbol	Condition	Ratings*1	Unit	Measurement conditions
Overload Current Vin > VDDQ Vin < VSS	Pins supplied by VDDQ33	IINJPM	1 pin	±2	mA	
		IINJNM	Sum of all absolute IINJPM + IINJNM of pins supplied as group *2	|50|	mA	24 signals
	Pins supplied by VDDQ18	IINJPM	1 pin	±2	mA	
		IINJNM	Sum of all absolute IINJPM + IINJNM of pins supplied as group *2	|50|	mA	36 signals
	Pins supplied by VDDQ18_CSI0 VDDQ18_CSI1	IINJPM	1 pin	±2	mA	
		IINJNM	Sum of all absolute IINJPM + IINJNM of pins supplied as group *2	|22|	mA	11 signals
	Pins supplied by VDDQ18_DSI0	IINJPM	1 pin	±2	mA	
		IINJNM	Sum of all absolute IINJPM + IINJNM of pins supplied as group *2	|22|	mA	11 signals
	Pins supplied by VDDQ18_25_AVB	IINJPM	1 pin	±2	mA	
		IINJNM	Sum of all absolute IINJPM + IINJNM of pins supplied as group *2	|50|	mA	63 signals
	Pins supplied by VDDQ18_33_I2C	IINJPM	1 pin	±2	mA	
		IINJNM	Sum of all absolute IINJPM + IINJNM of pins supplied as group *2	|28|	mA	14 signals
	Pins supplied by VDDQ18_33_SDHI	IINJPM	1 pin	±2	mA	
		IINJNM	Sum of all absolute IINJPM + IINJNM of pins supplied as group *2	|26|	mA	13 signals
	Pins supplied by VDDQ18_33_SPI	IINJPM	1 pin	±2	mA	
		IINJNM	Sum of all absolute IINJPM + IINJNM of pins supplied as group *2	|50|	mA	48 signals

Notes: 1. The Total current may be limited further by the total power dissipation.
2. The total overload current must be within the output current.
3. Observe the absolute maximum rated voltage
4. Do not inject during key-off

200.6 General Characteristics

200.6.1 Clock and Reset Timings

Table 200.36 Clock and Reset Timing

Conditions: **See 200.7.1 AC Characteristic Measurement Condition**

Pin	Item	Symbol	Min.	Max.	Unit	Figures
PRESET#, EXTAL	Power-on oscillation settling time (Period from power and EXTAL stable clock input to PRESET# rise.)	tOSC	5	—	ms	
		T	0*2	*3	ms	
TRST#, EXTAL	Power-on oscillation settling time (Period from power and EXTAL stable clock input to TRST#rise.)	tJTOSC	5	—	ms	
PRESET#	PRESET# input low level width	tWRSL	5	—	ms	
Mode signal*1	MD reset setup time	tMDRS	5	—	ms	
Mode signal*1	MD reset hold time	tMDRH	3	—	ns	
Mode signal*1	MD TRST# setup time	tMDJTRS	5	—	ms	

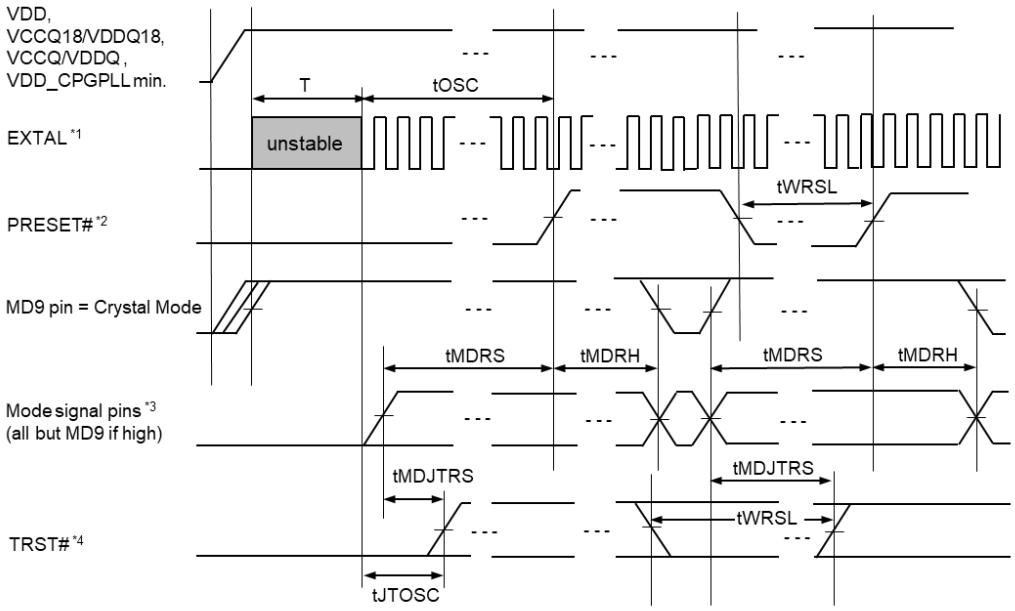
Notes: 1. MDn (n = 0, 1, 2 ...) and MDT [0]. For details of mode signals, refer to section 3.2, Mode Pin Settings.

2: Using 0 stabilization time requires an external clock. For mode setting refer to Table 3.8 MD9 Settings.

3: The oscillation stabilization time differs according to the matching with the external resonator circuit.

It is recommended to determine the oscillation stabilization time by a crystal resonator matching test.

For details of the stabilization time “T”, please contact the crystal manufacture.



Notes 1:
For EXTAL's waveform.
Since the unstable oscillation exists when using a crystal resonator, wait for T until clock is stabilized.
T depends on the circuit on the board.
2: For PRESET# input.
Note electromagnetic noise because that may cause malfunctions of the LSI.
Note an intermediate voltage level input because that may influence the long-term reliability of the LSI
3:
When TRST# is deasserted before PRESET# is deasserted, make sure that the mode signal value does not change during from TRST# deasserting to PRESET# deasserting.
4:
This restriction applies to the "TRST#" signal on both "MAIN JTAG" and "SUB JTAG".

Figure 200.1 Reset when Turning on Power Supply (PRESET# vs EXTAL and Mode signal)

200.6.2 EXTAL Clock Input Timing

Table 200.37 EXTAL Clock Input Timing

Conditions: **See 200.7.1 AC Characteristic Measurement Condition**

Item		Symbol	Min.	Typ.	Max.	Unit	Figure
EXTAL clock input frequency	MD[14:13] = LL	fEX	15.00	16.66	16.70	MHz	—
	MD[14:13] = LH		18.00	20.00	20.04	MHz	
	MD[14:13] = HH		30.00	33.33	33.40	MHz	
EXTAL clock input cycle time	MD[14:13] = LL	tEXcyc	59.88	60.00	66+2/3	ns	
	MD[14:13] = LH		49.90	50.00	55+5/9	ns	
	MD[14:13] = HH		29.94	30.00	33+1/3	ns	
EXTAL clock input Frequency Tolerance (MD9 = H)		—	-200	—	+200	ppm	
EXTAL clock input duty cycle time		tEXduty	0.4	0.5	0.6	tEXcyc	
EXTAL clock input low-level pulse width		tEXL	5	—	—	ns	
EXTAL clock input high-level pulse width		tEXH	5	—	—	ns	
EXTAL clock input rise time		tEXr	—	—	4	ns	
EXTAL clock input fall time		tEXf	—	—	4	ns	

Notes: 1. Set the MD9 pin to L (low) during power-on reset when using the EXTAL pin as external clock input and the XTAL pin must be open.
2. See Section 8.1.5 Clock Operating Modes to select an oscillator or resonator.

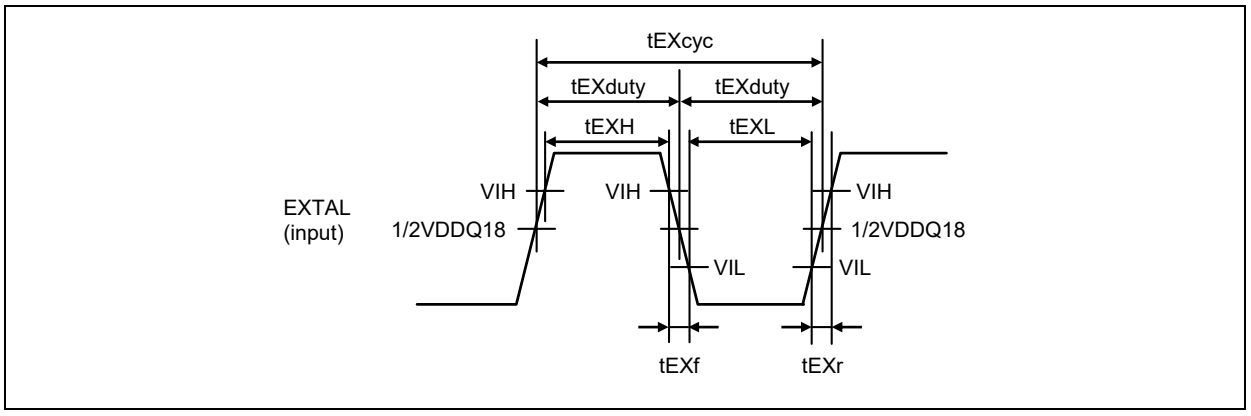


Figure 200.2 EXTAL Clock Input Timing

200.6.3 CLKOUT Clock Output Timing

Table 200.38 CLKOUT Clock Output Timing

Conditions: **See 200.7.1 AC Characteristic Measurement Condition**

Item	Symbol	Min.	Typ.	Max.	Unit	Figure
CLKOUT clock output frequency	fCKO	59.99	66.66	66.80	MHz	—
CLKOUT clock output cycle time	tCKOcyc	14.97	15.00	16.67	ns	
CLKOUT clock output duty cycle time	tCKOduty	0.4	0.5	0.6	tCKOcyc	
CLKOUT clock output low pulse width	tCKOL	4	—	—	ns	
CLKOUT clock output high pulse width	tCKOH	4	—	—	ns	
CLKOUT clock output rise time	tCKOr	—	—	4	ns	
CLKOUT clock output fall time	tCKOf	—	—	4	ns	

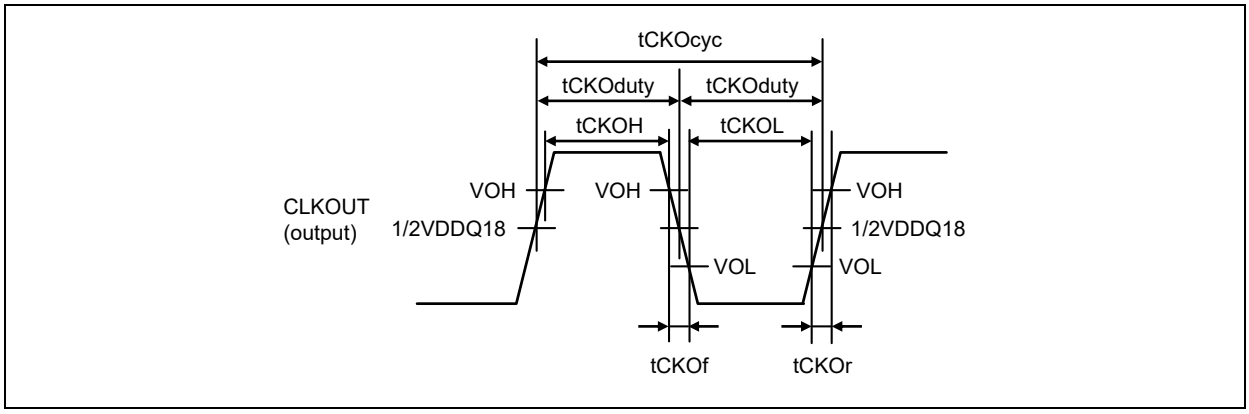

Figure 200.3 CLKOUT Clock Output Timing

200.6.4 EXTALR Input Timing

Conditions: **See 200.7.1 AC Characteristic Measurement Condition**

Table 200.39 EXTALR Characteristics

Item		Symbol	Min.	Typ.	Max.	Unit	Remarks
Input Frequency Range	MD29 = 0	—	32.5	32.768	33	kHz	
Input Frequency Tolerance		—	-200	—	+200	ppm	
EXTALR clock input rise time *2	MD29 = 0	—	—	—	1	µs	
EXTALR clock input fall time *2	MD29 = 0	—	—	—	1	µs	
OCO Frequency Deviation	MD29 = 1	—	29.5	32.786	36.06	kHz	
			-10	—	+10	%	

Notes: 1. No need to use EXTALR port when MD29 = 1
2. Input rise time and fall time to input clock pulse from crystal oscillator, which is to be applied between VIL and VIH at DC and AC.

200.6.5 THS/CIVM Characteristics

Conditions:

- **See 200.7.1 AC Characteristic Measurement Condition**.

Table 200.40 Thermal Sensor Characteristics*1*2*3*4

Item	Symbol	Condition	MIN	TYP	MAX	Unit
Temperature accuracy	ACCTS1	– 40 °C ≤ Tj ≤ + 125 °C	-3		3	°C
Temperature update period	tTSUP		—	—	1	ms
THS Operation stabilization waiting time	tTSSB		—	—	1	ms
Chip internal voltage monitor accuracy	ACCCIV1		-60		60	mV
Chip internal voltage update period	tCIVUP		—	—	0.5	ms
CIVM Operation stabilization waiting time	tCIVSB		—	—	0.5	ms

Note 1. The temperature borders need to be set keeping the temperature range (Tj(min) to Tj(max)) including the thermal sensor accuracy.

Note 2. It does not include accuracy of measuring equipment.

Note 3. Thermal sensor cannot detect local heat generation inside the chip.

Note 4. Thermal sensor accuracy is guaranteed within operation temperature.

200.6.6 CVM Characteristics

Table 200.41 CVM Characteristics(1/2)

Item	Symbol	Power domain	MIN.	TYP.	MAX.	Unit
Core voltage high detection level	V_{VDDMDH}	VDD	VDD (Max.) – 0.025	—	VDD (Max.)	V
Core voltage low detection level	V_{VDDMDL}	VDD	VDD (Min.) *1	—	VDD (Min.) *1 + 0.025	V

Note 1. Voltage itself depends on supplied one based on AVS configuration.

Table 200.42 CVM Characteristics(2/2)

Item	Symbol	Setting of "CVM digital output filter function control"	MIN.	TYP.	MAX.	Unit
CVM error detection filtering time	$t_{FCVMOUT}$	VMFLTFC=B'00 *1	5	—	15	µs
		VMFLTFC=B'01 *1	2.4	—	10	µs
		VMFLTFC=B'10 *1	6.7	—	20	µs
CVM_OUT# minimum pulse width	$t_{WCVMOUT}$	—	0.5	—	—	µs
VTHSENSE0 output voltage transition time	t_{SENSE_RISE}	Rise: 0V → 0.8V	90	—	195	µs
	t_{SENSE_FALL}	Fall: 0.8V → 0V	170	—	285	µs
VTHREF0 output voltage transition time	t_{REF_RISE0}	Rise: 0V → 0.8V	90	—	195	µs
	t_{REF_FALL0}	Fall: 0.8V → 0V	170	—	285	µs
	t_{REF_RISE1}	Rise: 0.8V → 1.24V	80	—	190	µs
	t_{REF_FALL1}	Fall: 1.24V → 0.8V	625	—	1435	µs
VTHSENSE0 / VTHREF0 output voltage range	V_{RANGE_L}	Output: 0V	—	0.0	0.2	V
	V_{RANGE_M}	Output: 0.8V	0.7	0.8	0.9	V
	V_{RANGE_H}	Output: 1.24V	1.19	1.24	1.29	V
VTHSENSE0 connect capacitor	C1	*2	0.09	—	0.11	µF
VTHREF0 connect capacitor	C2	*2	0.09	—	0.11	µF

Note 1. See Section 13.2 for register descriptions

Note 2. See Section 13.1.3 for capacitors ("Figure 13.2 Connect capacitors to Analog Pin")

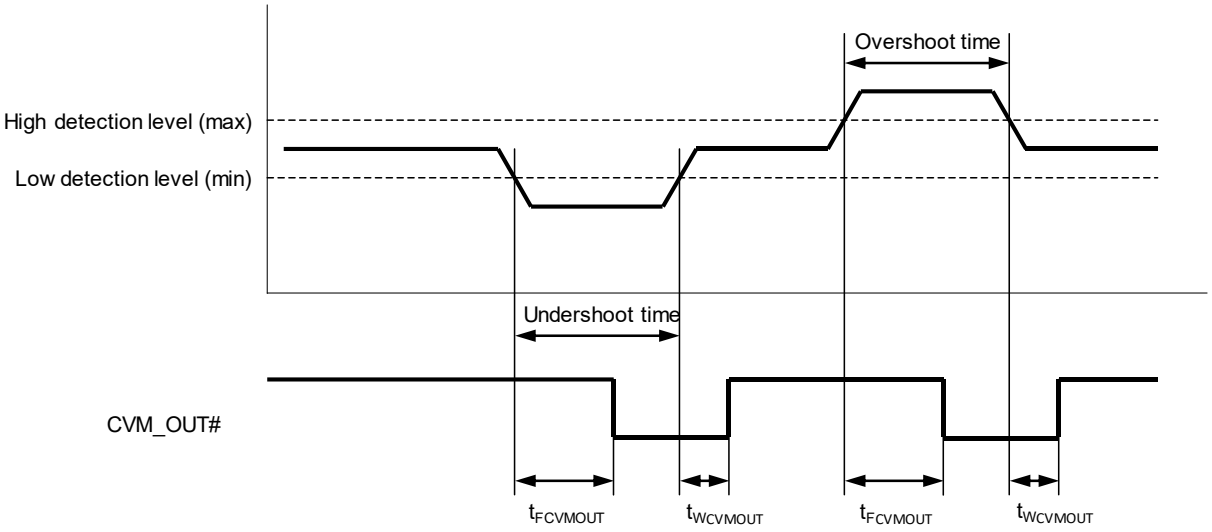

Figure 200.4 CVM Characteristics

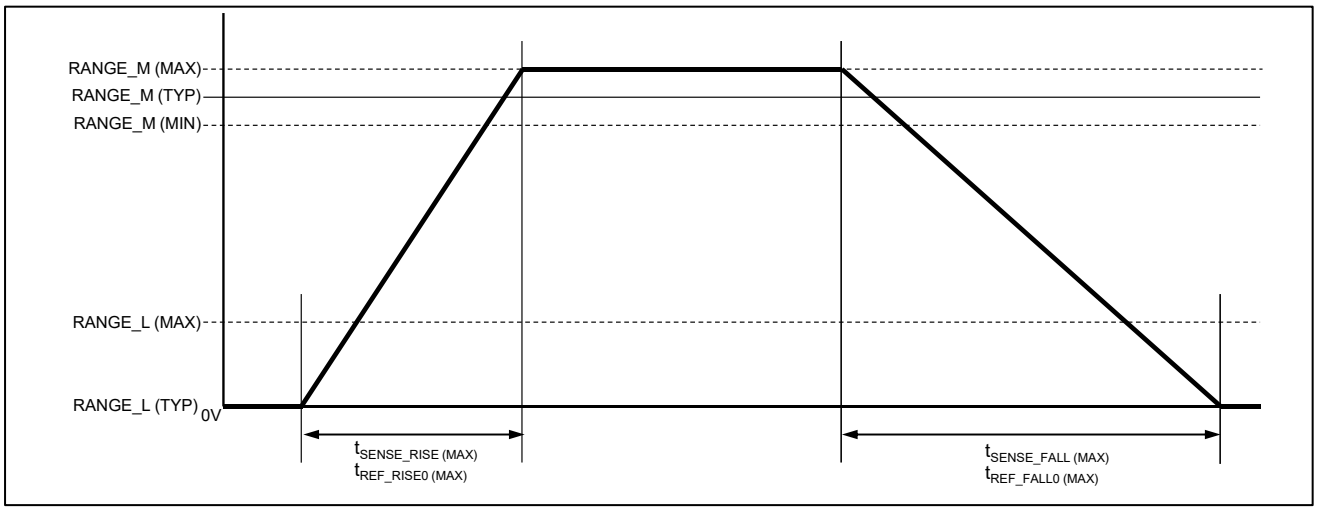

Figure 200.5 VTHSENSE0/VTHREF0 output voltage transition time (0V → 0.8V, 0.8V → 0V)

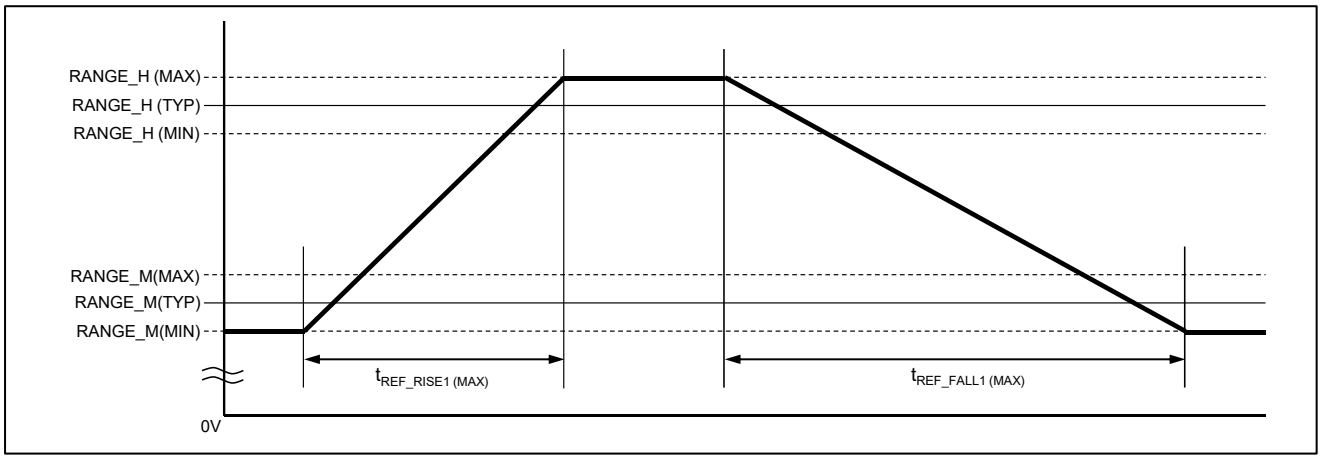

Figure 200.6 VTHREF0 output voltage transition time (0.8V → 1.24V, 1.24V → 0.8V)

200.6.7 PLL Characteristics

Conditions:

- **See 200.7.1 AC Characteristic Measurement Condition.**

Table 200.43 PLL Characteristics (PLL 1,2,3,4,5,6,7)

Item	Symbol	Condition		MIN	TYP	MAX	Unit
Long term jitter	—	SSMODE=000, or 001 *1	Term=1us	-300	—	+300	ps
			Term=10us	-500	—	+500	
			Term=20us	-500	—	+500	
		SSMODE=100 or 101 *1	Term=1us	-300	—	+300	
			Term=10us	-500	—	+500	
			Term=20us	-500	—	+500	

Note 1. See Section 8.1.5 Clock Operating Modes

200.7 AC Characteristics

200.7.1 AC Characteristic Measurement Condition

(1) General Conditions

Below conditions are valid for all subsequent timing specifications if not noted otherwise:

- See **200.2, Power Supply**.
- Drive capability = **7** (DRV3,DRV2,DRV1=110) for 1.8V/3.3V IO
- Drive capability = **7** (DRV3,DRV2,DRV1=110) for 1.8V/2.5V/ IO
- Drive capability = **7** (DRV3,DRV2,DRV1=110) for 3.3V/ IO
- Drive capability = **3** (DRV2,DRV1=10) for 1.8V IO
- CL = **30** pF
- Buffer type = CMOS

(2) General Input Measurement Points

If not stated otherwise, the below given AC timing specification is based on the measurements points as follows:VDD*_ include Refer to Power Supply
the measurement points of the timing chart for AC timing chapter are:
Dot mark indicates 0.5xVDD, bar or dotted line notation indicates 0.7xVDD/0.3xVDD.
As for functions that have individual standards about L/H thresholds,
See "Conditions" described in each function.

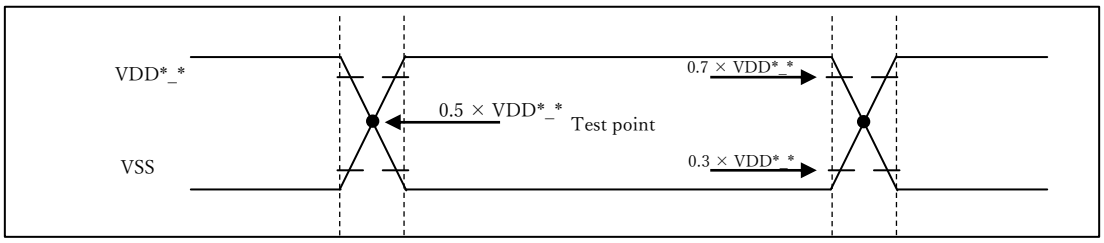

Figure 200.7 AC Input Measurement Points

(3) General Output Measurement Points

If not stated otherwise, the below given AC timing specification is based on the measurements points as follows: VDD*_ include Refer to Power Supply
the measurement points of the timing chart for AC timing chapter are:
Dot mark indicates 0.5xVDD, bar or dotted line notation indicates 0.7xVDD/0.3xVDD.

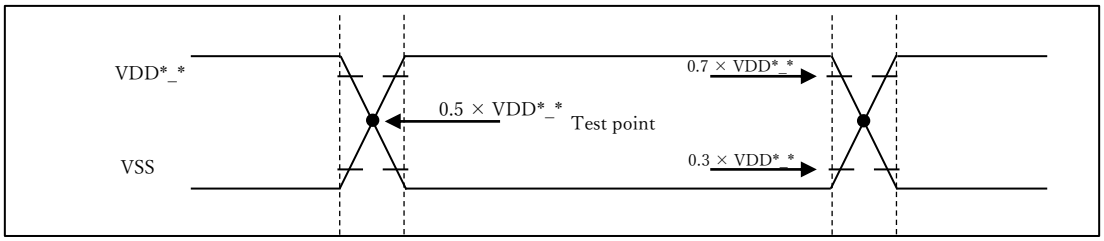

Figure 200.8 AC Output Measurement Points

(4) Load conditions

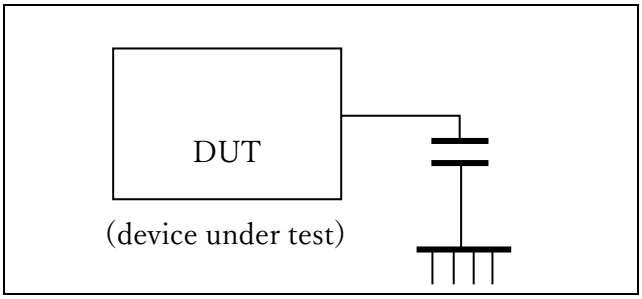

Figure 200.9 AC Load Conditions

(5) General output clock frequency and cycle time (period) minimum specification

If not stated otherwise, maximum and minimum value described as output clock frequency and cycle time (period) of each module means ideal value derived from setting described in section 8. Clock Pulse Generator(CPG) or module clock division settings.

To obtain detailed information, please refer to section 8. Clock Pulse Generator(CPG) or module clock division settings.

200.7.2 AC Characteristics (1.2-V I/O [CSI2])

Table 200.44 AC Characteristics (1.2-V I/O [CSI2])

Conditions: **See 200.7.1 AC Characteristic Measurement Condition**

The description in this section is compliant with the following MIPI standard: 'MIPI D-PHY specification Version 1.2'.

Item	Symbol	Min.	Typ.	Max.	Unit	Measurement condition	Remarks
Data to Clock Receiver Setup time	$T_{SETUP(RX)}$	0.15	—	—	UI	>= 0.08Gbps <= 1.0Gbps	HS Receiver
		0.20	—	—	UI	> 1.0Gbps <= 1.5Gbps	
Data to Clock Receiver Hold time	$T_{HOLD(RX)}$	0.15	—	—	UI	>= 0.08Gbps <= 1.0Gbps	HS Receiver
		0.20	—	—	UI	> 1.0Gbps <= 1.5Gbps	
Static Data to Clock Skew (RX)	$T_{SKEW[RX]}$ static	-0.20		0.20	UI	> 1.5Gbps	HS Receiver
Dynamic Data to Clock Skew Window RX Tolerance	$T_{SETUP[RX]}$ + $T_{HOLD[RX]}$ dynamic	0.50			UI	> 1.5Gbps	HS Receiver
Minimum pulse width response	T_{MIN-RX}	20	—	—	ns	—	LP Receiver

200.7.3 AC Characteristics (1.2-V I/O [DSI])

Table 200.45 AC Characteristics (1.2-V I/O [DSI])

Conditions: **See 200.7.1 AC Characteristic Measurement Condition**

The description in this section is compliant with the following MIPI standard: 'MIPI D-PHY specification Version 1.2'.

Item	Symbol	Min.	Typ.	Max.	Unit	Measurement condition	Remarks
Data to Clock Skew	$T_{SKEW[TX]}$	-0.15	—	0.15	UI	>= 0.08Gbps <= 1.0Gbps	HS Transmitter
		-0.20	—	0.20	UI	> 1.0Gbps <= 1.5Gbps	
Static Data to Clock Skew (TX)	$T_{SKEW[TX]}$ static	-0.20	—	0.20	UI	> 1.5Gbps	HS Transmitter
Dynamic Data to Clock Skew (TX)	$T_{SKEW[TX]}$ dynamic	-0.15	—	0.15	UI	> 1.5Gbps	HS Transmitter
Pulse width of the LP exclusive-OR clock	$T_{LP-PULSE-TX}$	40			ns		LP Transmitter
Period of the LP exclusive-OR clock	$T_{LP-PER-TX}$	90			ns		LP Transmitter
Minimum pulse width response	T_{MIN-RX}	20	—	—	ns	—	LP Receiver

200.7.4 SSI Interface

Table 200.46 SSI Interface Signal Timing

Conditions: **See 200.7.1 AC Characteristic Measurement Condition**

Item	Symbol	Min.	Typ.	Max.	Unit	Note	Figure
Output clock cycle	tO	80	—	15625	ns	—	Figure 200.10

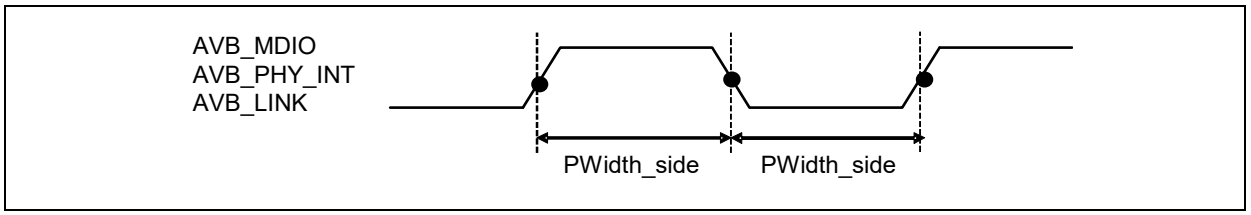

Figure 200.31 Sideband signals input Timing

Note: About AVB*_MDC, in case of connecting to a device that does not have a built-in pull resistor, should add pull register at external.

(10) RGMII signal AC Characteristic Measurement Condition

Below conditions are valid for RGMII output timing specifications:

- See **200.2, Power Supply**.
- Drive capability = **7** (DRV3,DRV2,DRV1=110) for 1.8V
- Drive capability = **8** (DRV3,DRV2,DRV1=111) for 2.5V

Load condition

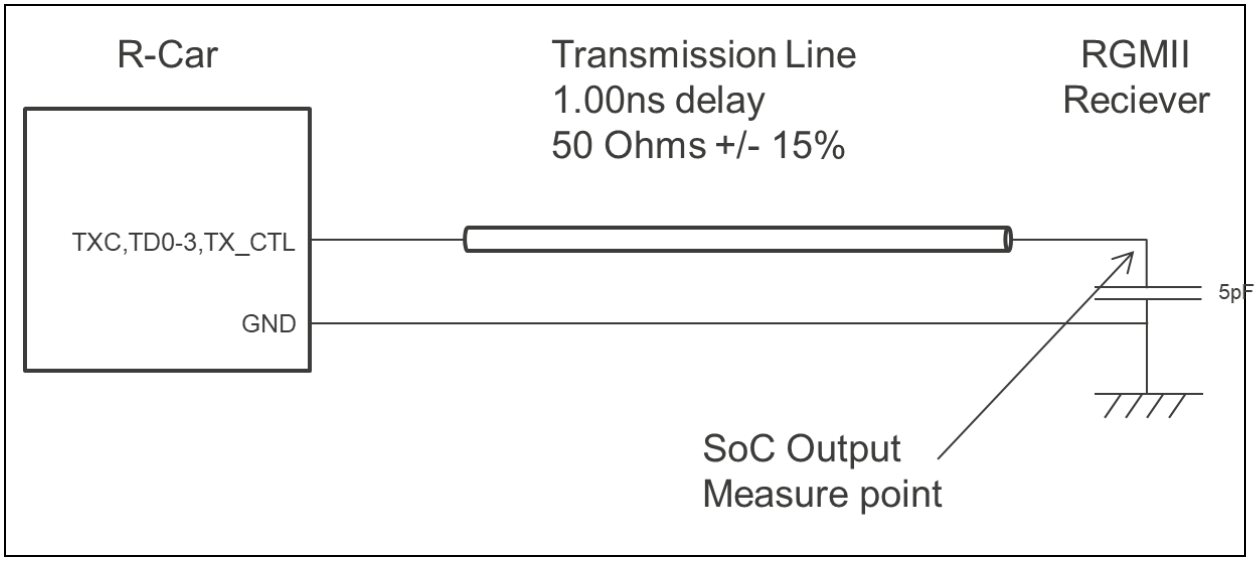

Figure 200.32 RGMII output signal AC Characteristic Measurement Condition

The AC timing of the RGMII interface is referenced to the point where the signal passes through half of the power supply voltage.

200.7.6 CAN, CAN-FD

200.7.7 PCIE Controller

The description in this section is compliant with the following PCIe standards:
PCI Express® Base Specification Revision 4.0, Version 1.0, September 27, 2017.
PCI Express® Card Electromechanical Specification, Revision 4.0, Version 1.0, August 7, 2019.

Table 200.57 PCIE Controller Characteristics

Test Item	Symbol	Min.	Typ.	Max.	Unit	Remarks
Differential Peak to Peak Output Voltage (2.5 & 5 GT/s)	VTX-DIFFp-p	0.800	—	1.200	V	*1
Differential Peak to Peak Output Voltage (8 & 16 GT/s)	VTX-DIFFp-p	0.800	—	1.300	V	*1
Unit Interval (2.5 GT/s)	UI	399.88	—	400.12	ps	*2
Unit Interval (5 GT/s)	UI	199.94	—	200.06	ps	*2
Unit Interval (8 GT/s)	UI	124.9625	—	125.0375	ps	*2
Unit Interval (16 GT/s)	UI	62.48125	—	62.51875	ps	*2
External reference clock frequency	—	-100ppm	100.000	+100ppm	MHz	—

Notes: 1. TXP, TXN: DC test
2. Need Reference Clock (Low Voltage Swing, Differential Clocks). The nominal single-ended swing for each clock is 0 to 0.7 V and a nominal frequency of 100 MHz ± 100 ppm.

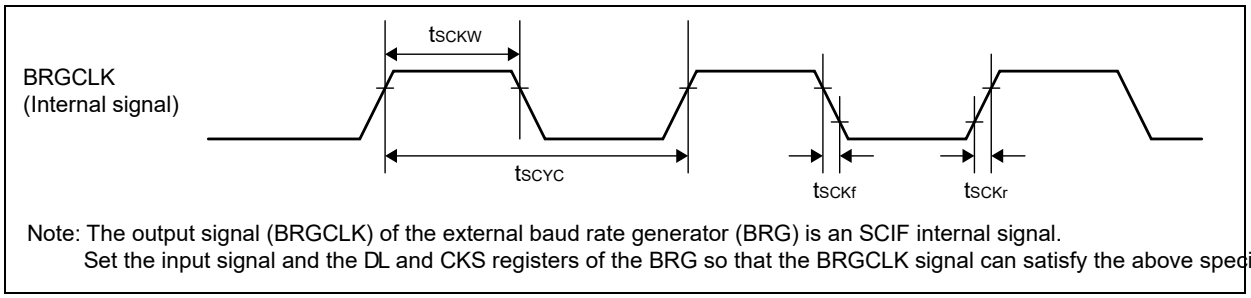
200.7.8 SCIF

Table 200.58 SCIF Signal Timing

Conditions: **See 200.7.1 AC Characteristic Measurement Condition**

Item	Symbol	Min.	Typ.	Max.	Unit	Figures
Input clock cycle (asynchronous)	tSCYC	4	—	—	tCYC	Figure 200.34
Input clock cycle (synchronous)	tSCYC	8	—	—	tCYC	
Input clock pulse width	tSCKW	0.4	—	0.6	tSCYC	
Input clock rise time	tSCKr	—	—	0.8	tCYC	
Input clock fall time	tSCKf	—	—	0.8	tCYC	
Transmit data delay time	tTXD	—	—	4	tCYC	Figure 200.35
Receive data setup time (synchronous)	tRXS	5	—	—	tCYC	
Receive data hold time (synchronous)	tRXH	2	—	—	tCYC	

Note: tCYC is for one cycle of the SASYNCPERD4ϕ clock.



Note: The output signal (BRGCLK) of the external baud rate generator (BRG) is an SCIF internal signal.
Set the input signal and the DL and CKS registers of the BRG so that the BRGCLK signal can satisfy the above specification

U10.1. E-FUSE

U10.1.1 Overview

The E-FUSE is a type of non-volatile memory fabricated in standard CMOS logic process. This E-FUSE macro is used for hardware macro trimming, recording Chip information, disabling certain features, etc. Data read from E-Fuse macro is latched in Buffer and output to other modules.

U10.1.2 Register description

The E-FUSE does not have a register.

U10.1.3 Operation

See U10.1.1 Overview.
The FUSE output value is automatically read from the E-FUSE macro and latched into buffer when the chip is powered on, and it is output from that buffer to each module using E- FUSE signal.

U10.1.4 Usage Notes

There is no attention of the usage.

U10.1.5 Safety Mechanisms

Note: The suitability of the safety mechanisms referenced in this manual will finally be judged during the safety analysis and safety assessment of the SoC. Therefore, the safety documentation shall always be considered as additional requirements for the system or software derived from the results of the safety analysis.

U10.1.5.1 FUSE Monitoring Register

U10.1.5.1.1 Overview

E-FUSE bits of enable/disable switch can be monitored by FUSE monitor register in OTP in order to detect mismatching to expected FUSE bit. FUSE monitor register shall be read by software periodically to confirm each bit condition.

U10.1.5.1.2 Hardware Description

The FUSE status, for which the signal is the same as that sent to other modules, can be read from the register in the OTP module.

Figure U10.1.1 shows the relations between the OTP, E-FUSE and other modules.

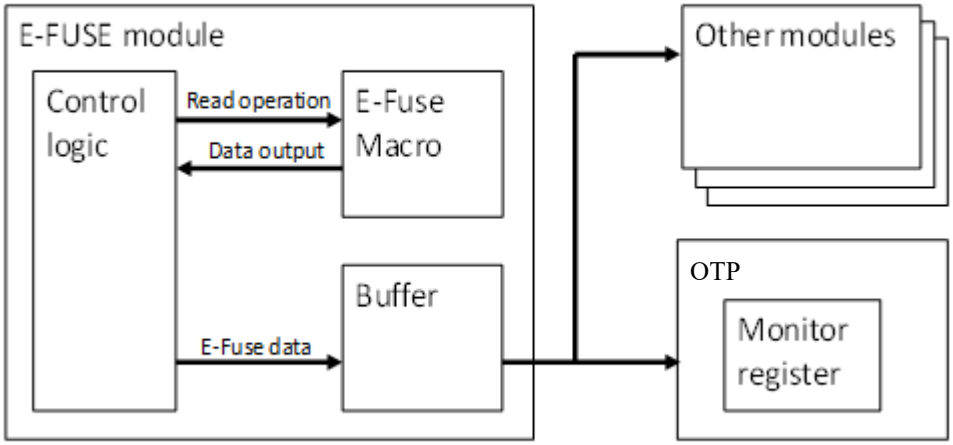

Figure U10.1.1 Relations between OTP, E-FUSE and other modules

Table U10.1.1 Register Configuration

Register Name	Abbreviation	R/W	Base Address	Initial Value	Offset Address [lower 9bits]	Access Size
OTP_MEM Monitor Register 0	OTPMONITOR0	R	H'E61B_F000	-	H'100	32
OTP_MEM Monitor Register 3	OTPMONITOR3	R	H'E61B_F000	-	H'10C	32

(1) OTP_MEM Monitor Register 0 (OTPMONITOR0)

Function: OTPMONITOR0 can read fuse bits for safety mechanisms.
OTP can read some fuse bits of some modules, because they cannot read fuse bits itself.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	otpmonitor0[9]	otpmonitor0[8]	otpmonitor0[7]	otpmonitor0[6]	-	otpmonitor0[4]	-	-	otpmonitor0[1]	otpmonitor0[0]
Initial value:	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

This register is functional safety use only. Keep initial value.

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	-	-	R	Reserved.
9	otpmonitor0[9]	-	R	This bit is always read as 0.
8	otpmonitor0[8]	-	R	This bit is always read as 0.
7	otpmonitor0[7]	-	R	This bit is always read as 0.
6	otpmonitor0[6]	-	R	GPU disable 0: GPU function operation 1: GPU function stop
5	-	-	R	Reserved.
4	otpmonitor0[4]	-	R	This bit is always read as 0.
3 to 2	-	-	R	Reserved.
1	otpmonitor0[1]	-	R	VDSP1 disabling 0: VDSP1 function operation 1: VDSP1 function stop
0	otpmonitor0[0]	-	R	This bit is always read as 0.

(2) OTP_MEM Monitor Register 3 (OTPMONITOR3)

Function: OTPMONITOR3 can read fuse bits for safety mechanisms.
OTP can read some fuse bits of some modules, because they cannot read fuse bits itself.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	otpmonitor3[5]	otpmonitor3[4]	otpmonitor3[3]	otpmonitor3[2]	otpmonitor3[1]	otpmonitor3[0]
Initial value:	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

This register is functional safety use only. Keep initial value.

Bit	Bit Name	Initial Value	R/W	Description
31 to 6	-	-	R	Reserved.
5 to 2	otpmonitor3[5:2]	-	R	These bits show the AVS code. otpmonitor3[5:2] 0000: Non-AVS 0011: AVS0 1100: AVS1 1111: AVS2 Others: not available
1	otpmonitor3[1]	-	R	This bit is always read as 0.
0	otpmonitor3[0]	-	R	This bit is always read as 0.

U10.1.5.2 Hardware Redundancy for E-FUSE

U10.1.5.2.1 Overview

Dual circuit is applied to E-FUSE in order to detect mismatching expected FUSE bit of E-FUSE.

U10.1.5.2.2 Hardware Description

Figure U10.1.2 shows a block diagram of this safety mechanisms.

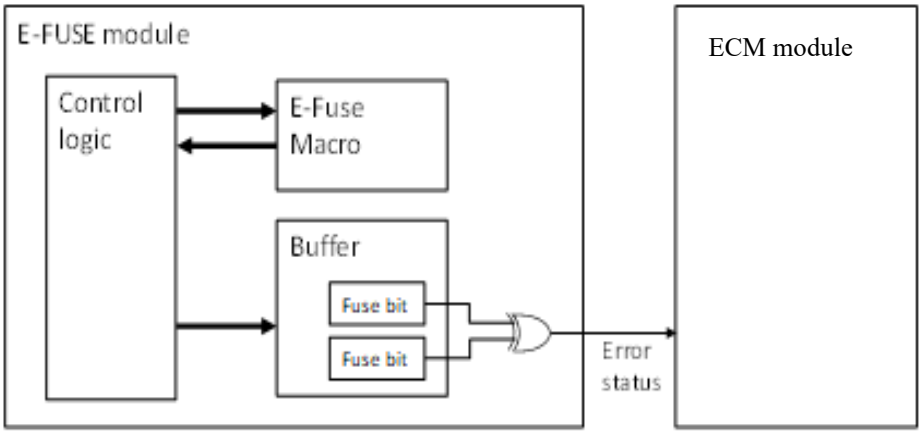

Figure U10.1.2 Block Diagram of Hardware Redundancy for E-FUSE

There are plural error notification signals to ECM (shown as Error status) and their implementations for the products are different from each other.

U10.2. OTP_MEM

U10.2.1 Overview

The OTP_MEM is a type of non-volatile memory fabricated in standard CMOS logic process. This OTP_MEM macro is used for hardware macro trimming, recording Chip information, disabling certain features, etc. Data read from OTP-MEM is latched in Buffer and output to other modules.

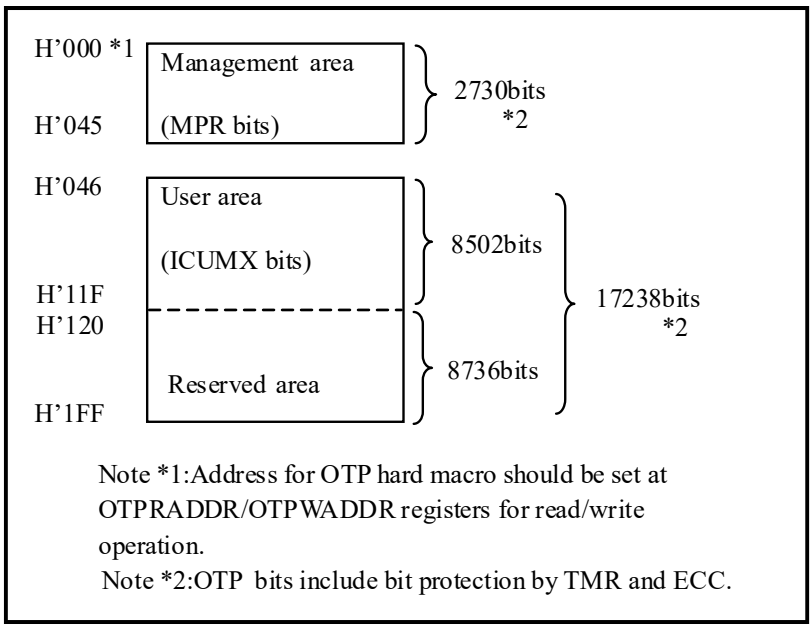

Figure U10.2.1 OTP bit map area and size

U10.2.1.1 Feature

OTP(One Time Programmable device) hard macro uses antifuse based technology. Customers writes/reads OTP at run time.

- OTP hard macro : 512address x 39bits x 1macro
- Read OTP after POR(Power On Reset by use of external reset pin (PRESET#)).
- Write OTP by CPU(Controlled by APB master side for security)
- Read OTP by CPU(Controlled by APB master side for security)
- Read/Write Protection by MPR (Protect one address with MPR one bit))
- ECC for OTP bits (FuSa requirement (ECC shall be checked by POST))
- Redundancy bits for OTP bits (for safety and security)
- Monitoring registers for eFuse and OTP bits.
- DCLS (FuSa requirement)
- ID authentication function from eFUSE to OTP
- Register Access Protection by Region ID(Two 4KB areas, Secure and Non-Secure)

  (OTP control register for Read/Write OTP and Test function is a Secure area.

  FuSa, eFUSE monitor and OTP monitor register is a Non-Secure area.)
- Each product ID can be referenced from OTPMONITOR17

U10.2.1.2 Register Configuration

Refer to R-CarV4M_UM_U10_2_OTP_MEM_G_r1p00.xlsx

U10.2.2 Register Description

The base-address of OTP is H'E61B_E000 and H'E61B_F000.

OTP has register access protection by Region ID. The register can only access to permitted protection base-address.

There are 1 protection base-address (H'E61B_E000).

Registers related to OTP control function.

- Accessible by ICUMX for security:
  - The base-address is H'E61B_E000 registers.

Registers related to FuSa function, eFUSE monitor, OTP monitor.

- All error control registers are writable.
  - The base-address is H'E61B_F000 registers.

Do not write to addresses other than those listed below, otherwise normal operation cannot be guaranteed. Values read from other addresses are undefined.

Access size are all 32bits.

Legend for Register Configuration

Initial value : Register value after a reset

– : Undefined value

R/W : Readable/writable. The written value can be read.

R : Read-only.

W : Write-only. The read value is undefined.

Refer to R-CarV4M_UM_U10_2_OTP_MEM_G_r1p00.xlsx

U10.2.3 Operation

U10.2.3.1 Initial read OTP hard macro

The OTP output value is automatically read from the OTP hard macro and latched into buffer when the chip is powered on, and it is output from that buffer to each module using OTP signal.

U10.2.3.2 Program OTP hard macro by registers

1 Write address to the register (OTPWADDR).

2 Write data to the register (OTPWDATA).

3 Write keycode 0xA7141222 to the register (OTPKEYCODE).

4 Write 1 to the write start bit (OTPWCONF[0]).

5 Wait for the write end bit (OTPWSTATUS[1]) to be 1.

(Wait from 4195 cycles to maximum 13204 cycles of CL16Mϕ.

It increases by 231 cycles according to the number of bits to be written from 4195 cycles.)

6 Write 0 to the register (OTPKEYCODE).

7 Check the write status register (OTPWSTATUS) is 0x00000002.

8 Check the error status register (OTPERRSTATUS) is 0x00000000.

U10.2.3.3 Read OTP hard macro by registers

1 Write address to the register (OTPRADDR).

2 Write 1 to the read start bit (OTPRCONF[0]).

3 Wait for the read end bit (OTPRSTATUS[1]) to be 1. (Wait 1361 cycles of CL16Mϕ).

4 Check the read status register (OTPRSTATUS) is 0x00000002.

5 Check the error status register (OTPERRSTATUS) is 0x00000000.

6 Check the read data register (OTPRDATA).

U10.2.3.4 Initial/PGM Margin Read OTP hard macro by registers

1. Write address to the register (OTPRADDR).
2. Write 0x00000108 to the register (OTPTESTCONF).

   Set 1 to the margin read mode bit (OTPTESTCONF [3]).

   Set 1 to the margin read mode select bit (OTPTESTCONF[11:8]). *1
3. Write 1 to the read start bit (OTPRCONF[0]).
4. Wait for the read end bit (OTPRSTATUS[1]) to be 1. (Wait 1361 cycles of CL16Mϕ).
5. Check the read status register (OTPRSTATUS) is 0x00000002.
6. Check the error status register (OTPERRSTATUS) is 0x00000000.
7. Check the read data register (OTPRDATA).
8. Write 0x00000000 to the register (OTPTESTCONF).

Note *1: If you need other margin read mode, change register value of OTPTESTCONF [11:8]. Refer to register description. OTP has 5 kinds of margin read mode. (Initial Margin Read Mode (for LT*2 and RT*3), HT*4 initial Margin Read Mode (for HT), PGM*5 Margin Read Mode (for RT), HT PGM Margin Read Mode (for HT) and LT PGM Margin Read Mode (for LT))

Note *2: LT is an abbreviation for Low Temperature. LT is a test mode for CP sorting at low temp (<0degC).

Note *3: RT is an abbreviation for Room Temperature.

Note *4: HT is an abbreviation for High Temperature. The HT is a test mode for CP sorting at high temp (>85degC).

Note *5: PGM is the abbreviation for program.

U10.2.3.5 Read OTP hard macro by test function registers

1. Write address to the register (OTPTESTRADDR).
2. Write 0x00000002 to the register (OTPTESTCONF).

   Set 1 to the test mode bit (OTPTESTCONF [1]).
3. Write 1 to the read start bit (OTPRCONF[0]).
4. Wait for the read end bit (OTPRSTATUS[1]) to be 1. (Wait 1361 cycles of CL16Mϕ).
5. Check the read status register (OTPRSTATUS) is 0x00000002.
6. Check the error status register (OTPERRSTATUS) is 0x00000000.
7. Check the test status register (OTPTESTSTATUS) is 0x00000000.
8. Check the read data register (OTPTESTRUDATA[6:0], OTPTESTRLDATA[31:0]).
9. Write 0x00000000 to the register (OTPTESTCONF).

U10.2.3.6 Initial/PGM Margin Read OTP hard macro by test function registers

1. Write address to the register (OTPTESTRADDR).
2. Write 0x0000010A to the register (OTPTESTCONF).

   Set 1 to the test mode bit (OTPTESTCONF [1]).

   Set 1 to the margin read mode bit (OTPTESTCONF [3]).

   Set 1 to the margin read mode select bit (OTPTESTCONF[11:8]). *1
3. Write 1 to the read start bit (OTPRCONF[0]).
4. Wait for the read end bit (OTPRSTATUS[1]) to be 1. (Wait 1361 cycles of CL16Mϕ).
5. Check the read status register (OTPRSTATUS) is 0x00000002.
6. Check the error status register (OTPERRSTATUS) is 0x00000000.
7. Check the test status register (OTPTESTSTATUS) is 0x00000000.
8. Check the read data register (OTPTESTRUDATA[6:0], OTPTESTRLDATA[31:0]).
9. Write 0x00000000 to the register (OTPTESTCONF).

Note *1: If you need other margin read mode, change register value of OTPTESTCONF [11:8]. Refer to register description. OTP has 5 kinds of margin read mode. (Initial Margin Read Mode (for LT*2 and RT*3), HT*4 initial Margin Read Mode (for HT), PGM*5 Margin Read Mode (for RT), HT PGM Margin Read Mode (for HT) and LT PGM Margin Read Mode (for LT))

Note *2: LT is an abbreviation for Low Temperature. LT is a test mode for CP sorting at low temp (<0degC).

Note *3: RT is an abbreviation for Room Temperature.

Note *4: HT is an abbreviation for High Temperature. The HT is a test mode for CP sorting at high temp (>85degC).

Note *5: PGM is the abbreviation for program.

U10.2.4 User Programming Guide

U10.2.4.1 For customer

This guide provides guidelines for OTP programming. The OTP has the bits including in user area and management (write/read protection) area. Refer to the attached “U10_2_R-CarV4M_OTP_Bit_Map_r0p70.xlsx”. Figure U10.2.2 User Programming Guide for customer show a flowchart of the User Programming Guide for customer.
Refer to Table 200.2 Power Supply and set VDD and VDD18_OTP within specification.
Refer to Table 200.1 Absolute Maximum Ratings and set operating temperature within specification.
Please refer to the security manual for details of OTP bit information.

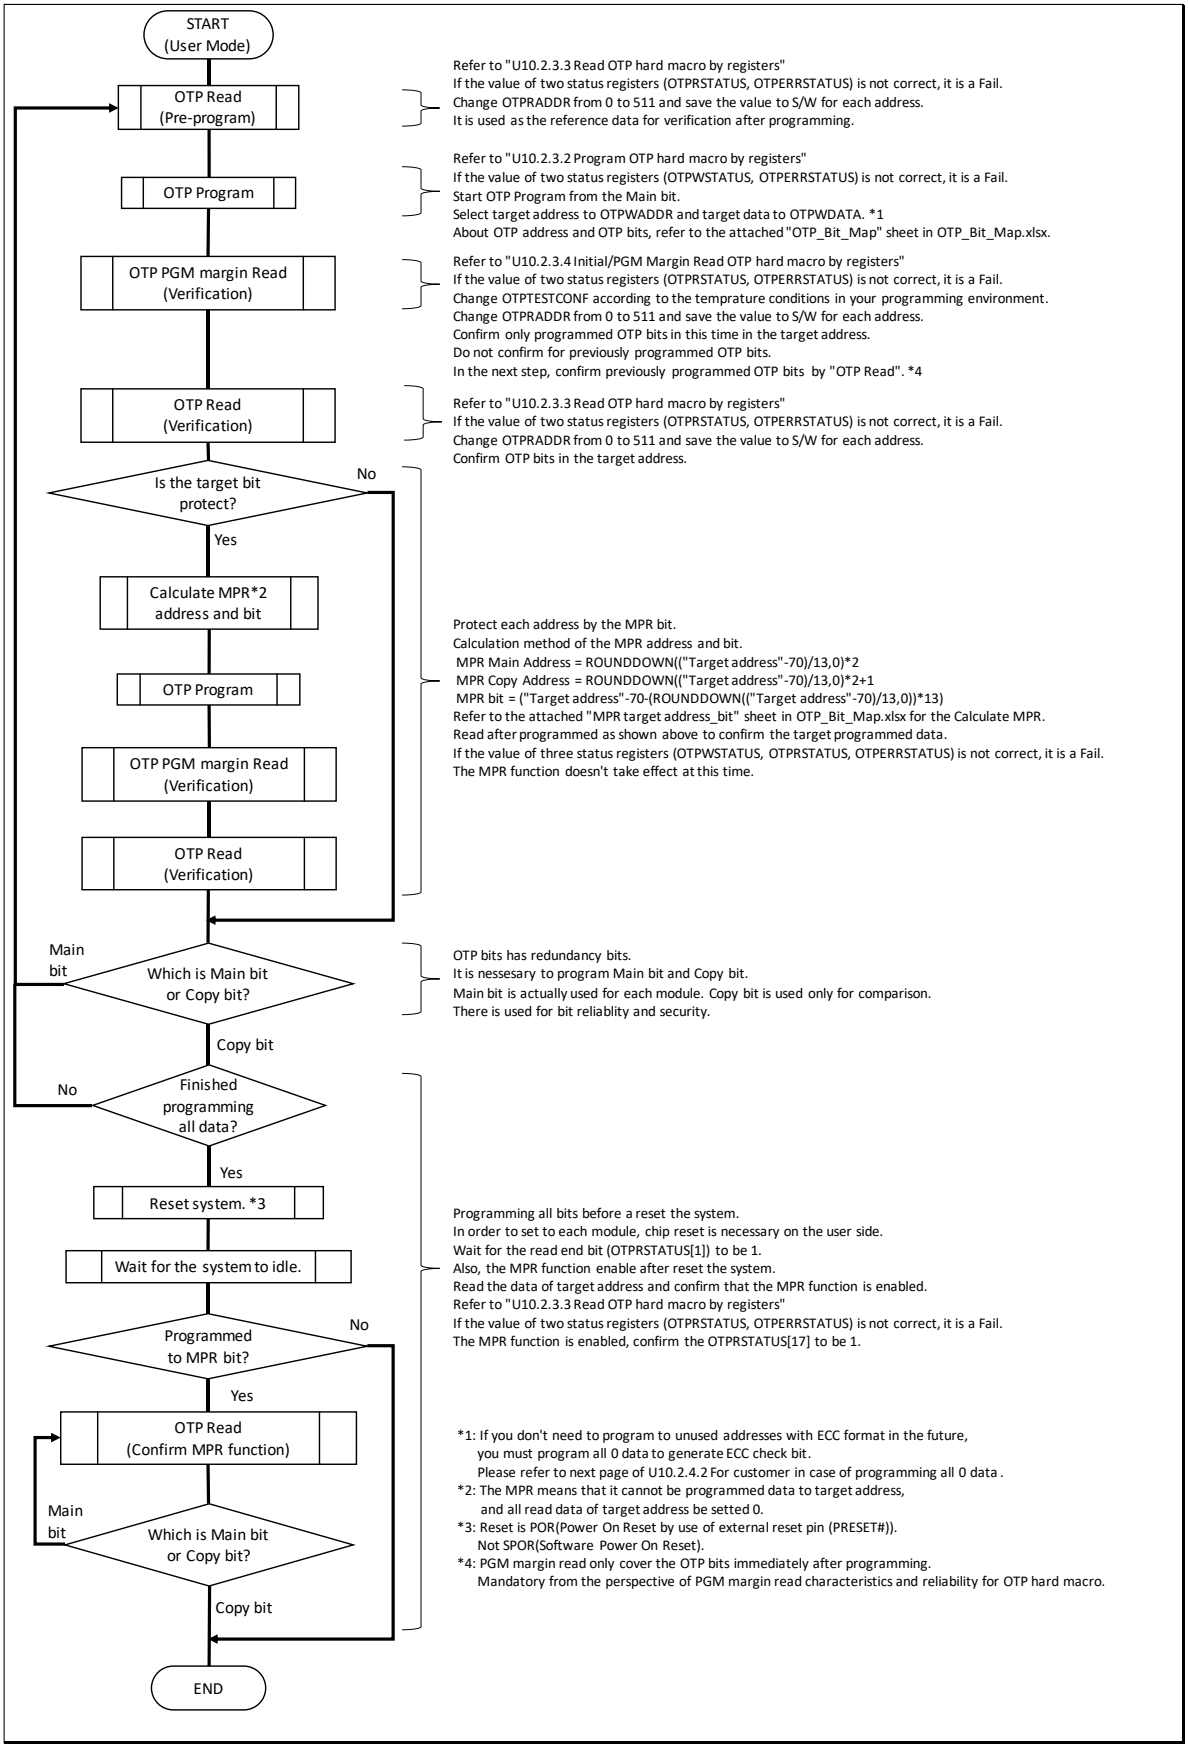

Figure U10.2.2 User Programming Guide for customer

U10.2.4.2 For customer in case of programming all 0 data

This guide provides guidelines for OTP in case of programming all 0 data. If you don't need to program to unused addresses with ECC format in the future, you must program all 0 data to generate ECC check bit. The OTP has the bits including in user area and management (write/read protection) area.

Refer to the attached “U10_2_R-CarV4M_OTP_Bit_Map_r0p70.xlsx”. Figure U10.2.3 User Programming Guide for customer in case of programming all 0 data show a flowchart of the User Programming Guide for customer in case of programming all 0 data.

Refer to Table 200.2 Power Supply and set VDD and VDD18_OTP within specification.

Refer to Table 200.1 Absolute Maximum Ratings and set operating temperature within specification.

Please refer to the security manual for details of OTP bit information.

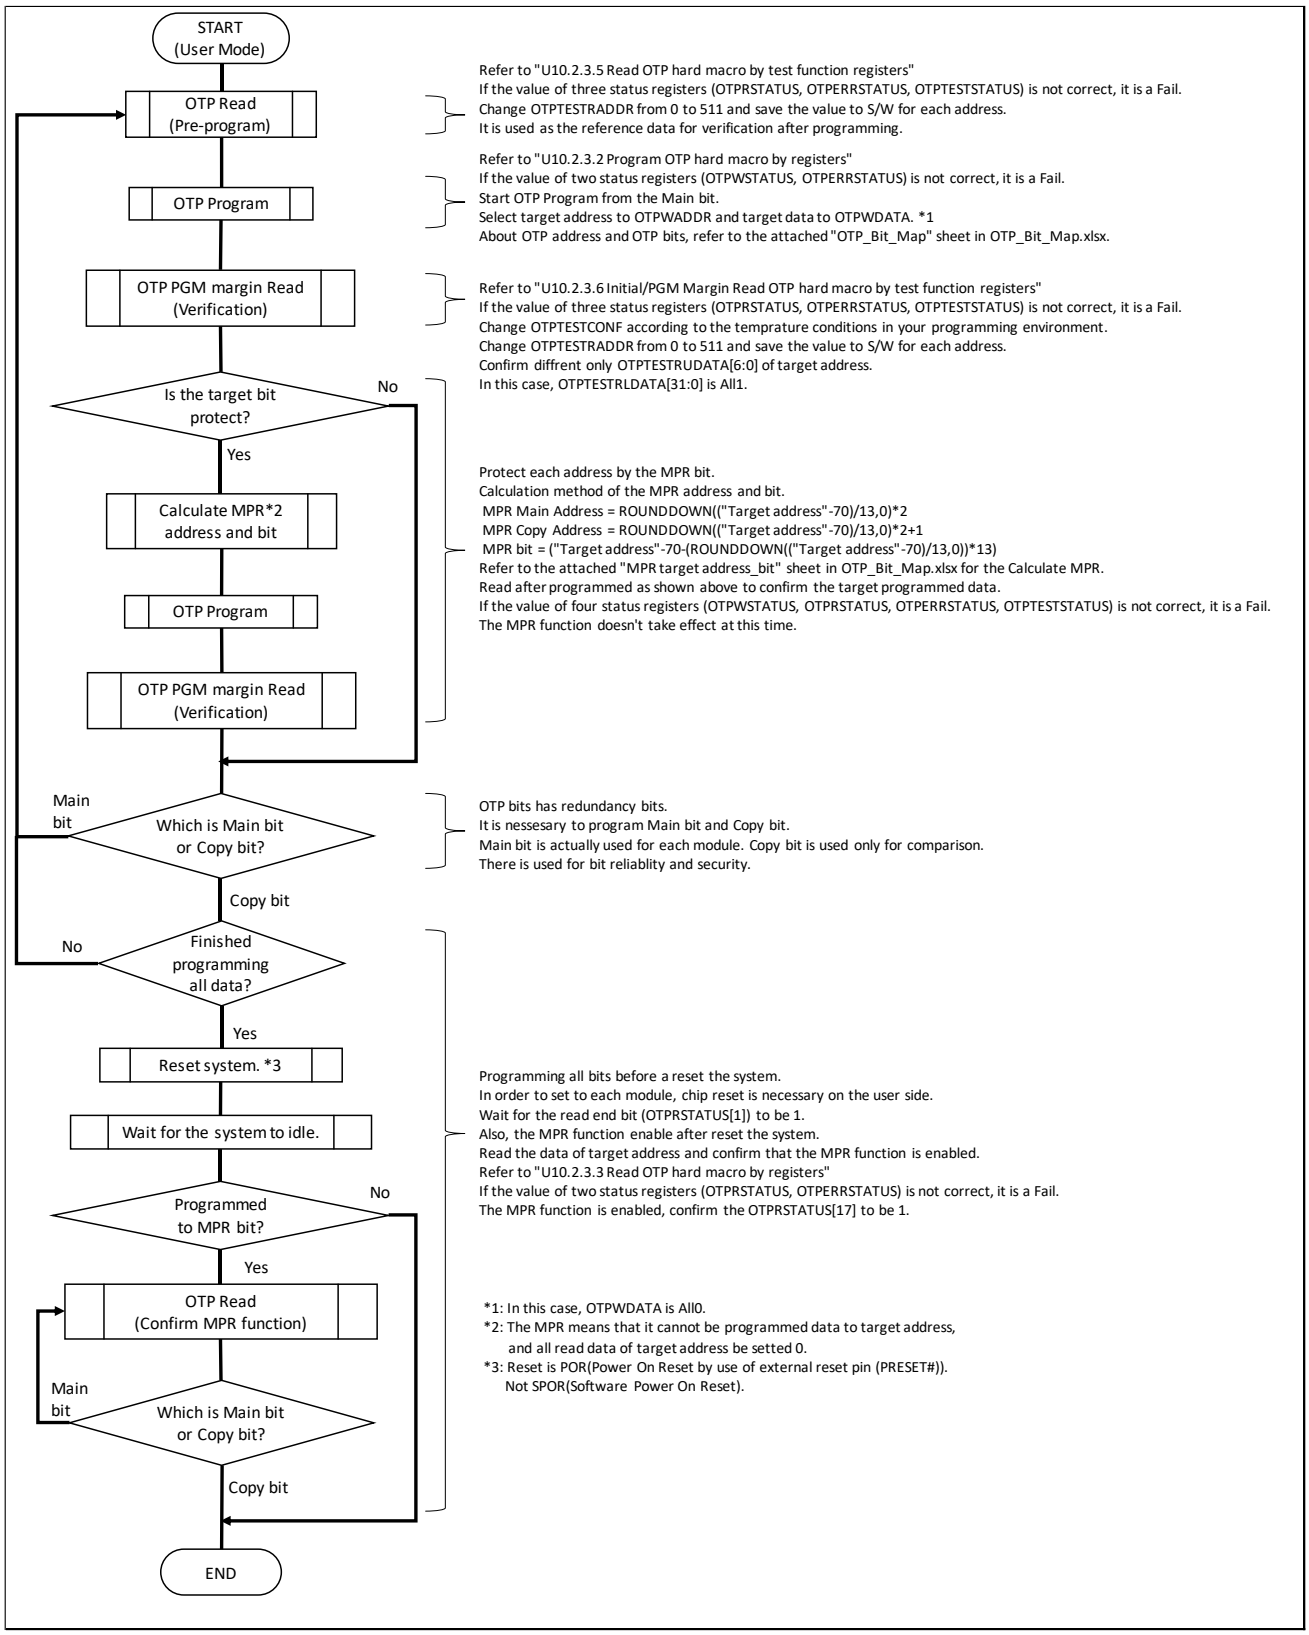

Figure U10.2.3 User Programming Guide for customer in case of programming all 0 data

U10.2.5 Usage Notes

U10.2.5.1 OTP Bit Map

Refer to the attached "U10_2_R-CarV4M_OTP_Bit_Map_r0p70.xlsx".

Note:

- The TMR is the majority logic format. (Write bits one by one)

	[38:26]	[25:13]	[12:0]
address 2n	copy of main data	copy of main data	Main data
address 2n+1	copy of copy data	copy of copy data	Copy data

n < 255

OTP uses output data of majority logics of [38:26], [25:13], and [12:0].

OTP compares output data of majority logics of address 2n and address 2n+1.

- The ECC is the ECC format. (Write 32bit at only one time)

	[38:32]	[31:0]
address 2n	ECC check bit (Generated by address 9bit + data 32bit)	Main data
address 2n+1	ECC check bit (Generated by address 9bit + data 32bit)	Copy data

n < 255

OTP uses data corrected by ECC check bits.

OTP compares corrected data of address 2n and address 2n+1.

- The MPR is used to mask the bit of the target address for security.

  If MPR bit 0 to 1, it will not be able to write to the target address. And it all 0 will be read.

- The OTP bit is like an eFUSE bit. It is connected to each module.

U10.2.5.2 Cautionary point for programming operation

- Shall not be programming operation at frequencies lower than the CL16Mφ specifications (OTP clock).
- Shall not be turning off the power during programming.
- The ECC format cannot be written twice.
- The TMR format only the bit to be written is set to 1.
- Shall be programming the same data for the Main/Copy bits and then resets the system.
- If there are bits to protect, the MPR bit of the target address is set to 1.

- The MPR bit protection is enabled by system reset after programming.

U10.2.6 Safety Mechanisms

- DCLS
- OTP Data format (ECC or Majority logics)
- ECC check bits(7bits) are generated by 41bit {address 9bit, data 32bit}
- Redundancy bits
  - address 2n : data is connected to other modules
  - address 2n+1 : Redundancy bits (data shall be the same to data of address 2n)
  - n < 255
- Error injection
- OTP Monitor Register
- eFUSE Monitor Register

U11. ROM

U11.1 Overview

This module is treated as safety-related function in case of the products supporting functional safety. For details, refer to the functional safety documents.

The boot ROM is used for booting processor codes. R-Car V4M supports Cortex-R52 and ICUMX booting.

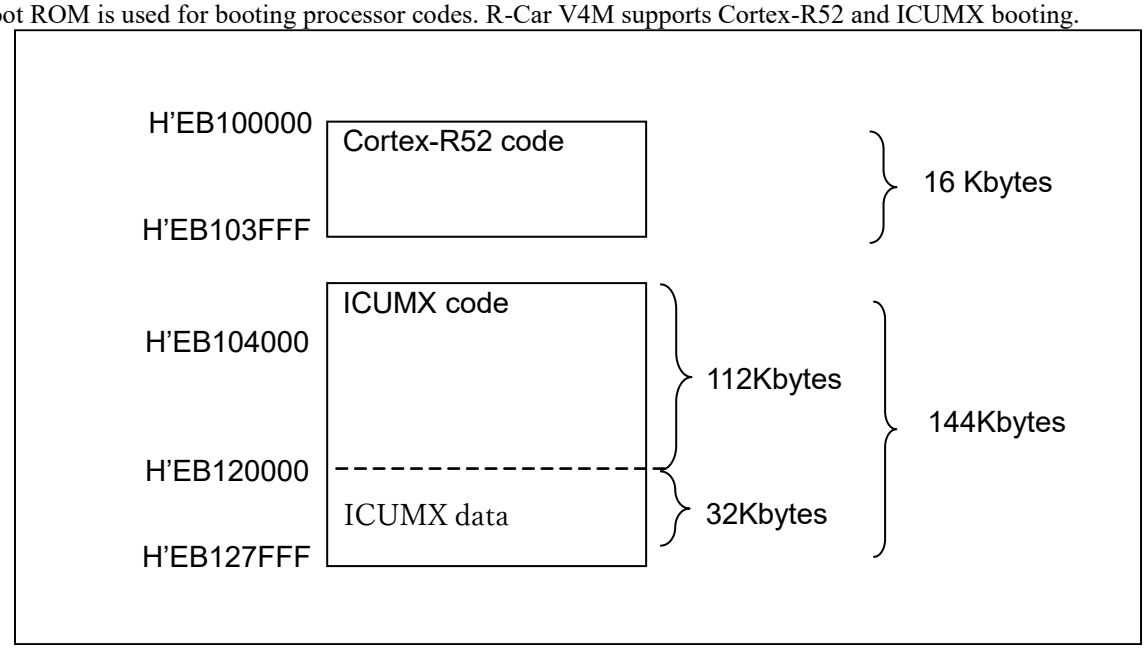

Figure U11.1 Boot ROM memory map

U11.1.1 Features

•EDC protection for ROM code loading.

• Capacity 160KB

• ROM code repair function

•64-b AXI interface

•Return AXI error response if EDC error occurs.

•ICUMX code can only read by fetch access from ICUMX.
(The ICUMX code cannot be read from other master (Cortex-R52, Debugger, etc.).)

•Error notification if read to the ICUMX code area other than instruction fetch access from ICUMX occurs.

U11.1.2 Register configuration

Base Address Name	Base Address
ROM	H'EB12 0000

Module Name	Register Name	Symbol	R/W	Address	Initial Value	Access Size
ROM	Access error status 1	ACCERRSTS1	RC	<ROM>+H'D000	H'0000 0000	32

ROM	Error injection enable control 3	INJ_ERR_CTR3	R	<ROM>+H'F300	H'0000 0000	32

U11.2 Register description

U11.2.1 Access error status 1(ACCERRSTS1)

This register indicates the status of access error to ICUMX code area from ICUP code access I/F in ICUMX.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	err
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RC

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	H'0	R	Reserved The read value of these bits are always 0.
0	err	H'0	RC	0 : No access error from ICUP code access I/F in ICUMX. 1 : Access error occurs from ICUP code access I/F in ICUMX. This bit can be cleared by read access.

U11.2.2 Access error status 2(ACCERRSTS2)

This register indicates the status of access error to ICUMX code area fromother than ICUP code access I/F.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	err
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RC

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	H'0	R	Reserved The read value of these bits are always 0.
0	err	H'0	RC	0 : No access error from other than ICUP code access I/F in ICUMX. 1 : Access error occurs from other than ICUP code access I/F in ICUMX. This bit can be cleared by read access.

U11.2.3 Single bit error injection(INJ_ERR_S)

Access read to this register will trigger error injection for EDC single error

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	err_inj															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	err_inj															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	err_inj	H'0	R	trigger of error injection for EDC single bit error. The read value of these bits are always 0.

U11.2.4 Multi bits error injection(INJ_ERR_M)

Access read to this register will trigger error injection for EDC multiple error

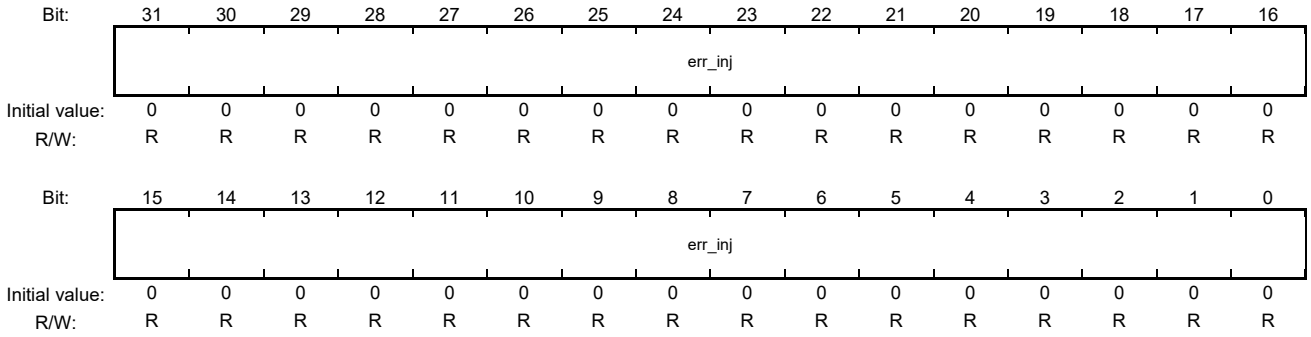
Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	err_inj															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	err_inj															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	err_inj	H'0	R	trigger of error injection for EDC single and multi bit error. The read value of these bits are always 0.

U11.2.5 Single bit error2 injection(INJ_ERR_S2)

Access read to this register will trigger error injection for EDC single bit error2



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	err_inj	H'0	R	trigger of error injection for EDC single bit error2. The read value of these bits are always 0.

U11.2.6 Multi bits error2 injection(INJ_ERR_M2)

Access read to this register will trigger error injection for EDC multiple bit error2

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	err_inj															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	err_inj															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	err_inj	H'0	R	trigger of error injection for EDC single and multi bit error2. The read value of these bits are always 0.

U11.2.7 Error injection enable control 0(INJ_ERR_CTR0)

These registers control the enable of error injection.
See U11.4.1 for error injection procedure.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	err_inj_ctr															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	err_inj_ctr															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	err_inj_ctr	H'0	R	error injection enable control. The read value of these bits are always 0.

U11.2.8 Error injection enable control 1(INJ_ERR_CTR1)

These registers control the enable of error injection.
See U11.4.1 for error injection procedure.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	err_inj_ctr															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	err_inj_ctr															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	err_inj_ctr	H'0	R	error injection enable control. The read value of these bits are always 0.

U11.2.9 Error injection enable control 2(INJ_ERR_CTR2)

These registers control the enable of error injection.
See U11.4.1 for error injection procedure.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	err_inj_ctr															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	err_inj_ctr															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	err_inj_ctr	H'0	R	error injection enable control. The read value of these bits are always 0.

U11.2.10 Error injection enable control 3(INJ_ERR_CTR3)

These registers control the enable of error injection.
See U11.4.1 for error injection procedure.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	err_inj_ctr															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	err_inj_ctr															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	err_inj_ctr	H'0	R	error injection enable control. The read value of these bits are always 0.

U11.3 Operation

No description on this section.

U11.4 Usage Notes

U11.4.1 EDC Error Injection

To use this function, it must be access by the following procedure.

1. Read Access to INJ_ERR_CTR0
2. Read Access to INJ_ERR_CTR1
3. Read Access to INJ_ERR_CTR2
4. Read Access to INJ_ERR_CTR3
5. Read Access to INJ_ERR_S or INJ_ERR_M or INJ_ERR_S2 or INJ_ERR_M2
   -> Error injecting (1 pulse)

U11.5 Safety Mechanisms

U11.5.1 Overview

EDC protection is applied to BootROM.

U11.5.2 Hardware Description

Figure U11.2 shows block diagram of EDC for Boot ROM.

EDC check is always enabled.

When an EDC error is detected, the error notified to ECM module shall be reported to the external systems through ERROROUT# pin.

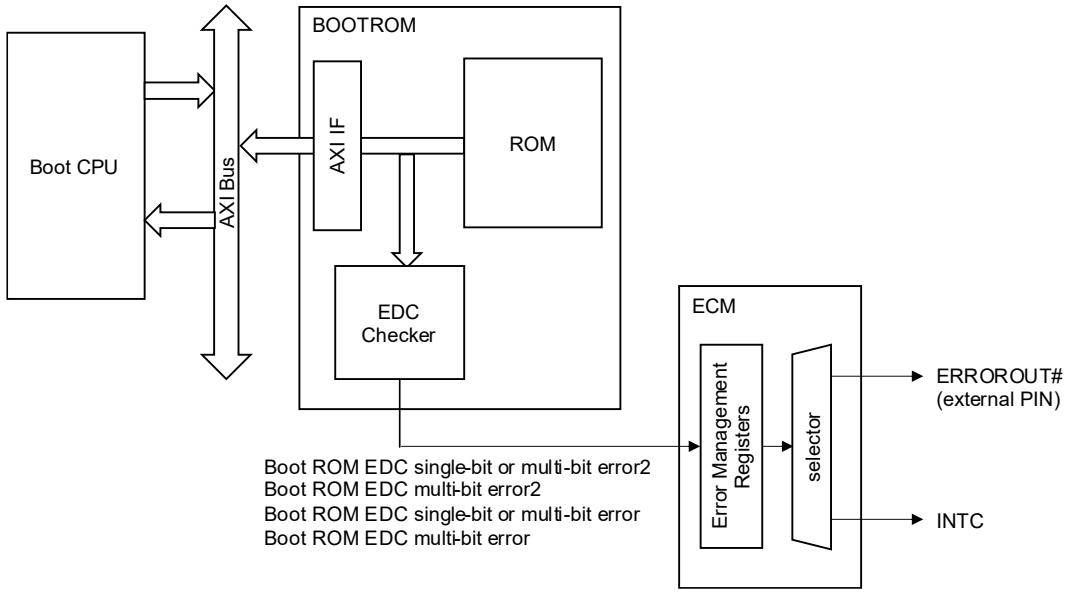


Figure U11.2 Block Diagram of EDC for Boot ROM

U20. Measurement Trace Interface (MTI)

U20.1 Overview

The measurement transmission interface (MTI) module is intended for use in debugging. Specifically, this module produces an output of the internal image transfer data being processed. To output the data, paths for connection of the module to an image signal processor (ISP), and to a module functionally equivalent to CoreSight (CSD), PCI express(PCIe) module are formed.

U20.1.1 Features

The MTI module consists of three blocks; the MTI block itself, the MTI retiming (MTIRT) block, and the RT interface (MTIRI).

(1) The MTI block receives monitored signals from the ISPCS and rearranges each kind of signal into the specified data transfer format. After that, it transmits the rearranged data as image data to the MTIRT block.

ISP monitor channel number :

ISPCS -> ISPCORE: ispin x 1ch

ISPCS -> VIN: ispout x 8ch

The MTI block monitors data with the desired tag value as determined by the setting in a register (selecting all tag values is also possible).

When multiple monitors are selected, the MTI block divides the data into those from each monitor and repeats the output of the divided data while changing the monitor number.

To restrain the amount of data to be transmitted, the MTI block transmits a single cycle of synchronization signals (vsync and hsync) with the valid image data.

(2) The MTIRT block transmits the data to the MTIRI block where they are passed through two sets of flip-flop stages.

(3) The MTIRI block converts the image data to an AXI4 protocol stream and transmits the converted data to the CSD.

(4) CSD transmits data to PCIe .

(5) When the buffer memory within the MTI or MTIRI blocks overflows, the MTI block notifies to the CSD At the same time, it reports to cpu by interrupt.

U20.1.2 Block Diagram

Figure U20.1 shows the block diagram of MTI.

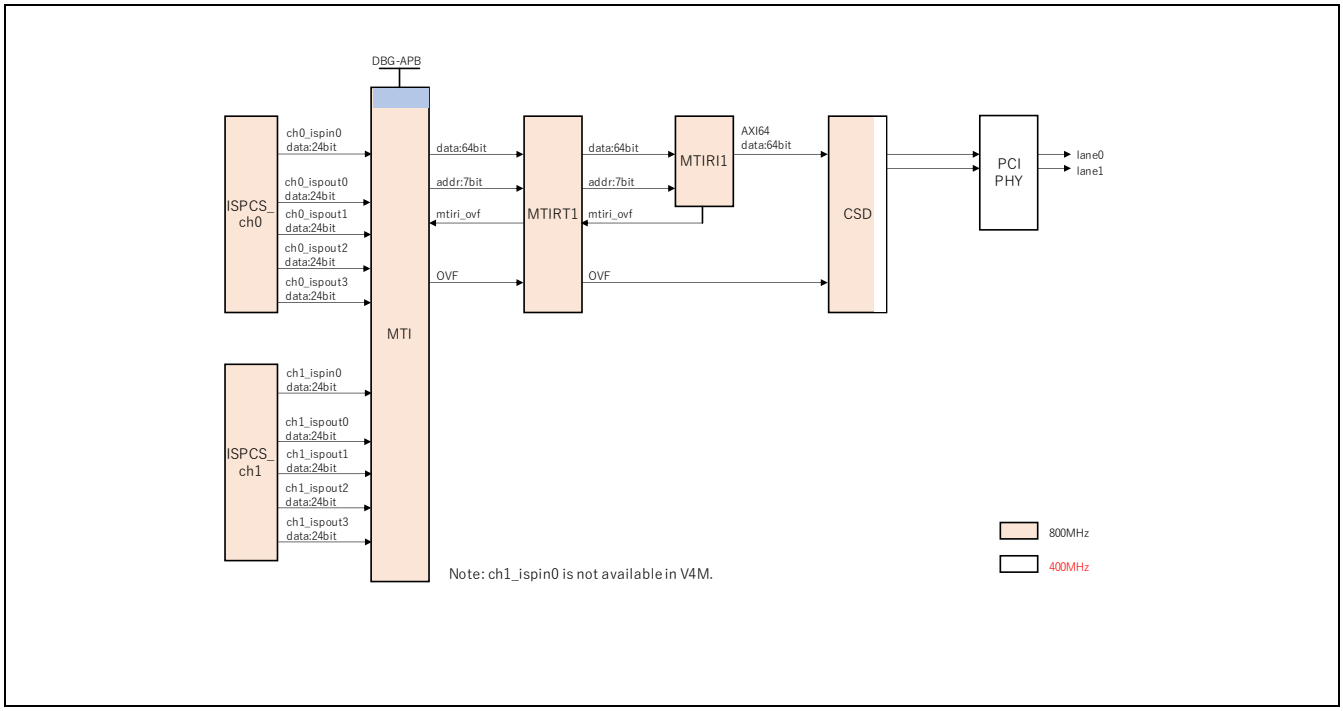

Figure U20.1 MTI Block Diagram

U20.1.3 External Pins

MTI does not have external pins

U20.1.4 Register Configuration

MTI instance added, base address for new instance is prepared.

On the CPU side : 0x00_F820_0XXX

On the debugger side : 0x8020_0XXX

Attempted write access to unused addresses is ignored, and read access returns all 0s.

The MTI registers are accessed through the APB interface for debugging (DEBUG-APB), which the CSD module controls. Registers at address H'FB0 and subsequent addresses (DEBUG-APB control registers) are required in control of the DEBUG-APB.

Table U20.1 shows the Register Configuration

Table U20.1 Register Configuration

Register Name	Abbreviation	R/W	Initial value	APB Address Offset	Access Size
ispin monitoring enable Register for ISP_ch0	MONI_ENABLE0_0	R/W	H'0000_0000	H'000	32

Bit	Bit Name	Initial Value	R/W	Description
31	M6_TAGEN1 [7]	0	R/W	ISP_ch1_ispout3 Monitoring Enable 1: Data from ispout3 with 7 as the tag value are monitored.
30	M6_TAGEN1 [6]	0	R/W	ISP_ch1_ispout3 Monitoring Enable 1: Data from ispout3 with 6 as the tag value are monitored.
29	M6_TAGEN1 [5]	0	R/W	ISP_ch1_ispout3 Monitoring Enable 1: Data from ispout3 with 5 as the tag value are monitored.
28	M6_TAGEN1 [4]	0	R/W	ISP_ch1_ispiout3 Monitoring Enable 1: Data from ispout3 with 4 as the tag value are monitored.
27	M6_TAGEN1 [3]	0	R/W	ISP_ch1_ispout3 Monitoring Enable 1: Data from ispout3 with 3 as the tag value are monitored.
26	M6_TAGEN1 [2]	0	R/W	ISP_ch1_ispout3 Monitoring Enable 1: Data from isput3 with 2 as the tag value are monitored.
25	M6_TAGEN1 [1]	0	R/W	ISP_ch1_ispout3 Monitoring Enable 1: Data from ispout3 with 1 as the tag value are monitored.
24	M6_TAGEN1 [0]	0	R/W	ISP_ch1_ispout3 Monitoring Enable 1: Data from ispout3 with 0 as the tag value are monitored.
23	M5_TAGEN1 [7]	0	R/W	ISP_ch1_ispout2 Monitoring Enable 1: Data from ispout2 with 7 as the tag value are monitored.
22	M5_TAGEN1 [6]	0	R/W	ISP_ch1_ispout2 Monitoring Enable 1: Data from ispout2 with 6 as the tag value are monitored.
21	M5_TAGEN1 [5]	0	R/W	ISP_ch1_ispout2 Monitoring Enable 1: Data from ispout2 with 5 as the tag value are monitored.
20	M5_TAGEN1 [4]	0	R/W	ISP_ch1_ispiout2 Monitoring Enable 1: Data from ispout2 with 4 as the tag value are monitored.
19	M5_TAGEN1 [3]	0	R/W	ISP_ch1_ispout2 Monitoring Enable 1: Data from ispout2 with 3 as the tag value are monitored.
18	M5_TAGEN1 [2]	0	R/W	ISP_ch1_ispout2 Monitoring Enable 1: Data from isput2 with 2 as the tag value are monitored.
17	M5_TAGEN1 [1]	0	R/W	ISP_ch1_ispout2 Monitoring Enable 1: Data from ispout2 with 1 as the tag value are monitored.
16	M5_TAGEN1 [0]	0	R/W	ISP_ch1_ispout2 Monitoring Enable 1: Data from ispout2 with 0 as the tag value are monitored.
15	M4_TAGEN1[7]	0	R/W	ISP_ch1_ispout1 Monitoring Enable 1: Data from ispout1 with 7 as the tag value are monitored.
14	M4_TAGEN1 [6]	0	R/W	ISP_ch1_ispout1 Monitoring Enable 1: Data from ispout1 with 6 as the tag value are monitored.
13	M4_TAGEN1 [5]	0	R/W	ISP_ch1_ispout1 Monitoring Enable 1: Data from ispout1 with 5 as the tag value are monitored.
12	M4_TAGEN1 [4]	0	R/W	ISP_ch1_ispout1 Monitoring Enable 1: Data from ispout1 with 4 as the tag value are monitored.
11	M4_TAGEN1 [3]	0	R/W	ISP_ch1_ispout1 Monitoring Enable 1: Data from ispout1 with 3 as the tag value are monitored.
10	M4_TAGEN1 [2]	0	R/W	ISP_ch1_ispout1 Monitoring Enable 1: Data from ispout1 with 2 as the tag value are monitored.

9	M4_TAGEN1 [1]	0	R/W	ISP_ch1_ispout1 Monitoring Enable 1: Data from ispout1 with 1 as the tag value are monitored.
8	M4_TAGEN1 [0]	0	R/W	ISP_ch1_ispout1 Monitoring Enable 1: Data from ispout1 with 0 as the tag value are monitored.
7	M3_TAGEN1 [7]	0	R/W	ISP_ch1_ispout0 Monitoring Enable 1: Data from ispout0 with 7 as the tag value are monitored.
6	M3_TAGEN1 [6]	0	R/W	ISP_ch1_ispout0 Monitoring Enable 1: Data from ispout0 with 6 as the tag value are monitored.
5	M3_TAGEN1 [5]	0	R/W	ISP_ch1_ispout0 Monitoring Enable 1: Data from ispout0 with 5 as the tag value are monitored.
4	M3_TAGEN1 [4]	0	R/W	ISP_ch1_ispiout0 Monitoring Enable 1: Data from ispout0 with 4 as the tag value are monitored.
3	M3_TAGEN1 [3]	0	R/W	ISP_ch1_ispout0 Monitoring Enable 1: Data from ispout0 with 3 as the tag value are monitored.
2	M3_TAGEN1 [2]	0	R/W	ISP_ch1_ispout0 Monitoring Enable 1: Data from isput0 with 2 as the tag value are monitored.
1	M3_TAGEN1 [1]	0	R/W	ISP_ch1_ispout0 Monitoring Enable 1: Data from ispout0 with 1 as the tag value are monitored.
0	M3_TAGEN1 [0]	0	R/W	ISP_ch1_ispout0 Monitoring Enable 1: Data from ispout0 with 0 as the tag value are monitored.

U20.2.9 Interrupt Status Register (INT_STATUS)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	INT_STATUS[17:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	—	All 0	R	Reserved
17	INT_STATUS[17]	0	R	Overflow of buffer holding data from ISP_ch1_ispin3 0: No overflow. 1: The buffer has overflowed.
16	INT_STATUS[16]	0	R	Overflow of buffer holding data from ISP_ch1_ispin2 0: No overflow. 1: The buffer has overflowed.
15	INT_STATUS[15]	0	R	Overflow of buffer holding data from ISP_ch0_ispin3 0: No overflow. 1: The buffer has overflowed.
14	INT_STATUS[14]	0	R	Overflow of buffer holding data from ISP_ch0_ispin2 0: No overflow. 1: The buffer has overflowed.
13	INT_STATUS[13]	0	R	Overflow of buffer holding data from ISP_ch1_ispout3 0: No overflow. 1: The buffer has overflowed.
12	INT_STATUS[12]	0	R	Overflow of buffer holding data from ISP_ch1_ispout2 0: No overflow. 1: The buffer has overflowed.
11	INT_STATUS[11]	0	R	Overflow of buffer holding data from ISP_ch1_ispout1 0: No overflow. 1: The buffer has overflowed.
10	INT_STATUS[10]	0	R	Overflow of buffer holding data from ISP_ch1_ispout0 0: No overflow. 1: The buffer has overflowed.
9	INT_STATUS[9]	0	R	Overflow of buffer holding data from ISP_ch1_ispin1 0: No overflow. 1: The buffer has overflowed.
8	INT_STATUS[8]	0	R	Overflow of buffer holding data from ISP_ch1_ispin0 0: No overflow. 1: The buffer has overflowed.
7	INT_STATUS[7]	0	R	Overflow of buffer holding data from ISP_ch0_ispout3 0: No overflow. 1: The buffer has overflowed.
6	INT_STATUS[6]	0	R	Overflow of buffer holding data from ISP_ch0_ispout2 0: No overflow. 1: The buffer has overflowed.
5	INT_STATUS[5]	0	R	Overflow of buffer holding data from ISP_ch0_ispout1 0: No overflow. 1: The buffer has overflowed.
4	INT_STATUS[4]	0	R	Overflow of buffer holding data from ISP_ch0_ispout0 0: No overflow. 1: The buffer has overflowed.

Bit	Bit Name	Initial Value	R/W	Description
3	INT_STATUS[3]	0	R	Overflow of buffer holding data from ISP_ch0_ispin1 0: No overflow. 1: The buffer has overflowed.
2	INT_STATUS[2]	0	R	Overflow of buffer holding data from ISP_ch0_ispin0 0: No overflow. 1: The buffer has overflowed.
1	INT_STATUS[1]	0	R	Overflow of buffer in the MTIRI 0: No overflow. 1: The buffer has overflowed.
0	INT_STATUS[0]	0	R	bresp error (AXI slave error or AXI decoding error) in the MTIRI 0: No error. 1: An error has occurred.

U20.2.10 Interrupt Enable Register (INT_ENABLE)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	INT_ENABLE[17:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	—	All 0	R/W	Reserved
17	INT_ENABLE[17]	0	R/W	Overflow of buffer holding data from ISP_ch1_ispin3 0: The interrupt request is masked. 1: The interrupt request is not masked.
16	INT_ENABLE[16]	0	R/W	Overflow of buffer holding data from ISP_ch1_ispin2 0: The interrupt request is masked. 1: The interrupt request is not masked.
15	INT_ENABLE[15]	0	R/W	Overflow of buffer holding data from ISP_ch0_ispin3 0: The interrupt request is masked. 1: The interrupt request is not masked.
14	INT_ENABLE[14]	0	R/W	Overflow of buffer holding data from ISP_ch0_ispin2 0: The interrupt request is masked. 1: The interrupt request is not masked.
13	INT_ENABLE[13]	0	R/W	Overflow of buffer holding data from ISP_ch1_ispout3 0: The interrupt request is masked. 1: The interrupt request is not masked.
12	INT_ENABLE[12]	0	R/W	Overflow of buffer holding data from ISP_ch1_ispout2 0: The interrupt request is masked. 1: The interrupt request is not masked.
11	INT_ENABLE[11]	0	R/W	Overflow of buffer holding data from ISP_ch1_ispout1 0: The interrupt request is masked. 1: The interrupt request is not masked.
10	INT_ENABLE[10]	0	R/W	Overflow of buffer holding data from ISP_ch1_ispout0 0: The interrupt request is masked. 1: The interrupt request is not masked.
9	INT_ENABLE[9]	0	R/W	Overflow of buffer holding data from ISP_ch1_ispin1 0: The interrupt request is masked. 1: The interrupt request is not masked.
8	INT_ENABLE[8]	0	R/W	Overflow of buffer holding data from ISP_ch1_ispin0 0: The interrupt request is masked. 1: The interrupt request is not masked.
7	INT_ENABLE[7]	0	R/W	Overflow of buffer holding data from ISP_ch0_ispout3 0: The interrupt request is masked. 1: The interrupt request is not masked.
6	INT_ENABLE[6]	0	R/W	Overflow of buffer holding data from ISP_ch0_ispout2 0: The interrupt request is masked. 1: The interrupt request is not masked.
5	INT_ENABLE[5]	0	R/W	Overflow of buffer holding data from ISP_ch0_ispout1 0: The interrupt request is masked. 1: The interrupt request is not masked.
4	INT_ENABLE[4]	0	R/W	Overflow of buffer holding data from ISP_ch0_ispout0 0: The interrupt request is masked. 1: The interrupt request is not masked.

Bit	Bit Name	Initial Value	R/W	Description
3	INT_ENABLE[3]	0	R/W	Overflow of buffer holding data from ISP_ch0_ispin1 0: The interrupt request is masked. 1: The interrupt request is not masked.
2	INT_ENABLE[2]	0	R/W	Overflow of buffer holding data from ISP_ch0_ispin0 0: The interrupt request is masked. 1: The interrupt request is not masked.
1	INT_ENABLE[1]	0	R/W	Overflow of buffer in the MTIRI 0: The interrupt request is masked. 1: The interrupt request is not masked.
0	INT_ENABLE[0]	0	R/W	bresp error in the MTIRI 0: The interrupt request is masked. 1: The interrupt request is not masked.

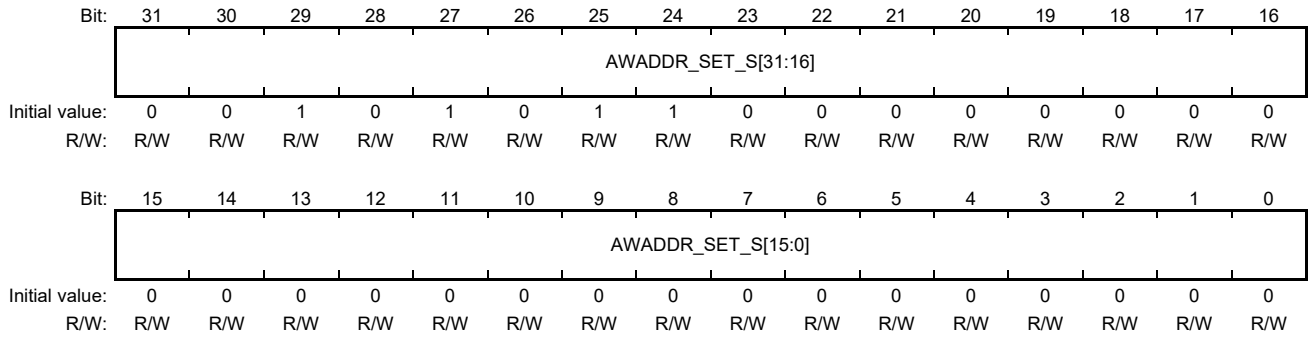
U20.2.11 Interrupt Clearing Register (INT_CLEAR)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	INT_CLEAR[17:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

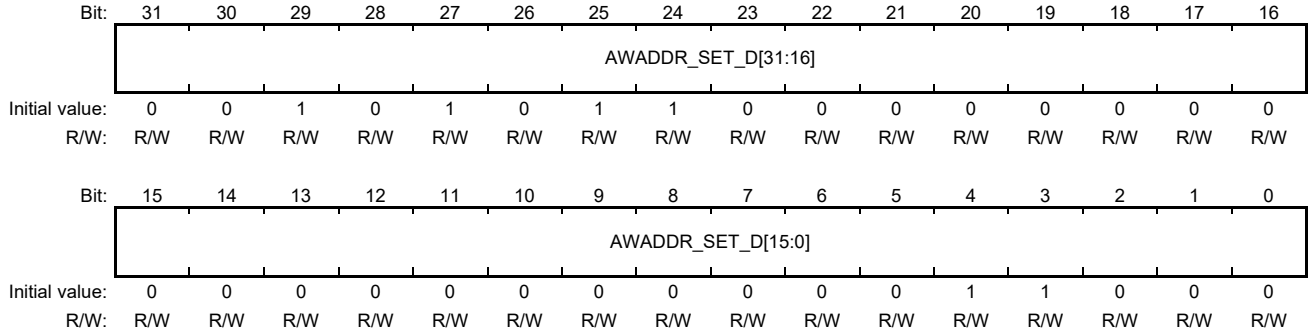
Bit	Bit Name	Initial Value	R/W	Description
31 to 18	—	All 0	W	Reserved
17	INT_CLEAR[17]	0	W	Overflow of buffer holding data from ISP_ch1_ispin3 1: The corresponding bit in the interrupt status register is cleared.
16	INT_CLEAR[16]	0	W	Overflow of buffer holding data from ISP_ch1_ispin2 1: The corresponding bit in the interrupt status register is cleared.
15	INT_CLEAR[15]	0	W	Overflow of buffer holding data from ISP_ch0_ispin3 1: The corresponding bit in the interrupt status register is cleared.
14	INT_CLEAR[14]	0	W	Overflow of buffer holding data from ISP_ch0_ispin2 1: The corresponding bit in the interrupt status register is cleared.
13	INT_CLEAR[13]	0	W	Overflow of buffer holding data from ISP_ch1_ispout3 1: The corresponding bit in the interrupt status register is cleared.
12	INT_CLEAR[12]	0	W	Overflow of buffer holding data from ISP_ch1_ispout2 1: The corresponding bit in the interrupt status register is cleared.
11	INT_CLEAR[11]	0	W	Overflow of buffer holding data from ISP_ch1_ispout1 1: The corresponding bit in the interrupt status register is cleared.
10	INT_CLEAR[10]	0	W	Overflow of buffer holding data from ISP_ch1_ispout0 1: The corresponding bit in the interrupt status register is cleared.
9	INT_CLEAR[9]	0	W	Overflow of buffer holding data from ISP_ch1_ispin1 1: The corresponding bit in the interrupt status register is cleared.
8	INT_CLEAR[8]	0	W	Overflow of buffer holding data from ISP_ch1_ispin0 1: The corresponding bit in the interrupt status register is cleared.
7	INT_CLEAR[7]	0	W	Overflow of buffer holding data from ISP_ch0_ispout3 1: The corresponding bit in the interrupt status register is cleared.
6	INT_CLEAR[6]	0	W	Overflow of buffer holding data from ISP_ch0_ispout2 1: The corresponding bit in the interrupt status register is cleared.
5	INT_CLEAR[5]	0	W	Overflow of buffer holding data from ISP_ch0_ispout1 1: The corresponding bit in the interrupt status register is cleared.
4	INT_CLEAR[4]	0	W	Overflow of buffer holding data from ISP_ch0_ispout0 1: The corresponding bit in the interrupt status register is cleared.
3	INT_CLEAR[3]	0	W	Overflow of buffer holding data from ISP_ch0_ispin1 1: The corresponding bit in the interrupt status register is cleared.
2	INT_CLEAR[2]	0	W	Overflow of buffer holding data from ISP_ch0_ispin0 1: The corresponding bit in the interrupt status register is cleared.
1	INT_CLEAR[1]	0	W	Overflow of buffer in the MTIRI1 1: The corresponding bit in the interrupt status register is cleared.
0	INT_CLEAR[0]	0	W	bresp error in the MTIRI1 1: The corresponding bit in the interrupt status register is cleared.

U20.2.12 MTIRI AXI Address Setting Register for sync (AWADDR_SET_S)



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	AWADDR_SET_S [31:0]	H'2B00 0000	R/W	AWADDR address for sync(VSYNC, HSYNC)

U20.2.13 MTIRI AXI Address Setting Register for data (AWADDR_SET_D)



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	AWADDR_SET_D [31:0]	H'2B00 0018	R/W	AWADDR address for data

U20.2.14 Reserved Register for MTIRI (MTIRI_REG_RESERVE)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20		19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—		—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0		0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W		R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4		3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—		—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0		0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W		R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	—	All 0	R/W	Reserved

U20.2.15 Image Data Storage Size Setting Register 1 (MONI_LEN1)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	CH0_MON2_W_LEN_MAX[6:0]						
Initial value:	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	CH0_MON1_W_LEN_MAX[6:0]						
Initial value:	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 23	—	All 0	R/W	Reserved
22 to 16	CH0_MON2_W_LEN_MAX[6:0]	H'1E	R/W	Data Storage Size Setting for ISP_ch0_ispin1 The amount of data stored in the RAM is the setting of these bits plus 1.
15 to 7	—	All 0	R/W	Reserved
6 to 0	CH0_MON1_W_LEN_MAX[6:0]	H'1E	R/W	Data Storage Size Setting for ISP_ch0_ispin0 The amount of data stored in the RAM is the setting of these bits plus 1.

U20.2.16 Image Data Storage Size Setting Register 2 (MONI_LEN2)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	CH0_MON4_W_LEN_MAX[6:0]						
Initial value:	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit	Bit Name	Initial Value	R/W	Description
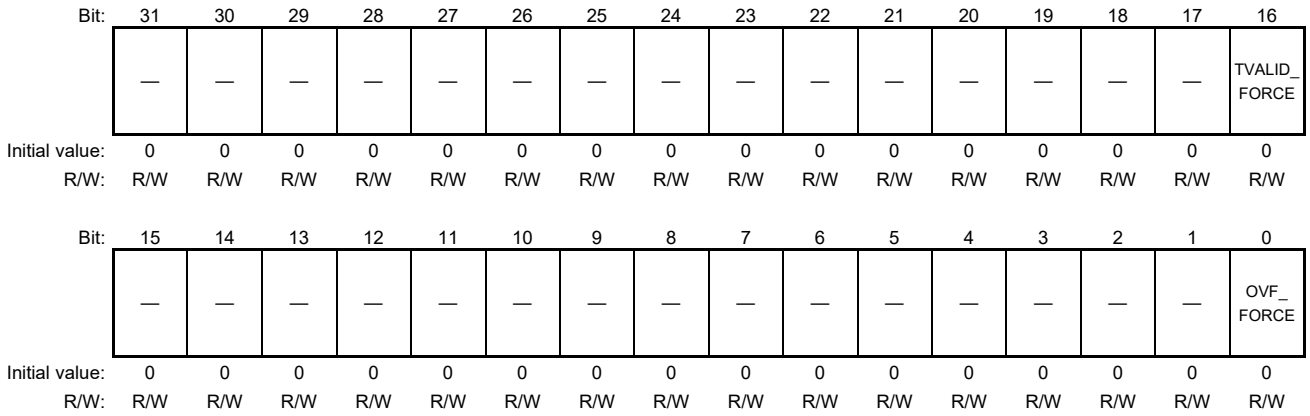
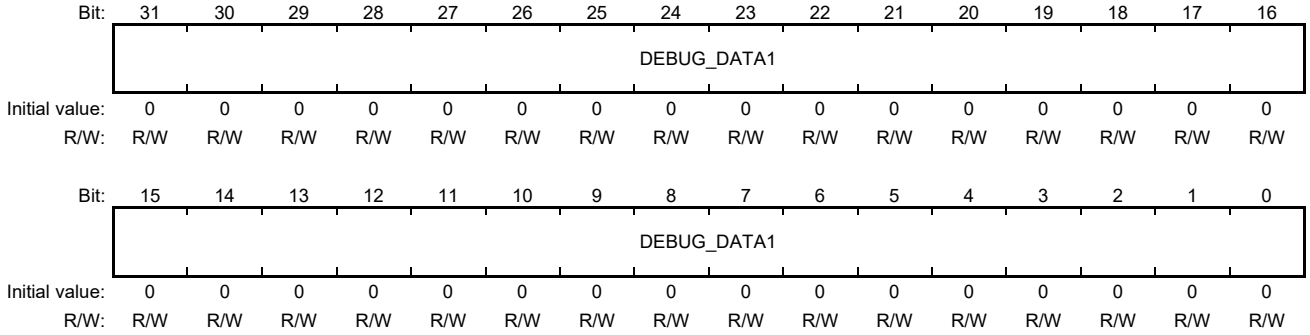
31 to 1	—	All 0	R/W	Reserved
0	HOLD	0	R/W	0:read value SIG_COUNT1-15 register 1:hold value SIG_COUNT1-15 register

U20.2.44 Debugging Mode Register (DEBUG_MODE)



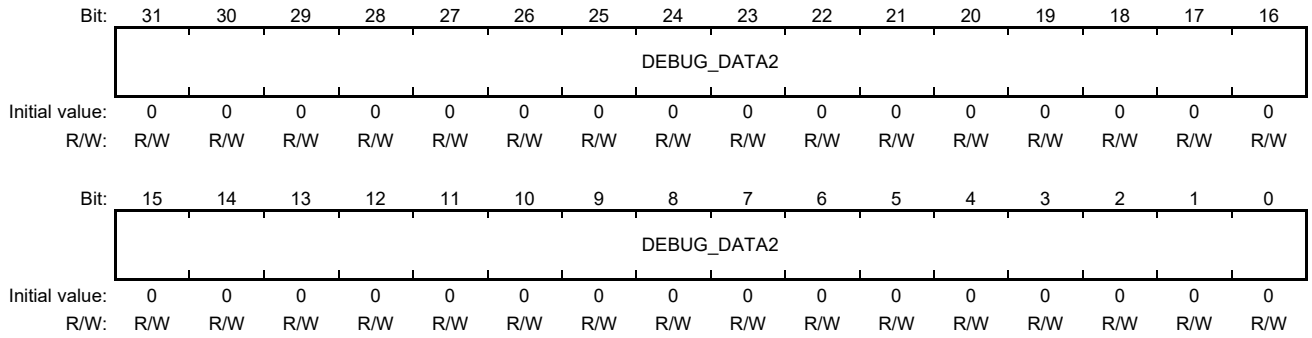
Bit	Bit Name	Initial Value	R/W	Description
31 to 17	—	All 0	R/W	Reserved
16	TVALID_FORCE	0	R/W	1: Sets the mti_tvalid1 signal to 1.
15 to 1	—	All 0	R/W	Reserved
0	OVF_FORCE	0	R/W	1: Sets the mti_common_ovf_err1 signal to 1.

U20.2.45 Debugging Mode Data 1 (DEBUG_DATA1)



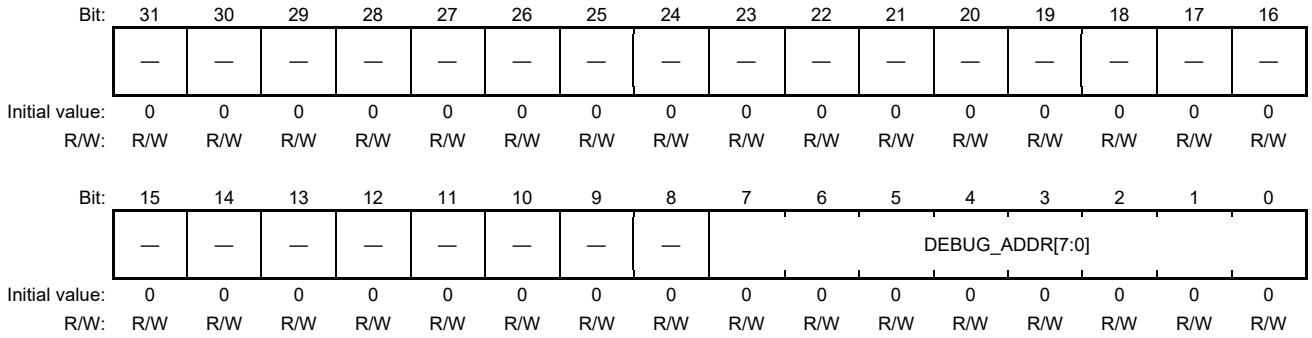
Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DEBUG_DATA1	0	R/W	Sets the mti_tdata1[31:0] signal. This setting is valid when register DEBUG_MODE.TVALID_FORCE = 1.

U20.2.46 Debugging Mode Data 2 (DEBUG_DATA2)



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DEBUG_DATA2	0	R/W	Sets the mti_tdata1[63:32] signal. This setting is valid when register DEBUG_MODE.TVALID_FORCE = 1.

U20.2.47 Debugging Mode Addr (DEBUG_ADDR)



Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R/W	Reserved
7 to 0	DEBUG_ADDR [7:0]	0	R/W	Sets the mti_taddr1[7:0] signal. This setting is valid when register DEBUG_MODE.TVALID_FORCE = 1.

U20.2.48 Lock Access Register (LOCKACCESS)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0		All 0	W	

U20.2.49 Lock Status Register (LOCKSTATUS)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0		H'0000 0003	R	

U20.2.50 Peripheral Identification Register 4 (Peripheral_ID4)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

31 to 8	—	All 0	R	Reserved
7 to 0	Preamble	H'B1	R	

U20.3 Operation

U20.3.1 initial setting

In order to correctly output ISP's image data to LVDS or PCIe, it is necessary to set CSD, AUR, LVDS, PCIe and ISP as well as MTI settings. Please follow the setting order as follows.

(1) CSD,AUR,LVDS,PCIe setting

Refer to U10 HSSTP for the setting contents.

(2) MTI setting

See U20.5.2 MTI setting. If (3) ISP setting is done before this setting, monitoring of the image data of the ISP is started halfway, there is a possibility that the monitor data can not be generated correctly.

(3) ISP setting

Refer to 25B ISP for the setting contents.

U20.3.2 MTI setting

In order to make MTI operate correctly, perform the setting in the following procedure.

(1) MTI standby release

MTI setting

procedure	contents	Register [Address]	Setting value
1	Set Soft Reset	CPGWPR [H'E6150000]	Bit4 = 0
		SFTRST13[H'E6152C34]	Bit4 = 1
2	Clear Module stop	CPGWPR [H'E6150000]	Bit4 = 1
		MSTPCR13 [H'E6152D34]	Bit4 = 0
		MSTPSR13 [H'E6152E34]	Bit4 = 0
3	Clear Soft Reset	CPGWPR [H'E6150000]	Bit4 = 0
		SFTRSTCLR13 [H'E6152CB4]	Bit4= 1

MTI register access permission setting

After this setting is forgotten, subsequent register access can not be performed.

procedure	contents	MTI Register	Setting value
1	Register access permission	LOCKACCESS	H'C5ACCE55

(2) Set target of image data collection

a) Specification target for ispin

Specify the collection target with ISPIN_MONI_MODE0 and 1 register.

MTI Register	bit	Setting value	Contents
ISPIN_MONI_MODE0	1:0	0	Target all bit(24bit) image data of ISP_ch0_ispin0.
		1	Target lower 12bit image data of ISP_ch0_ispin0.
		2	Target lower 20bit image data of ISP_ch0_ispin0.
		3	Target lower 8bit image data of ISP_ch0_ispin0.
	9:8	0	Target all bit(24bit) image data of ISP_ch0_ispin1.
		1	Target lower 12bit image data of ISP_ch0_ispin1.
		2	Target lower 20bit image data of ISP_ch0_ispin1.
		3	Target lower 8bit image data of ISP_ch0_ispin1.
ISPIN_MONI_MODE1	1:0	0	Target all bit(24bit) image data of ISP_ch1_ispin0.
		1	Target lower 12bit image data of ISP_ch1_ispin0.
		2	Target lower 20bit image data of ISP_ch1_ispin0.
		3	Target lower 8bit image data of ISP_ch1_ispin0.
	9:8	0	Target all bit(24bit) image data of ISP_ch1_ispin1.
		1	Target lower 12bit image data of ISP_ch1_ispin1.
		2	Target lower 20bit image data of ISP_ch1_ispin1.
		3	Target lower 8bit image data of ISP_ch1_ispin1.
ISPIN_MONI_MODE2	1:0	0	Target all bit(24bit) image data of ISP_ch2_ispin0.
		1	Target lower 12bit image data of ISP_ch2_ispin0.

		2	Target lower 20bit image data of ISP_ch2_ispin0.
		3	Target lower 8bit image data of ISP_ch2_ispin0.
	9:8	0	Target all bit(24bit) image data of ISP_ch2_ispin1.
		1	Target lower 12bit image data of ISP_ch2_ispin1.
		2	Target lower 20bit image data of ISP_ch2_ispin1.
		3	Target lower 8bit image data of ISP_ch2_ispin1.
ISPIN_MONI_MODE3	1:0	0	Target all bit(24bit) image data of ISP_ch3_ispin0.
		1	Target lower 12bit image data of ISP_ch3_ispin0.
		2	Target lower 20bit image data of ISP_ch3_ispin0.
		3	Target lower 8bit image data of ISP_ch3_ispin0.
	9:8	0	Target all bit(24bit) image data of ISP_ch3_ispin1.
		1	Target lower 12bit image data of ISP_ch3_ispin1.
		2	Target lower 20bit image data of ISP_ch3_ispin1.
		3	Target lower 8bit image data of ISP_ch3_ispin1.

b) Specification target for ispout

Specify the collection target with ISP_MONI_MODE0 and 1 register.

MTI Register	bit	Setting value	Contents
ISP_MONI_MODE0	1:0	0	Target all bit(24bit) image data of ISP_ch0_ispout0.
		1	Target lower 12bit image data of ISP_ch0_ispout0.
		2	Target lower 20bit image data of ISP_ch0_ispout0.
		3	Target lower 8bit image data of ISP_ch0_ispout0.
	9:8	0	Target all bit(24bit) image data of ISP_ch0_ispout1.
		1	Target lower 12bit image data of ISP_ch0_ispout1.
		2	Target lower 20bit image data of ISP_ch0_ispout1.
		3	Target lower 8bit image data of ISP_ch0_ispout1.
	17:16	0	Target all bit(24bit) image data of ISP_ch0_ispout2.
		1	Target lower 12bit image data of ISP_ch0_ispout2.
		2	Target lower 20bit image data of ISP_ch0_ispout2.
		3	Target lower 8bit image data of ISP_ch0_ispout2.
	25:24	0	Target all bit(24bit) image data of ISP_ch0_ispout3.
		1	Target lower 12bit image data of ISP_ch0_ispout3.
		2	Target lower 20bit image data of ISP_ch0_ispout3.
		3	Target lower 8bit image data of ISP_ch0_ispout3.
ISP_MONI_MODE1	1:0	0	Target all bit(24bit) image data of ISP_ch1_ispout0.
		1	Target lower 12bit image data of ISP_ch1_ispout0.
		2	Target lower 20bit image data of ISP_ch1_ispout0.
		3	Target lower 8bit image data of ISP_ch1_ispout0.
	9:8	0	Target all bit(24bit) image data of ISP_ch1_ispout1.
		1	Target lower 12bit image data of ISP_ch1_ispout1.
		2	Target lower 20bit image data of ISP_ch1_ispout1.
		3	Target lower 8bit image data of ISP_ch1_ispout1.

(3) Setting interrupt enable

To report the error interrupt detected by the MTI to the CPU, set the corresponding bit in the INT_ENABLE register to 1.

(4) Start MTI

MTI is started with the MONI_ENABLE0 and 1 register.
Set the bit to be activated to 1.

MTI Register	bit	Setting value	Contents
MONI_MODE0	0	1	Allow collecting image data of TAG number ”0” of ISP_ch0_ispin0.
	1	1	Allow collecting image data of TAG number ”1” of ISP_ch0_ispin0.
	2	1	Allow collecting image data of TAG number ”2” of ISP_ch0_ispin0.
	3	1	Allow collecting image data of TAG number ”3” of ISP_ch0_ispin0.
	4	1	Allow collecting image data of TAG number ”4” of ISP_ch0_ispin0.
	5	1	Allow collecting image data of TAG number ”5” of ISP_ch0_ispin0.
	6	1	Allow collecting image data of TAG number ”6” of ISP_ch0_ispin0.
	7	1	Allow collecting image data of TAG number ”7” of ISP_ch0_ispin0.
	15:8	1	Allow collecting image data of TAG number ”X” (x:0-7)of ISP_ch0_ispin1. Bit assignment is the same as bit7:0.
	16	1	Allow collecting image data of ISP_ch0_ispout0.
	17	1	Allow collecting image data of ISP_ch0_ispout1.
	18	1	Allow collecting image data of ISP_ch0_ispout2.
	19	1	Allow collecting image data of ISP_ch0_ispout3.
MONI_MODE1	19:0	1	Allow collecting image data of ISP_ch1_ispin0-1,ispout0-3. Bit assignment is the same as MONI_MODE0 register.

U20.3.3 Data Format

The image data of the ISP is notified to the CSD via the AXI4 bus. Transfer format will be below.

U20.3.3.1 AWID

The format differs between ispin* and ispout*.

For ispin*, the TAG number is stored.
AXI4 issues an outstanding write request for each TAG number.

For ispout*, the ispout_no(0-3) is stored.
AXI4 issues an outstanding write request for each ispout_no.

U20.3.3.2 AWADDR

Contents of AWADDR		
Bit[31:24]	Bit[23:17]	Bit[16:0]
(*2)	(*1)	(*2)

(*1) When the content WDATA is image data of ispin

Bit	Contents
23	ISP_ch number(0-1)
22	Fixed to 0
21:20	ispin number (0-3)
19:17	tag number(0-7)

When the content WDATA is image data of ispout

Bit	Contents
23	ISP_ch number(0-1)
22	Fixed to 1
21:20	ispout number (0-3)
19:17	tag number(0-7)

(*2) When the content of WDATA is VSYNC or HSYNC, AWADDR_SET_S register
When the content of WDATA is image data, the AWADDR_SET_D register is reflected.

U20.3.3 WDATA

(1) Transfer of VSYNC

a) When ispin is to be monitored, data is transferred under the following conditions.
At the rising edge of the VSYNC signal

[Transfer format]

VSYNC		Bit							
		7	6	5	4	3	2	1	0
Byte	0	1	1	fmt[5:0] (H'00-3F)					
	1-7	Fixed to 0							

b) When ispout is to be monitored, data is transferred under the following conditions.
At the rising edge of the VSYNC signal

[Transfer format]

VSYNC		Bit							
		7	6	5	4	3	2	1	0
Byte	0	1	1	Fixed to 0					
	1-7	Fixed to 0							

(2) Transfer of HSYNC

a) When ispin is to be monitored, data is transferred under the following conditions.
At the rising edge of the HSYNC signal
However, in order to minimize data overhead,
data transfer at the rise of HSYNC following the rise of VSYNC is omitted.

[Transfer format]

HSYNC	Bit							
	7	6	5	4	3	2	1	0

Byte	0	0	1	fmt[5:0] (H'00-3F)
	1-7	Fixed to 0		

b) When ispout is to be monitored, data is transferred under the following conditions.
At the rising edge of the HSYNC signal
However, in order to minimize data overhead,
data transfer at the rise of HSYNC following the rise of VSYNC is omitted.

[Transfer format]

HSYNC		Bit							
		7	6	5	4	3	2	1	0
Byte	0	0	1	Fixed to 0					
	1-7	Fixed to 0							

(3) Transfer of image data
0 is stored in the invalid data area.

a) When transferring image data of ispin to the lower 8bit

[Transfer format]

ispin 8bit lsb		Bit							
		7	6	5	4	3	2	1	0
Byte	0	data[7:0] (cycle n)							
	1	data[7:0] (cycle n+1)							
	2	data[7:0] (cycle n+2)							
	3	data[7:0] (cycle n+3)							
	4	data[7:0] (cycle n+4)							
	5	data[7:0] (cycle n+5)							
	6	data[7:0] (cycle n+6)							
	7	data[7:0] (cycle n+7)							

b) When transferring image data of ispin to the lower 12bit, three WDATA's become one set

[Transfer format]
First WDATA format

ispin 12bit lsb		Bit							
		7	6	5	4	3	2	1	0
Byte	0	data[7:0] (cycle n)							
	1	data[3:0] (cycle n+1)				data[11:8] (cycle n)			
	2	data[11:4] (cycle n+1)							
	3	data[7:0] (cycle n+2)							
	4	data[3:0] (cycle n+3)				data[11:8] (cycle n+2)			
	5	data[11:4] (cycle n+3)							
	6	data[7:0] (cycle n+4)							
	7	data[3:0] (cycle n+5)				data[11:8] (cycle n+4)			

Second WDATA format

ispin 12bit lsb		Bit							
		7	6	5	4	3	2	1	0
Byte	0	data[11:4] (cycle n+5)							
	1	data[7:0] (cycle n+6)							

	2	data[3:0] (cycle n+7)	data[11:8] (cycle n+6)
	3	data[11:4] (cycle n+7)	
	4	data[7:0] (cycle n+8)	
	5	data[3:0] (cycle n+9)	data[11:8] (cycle n+8)
	6	data[11:4] (cycle n+9)	
	7	data[7:0] (cycle n+10)	

Third WDATA format

ispin 12bit lsb		Bit 7	6	5	4	3	2	1	0
Byte	0	data[3:0] (cycle n+11)				data[11:8] (cycle n+10)			
	1	data[11:4] (cycle n+11)							
	2	data[7:0] (cycle n+12)							
	3	data[3:0] (cycle n+13)				data[11:8] (cycle n+12)			
	4	data[11:4] (cycle n+13)							
	5	data[7:0] (cycle n+14)							
	6	data[3:0] (cycle n+15)				data[11:8] (cycle n+14)			
	7	data[11:4] (cycle n+15)							

c) When transferring image data of ispin to the lower 20bit, five WDATA's become one set

[Transfer format]

First WDATA format

ispin 20bit lsb		Bit 7	6	5	4	3	2	1	0
Byte	0	data[7:0] (cycle n)							
	1	data[15:8] (cycle n)							
	2	data[3:0] (cycle n+1)				data[19:16] (cycle n)			
	3	data[11:4] (cycle n+1)							
	4	data[19:12] (cycle n+1)							
	5	data[7:0] (cycle n+2)							
	6	data[15:8] (cycle n+2)							
	7	data[3:0] (cycle n+3)				data[19:16] (cycle n+2)			

Second WDATA format

ispin 20bit lsb		Bit 7	6	5	4	3	2	1	0
Byte	0	data[11:4] (cycle n+3)							
	1	data[19:12] (cycle n+3)							
	2	data[7:0] (cycle n+4)							
	3	data[15:8] (cycle n+4)							
	4	data[3:0] (cycle n+5)				data[19:16] (cycle n+4)			
	5	data[11:4] (cycle n+5)							
	6	data[19:12] (cycle n+5)							
	7	data[7:0] (cycle n+6)							

Third WDATA format

ispin 20bit lsb		Bit 7	6	5	4	3	2	1	0
Byte	0	data[15:8] (cycle n+6)							
	1	data[3:0] (cycle n+7)				data[19:16] (cycle n+6)			
	2	data[11:4] (cycle n+7)							

	3	data[19:12] (cycle n+7)
	4	data[7:0] (cycle n+8)
	5	data[15:8] (cycle n+8)
	6	data[3:0] (cycle n+9) / data[19:16] (cycle n+8)
	7	data[11:4] (cycle n+9)

Fourth WDATA format

ispin 20bit lsb		Bit 7	6	5	4	3	2	1	0
Byte	0	data[19:12] (cycle n+9)							
	1	data[7:0] (cycle n+10)							
	2	data[15:8] (cycle n+10)							
	3	data[3:0] (cycle n+11)				data[19:16] (cycle n+10)			
	4	data[11:4] (cycle n+11)							
	5	data[19:12] (cycle n+11)							
	6	data[7:0] (cycle n+12)							
	7	data[15:8] (cycle n+12)							

Fifth WDATA format

ispin 20bit lsb		Bit 7	6	5	4	3	2	1	0
Byte	0	data[3:0] (cycle n+13)				data[19:16] (cycle n+12)			
	1	data[11:4] (cycle n+13)							
	2	data[19:12] (cycle n+13)							
	3	data[7:0] (cycle n+14)							
	4	data[15:8] (cycle n+14)							
	5	data[3:0] (cycle n+15)				data[19:16] (cycle n+14)			
	6	data[11:4] (cycle n+15)							
	7	data[19:12] (cycle n+15)							

d) When transferring image data of ispin to the all bit(24bit), three WDATA's become one set

[Transfer format]
First WDATA format

ispin 24bit		Bit 7	6	5	4	3	2	1	0
Byte	0	data[7:0] (cycle n)							
	1	data[15:8] (cycle n)							
	2	data[23:16] (cycle n)							
	3	data[7:0] (cycle n+1)							
	4	data[15:8] (cycle n+1)							
	5	data[23:16] (cycle n+1)							
	6	data[7:0] (cycle n+2)							
	7	data[15:8] (cycle n+2)							

Second WDATA format

ispin 24bit		Bit 7	6	5	4	3	2	1	0
Byte	0	data[23:16] (cycle n+2)							
	1	data[7:0] (cycle n+3)							
	2	data[15:8] (cycle n+3)							

	3	data[23:16] (cycle n+3)
	4	data[7:0] (cycle n+4)
	5	data[15:8] (cycle n+4)
	6	data[23:16] (cycle n+4)
	7	data[7:0] (cycle n+5)

Third WDATA format

ispin 24bit		Bit							
		7	6	5	4	3	2	1	0
Byte	0	data[15:8] (cycle n+5)							
	1	data[23:16] (cycle n+5)							
	2	data[7:0] (cycle n+6)							
	3	data[15:8] (cycle n+6)							
	4	data[23:16] (cycle n+6)							
	5	data[7:0] (cycle n+7)							
	6	data[15:8] (cycle n+7)							
	7	data[23:16] (cycle n+7)							

When transferring image data of ispout to the lower 8bit

[Transfer format]

ispout 8bit lsb		Bit							
		7	6	5	4	3	2	1	0
Byte	0	data[7:0] (cycle n)							
	1	data[7:0] (cycle n+1)							
	2	data[7:0] (cycle n+2)							
	3	data[7:0] (cycle n+3)							
	4	data[7:0] (cycle n+4)							
	5	data[7:0] (cycle n+5)							
	6	data[7:0] (cycle n+6)							
	7	data[7:0] (cycle n+7)							

e) When transferring image data of ispout to the upper 8bit

[Transfer format]

ispout 8bit msb		Bit							
		7	6	5	4	3	2	1	0
Byte	0	data[11:4] (cycle n)							
	1	data[11:4] (cycle n+1)							
	2	data[11:4] (cycle n+2)							
	3	data[11:4] (cycle n+3)							
	4	data[11:4] (cycle n+4)							
	5	data[11:4] (cycle n+5)							
	6	data[11:4] (cycle n+6)							
	7	data[11:4] (cycle n+7)							

f) When transferring image data of ispout to the all bit(12bit), three WDATA's become one set

[Transfer format]
First WDATA format

ispout 12bit lsb		Bit 7	6	5	4	3	2	1	0
Byte	0	data[7:0] (cycle n)							
	1	data[3:0] (cycle n+1)				data[11:8] (cycle n)			
	2	data[11:4] (cycle n+1)							
	3	data[7:0] (cycle n+2)							
	4	data[3:0] (cycle n+3)				data[11:8] (cycle n+2)			
	5	data[11:4] (cycle n+3)							
	6	data[7:0] (cycle n+4)							
	7	data[3:0] (cycle n+5)				data[11:8] (cycle n+4)			

Second WDATA format

ispout 12bit lsb		Bit 7	6	5	4	3	2	1	0
Byte	0	data[11:4] (cycle n+5)							
	1	data[7:0] (cycle n+6)							
	2	data[3:0] (cycle n+7)				data[11:8] (cycle n+6)			
	3	data[11:4] (cycle n+7)							
	4	data[7:0] (cycle n+8)							
	5	data[3:0] (cycle n+9)				data[11:8] (cycle n+8)			
	6	data[11:4] (cycle n+9)							
	7	data[7:0] (cycle n+10)							

Third WDATA format

ispout 12bit lsb		Bit 7	6	5	4	3	2	1	0
Byte	0	data[3:0] (cycle n+11)				data[11:8] (cycle n+10)			
	1	data[11:4] (cycle n+11)							
	2	data[7:0] (cycle n+12)							
	3	data[3:0] (cycle n+13)				data[11:8] (cycle n+12)			
	4	data[11:4] (cycle n+13)							
	5	data[7:0] (cycle n+14)							
	6	data[3:0] (cycle n+15)				data[11:8] (cycle n+14)			
	7	data[11:4] (cycle n+15)							

U20.4 Usage Notes

(1) Restriction on the number of collected channels
Monitoring of multiple image data can be specified by setting the MONI_ENABLE register.
If you do not use it within the band limit of the transfer path,
overflow will occur and correct data transfer will not be possible

When the output destination is PCIe

Bandwidth limit formula =
[(Amount of data per channel[bit]×ch number)÷(1000/Pixel clock[MHz])÷8] ≦ 1.0GB/s

[Example of combination]

Pixel clock [MHz]	ispin/ispout	Data width [bit]	Ch number	Used bandwidth [GB/s]
166.7	ispin	24	1	0.5
166.7	ispout	8	3	0.5
			total	1.0

Pixel clock [MHz]	ispin/ispout	Data width [bit]	Ch number	Used bandwidth [GB/s]
166.7	ispin	12	2	0.5
166.7	ispout	12	2	0.5
			total	1.0

Pixel clock [MHz]	ispin/ispout	Data width [bit]	Ch number	Used bandwidth [GB/s]
166.7	ispin	8	2	0.5
166.7	ispout	8	4	0.5
			total	1.0

U20.5 Safety Mechanisms

Not supported any safety mechanisms

U25. Vision-IP

U25.1 Overview

The Vision-IP captures image data from the DDR-SDRAM and processes images. As image processing algorithms, it supports optical flow (optical flow vectors generation from a pair of images), and SfM engine (Structure from motion).

It's sometimes indicated on this document by another name, so please paraphrase.

- DOF or UMF : Dense type of Optical Flow vectors generation.
- SMD-PS/SMD-POST or SMPS/SMPO : Structure from motion engines.

U25.1.1 Features

The Vision-IP which includes the DOF and SMD-* cores, and DMAC engines integrated in each core which can accelerate as an accelerator for image processing at high speed. These cores realize computer vision algorithm such as optical flow, structure from motion with co-operation with software.

(1) DOF core

The DOF core is inherently running through a sequence of three elementary generations of flow vectors; each one is matching a pyramid level. The input for each pyramid level is not built inside the DOF core and is assumed to be prepared by another unit in the system and ready in system memory once DOF core needs them. The detail information is described in licensee guide.

(2) SMD-* core

The SMD cores are a hardware unit to support structure from motion. The detail information is described in licensee guide.

(3) Wrapper function

All wrapper modules have several functions such as AXI-BUS bridge, software reset function and so on. Only UMF wrapper has a format conversion function (OTFDCR) that is converted the format of input image data on the fly. In addition, there is a register block to control functions in the wrapper. The description of this register in the wrapper is specify in Register Description section in this document. On the other hand, the register description in IP cores are in each licensee guide.

U25.1.2 Block diagram

Figure U25.1 shows the block diagram of UMF module. UMF module have some kind of function in the wrapper module such as software reset control (rst_ctl/is_ctl), on the fly data format converter (OTFDCR), AXI-BUS bridge which is converting bus width from 64bits to 256bits (X2X), and register block in order to control each function in “umf_wrap”. And also, there is “fcprm” which is data compression function in “UMF_TOP”.

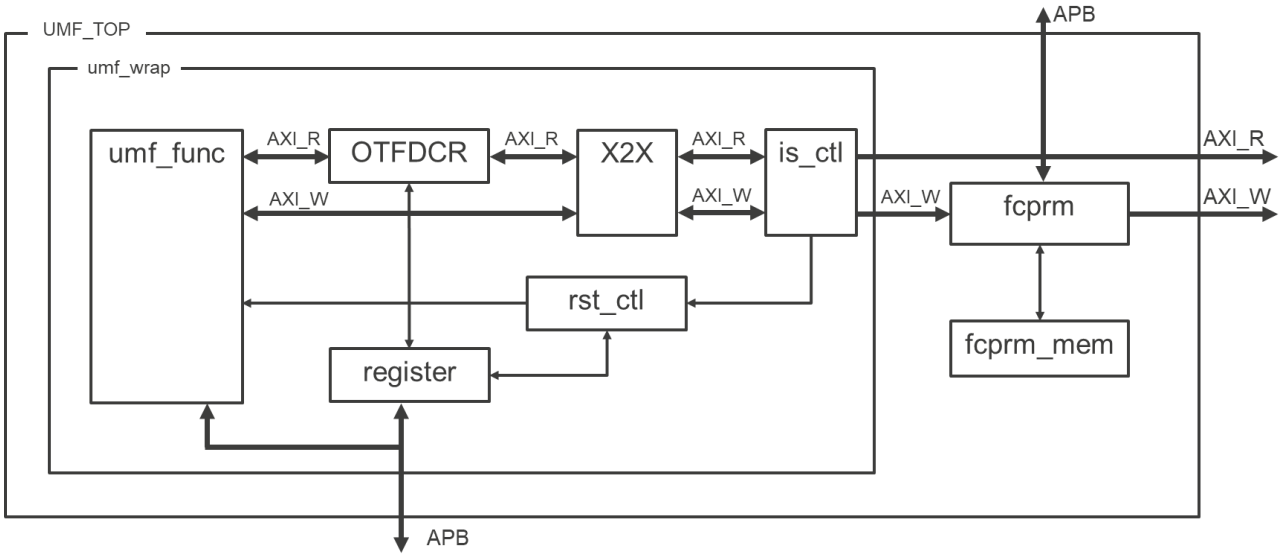

Figure U25.1 UMF block diagram

Figure U25.2 shows the block diagram of SMD_PS and SMD_POST module. These module have some kind of function in the wrapper module such as software reset control (rst_ctl/is_ctl), AXI-BUS bridge which is converting bus width from 64bits to 256bits (X2X), and register block in order to control each function.

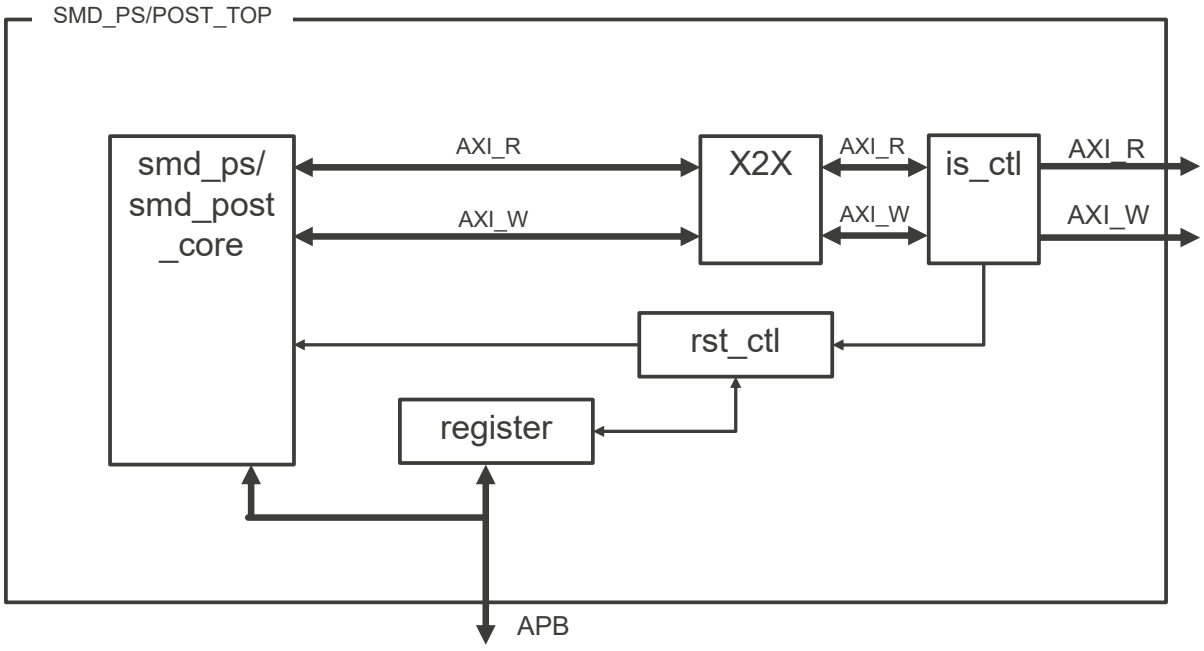

Figure U25.2 SMD_PS and SMD_POST block diagram

U25.1.3 Specifications of the Vision-IP by Products

Table U25.1 Specifications of the Vision-IP

	AXI master	APB slave	DOF core	SMD-PS core	SMD-POST core
Bus Width	256bits (*)	32bits	-	-	-
Clock	SVD1_VIPϕ	SVD2_VIPϕ	SVD1_VIPϕ	SVD2_VIPϕ	SVD2_VIPϕ
Number of cores	1 for each core	1 for each core	1	1	1

(*) DMAC engine's AXI interface is 64 bits, but it connects with external BUS by 256bits AXI interface.

U25.1.4 Register Configuration

Module	Wrap register base Address
UMF wrap	H'00 E7B3 B000
SMD_PS wrap	H'00 E7B3 B400
SMD_POST wrap	H'00 E7B3 BC00

Table U25.2 Register configuration in the wrapper

Name	Abbreviation	R/W	Address	Access Size	Module (*)
Reset control register	RST_CTRL	R/W	Base Address + H'00	32	All
Software reset status register	SWRST_STA	R	Base Address + H'04	32	All
Channel control register1	CH_CTRL1	R/W	Base Address + H'40	32	UMF
Input picture horizontal size register1	SRC_HSIZE1	R/W	Base Address + H'44	32	UMF
Input picture vertical size register1	SRC_VSIZE1	R/W	Base Address + H'48	32	UMF
Input picture format register1	SRC_FMT1	R/W	Base Address + H'4C	32	UMF
Input picture address register1	SRC_ADR1	R/W	Base Address + H'50	32	UMF
Input picture stride register1	SRC_PSTRIDE1	R/W	Base Address + H'54	32	UMF
Output picture format register1	DST_FMT1	R/W	Base Address + H'58	32	UMF
Output padding pixel value register1	PAD_VALUE1	R/W	Base Address + H'5C	32	UMF
Channel control register2	CH_CTRL2	R/W	Base Address + H'70	32	UMF
Input picture horizontal size register2	SRC_HSIZE2	R/W	Base Address + H'74	32	UMF
Input picture vertical size register2	SRC_VSIZE2	R/W	Base Address + H'78	32	UMF
Input picture format register2	SRC_FMT2	R/W	Base Address + H'7C	32	UMF
Input picture address register2	SRC_ADR2	R/W	Base Address + H'80	32	UMF

Output picture format register2	DST_FMT2	R/W	Base Address + H'88	32	UMF

Name	Abbreviation	R/W	Address	Access Size	Module (*)
Output padding pixel value register2	PAD_VALUE2	R/W	Base Address + H'8C	32	UMF
Channel control register3	CH_CTRL3	R/W	Base Address + H'A0	32	UMF
Input picture horizontal size register3	SRC_HSIZE3	R/W	Base Address + H'A4	32	UMF
Input picture vertical size register3	SRC_VSIZE3	R/W	Base Address + H'A8	32	UMF
Input picture format register3	SRC_FMT3	R/W	Base Address + H'AC	32	UMF
Input picture address register3	SRC_ADR3	R/W	Base Address + H'B0	32	UMF
Input picture stride register3	SRC_PSTRIDE3	R/W	Base Address + H'B4	32	UMF
Output picture format register3	DST_FMT3	R/W	Base Address + H'B8	32	UMF
Output padding pixel value register3	PAD_VALUE3	R/W	Base Address + H'BC	32	UMF

(*) ALL: UMF, SMD_PS and SMD_POST have these registers. UMF: Only UMF has these registers.

U25.1.5 Connected Module

Table U25.3 Vision-IP connected Module

Module	Connected module	Description
UMF (DOF)	AXI-BUS	Address map (core) to H'00 E7A1 0000 to H'00 E7A1 FFFF (*)
SMD-PS	AXI-BUS	Address map (core) to H'00 E7A2 0000 to H'00 E7A2 FFFF (*)
SMD-POST	AXI-BUS	Address map (core) to H'00 E7A4 0000 to H'00 E7A4 FFFF (*)
UMF (DOF)	Reset	S/W reset signals comes from CPG, for details refer to register description in Module Standby Software Reset section.
SMD-PS	Reset	S/W reset signals comes from CPG, for details refer to register description in Module Standby Software Reset section.
SMD-POST	Reset	S/W reset signals comes from CPG, for details refer to register description in Module Standby Software Reset section.
UMF (DOF)	Clock	Clock to SVD1_VIPϕ Clock to SVD2_VIPϕ
SMD-PS	Clock	Clock to SVD1_VIP ϕ Clock to SVD2_VIP ϕ
SMD-POST	Clock	Clock to SVD1_VIP ϕ Clock to SVD2_VIP ϕ
UMF (DOF)	Interrupt	Status interrupt signals connect to INTC module and Error interrupt signal connect to ECM module, for details refer to INTC and ECM section.
SMD-PS	Interrupt	Status interrupt signals connect to INTC module and Error interrupt signal connect to ECM module, for details refer to INTC and ECM section.
SMD-POST	Interrupt	Status interrupt signals connect to INTC module and Error interrupt signal connect to ECM module, for details refer to INTC and ECM section.
UMF (DOF)	IPMMU	uTLB information is described in IPMMU section.
SMD-PS	IPMMU	uTLB information is described in IPMMU section.
SMD-POST	IPMMU	uTLB information is described in IPMMU section.

(*) Note: Do not access undefined register.

U25.2 Register Description

U25.2.1 Reset control register (RST_CTRL)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SWRST_EN
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	SWRST_EN	0	R/W	Software reset enable This is the enable bit of software reset for AXI-BUS bridges, OTFDCR in Wrapper, and the AXI interface of IP cores. Write 1 to this bit to enable software reset, right after being set to 1, this bit will be autonomously clear to 0. The read value should be 0. Note: The usage of this register shall be limited as same as IP errata: IP SW resets usage forbidden in product. Some sub-modules in the IP provide a SW reset: IP Core, AXI_DMA_AEI, CSC, AEI_MUX, PCHK.When one of these sub-modules SW reset is asserted, its interface may become unstable. So this software reset is only for AXI-BUS bridges, OTFDCR in Wrapper, and the AXI interface of IP cores

U25.2.2 Software reset status register (SWRST_STA)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SWRST_STA
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
0	SWRST_STA	0	R	Software reset status This bit shows the status of software reset, after SWRST_EN is set to 1, this bit is immediately set to 1. After the end of software reset sequence, this status bit returns to 0. 0: Software reset procedure has been completed. 1: Software reset procedure has not been competed yet.

U25.2.3 Channel control register1 (CH_CTRL1)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ACT
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	ACT	0	R/W	Channel activation. 0: Inactive, transaction's address belongs to inactive channel will be assigned to "Bypass" channel. 1: Channel activated.

U25.2.4 Input picture horizontal size register1 (SRC_HSIZE1)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	HSIZE[26:16]										
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	HSIZE[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 27	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
26 to 0	HSIZE	0	R/W	Input picture Horizontal size Value range: 1~8191 pixels (2D) or 1~8192*8192 (1D)

U25.2.5 Input picture vertical size register1 (SRC_VSIZE1)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	VSIZE[13:0]													
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13 to 0	VSIZE	0	R/W	Input picture vertical size Value range: 1~8192 pixels (2D) or 0 (1D)

U25.2.6 Input picture format register1 (SRC_FMT1)

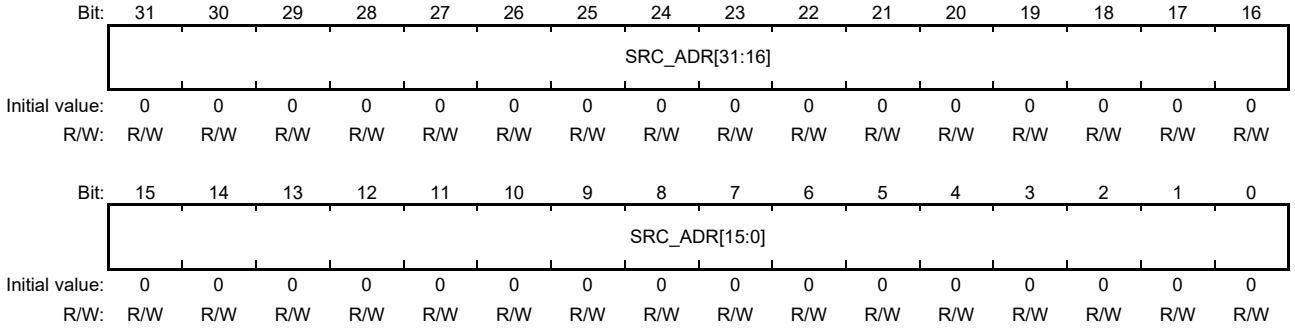
Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MSBOFS				LSBOFS				—	—	—	BPP	—	—	—	TBPPCE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 12	MSBOFS	0	R/W	MSB offset bit. Range: 0~15. It shall be fixed 0 in 1 Byte/pixel
11 to 8	LSBOFS	0	R/W	LSB offset bit. Range: 0~15. It shall be fixed 0 in 1 Byte/pixel
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	BPP	0	R/W	Byte per pixels 0: 2 Bytes/pixel; 1: 1 Byte/pixel
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

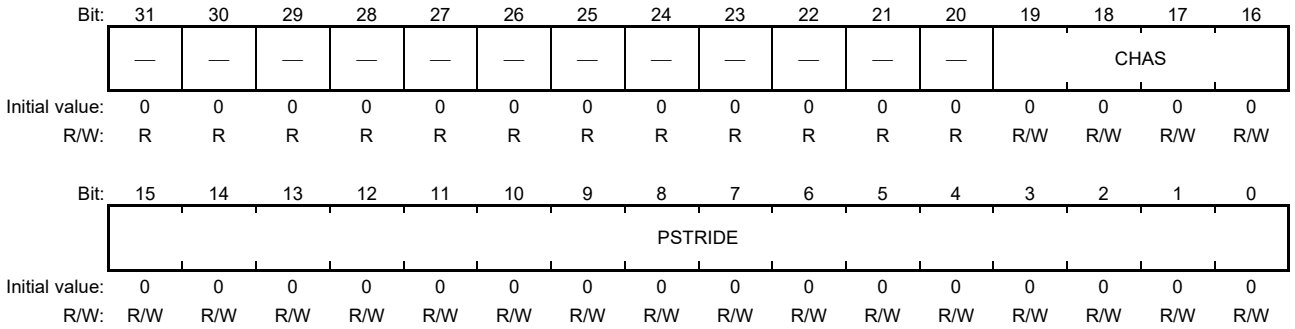
Bit	Bit Name	Initial Value	R/W	Description
0	TBPPCE	0	R/W	2BPP conversion enabled 0: Disabled; 1: Enabled

U25.2.7 Input picture address register1 (SRC_ADR1)



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	SRC_ADR	0	R/W	Source picture address (always align 8Bytes) Bit [31:16] and SRC_PSTRIDE{n}.CHAS are used to identify channel ID

U25.2.8 Input picture stride register1 (SRC_PSTRIDE1)



Bit	Bit Name	Initial Value	R/W	Description
31 to 20	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
19 to 16	CHAS	0	R/W	Channel address space Specify how many Least Significant Bit of SRC_ADR are used Source picture address range = SRC_ADR[31-(CHAS+1):0] when D'2 <= CHAS <= D'15 Source picture address range = SRC_ADR[29:0] when D'0 <= CHAS <= D'1
15 to 0	PSTRIDE	0	R/W	Source picture memory stride (always align 8Bytes)

U25.2.9 Output picture format register1 (DST_FMT1)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MSBOFS				LSBOFS				—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 12	MSBOFS	0	R/W	MSB offset bit. Range: 0~15. User shall fix 0 in 1 Byte/pixel
11 to 8	LSBOFS	0	R/W	LSB offset bit. Range: 0~15. User shall fix 0 in 1 Byte/pixel
7 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

U25.2.10 Output padding pixel value register1 (PAD_VALUE1)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MSB_PAD															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	LSB_PAD															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	MSB_PAD	0	R/W	Padding value for MSB. Example if MSBOFS is 4, MSB_PAD[3:0] are filled to 4 MSB output pixel.
15 to 0	LSB_PAD	0	R/W	Padding value for LSB. Example if LSBOFS is 4, LSB_PAD[3:0] are filled to 4 LSB output pixel.

U25.2.11 Channel control register2 (CH_CTRL2)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ACT
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	ACT	0	R/W	Channel activation. 0: Inactive, transaction's address belongs to inactive channel will be assigned to "Bypass" channel. 1: Channel activated.

U25.2.12 Input picture horizontal size register2 (SRC_HSIZE2)

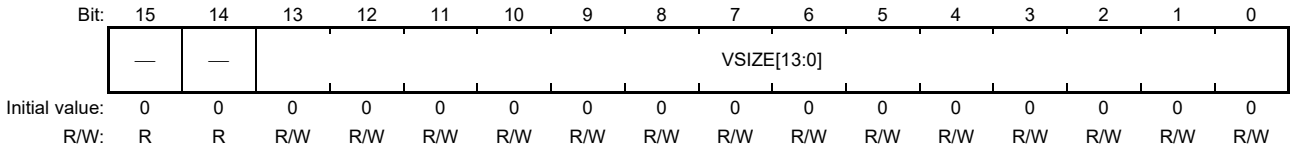
Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	HSIZE[26:16]										
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	HSIZE[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 27	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
26 to 0	HSIZE	0	R/W	Input picture Horizontal size Value range: 1~8191 pixels (2D) or 1~8192*8192 (1D)

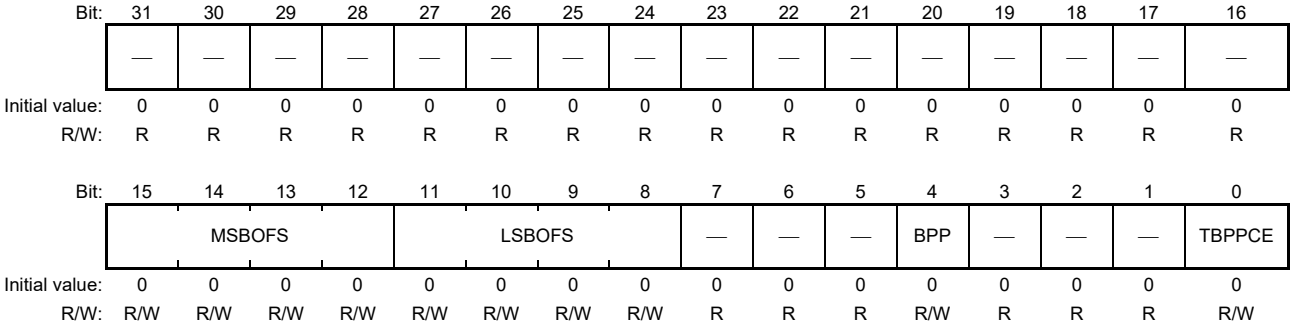
U25.2.13 Input picture vertical size register2 (SRC_VSIZE2)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R



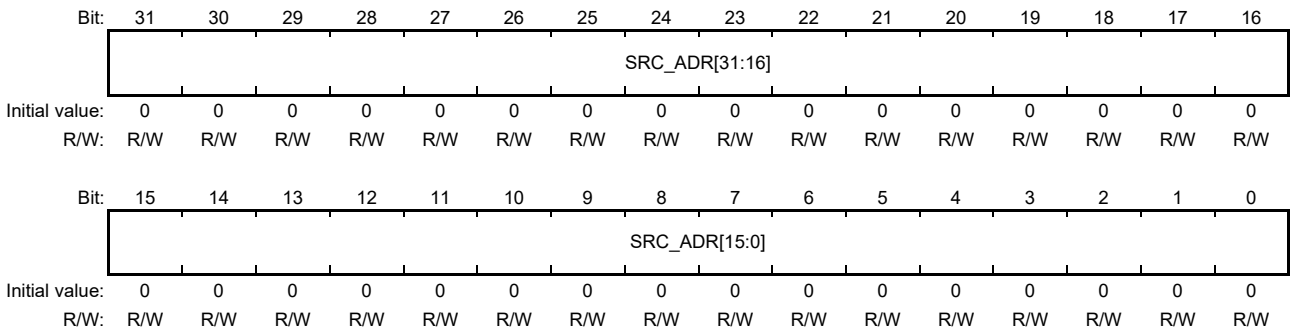
Bit	Bit Name	Initial Value	R/W	Description
31 to 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13 to 0	VSIZE	0	R/W	Input picture vertical size Value range: 1~8192 pixels (2D) or 0 (1D)

U25.2.14 Input picture format register2 (SRC_FMT2)



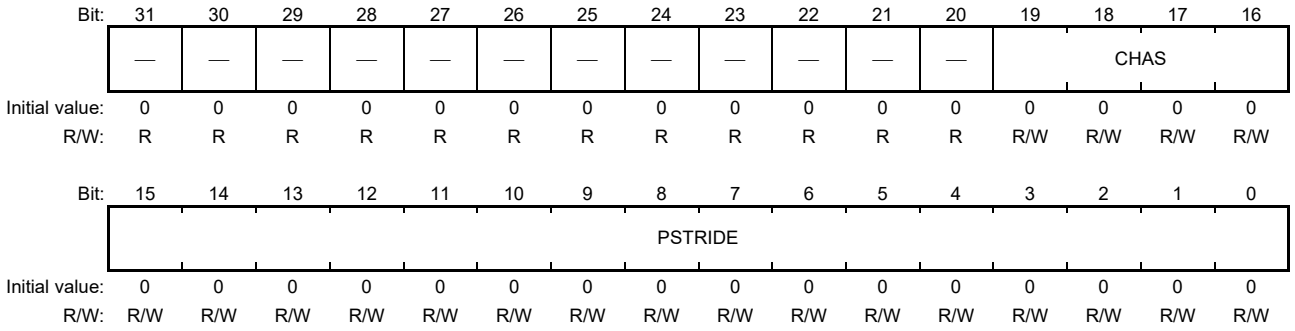
Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 12	MSBOFS	0	R/W	MSB offset bit. Range: 0~15. It shall be fixed 0 in 1 Byte/pixel
11 to 8	LSBOFS	0	R/W	LSB offset bit. Range: 0~15. It shall be fixed 0 in 1 Byte/pixel
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	BPP	0	R/W	Byte per pixels 0: 2 Bytes/pixel; 1: 1 Byte/pixel
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	TBPPCE	0	R/W	2BPP conversion enabled 0: Disabled; 1: Enabled

U25.2.15 Input picture address register2 (SRC_ADR2)



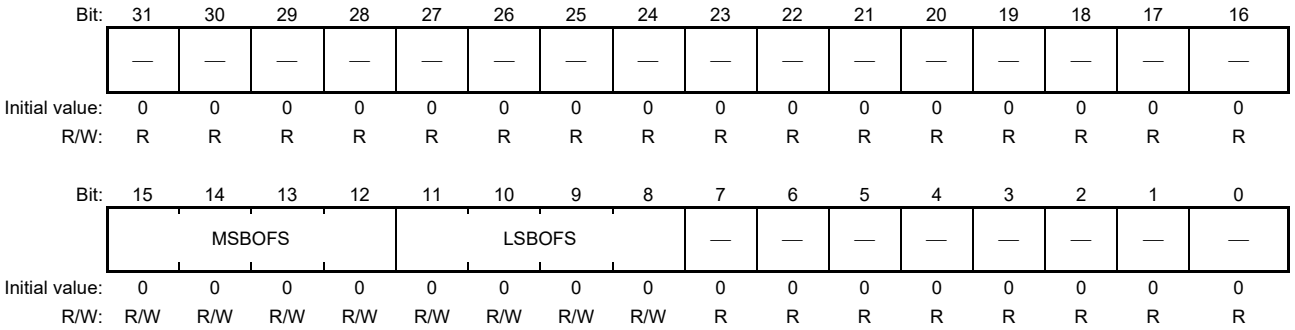
Bit	Bit Name	Initial Value	R/W	Description
31 to 0	SRC_ADR	0	R/W	Source picture address (always align 8Bytes) Bit [31:16] and SRC_PSTRIDE{n}.CHAS are used to identify channel ID

U25.2.16 Input picture stride register2 (SRC_PSTRIDE2)



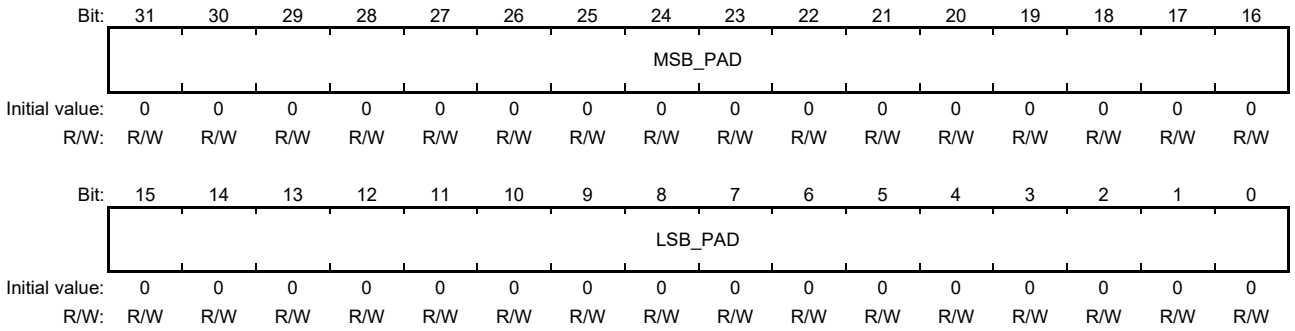
Bit	Bit Name	Initial Value	R/W	Description
31 to 20	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
19 to 16	CHAS	0	R/W	Channel address space Specify how many Least Significant Bit of SRC_ADR are used Source picture address range = SRC_ADR[31-(CHAS+1):0] when D'2 <= CHAS <= D'15 Source picture address range = SRC_ADR[29:0] when D'0 <= CHAS <= D'1
15 to 0	PSTRIDE	0	R/W	Source picture memory stride (always align 8Bytes)

U25.2.17 Output picture format register2 (DST_FMT2)



Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 12	MSBOFS	0	R/W	LSB offset bit. Range: 0~15. It shall be fixed 0 in 1 Byte/pixel
11 to 8	LSBOFS	0	R/W	MSB offset bit. Range: 0~15. It shall be fixed 0 in 1 Byte/pixel
7 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

U25.2.18 Output padding pixel value register2 (PAD_VALUE2)



Bit	Bit Name	Initial Value	R/W	Description
31 to 16	MSB_PAD	0	R/W	Padding value for MSB. Example if MSBOFS is 4, MSB_PAD[3:0] are filled to 4 MSB output pixel.
15 to 0	LSB_PAD	0	R/W	Padding value for LSB. Example if LSBOFS is 4, LSB_PAD[3:0] are filled to 4 LSB output pixel.

U25.2.19 Channel control register3 (CH_CTRL3)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ACT
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	ACT	0	R/W	Channel activation. 0: Inactive, transaction's address belongs to inactive channel will be assigned to "Bypass" channel. 1: Channel activated.

U25.2.20 Input picture horizontal size register3 (SRC_HSIZE3)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	HSIZE[26:16]										
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	HSIZE[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 27	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
26 to 0	HSIZE	0	R/W	Input picture Horizontal size Value range: 1~8191 pixels (2D) or 1~8192*8192 (1D)

U25.2.21 Input picture vertical size register3 (SRC_VSIZE3)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	VSIZE[13:0]													
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13 to 0	VSIZE	0	R/W	Input picture vertical size Value range: 1~8192 pixels (2D) or 0 (1D)

U25.2.22 Input picture format register3 (SRC_FMT3)

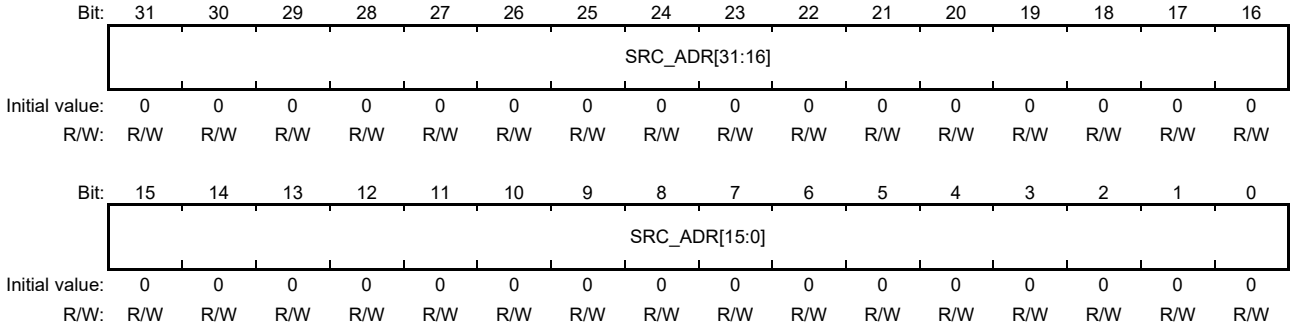
Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MSBOFS				LSBOFS				—	—	—	BPP	—	—	—	TBPPCE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 12	MSBOFS	0	R/W	MSB offset bit. Range: 0~15. It shall be fixed 0 in 1 Byte/pixel
11 to 8	LSBOFS	0	R/W	LSB offset bit. Range: 0~15. It shall be fixed 0 in 1 Byte/pixel
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	BPP	0	R/W	Byte per pixels 0: 2 Bytes/pixel; 1: 1 Byte/pixel
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

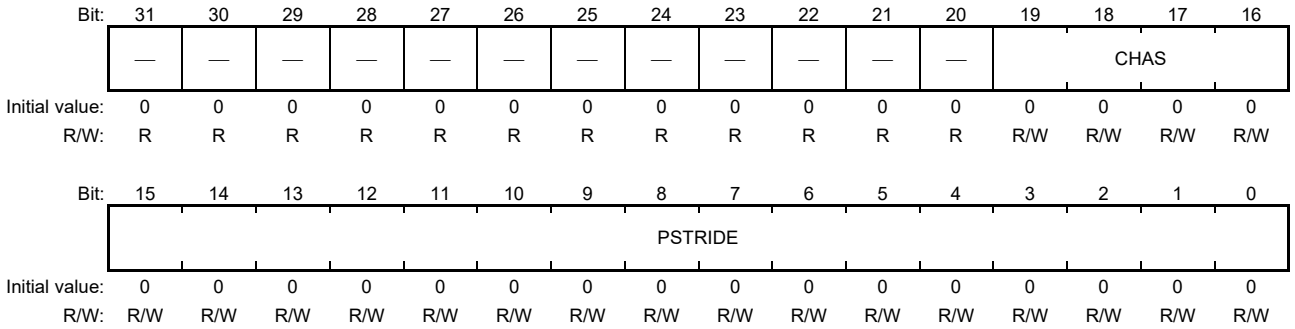
Bit	Bit Name	Initial Value	R/W	Description
0	TBPPCE	0	R/W	2BPP conversion enabled 0: Disabled; 1: Enabled

U25.2.23 Input picture address register3 (SRC_ADR3)



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	SRC_ADR	0	R/W	Source picture address (always align 8Bytes) Bit [31:16] and SRC_PSTRIDE{n}.CHAS are used to identify channel ID

U25.2.24 Input picture stride register3 (SRC_PSTRIDE3)



Bit	Bit Name	Initial Value	R/W	Description
31 to 20	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
19 to 16	CHAS	0	R/W	Channel address space Specify how many Least Significant Bit of SRC_ADR are used Source picture address range = SRC_ADR[31-(CHAS+1):0] when D'2 <= CHAS <= D'15 Source picture address range = SRC_ADR[29:0] when D'0 <= CHAS <= D'1
15 to 0	PSTRIDE	0	R/W	Source picture memory stride (always align 8Bytes)

U25.2.25 Output picture format register3 (DST_FMT3)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MSBOFS				LSBOFS				—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 12	MSBOFS	0	R/W	MSB offset bit. Range: 0~15. It shall be fixed 0 in 1 Byte/pixel
11 to 8	LSBOFS	0	R/W	LSB offset bit. Range: 0~15. It shall be fixed 0 in 1 Byte/pixel
7 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

U25.2.26 Output padding pixel value register3 (PAD_VALUE3)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MSB_PAD															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	LSB_PAD															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	MSB_PAD	0	R/W	Padding value for MSB. Example if MSBOFS is 4, MSB_PAD[3:0] are filled to 4 MSB output pixel.
15 to 0	LSB_PAD	0	R/W	Padding value for LSB. Example if LSBOFS is 4, LSB_PAD[3:0] are filled to 4 LSB output pixel.

U25.3 Register relationship

Because OTFDCR function in UMF wrapper works in cooperation with UMF DMA function, the settings of OTFDCR shall match the some UMF DMA settings. The below table shows the relationship with each register.

Table U25.4 Register relationship with UMF core and OTFDCR

DMA normal entry	OTFDCR Register	Note
DMA Address	SRC_ADR	Always 8 bytes align
XSize	roundup_8((SRC_ADR & 0x7) + SRC_HSIZE*BPP)	BPP = (SRC_FMT.BPP == 0) ? 2 : 1 roundup_8 : round up a number to nearest multiple of 8
XOffset	SRC_PSTRIDE.PSTRIDE	Always 8 bytes align
YSize	SRC_VSIZE	-

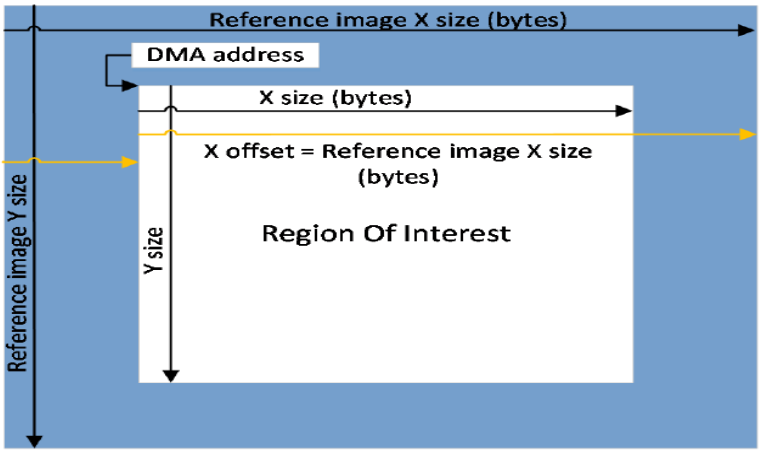


Figure U25.3 2D transfer regarding a 2D image definition

U25.4 Operation

- Detail information is described in IP licensee guide.

U25.5 Usage Notes

U25.5.1 Module Standby and power-shutoff

- Enter Module Standby (stop clock supply) by CPG
- Enter power-shutoff status (stop power supply) by SYSC

U25.5.2 Usage notes for IP core

- Detail information is described in IP licensee guide.

U25.5.3 Usage notes for OTFDCR

U25.5.3.1 Pixel conversion setting guide

Set according to the following register setting guide.

- For 16bit/pixel input (conversion from 12bit/pixel or 14bit/pixel to 16bit/pixel), set CH_CTRL{n}.ACT=1 and set the following.

  SRC_FMT{n}.TBPPCE = 1

- For 8bit/pixel input (conversion from 8bit/pixel to 16bit/pixel), set CH_CTRL{n}.ACT=1 and set the following.

  SRC_FMT{n}.MSBOFS = 0

  DST_FMT{n}.MSBOFS = 8

  SRC_FMT{n}.LSBOFS = 0

  DST_FMT{n}.LSBOFS = 0

- When padding for 8bit/pixel input, set the value to be stored in the lower 8 bits in the following registers.

  PAD_VALUE{n}.MSB_PAD[15:8]

Registers can be set independently for each channel.

U25.5.3.2 Channel address space usage notes

Because OTFDCR uses SRC_PSTRIDE{n}.CHAS and 16 high-order bits of source address to identify channel's ID and address space, following conditions shall be followed:

- 64K-Byte align of source image is necessary to use multiple channels.
- Source picture address range = SRC_ADR[31-(CHAS+1):0] must not overlap and evaluation priority. If you use overlapping of masked area in CHAS, image that has bigger mask should be set to smaller index channel register.

U25.6 Safety Mechanism

U25.6.1 Overview

All memories in Vision IP are protected by EDC or parity.

U25.6.2 Hardware Description

U25.6.2.1 Block Diagrams

Figure U25.4 shows a block diagram of the UMF protection for functional safety.

U30. IMP DMAC

U30.1 Overview

The IMP DMAC/Slim-IMP DMAC is one of the modules that make up IMP-X7. IMP DMAC/Slim-IMP DMAC performs data transfer between external memory and IMP dedicated internal memory at high speed.

The IMP DMAC logically operates two input sources (Source 0, Source 1) at maximum, and outputs them to one destination (Destination 0).

The Slim-IMP DMAC operates one input source (Source0), and output it to one destination (Destination0)

The IMP DMAC/Slim-IMP DMAC process uses little endian.

Note: The actual modules are referred to as the IMP DMAC and Slim-IMP DMAC in the R-Car Gen4.

Table 30.1 Base Address of IMP DMAC

Channel	Base Address	Number of Threads *1
0	H'FFA8 0000 (Thread0) H'FFA8 1000 (Thread1)	2
1	H'FFB8 0000 (Thread0) H'FFB8 1000 (Thread1)	2

Table 30.2 Base Address of Slim-IMP DMAC

Channel	Base Address	Number of Threads *1
0	H'FFA9 0000 (Thread0) H'FFA9 1000 (Thread1)	2
1	H'FFA9 4000 (Thread0) H'FFA9 5000 (Thread1)	2

Notes: 1. Thread implements registers that are necessary for the instruction fetch/decode circuit and data transmission.
Each Thread shares a transfer circuit, and each Thread is arbitrated for each data transfer unit. If the data transmission of Thread0 and Thread1 starts at the same time, that of Thread0 will take precedence.

U30.1.1 Features

- Command List (CL) system
  - No Operation Instruction (NOP)
  - CL Close Instruction (TRAP)
  - Register Write Instruction (WPR)
  - Interrupt Generation Instruction (INT)
  - Data Transmission Completion Synchronization Instruction (SYNCS)
  - Instruction string control (GOSUB, RET), Relative and Absolute addressing, Conditional GOSUB
  - JUMP Instruction (JUMP), Relative and Absolute addressing
  - Synchronization Instruction with other modules (WUP, SLP)
  - CL break(debug) function.

- **IMP DMAC/ Slim-IMP DMAC**
  - Support transfer of 8, 16, 32bpp data
  - Perform various logical operations (LOP) between data of 2 sources Source0 and Source1, then transfer to Destination *2
  - Support for constant write to the destination memory
  - Support BitCount function that counts the number of 1 after logical operation*3
  - Support tile addressing mode*1*3.
  - Support the data swap function (SWAP) that can be used in endian conversion
  - Support alignment of 1 pixel unit in linear addressing mode
  - Support shifting, rounding and saturation for the output of various logical operations. *3
  - Support Source and destination address wraparound. *4

Notes:

1. Only supported by Source0, Destination. Source1 supports linear addressing only.
2. In Slim-IMP DMAC, the source data of the Source0 is transfer to the Destination and does not support LOP. Slim-IMP DMAC does not support Source1, and source buffer is half of IMPDMAC.
3. These features are not supported in Slim-IMP DMAC.
4. This feature is supported in Slim-IMP DMAC only.

U30.1.2 Block diagram

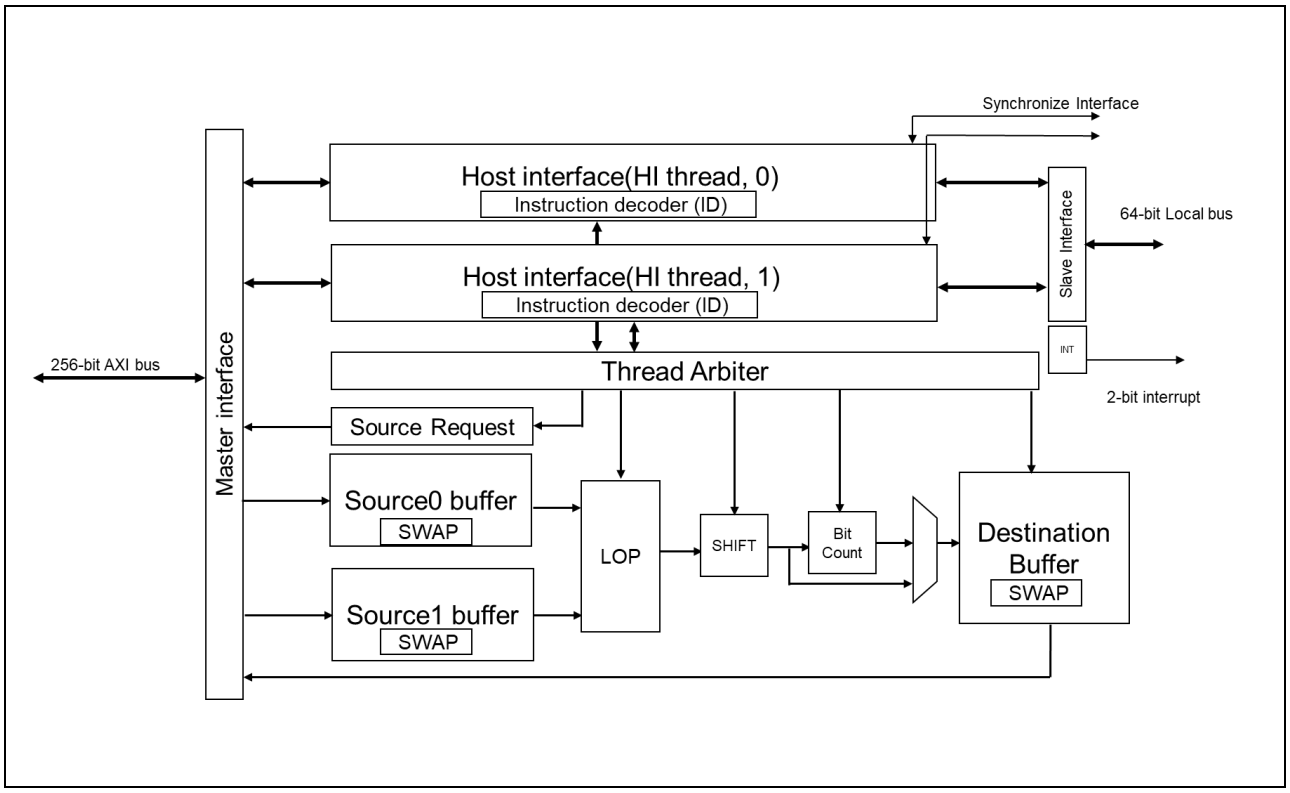

Figure U30.1 Block Diagram [IMP DMAC]

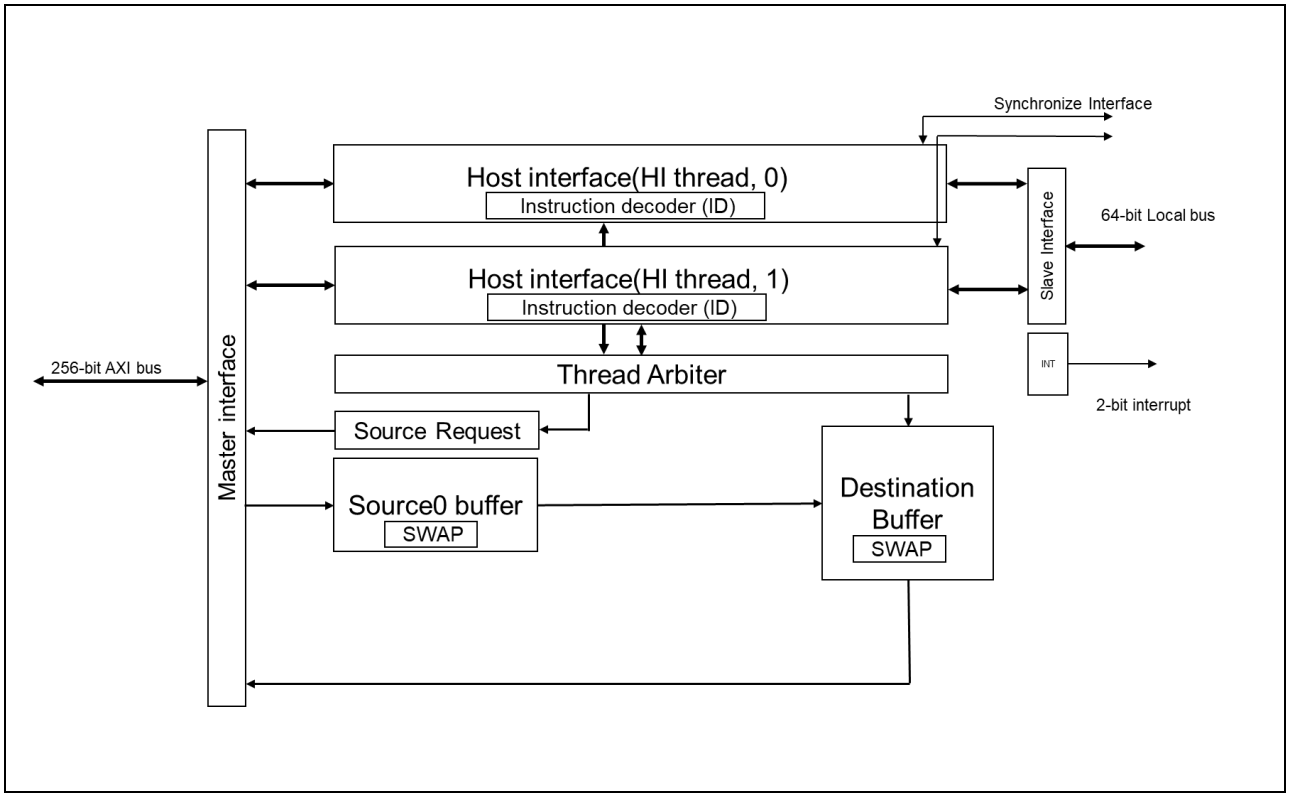

Figure U30.2 Block Diagram [Slim-IMP DMAC]

U30.1.3 Register Configuration

Accessing to addresses not listed in this register list is prohibited. Operation cannot be guaranteed when accessing to an address, which is not listed. Access size is 32-bit. Operation cannot be guaranteed when accessing by other than 32-bit. Operation cannot be guaranteed when writing to a register, which can't be accessed during IMP DMAC execution *1.

Table 30.3 Register Configuration

Name	Symbol	R/W	Offset	CPU Write Access during dmac execution *2	Initial value	Reset*3	WPR support

Destination0 Start Address Offset Register	D0SAR_OFS	W	H'0358	—	H'00000000	S/H	√
CL Break Address Register	CLBRKADDRR	R/W	H'03F4	√	H'00000000	S/H	—
CL Conditinal GOSUB Register	CLCNDGSBR	R/W	H'03FC	√	H'00000000	S/H	—

Notes: 1. It includes the time during CL execution.

2. DMAC execution is the state that DMAEN bit of SCTLR0 register = 1, or CLE bit of SCTLR1 register = 1.
3. H: Power on reset S: Software reset by SWRST bit of SCTLR0 register.
4. These registers are not support for Slim-IMP DMAC.
5. For the IMP DMAC, initial value is H'00220002. For Slim-IMP DMAC initial value is H'00030003.
6. The value to be read varies depending on the product. Refer register description for the initial value.
7. Initial value is varies depending on the product. Refer register description for the initial value.

U30.2 Register Description

[Legend]

Initial value: Register value after a reset

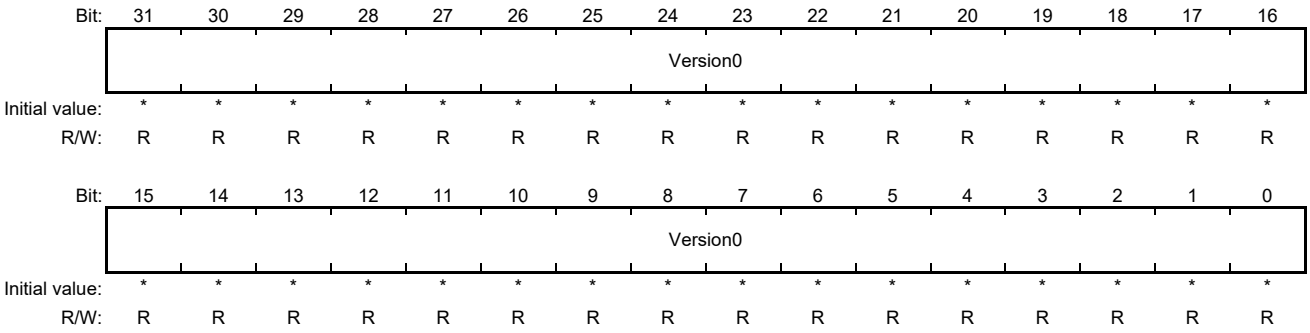
—: Undefined value

R/W: Readable/writable. The written value can be read.

R: Read-only. The write value should be the same as the read value. Only modify the target bit (Read Modify Write) because the initial value should not be changed.

-/W: Write-only. The read value is undefined.

U30.2.1 Version Control Register (VCR)



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	Version0	*	R	These bits indicate the version of this module.

Note: The value to be read varies depending on the product.
IMP DMAC/ Slim-IMP DMAC: H’21111616

U30.2.2 System Control Register 0 (SCTLR0)

This is the register to control the reset (software), and the start of DMA.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SWRST	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DMAEN
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	SWRST	0	R/W	Software reset Writing 1 to this bit applies a software reset and writing 0 cancels a software reset. 0: Cancels a software reset for this module. 1: Applies a software reset to this module. When setting to 1, the value of the register with the notation 'S' written in the "Reset" column of Table 30.3 Register Configuration will be initialized. When the DMAEN bit of SCTLR0 register is 1 or the CLE bit of CTLR1 register is 1, setting to 1 is prohibited. In that case, the operation cannot be guaranteed. Setting this bit and the DMAEN bit to 1 at the same time is prohibited. In that case, the operation cannot be guaranteed. In order to cancel the reset, write 0 to this bit, then read this bit to check if that the value is 0. Setting this bit to 1 with WPR is prohibited. In that case, the operation cannot be guaranteed.
30 to 1	—	All 0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.
0	DMAEN	0	R/W	DMA transmission start bit [Write] 0: NOP 1: DMA transmission starts [Read] 0: DMA transmission has not been performed 1: DMA transmission is in progress After DMA transmission is completed, this bit automatically becomes 0. At this time, if the TENDE bit of SER register is 1, the TEND bit of SR0 register will become 1. Setting this bit to 0 or 1 while it is 1 is prohibited. In that case, the operation cannot be guaranteed. Setting this bit to 1 from the CPU is prohibited while the CLE bit of SCTLR1 register is 1. In that case, the operation cannot be guaranteed.

U30.2.3 Status Register 0 (SR0)

This register displays every status generated by IMP DMAC.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*

Bit	Bit Name	Initial Value	R/W	Description
31 to 11	—	Undefined	R	Reserved The read value is undefined. Operation cannot be guaranteed if a value other than the read value is written.
10	CLBRK	0	R	CL break status. 0: CL does not break 1: CL break CL break can not be used if CLBRKENB of SER register is 0. Set CLBRKENB of SER register to 1 to use CL break function. Command list continue execution after clearing this bit using CLBRKC bit of SCR register.
9 to 8	—	Undefined	R	Reserved The read value is undefined. Operation cannot be guaranteed if a value other than the read value is written.
7	WUPOVF	0	R	WUP counter overflow This bit indicates the overflow of WUP instruction. 0: WUP overflow has not been occured 1: WUP overflow has been occured Note: When WUPOVFE bit in SER is 0, this bit is not set to 1 even if the WUP overflow occured. When WUPOVFE bit in SER is 1, this bit is set to 1 if the WUP overflow is occured.
6	INT	0	R	INT instruction decoding This bit indicates the decoding of INT instruction. Once this bit becomes 1, the next instruction will not start until this bit is cleared to 0. 0: INT instruction has not been decoded 1: INT instruction has been decoded Note: When INTE bit in SER is 0, this bit is not set to 1 even if the INT instruction is decoded. When INTE bit in SER is 1, this bit is set to 1 if the INT instruction is decoded.

Bit	Bit Name	Initial Value	R/W	Description
5	IER	0	R	Illegal instruction decoding or GOSUB overflow/underflow. This bit indicates the decoding of the illegal instruction. Once this bit becomes 1, the CL execution will end. Illegal instructions are instructions that are not listed in Table 30.4. 0: Illegal instruction has not been decoded 1: Illegal instruction has been decoded Note: When IERE bit in SER is 0, this bit is not set to 1 even if illegal instructions are decoded. When IERE bit in SER is 1, this bit is set to 1 if illegal instructions are decoded. Reset IMP DMAC by using SWRST bit of SCTLR0 after the IER error.
4	TRA	0	R	TRAP instruction decoding This bit indicates the decoding of TRAP instruction. After TRAP instruction is decoded, the CL execution will end. 0: TRAP instruction has not been decoded 1: TRAP instruction has been decoded Note: When TRAE bit in SER is 0, this bit is not set to 1 even if the TRAP instruction is decoded. When TRAE bit in SER is 1, this bit is set to 1 if the TRAP instruction is decoded.
3 to1	—	All 0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.
0	TEND	0	R	Transmission completion When DMA transmission ends, this bit is set to 1. [Load] 0: Transmission has not been started or it is in progress 1: Transmission has ended Note: When TENDE bit in SER is 0, this bit is not set to 1 even if the DMA transmission has ended. When TENDE bit in SER is 1, this bit is set to 1 if the DMA transmission has ended. When using CL, set the TENDE bit of SER register to 0 and do not use this bit.

U30.2.4 Status Clear Register (SCR)

This register clears every status displayed in SR0. Write 1 to clear, writing 0 is disabled.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	CLBRKC	—	—	WUPOVFC	INTC	IERC	TRAC	—	—	—	TENDC
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	-/W	R	R	-/W	-/W	-/W	-/W	R	R	R	-/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 11	—	All 0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.
10	CLBRKC	0	-/W	CL break status clear. By writing 1, the 0 in the CLBRK bit of SR0 register will be cleared. This bit is always read as 0. Command list continues execution after clearing CLBRK bit of SR0 register.
9 to 8	—	0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than the read value is written.
7	WUPOVFC	0	-/W	WUPOVF bit clearing By writing 1, the 0 in the WUPOVF bit of SR0 register will be cleared. This bit is always read as 0.
6	INTC	0	-/W	INT bit clearing By writing 1, the 0 in the INT bit of SR0 register will be cleared. This bit is always read as 0.
5	IERC	0	-/W	IER bit clearing By writing 1, the 0 in the IER bit of SR0 register will be cleared. This bit is always read as 0.
4	TRAC	0	-/W	TRA bit clearing By writing 1, the 0 in the TRA bit of SR0 register will be cleared. This bit is always read as 0.
3 to1	—	All 0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.
0	TENDC	0	-/W	TEND bit clearing By writing 1, the TEND bit of SR0 register will be cleared. This bit is always read as 0.

U30.2.5 Status Enable Register (SER)

This register is used to set whether to reflect status in each bit of SR0 register.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	— —
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	CLBRK ENB	—	—	WUPO VFE	INTE	IERE	TRAE	—	—	—	TENDE
Initial value:	1	1	1	1	0	0	1	1	1	1	1	1	0	0	0	1
R/W:	R	R	R	R	R	R/W	R	R	R/W	R/W	R/W	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	—	All 0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.
16	—	1	R	Reserved The read value should always be 1. Operation cannot be guaranteed if a value other than 1 is written.
15 to 12	—	B’1111	R	Reserved The read value should always be 1. Operation cannot be guaranteed if a value other than 1 is written.
11	—	0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.
10	CLBRKENB	0	R/W	CL break status/CL break enable. 0: CL break disable When CLBRK is not detected, 1 is not set to CLBRK bit of SR0 register. 1: CL break enable When CLBRK is detected, 1 is set to CLBRK bit of SR0 register. When this bit is 0, CL break operation is not be possible.
9 to 8	—	B’11	R	Reserved The read value should always be 1. Operation cannot be guaranteed if a value other than 1 is written.
7	WUPOVFE	1	R/W	WUPOVF bit set enable 0: When WUP overflow is detected, 1 is not set to WUPOVF bit of SR0 register. 1: When WUP overflow is detected, 1 is set to WUPOVF bit of SR0 register. Refer to the **U34.IMP-X7_system, U34.10.3 Inter Module Synchronization** when setting this bit.

Bit	Bit Name	Initial Value	R/W	Description
6	INTE	1	R/W	INT bit set enable 0: When the INT instruction is decoded, 1 is not set to the INT bit of SR0 register. 1: When the INT instruction is decoded, 1 is set to the INT bit of SR0 register
5	IERE	1	R/W	IER bit set enable 0: When the illegal instruction is decoded, 1 is not set to the IER bit of SR0 register 1: When the illegal instruction is decoded, 1 is set to the IER bit of SR0 register
4	TRAE	1	R/W	TRA bit set enable 0: When the TRAP instruction is decoded, 1 is not set to the TRA bit of SR0 register. 1: When the TRAP instruction is decoded, 1 is set to the TRA bit of SR0 register
3 to1	—	All 0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.
0	TENDE	1	R/W	TEND bit set enable 0: Even if DMA transmission ends, 1 is not set to the TEND bit of SR0 register. 1: If DMA transmission ends, 1 is set to the TEND bit of SR0 register.

U30.2.6 Interrupt Mask Register (IMR)

This register is used to set whether to generate an interrupt or mask an interrupt according to occurrence of each status.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	CLBRKM	—	—	WUPOVFM	INTM	IERM	TRAM	—	—	—	TENDM
Initial value:	1	1	1	1	0	1	1	1	1	1	1	1	0	0	0	1
R/W:	R	R	R	R	R	R/W	R	R	R/W	R/W	R/W	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	—	All 0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.
16	—	1	R	The read value should always be 1. Operation cannot be guaranteed if a value other than 1 is written.
15 to 12	—	B’1111	R	Reserved The read value should always be 1. Operation cannot be guaranteed if a value other than 1 is written.
11	—	0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.
10	CLBRKM	1	R/W	Mask setting of interrupt by CLBRK status 0: The generation of CLBRK interrupt is not masked. 1: The generation of CLBRK interrupt is masked.
9 to 8	—	B’11	R	Reserved The read value should always be 1. Operation cannot be guaranteed if a value other than 1 is written.
7	WUPOVFM	1	R/W	Mask setting of interrupt by WUPOVF status 0: The generation of WUPOVF interrupt is not masked. 1: The generation of WUPOVF interrupt is masked.
6	INTM	1	R/W	Mask setting of interrupt by INT status 0: The generation of INT interrupt is not masked. 1: The generation of INT interrupt is masked.
5	IERM	1	R/W	Mask setting of interrupt by IER status 0: The generation of IER interrupt is not masked. 1: The generation of IER interrupt is masked.
4	TRAM	1	R/W	Mask setting of interrupt by TRA status 0: The generation of TRA interrupt is not masked. 1: The generation of TRA interrupt is masked.

Bit	Bit Name	Initial Value	R/W	Description
3 to1	—	All 0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.
0	TENDM	1	R/W	Mask setting of interrupt by TEND status 0: The generation of TEND interrupt is not masked. 1: The generation of TEND interrupt is masked.

U30.2.7 System Control Register1 (SCTLR1)

This is the register to control the start of CL.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CLE	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	CLE	0	R/W	IMP DMAC's CL starting bit [Write] 0: - (Prohibited) 1: Start CL [Read] 0: CL is not in progress. 1: CL is in progress. When 1 is written to this bit, IMP DMAC fetches the CL from the address which set CL to CLSAR, and executes the instruction. This bit is read as 1 during the CL execution and read as 0 when execution is completed. Writing 1 to this bit during the CL execution is prohibited. If it is written, the operation cannot be guaranteed.
30 to 0	—	All 0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.

U30.2.8 Transaction Size Control Register (TSCR)

[IMP DMAC]

Source0, Source1, Destination specifies the transaction size to access for the bus.

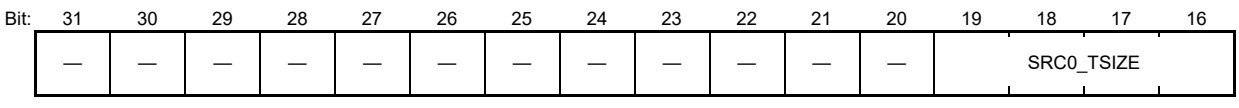
Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	SRC1_TSIZE				SRC0_TSIZE			
Initial value:	0	0	0	0	0	0	0	0	0	0	1	0	0	0	1	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	DST0_TSIZE			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.
23 to 20	SRC1_TSIZE	0010	R/W	These bits define the transmission size of Source1. 2: The read request of Source1 is performed in 64-byte unit. 3: The read request of Source1 is performed in 128-byte unit. 4: The read request of Source1 is performed in 256-byte unit. Others: Setting prohibited When the PXALIGN bit of FCR1 register is 0: Setting this bit to other than 2 and 3 is prohibited. Set the same value as SRC0_TSIZE bit and DST0_TSIZE bit. When the PXALIGN bit of FCR1 register is 1: Setting this bit to other than 3 and 4 is prohibited. Set the same value as SRC0_TSIZE bit.
19 to 16	SRC0_TSIZE	0010	R/W	These bits define the transmission size of Source0. 2: The read request of Source0 is performed in 64-byte unit. 3: The read request of Source0 is performed in 128-byte unit. 4: The read request of Source0 is performed in 256-byte unit. Others: Setting prohibited When the PXALIGN bit of FCR1 register is 0: Setting this bit to other than 2 and 3 is prohibited. Set the same value as SRC1_TSIZE bit and DST0_TSIZE bit. When the PXALIGN bit of FCR1 register is 1: Setting this bit to other than 3 and 4 is prohibited. Set the same value as SRC1_TSIZE bit.
15 to 4	—	All 0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.
3 to 0	DST0_TSIZE	0010	R/W	These bits define the transmission size of Destination0. 0: The write request of Destination0 is performed in 4-byte unit. 2: The write request of Destination0 is performed in 64-byte unit. 3: The write request of Destination0 is performed in 128-byte unit. 4: The write request of Destination0 is performed in 256-byte unit. Others: Setting prohibited When the PXALIGN bit of FCR1 register is 0: Setting this bit to other than 0, 2 and 3 is prohibited. Set the same value as SRC0_TSIZE and SRC1_TSIZE. When the PXALIGN bit of FCR1 register is 1: Setting this bit to other than 0, 3 and 4 is prohibited.

[Slim-IMP DMAC]

This register is used to set the transaction size in bus access from each of the source0 and destination buffers.



Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	DST0_TSIZE			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 20	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
19 to 16	SRC0_TSIZE	0011	R/W	3: The read request of Source0 is performed in 128-byte unit. 4: The read request of Source0 is performed in 256-byte unit. Setting other than above is prohibited for this bit.
15 to 4	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
3 to 0	DST0_TSIZE	0011	R/W	3: The write request of Destination0 is performed in 128-byte unit. 4: The write request of Destination0 is performed in 256-byte unit. Setting other than above is prohibited for this bit.

U30.2.9 Command List Start Address Register (CLSAR)

This register is used to set the first address when fetching CL.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CLSAR															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CLSAR															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CLSAR	H'0000 0000	R/W	First address of CL These bits set the first address of CL execution in this register. Set it in 4-byte unit.

U30.2.10 Status Register1 (SR1)

This register displays the code value when IMP DMAC executes INT and TRAP instructions.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	INTCODE								TRAPCODE							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	INTCODE	H'00	R	INT interrupt code If the INT instruction is executed, the value specified in the CODE field (bit[7:0]) of this instruction will be reflected in this field. This field is updated independently of the setting of INTE bit in SER register.
23 to 16	TRAPCODE	H'00	R	TRAP interrupt code If the TRAP instruction is executed, the value specified in the CODE field (bit[7:0]) of this instruction will be reflected in this field. This field is updated independently of the setting of TRAE bit in SER register.
15 to 0	—	All 0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.

U30.2.11 Data Swap Register (DSWPR)

This register is used to set the swap of data in Source0, Source1, Destination0.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	S1SWP 128BIT	S1SWP 64BIT	S1SWP 32BIT	S1SWP 16BIT	S1SWP 8BIT	—	—	—	S0SWP 128BIT	S0SWP 64BIT	S0SWP 32BIT	S0SWP 16BIT	S0SWP 8BIT	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	D0SWP 128BIT	D0SWP 64BIT	D0SWP 32BIT	D0SWP 16BIT	D0SWP 8BIT	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 30	—	All 0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.
29	S1SWP128BIT	0	R/W	Source1 128-bit swap setting This bit swaps 256 bits of Source1 data in 128-bit unit. 0: It is not swapped 1: It is swapped When this bit is set to 1, set S1SAR, S1STR, and IWIDTH in 256-bit unit. When the S1PF bit of S1CR register is not 32bpp, 16bpp, 8bpp, setting this bit to 1 is prohibited. **[Slim-IMP DMAC]** Reserved. Operation cannot be guaranteed if a value other than 0 is written here.
28	S1SWP64BIT	0	R/W	Source1 64-bit swap setting This bit swaps 128 bits of Source1 data in 64-bit unit. When this bit is set to 1 by S1SWP128BIT=0, set S1SAR, S1STR, and IWIDTH in 128-bit unit. 0: It is not swapped 1: It is swapped When the S1PF bit of S1CR register is not 32bpp, 16bpp, 8bpp, setting this bit to 1 is prohibited. **[Slim-IMP DMAC]** Reserved. Operation cannot be guaranteed if a value other than 0 is written here.

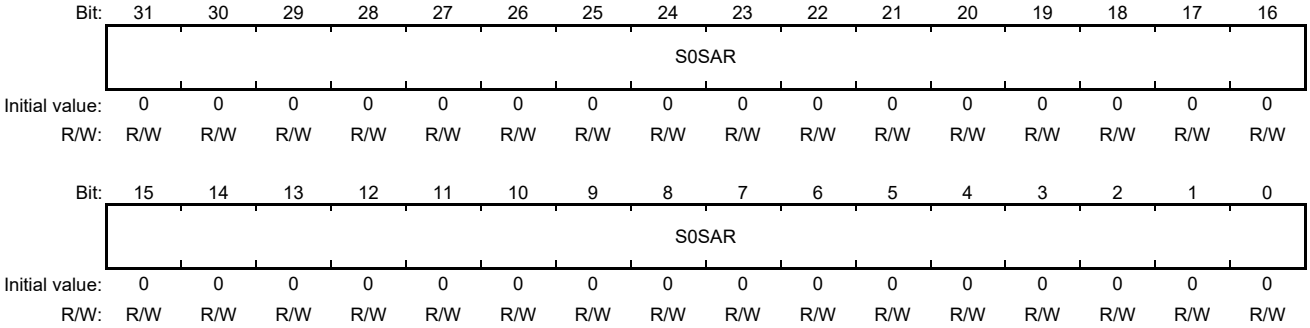
Bit	Bit Name	Initial Value	R/W	Description
27	S1SWP32BIT	0	R/W	Source1 32-bit swap setting This bit swaps 64 bits of Source1 data in 32-bit unit. When this bit is set to 1 by S1SWP128BIT=S1SWP64BIT=0, set S1SAR, S1STR, and IWIDTH in 64-bit unit. 0: It is not swapped 1: It is swapped When the S1PF bit of S1CR register is not 32bpp, 16bpp, 8bppsetting this bit to 1 is prohibited. **[Slim-IMP DMAC]** Reserved. Operation cannot be guaranteed if a value other than 0 is written here.
26	S1SWP16BIT	0	R/W	Source1 16-bit swap setting This bit swaps 32 bits of Source1 data in 16-bit unit. 0: It is not swapped 1: It is swapped When this bit is set to 1 by S1SWP128BIT=S1SWP64BIT=S1SWAP32BIT=0, set S1SAR, S1STR, and IWIDTH in 32-bit unit. When the S1PF bit of S1CR register is not 16bpp, 8bppsetting this bit to 1 is prohibited. **[Slim-IMP DMAC]** Reserved. Operation cannot be guaranteed if a value other than 0 is written here.
25	S1SWP8BIT	0	R/W	Source1 8-bit swap setting This bit swaps 16 bits of Source1 data in 8-bit unit. 0: It is not swapped 1: It is swapped When this bit is set to 1 by S1SWP128BIT=S1SWP64BIT=S1SWAP32BIT=S1SWAP16BIT=0, set S1SAR, S1STR, and IWIDTH in 16-bit unit. When the S1PF bit of S1CR register is not 8bpp, setting this bit to 1 is prohibited. **[Slim-IMP DMAC]** Reserved. Operation cannot be guaranteed if a value other than 0 is written here.
24 to 22	—	All 0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.
21	S0SWP128BIT	0	R/W	Source0 128-bit swap setting This bit swaps 256 bits of Source0 data in 128-bit unit. 0: It is not swapped 1: It is swapped When this bit is set to 1, set S0SAR, S0STR, and IWIDTH in 256-bit unit. When the S0PF bit of S0CR register is not 32bpp, 16bpp, 8bppsetting this bit to 1 is prohibited.

Bit	Bit Name	Initial Value	R/W	Description
20	S0SWP64BIT	0	R/W	Source0 64-bit swap setting This bit swaps 128 bits of Source0 data in 64-bit unit. 0: It is not swapped 1: It is swapped When this bit is set to 1 by S0SWP128BIT=0, set S0SAR, S0STR, and IWIDTH in 128-bit unit. When the S0PF bit of S0CR register is not 32bpp, 16bpp, 8bpp, setting this bit to 1 is prohibited.
19	S0SWP32BIT	0	R/W	Source0 32-bit swap setting This bit swaps 64 bits of Source0 data in 32-bit unit. 0: It is not swapped 1: It is swapped When this bit is set to 1 by S0SWP128BIT=S0SWP64BIT=0, set S0SAR, S0STR, and IWIDTH in 64-bit unit. When the S0PF bit of S0CR register is not 32bpp, 16bpp, 8bppsetting this bit to 1 is prohibited.
18	S0SWP16BIT	0	R/W	Source0 16-bit swap setting This bit swaps 32 bits of Source0 data in 16-bit unit. 0: It is not swapped 1: It is swapped When this bit is set to 1 by S0SWP128BIT=S0SWP64BIT=S0SWAP32BIT=0, set S0SAR, S0STR, and IWIDTH in 32-bit unit. When the S0PF bit of S0CR register is not 16bpp, 8bppsetting this bit to 1 is prohibited.
17	S0SWP8BIT	0	R/W	Source0 8-bit swap setting This bit swaps 16 bits of Source0 data in 8-bit unit. 0: It is not swapped 1: It is swapped When this bit is set to 1 by S0SWP128BIT=S0SWP64BIT=S0SWAP32BIT=S0SWAP16BIT=0, set S0SAR, S0STR, and IWIDTH in 16-bit unit. When the S0PF bit of S0CR register is not 8bpp, setting this bit to 1 is prohibited.
16to 6	—	All 0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.
5	D0SWP128BIT	0	R/W	Destination0 128-bit swap setting This bit swaps 256 bits of Destination0 data in 128-bit unit. 0: It is not swapped 1: It is swapped When this bit is set to 1, set D0SAR, D0STR, and IWIDTH in 256-bit unit. When the D0PF bit of D0CR register is not 32bpp, 16bpp, 8bpp, setting this bit to 1 is prohibited.

Bit	Bit Name	Initial Value	R/W	Description
4	D0SWP64BIT	0	R/W	Destination0 64-bit swap setting This bit swaps 128 bits of Destination0 data in 64-bit unit. 0: It is not swapped 1: It is swapped When this bit is set to 1 by D0SWP128BIT=0, set D0SAR, D0STR, and IWIDTH in 128-bit unit. When the D0PF bit of D0CR register is not 32bpp, 16bpp, 8bpp, setting this bit to 1 is prohibited.
3	D0SWP32BIT	0	R/W	Destination0 32-bit swap setting This bit swaps 64 bits of Destination0 data in 32-bit unit. 0: It is not swapped 1: It is swapped When this bit is set to 1 by D0SWP128BIT=D0SWP64BIT=0, set D0SAR, D0STR, and IWIDTH in 64-bit unit. When the D0PF bit of D0CR register is not 32bpp, 16bpp, 8bpp, setting this bit to 1 is prohibited.
2	D0SWP16BIT	0	R/W	Destination0 16-bit swap setting This bit swaps 32 bits of Destination0 data in 16-bit unit. 0: It is not swapped 1: It is swapped When this bit is set to 1 by D0SWP128BIT=D0SWP64BIT=D0SWAP32BIT=0, set D0SAR, D0STR, and IWIDTH in 32-bit unit. When the D0PF bit of D0CR register is not 16bpp, 8bppsetting this bit to 1 is prohibited.
1	D0SWP8BIT	0	R/W	Destination0 8-bit swap setting This bit swaps 16 bits of Destination0 data in 8-bit unit. 0: It is not swapped 1: It is swapped When this bit is set to 1 by D0SWP128BIT=D0SWP64BIT=D0SWAP32BIT=D0SWAP16BIT=0, set D0SAR, D0STR, and IWIDTH in 16-bit unit. When the D0PF bit of D0CR register is not 8bpp, setting this bit to 1 is prohibited.
0	—	0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.

U30.2.12 Source0 Start Address Register (S0SAR)

This register is used to set the start address of Source0 to read from external memory or internal memory.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	S0SAR	H'0000 0000	R/W	Set the start address of Source0 in byte unit. When PXALIGN of FCR1 register is 0, set according to the following. ・If SRC0_TSIZE bits of TSCR register are 2, set this register in 64-byte unit. ・If SRC0_TSIZE bits of TSCR register are 3, set this register in 128-byte unit. When PXALIGN of FCR1 register is 1, set according to the following. ・If S0PF bits of S0CR register are 3, set this register in 1-byte unit. ・If S0PF bits of S0CR register are 4, set this register in 2-byte unit. ・If S0PF bits of S0CR register are 5, set this register in 4-byte unit.

U30.2.13 Source0 Stride Register (S0STR)

This register is used to set the memory width of Source0 to read from external memory or internal memory.

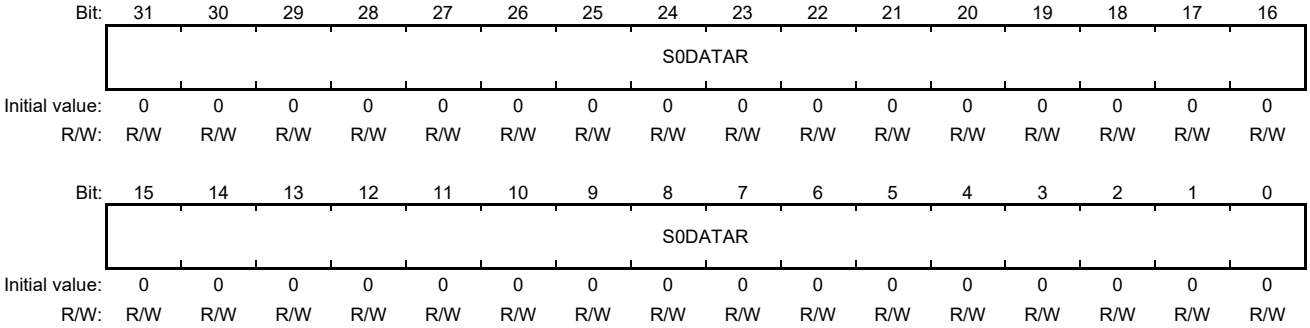
Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	S0STR														
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 15	—	All 0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.
14 to 0	S0STR	H'0000	R/W	These bits set the memory width of Source0 in byte unit. The setting range is 0~32767. Be sure to set the number of pixels, which is set in the IWIDTH bit of IMGSIZER register, to be equal to or greater than the byte converted value. When PXALIGN of FCR1 register is 0, set according to the following. ・If SRC0_TSIZE bits of TSCR register are 2, set this register in 64-byte unit. ・If SRC0_TSIZE bits of TSCR register are 3, set this register in 128-byte unit. When PXALIGN of FCR1 register is 1, set according to the following. ・If S0PF bits of S0CR register are 3, set this register in 1-byte unit. ・If S0PF bits of S0CR register are 4, set this register in 2-byte unit. ・If S0PF bits of S0CR register are 5, set this register in 4-byte unit.

U30.2.14 Source0 Data Register (S0DATAR)

This is the data register of Source0.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	S0DATAR	H'0000 0000	R/W	This is the data register of Source0. When the S0REN bit of S0CR register is 0, this register is used. If the pixel format is less than 32bpp, specify this data repeatedly until it reaches 32 bits in this register. For example, if it is 8 bpp, set four 8-bit data D8, D8, D8, D8. (A D8 represents one 8-bit data.)

U30.2.15 Source0 Control Register (S0CR)

This register is used to control Source0.

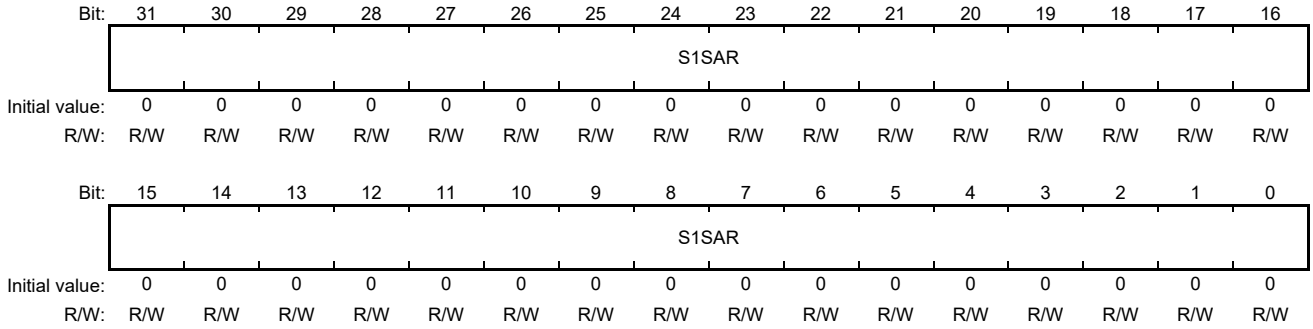
Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	S0REN	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	S0TAMODE				—	—	—	—	—	—	—	—	S0PF			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1
R/W:	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	S0REN	0	R/W	Source0 read enable 0: Do not read data from external memory or internal memory, use the value of S0DATAR register as the data of Source0. 1: Read data of Source0 from external memory or internal memory. If this bit is 0, setting the S1REN bit of S1CR register to 1 is prohibited.
30 to 16	—	All 0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.
15 to 12	S0TAMODE	0000	R/W	Source0 tile addressing mode 0: Read the data of Source0 by the linear addressing. 1: Read the data of Source0 by the IMP original tile addressing. For details of tile addressing, refer to chapter Operation. Settings other than above are prohibited. If they are set, the operation cannot be guaranteed. If this bit is 1, set S0PF bits in this register to 3 or 4. If this bit is 1, setting the S1REN bit of S1CR register to 1 is prohibited. If this bit is 1, setting the BITCNTEN bit of FCR0 register to 1 is prohibited. When PXALIGN of FCR1 register is 1, setting this bit to 1 is prohibited.
11 to 4	—	All 0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.
3 to 0	S0PF	0011	R/W	Source0 pixel format When the BITCNTEN bit of FCR0 register is 0, specify the same pixel format as the D0PF bits of D0CR register. 3: 8bit/pixel 4: 16bit/pixel 5: 32bit/pixel Settings other than above are prohibited.

U30.2.16 Source1 Start Address Register (S1SAR)

This register is used to set the start address of Source1 to read from external memory or internal memory.
Note: This register is not support for Slim-IMP DMAC. Do not set this register for Slim-IMP DMAC operation.
This register is always read as 0x00000000.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	S1SAR	H'0000 0000	R/W	Set the start address of Source1 in byte unit. When PXALIGN of FCR1 register is 0, set according to the following. ・If SRC1_TSIZE bits of TSCR register are 2, set this register in 64-byte unit. ・If SRC1_TSIZE bits of TSCR register are 3, set this register in 128-byte unit. When PXALIGN of FCR1 register is 1, set according to the following. ・If S1PF bits of S1CR register are 3, set this register in 1-byte unit. ・If S1PF bits of S1CR register are 4, set this register in 2-byte unit. ・If S1PF bits of S1CR register are 5, set this register in 4-byte unit.

U30.2.17 Source1 Stride Register (S1STR)

This register is used to set the memory width of Source1 to read from external memory or internal memory.
Note: This register is not support for Slim-IMP DMAC. Do not set this register for Slim-IMP DMAC operation.
This register is always read as 0x00000000.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	S1STR

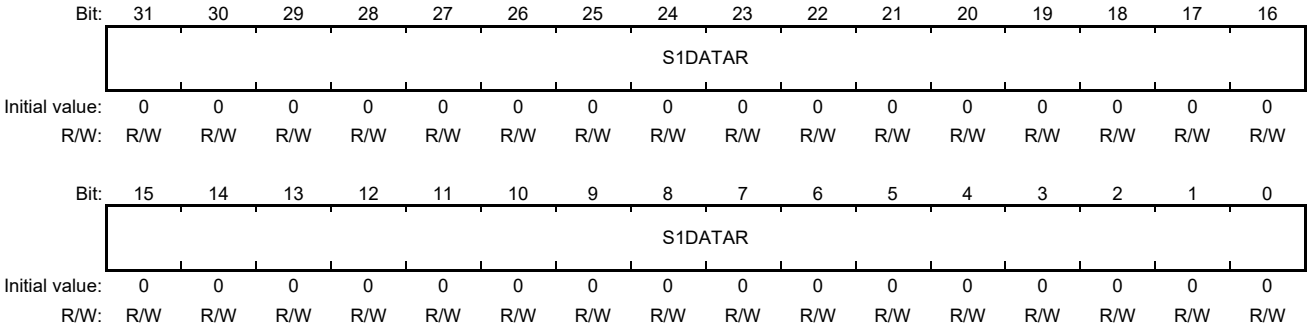
R/W:	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 15	—	All 0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.
14 to 0	S1STR	H'0000	R/W	These bits set the memory width of Source1 in byte unit. The setting range is 0~32767. Be sure to set the number of pixels, which is set in the IWIDTH bit of IMGSIZER register, to be equal to or greater than the byte converted value. When PXALIGN of FCR1 register is 0, set according to the following. ・If SRC1_TSIZE bits of TSCR register are 2, set this register in 64-byte unit. ・If SRC1_TSIZE bits of TSCR register are 3, set this register in 128-byte unit. When PXALIGN of FCR1 register is 1, set according to the following. ・If S1PF bits of S1CR register are 3, set this register in 1-byte unit. ・If S1PF bits of S1CR register are 4, set this register in 2-byte unit. ・If S1PF bits of S1CR register are 5, set this register in 4-byte unit.

U30.2.18 Source1 Data Register (S1DATAR)

This is the data register of Source1.
Note: This register is not support for Slim-IMP DMAC. Do not set this register for Slim-IMP DMAC operation. This register is always read as 0x00000000.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	S1DATAR	H'0000 0000	R/W	This is the data register of Source1. When the S1REN bit of S1CR register is 0, this register is used. If the pixel format is less than 32bpp, specify this data repeatedly until it reaches 32 bits in this register. For example, if it is 8 bpp, set four 8-bit data D8, D8, D8, D8. (A D8 represents one 8-bit data.)

U30.2.19 Source1 Control Register (S1CR)

This register is used to control Source1.
Note: This register is not support for Slim-IMP DMAC. Do not set this register for Slim-IMP DMAC operation.
This register is always read as 0x00000000.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	S1REN	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	S1PF

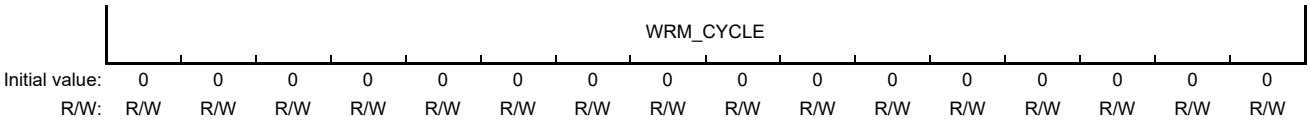
R/W:	R	R	R	R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	S1REN	0	R/W	Source1 read enable 0: Do not read data from external memory or internal memory, use the value of S1DATAR register as the data of Source1. 1: Read data of Source1 from external memory or internal memory. [Note] Do not use when (S0REN bit of S0CR register, S1REN bit of S1CR register)=(0,1). It is possible to set this bit to 1 when both S0TAMODE bits of S0CR register and D0TAMODE bits of D0CR register are 0. Otherwise, set this bit to 0.
30 to 4	—	All 0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.
3 to 0	S1PF	0011	R/W	Source1 pixel format Set the same value as the S0PF field of S0CR register. 3: 8bit/pixel 4: 16bit/pixel 5: 32bit/pixel Settings other than above are prohibited.

U30.2.20 Transaction control Register 0 (TCR0)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	WRM_EN	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/W	R	R	R	R	R	R	R	R	R	R	R

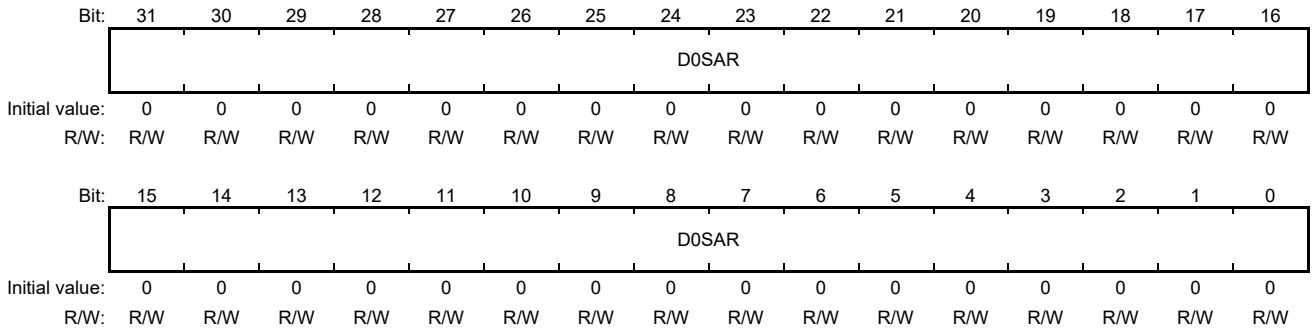
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0



Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	H'0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.
27	WRM_EN	0	R/W	Enabling minimum interval control of write request issuance This bit limits the interval of write request issuance by 1.
26 to 16	—	H'000	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.
15 to 0	WRM_CYCLE	H'0000	R/W	Setting minimum interval of write request issuance When WRM_EN=1, the write request is issued with the write request issuance interval greater than the value set in this bit. When writing to the internal memory, set an appropriate value of 32 or more according to the number of IPs using internal memory.

U30.2.21 Destination0 Start Address Register (D0SAR)

This register is used to set the start address of Destination0 to write to external memory or internal memory.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	D0SAR	H'0000 0000	R/W	Set the start address of Destination0 in byte unit. When PXALIGN of FCR1 register is 0, set according to the following. ・If DST0_TSIZE bits of TSCR register are 2, set this register in 64-byte unit. ・If DST0_TSIZE bits of TSCR register are 3, set this register in 128-byte unit. When PXALIGN of FCR1 register is 1, set according to the following. ・If D0PF bits of D0CR register are 3, set this register in 1-byte unit. ・If D0PF bits of D0CR register are 4, set this register in 2-byte unit. ・If D0PF bits of D0CR register are 5, set this register in 4-byte unit.

U30.2.22 Destination0 Stride Register (D0STR)

This register is used to set the memory width of Destination0 to write to external memory or internal memory.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	D0STR														
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 15	—	All 0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.
14 to 0	D0STR	H'0000	R/W	Memory width of Destination0 is set in byte unit. The setting range is 1~32767. Be sure to set the number of pixels, which is set in the IWIDTH bit of IMGSIZER register, to be equal to or greater than the byte converted value. When PXALIGN of FCR1 register is 0, set according to the following. ・If DST0_TSIZE bits of TSCR register are 2, set this register in 64-byte unit. ・If DST0_TSIZE bits of TSCR register are 3, set this register in 128-byte unit. When PXALIGN of FCR1 register is 1, set according to the following. ・If D0PF bits of D0CR register are 3, set this register in 1-byte unit. ・If D0PF bits of D0CR register are 4, set this register in 2-byte unit. ・If D0PF bits of D0CR register are 5, set this register in 4-byte unit.

U30.2.23 Destination0 Control Register (D0CR)

This register is used to control Destination0.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	D0TAMODE				—	—	—	—	—	—	—	—	D0PF			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1
R/W:	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.
15 to 12	D0TAMODE	0000	R/W	Destination0 tile addressing mode 0: Write Destination0 by the linear addressing. 1: Write Destination0 by the IMP original tile addressing. For details of tile addressing, refer to chapter Operation. Settings other than above are prohibited. If they are set, the operation cannot be guaranteed. If this bit is 1, set D0PF bits in this register to 3 or 4. If this bit is 1, setting the S1REN bit of S1CR register to 1 is prohibited. If this bit is 1, setting the BITCNTEN bit of FCR0 register to 1 is prohibited. When PXALIGN of FCR1 register is 1, setting this bit to 1 is prohibited. **[Slim-IMP DMAC]** Reserved. Operation cannot be guaranteed if a value other than 0000 is written here.
11 to 4	—	All 0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.
3 to 0	D0PF	0011	R/W	Destination0 pixel format When FCR0.BITCNTEN = 0, specify the same pixel format as the S0PF bit of S0CR register. If BITCNTEN bit of FCR0 register = 1 and S0PF, S1PF are 8bpp, 16bpp, 32bpp, set this field to 8bit/pixel. 3: 8bit/pixel 4: 16bit/pixel 5: 32bit/pixel Settings other than above are prohibited.

U30.2.24 Image Size Register (IMGSIZER)

This register is used to set the processing size (width and height) of Source and Destination. It is set in pixel unit.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	IWIDTH													
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	IHEIGHT													
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31, 30	—	All 0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.
29 to 16	IWIDTH	H'0000	R/W	These bits specify the width of the processed image. The horizontal size of Source and Destination is specified in pixel unit. When PXALIGN of FCR1 register is 0, set according to the following. If SRC0_TSIZE bit, SRC1_TSIZE bit, and DST0_TSIZE bit of TSCR register are 2, set the number of pixels so that it falls within the following ranges. ・If S0PF bit of S0CR register is 3, set within the range from 64 to 8192 pixels in 64-pixel unit. ・If S0PF bit of S0CR register is 4, set within the range from 32 to 4096 pixels in 32-pixel unit. ・If S0PF bit of S0CR register is 5, set within the range from 16 to 2048 pixels in 16-pixel unit. If SRC0_TSIZE bit, SRC1_TSIZE bit, and DST0_TSIZE bit of TSCR register are 3, set the number of pixels so that it falls within the following ranges. ・If S0PF bit of S0CR register is 3, set within the range from 128 to 8192 pixels in 128-pixel unit. ・If S0PF bit of S0CR register is 4, set within the range from 64 to 4096 pixels in 64-pixel unit. ・If S0PF bit of S0CR register is 5, set within the range from 32 to 2048 pixels in 32-pixel unit. When PXALIGN of FCR1 register is 1, set according to the following. ・If S0PF bit of S0CR register is 3, set within the range from 1 to 8192 pixels in 1-pixel unit. ・If S0PF bit of S0CR register is 4, set within the range from 1 to 4096 pixels in 1-pixel unit. ・If S0PF bit of S0CR register is 5, set within the range from 1 to 2048 pixels in 1-pixel unit.

Bit	Bit Name	Initial Value	R/W	Description
15, 14	—	All 0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.
13 to 0	IHEIGHT	H'0000	R/W	These bits specify the height of the processed image. The vertical size of Source and Destination is specified in line unit. Set the number of lines so that it is within the following ranges. ・If S0PF bit of S0CR register is 3, set within the range from 1 to 8192 lines. ・If S0PF bit of S0CR register is 4, set within the range from 1 to 4096 lines. ・If S0PF bit of S0CR register is 5, set within the range from 1 to 2048 lines.

U30.2.25 Function Control Register 0 (FCR0)

This register is used to control functions of IMP DMAC

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	BITCNTEN	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	LOP							
Initial value:	0	0	0	0	0	0	0	0	1	1	0	0	1	1	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	BITCNTEN	0	R/W	Bit count enable setting 0: Do not operate bit count 1: Operate bit count During bit count operation, the number of 1 after logical operation is counted. If this bit is 1, set LOP bits of FCR0 register to H'66 or H'99. Set this bit to 0 when S0TAMODE bits of S0CR register are 1 or when D0TAMODE bits of D0CR register is 1. When PXALIGN of FCR1 register is 1, set this bit to 0. **[Slim-IMP DMAC]** Reserved. Operation cannot be guaranteed if a value other than 0 is written here.
30 to 8	—	All 0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	LOP	H'CC	R/W	Logical operation setting When Source0 is s0 and Source1 is s1, the following logical operations will be performed. H'00 : All 0 H'11 : ~(s0 | s1) H'22 : (~s0) & s1 H'33 : ~s0 H'44 : s0 & (~s1) H'66 : s0 ^ s1 H'77 : ~(s0 & s1) H'88 : s0 & s1 H'99 : ~(s0^ s1) H'BB : (~s0) | s1 H'CC : s0 H'DD : s0 | (~s1) H'EE : s0 | s1 H'FF : All 1 Settings other than above are prohibited. **[Slim-IMP DMAC]** Reserved. Operation cannot be guaranteed if a value other than H'CC is written here.

U30.2.26 Function Control Register 1 (FCR1)

[IMP DMAC]

This register is used to control functions of IMP DMAC

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PXALIGN	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	SHIFT					RNDMD				SATEN	—	SATW	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	PXALIGN	0	R/W	Pixel alignment mode enable 0 : 64-byte or 128-byte alignment mode 1 : Pixel alignment mode This bit specifies the units that can be set to S0SAR, S0STR, S1SAR, S1STR, D0SAR, and DSTR registers. For the settable units, refer to each register.
30 to 28	—	B’001	R	Reserved The read value should always be 1. Operation cannot be guaranteed if a value other than 1 is written.
27 to 13	—	All 0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.
12 to 8	SHIFT	B’00000	R/W	Setting of shift amount after LOP These bits set the amount of shift to be performed for LOP output. -7~-1 : Logical right-shift 0 : No shift 1~7: Logical left-shift Set it by two's complement. The shift result is output in 16 bits. Set this bit to 0 unless all the following register settings are satisfied. ・PXALIGN bit of FCR1 register = 1 ・S0PF bits of S0CR register = 4 ・S1PF bits of S1CR register = 4 ・D0PF bits of D0CR register = 4

Bit	Bit Name	Initial Value	R/W	Description
7 to 4	RNDMD	B'0000	R/W	Setting rounding mode after shift These bits set the rounding mode for right-shift. 0: Towards neg.infinity (Round to negative infinity) 9: Towards nearest・Towards pos.infinity (Round to nearest/positive infinity) Settings other than above are prohibited. Set this bit to 0 except when SHIFT bits are from -7 to -1. Set this bit to 0 unless all the following register settings are satisfied. ・PXALIGN bit of FCR1 register = 1 ・S0PF bits of S0CR register = 4 ・S1PF bits of S1CR register = 4 ・D0PF bits of D0CR register = 4
3	SATEN	0	R/W	Saturation process enable This bit specifies whether or not saturation process is performed for the rounded 16-bit data. 0: Do not process saturation. 1: Process saturation. Set the bit width to process saturation by SATW bits. Set this bit to 0 unless all the following register settings are satisfied. ・PXALIGN bit of FCR1 register = 1 ・S0PF bits of S0CR register = 4 ・S1PF bits of S1CR register = 4 ・D0PF bits of D0CR register = 4
2	—	0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.
1, 0	SATW	B'00	R/W	Saturation bit width selection These bits set the bit width for saturation process when SATEN = "1". Saturation is processed as unsigned data. 1: Saturate to 10 bits 2: Saturate to 12 bits 3: Saturate to 14 bits If SATEN = 0, set this bit to 0. If SATEN = 1, setting this bit to 0 is prohibited. Set this bit to 0 unless all the following register settings are satisfied. ・PXALIGN bit of FCR1 register = 1 ・S0PF bits of S0CR register = 4 ・S1PF bits of S1CR register = 4 ・D0PF bits of D0CR register = 4

[Slim-IMP DMAC]

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PXALIGN	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	1	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R/W:	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	PXALIGN	1	R	Reserved This bit always read as 1. Operation cannot be guaranteed if a value other than 1 is written here.
30 to 0	—	H’10000000	R	Reserved These bits are always read as H’10000000. Operation cannot be guaranteed if a value other initial value is written here.

U30.2.27 Command List Fetch Address Register (CLFAR)

This register is used to display the address of CL fetch destination.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CLFAR															
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CLFAR														—	—
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	CLFAR	Undefined	R	These bits display bit31~bit2 of the address of CL fetch destination (during execution).
1, 0	—	All 0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.

U30.2.28 Command List Execute Instruction Register (CLEIR)

This register is used to display the instruction during CL execution.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CLEIR															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CLEIR															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CLEIR	H'0000 0000	R	These bits display the instruction during CL execution.

U30.2.29 RAM Test Register (RAMTSTR)

This is safety related register. Do not set this register during DMAC operation.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MEMINIT	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
15	MEMINIT	0	R/W	DMAC Memory Initialize Bit If this bit is set to "1", DMAC's SRAM area is initialized to "0". After setting this bit to "1", SYNCS command insert (waiting initialize complete) or CPU polling to this status bit is needed for data coherency. Read: 0: Not under initialization 1: Under initialization Write: 0: Invalid 1: Initiate initialization *Do not write 1, when this bit is 1.
14 to 0	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.

U30.2.30 DMAC Performance Control Register (DPCR)

This is the register to control the DPBSYCNT register.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	IFBSYCNTENB	DBSYCNTENB
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	—	All 0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.
1	IFBSYCNTENB	0	R/W	IFID operation count enable When this bit is 1, CYCLE is counted while CL is running. Setting both IFBSYCNTENB and DBSYCNTENB bit to 1 at same time is prohibited.
0	DBSYCNTENB	0	R/W	Data transmission operation count enable When this bit is 1, CYCLE is counted while DMAEN = 1. Setting both IFBSYCNTENB and DBSYCNTENB bit to 1 at same time is prohibited.

U30.2.31 DMAC Performance Busy Counter Register (DPBSYCNTR)

This register count cycles during operation.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DPBSYCNTR															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DPBSYCNTR															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DPBSYCNTR	H'0000 0000	R/W	This register count cycles during operation This reads the value counted in the condition set in DMAC Performance Control Register (DPCR). Counted value of this register is not guarenteed . When this register is written, the counter is set to the written value, and starts counts from set value onwards. Writing this register during the counting is prohibited.

U30.2.32 Synchronization Control Register 0 (SYNCCR0)

This register specifies the module corresponding to bits 0 to 3 in the SYNCC enable field of WUP and SLP instructions. Set the number of the module you want to specify in this register. For module number, refer to **U34.IMP-X7_system, U34.10.5 Inter Module Synchronization**. Set this register in CPU before setting the CLE bit of SCTLR1 register to 1. Rewriting this register is prohibited while CLE bit is 1.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SYNCC3								SYNCC2							
Initial value:	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SYNCC1								SYNCC0							
Initial value:	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

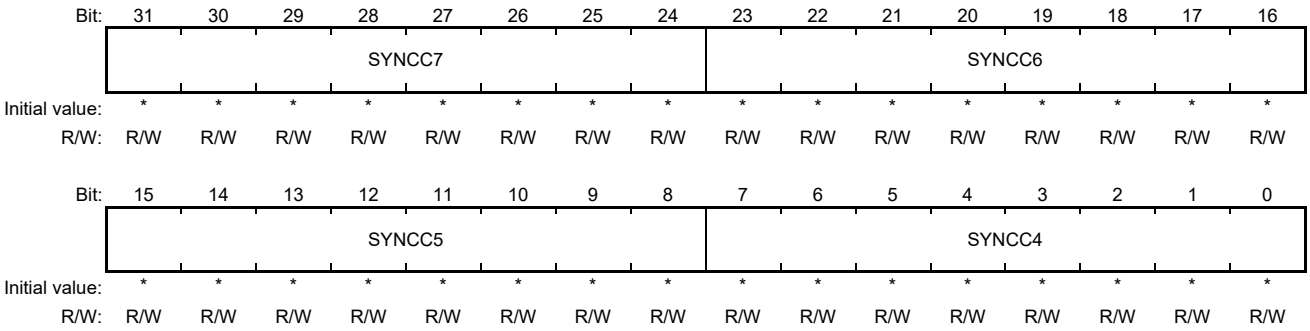
Bit	Bit Name	Initial Value	R/W	Description
31 to 24	SYNCC3	*	R/W	This register specifies the module corresponding to bit 3 in the SYNCC enable field of WUP and SLP instructions.
23 to 16	SYNCC2	*	R/W	This register specifies the module corresponding to bit 2 in the SYNCC enable field of WUP and SLP instructions.
15 to 8	SYNCC1	*	R/W	This register specifies the module corresponding to bit 1 in the SYNCC enable field of WUP and SLP instructions.
7 to 0	SYNCC0	*	R/W	This register specifies the module corresponding to bit 0 in the SYNCC enable field of WUP and SLP instructions.

Note: The initial value to be read varies depending on the product.

Initial value is H'FFFFFFFF

U30.2.33 Synchronization Control Register 1 (SYNCCR1)

This register specifies the module corresponding to bits 4 to 7 in the SYNCC enable field of WUP and SLP instructions. Set the number of the module you want to specify in this register. For module number, refer to **U34.IMP-X7_system, U34.10.5 Inter Module Synchronization**. Set this register in CPU before setting the CLE bit of SCTLR1 register to 1. Rewriting this register is prohibited while CLE bit is 1.



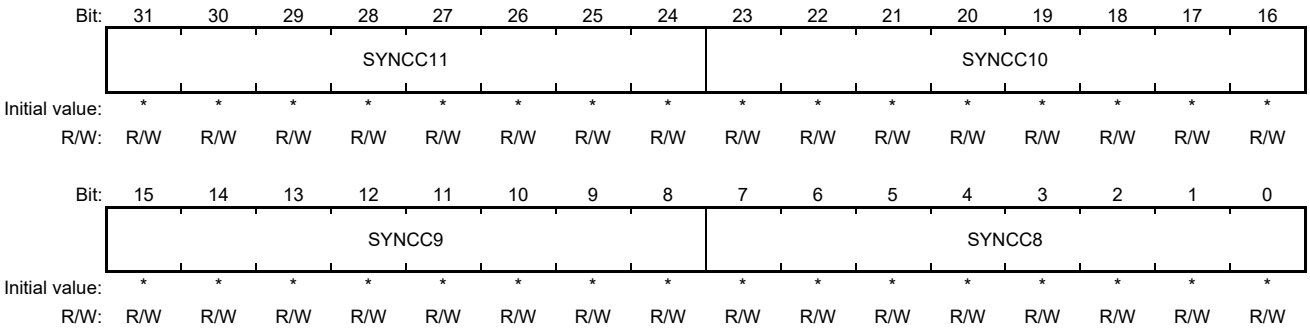
Bit	Bit Name	Initial Value	R/W	Description
31 to 24	SYNCC7	*	R/W	This register specifies the module corresponding to bit 7 in the SYNCC enable field of WUP and SLP instructions.
23 to 16	SYNCC6	*	R/W	This register specifies the module corresponding to bit 6 in the SYNCC enable field of WUP and SLP instructions.
15 to 8	SYNCC5	*	R/W	This register specifies the module corresponding to bit 5 in the SYNCC enable field of WUP and SLP instructions.
7 to 0	SYNCC4	*	R/W	This register specifies the module corresponding to bit 4 in the SYNCC enable field of WUP and SLP instructions.

Note: The initial value to be read varies depending on the product.

Initial value is H'FFFFFFFF

U30.2.34 Synchronization Control Register 2 (SYNCCR2)

This register specifies the module corresponding to bits 8 to 11 in the SYNCC enable field of WUP and SLP instructions. Set the number of the module you want to specify in this register. For module number, refer to **U34.IMP-X7_system, U34.10.5 Inter Module Synchronization**. Set this register in CPU before setting the CLE bit of SCTLR1 register to 1. Rewriting this register is prohibited while CLE bit is 1.



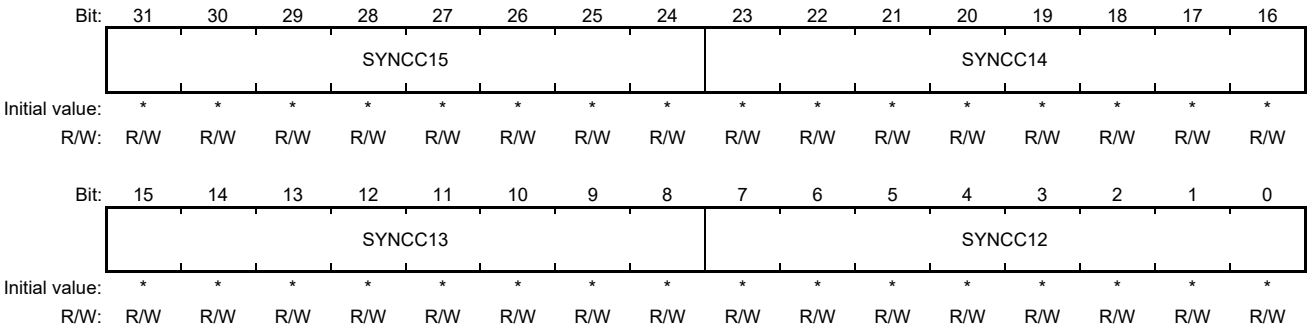
Bit	Bit Name	Initial Value	R/W	Description
31 to 24	SYNCC11	*	R/W	This register specifies the module corresponding to bit 11 in the SYNCC enable field of WUP and SLP instructions.
23 to 16	SYNCC10	*	R/W	This register specifies the module corresponding to bit 10 in the SYNCC enable field of WUP and SLP instructions.
15 to 8	SYNCC9	*	R/W	This register specifies the module corresponding to bit 9 in the SYNCC enable field of WUP and SLP instructions.
7 to 0	SYNCC8	*	R/W	This register specifies the module corresponding to bit 8 in the SYNCC enable field of WUP and SLP instructions.

Note: The initial value to be read varies depending on the product.

Initial value is H'FFFFFFFF

U30.2.35 Synchronization Control Register 3 (SYNCCR3)

This register specifies the module corresponding to bits 12 to 15 of the SYNCC enable field of WUP and SLP instruction. Set the number of the module you want to specify in this register. For module number, refer to **U34.IMP-X7_system, U34.10.5 Inter Module Synchronization**. Set this register in CPU before setting the CLE bit of SCTLR1 register to 1. Rewriting this register is prohibited while CLE bit is 1.



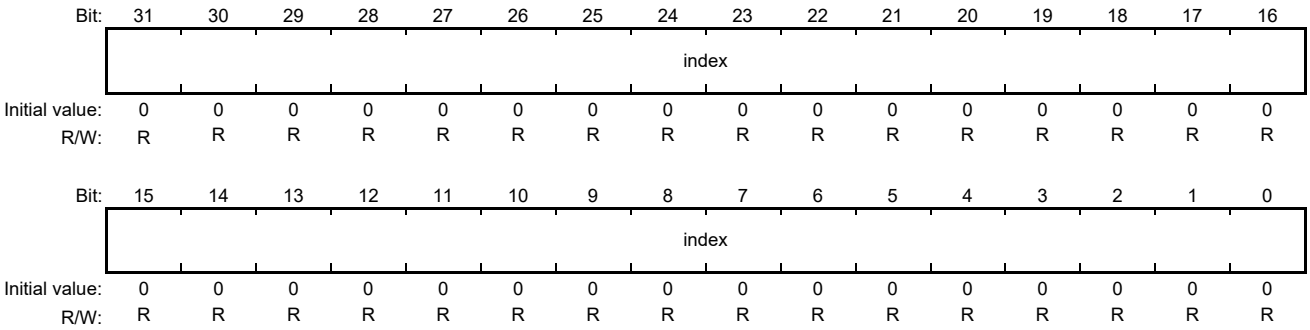
Bit	Bit Name	Initial Value	R/W	Description
31 to 24	SYNCC15	*	R/W	This register specifies the module corresponding to bit 15 in the SYNCC enable field of WUP and SLP instructions.
23 to 16	SYNCC14	*	R/W	This register specifies the module corresponding to bit 14 in the SYNCC enable field of WUP and SLP instructions.
15 to 8	SYNCC13	*	R/W	This register specifies the module corresponding to bit 13 in the SYNCC enable field of WUP and SLP instructions.
7 to 0	SYNCC12	*	R/W	This register specifies the module corresponding to bit 12 in the SYNCC enable field of WUP and SLP instructions.

Note: The initial value to be read varies depending on the product.

Initial value is H'FFFFFFFF

U30.2.36 Index Register 0

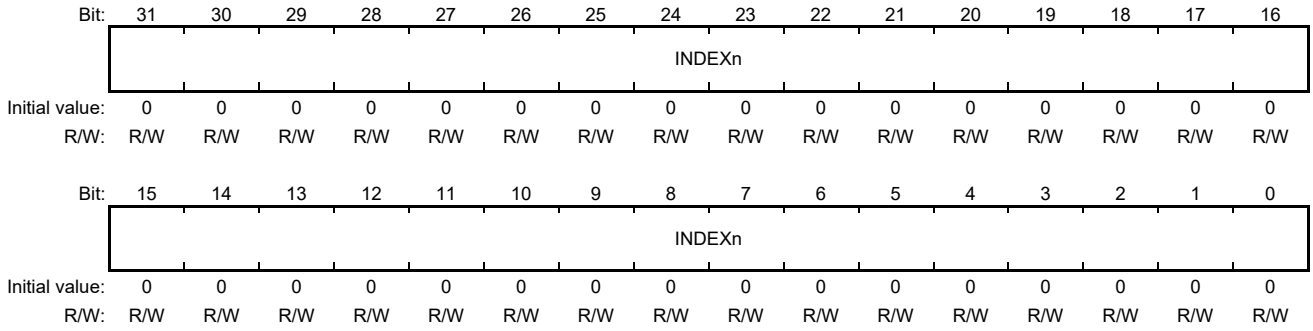
This is the register to control the source and destination addresses



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	index	H'0000 0000	R	This is the index register. Read value is always 0.

U30.2.37 Index Register (INDEXn) (n=1 to 7)

These are the registers to control the source and destination addresses.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	INDEXn	H'0000 0000	R/W	This is the index register. Value written in these register is added to the S0SAR, S1SAR and D0SAR according to the setting in Index Number in **U30A.4.3 WPR** command. Be sure to follow the alignment of S0SAR, S1SAR and D0SAR when setting these registers. Note that Slim-IMP DMAC does not use S1SAR.

U30.2.38 Wraparound enable register (WRAPER)

This is the register to control the SRC/DST wraparound min/max register register. This register is implemented for Slim-IMP DMAC only.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DST_WRAP_ENB	SRC_WRAP_ENB
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	—	All 0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.
1	DST_WRAP_ENB	0	R/W	Dst address wraparound enable 0: Not wraparound Dst address 1: Wraparound Dst address
0	SRC_WRAP_ENB	0	R/W	Src address wraparound enable 0: Not wraparound Src address 1: Wraparound Src address

U30.2.39 SRC minimum address wraparound register (WRAPS_MIN)

This is the register to control the SRC min wraparound address. This register is implemented for Slim-IMP DMAC only.

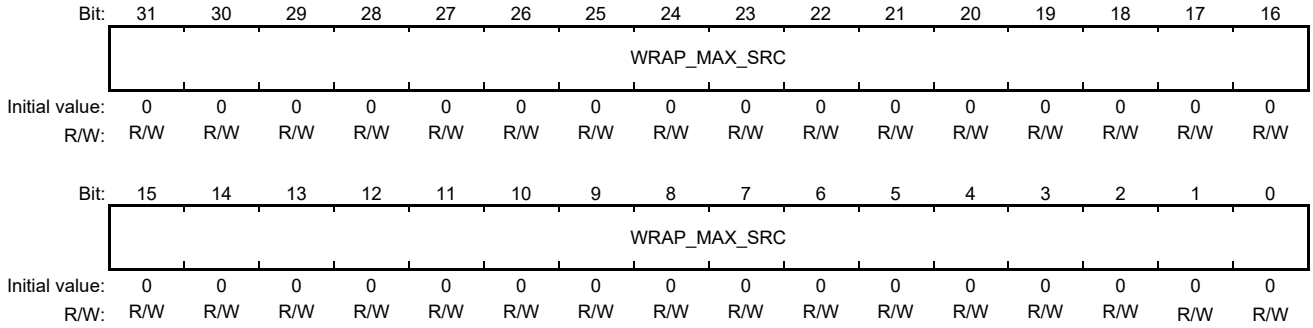
Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	WRAP_MIN_SRC															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	WRAP_MIN_SRC															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	WRAP_MIN_SRC	All 0	R/W	Minimum address of Src wraparound. If src_wrap_enb of WRAPER register is 0, setting in this register is not used. Start address of source (S0SAR) shall be in between the WRAPS_MIN and WRAPS_MAX address. WRAPS_MIN < WRAPS_MAX set this register in 512-byte alignment. (Bits 0~8 shall be 0).

U30.2.40 SRC maximum address wraparound register (WRAPS_MAX)

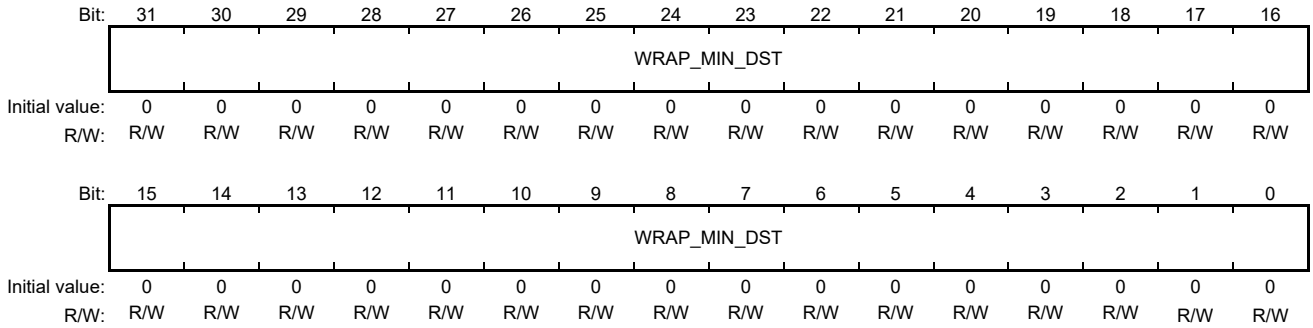
This is the register to control the SRC min wraparound address. This register is implemented for Slim-IMP DMAC only.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	WRAP_MAX_SRC	All 0	R/W	Maximum address of Src wraparound. If src_wrap_enb of WRAPER register is 0, setting in this register is not used. Start address of source (S0SAR) shall be in between the WRAPS_MIN and WRAPS_MAX address. WRAPS_MIN < WRAPS_MAX (WRAPS_MAX-WRAPS_MIN+1) shall be in 512-byte alignment. For ex: When wraparound between 512-byte and 1024-byte. WRAPS_MIN = 0x00000200 (512-byte). (WRAPS_MAX+1) shall be in 512 byte alignment. (WRAPS_MAX+1)= (0x000003FF+1) =0x00000400.

U30.2.41 DST minimum address wraparound register (WRAPD_MIN)

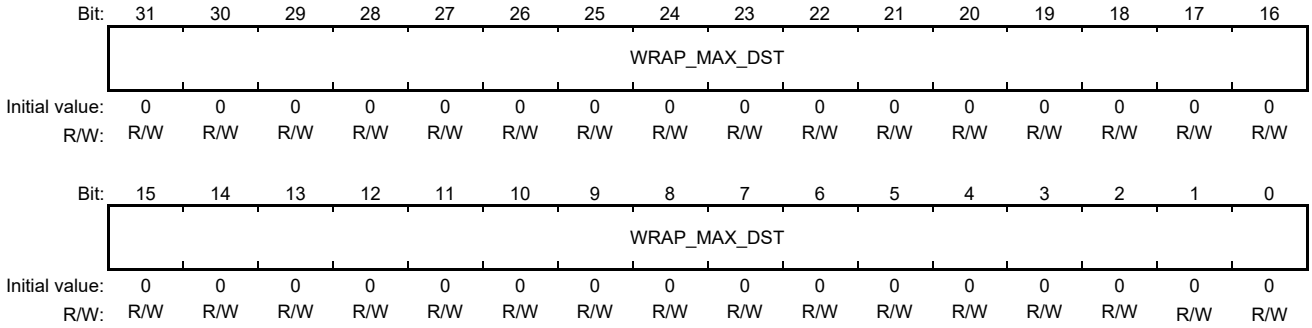
This is the register to control the SRC min wraparound address. This register is implemented for Slim-IMP DMAC only.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	WRAP_MIN_DST	All 0	R/W	Minimum address of Dst wraparound. If dst_wrap_enb of WRAPER register is 0, setting in this register is not used. Start address of destination (D0SAR) shall be in between the WRAPD_MIN and WRAPD_MAX address. WRAPD_MIN < WRAPD_MAX set this register in 512-byte alignment. (Bits 0~8 shall be 0).

U30.2.42 DST maximum address wraparound register (WRAPD_MAX)

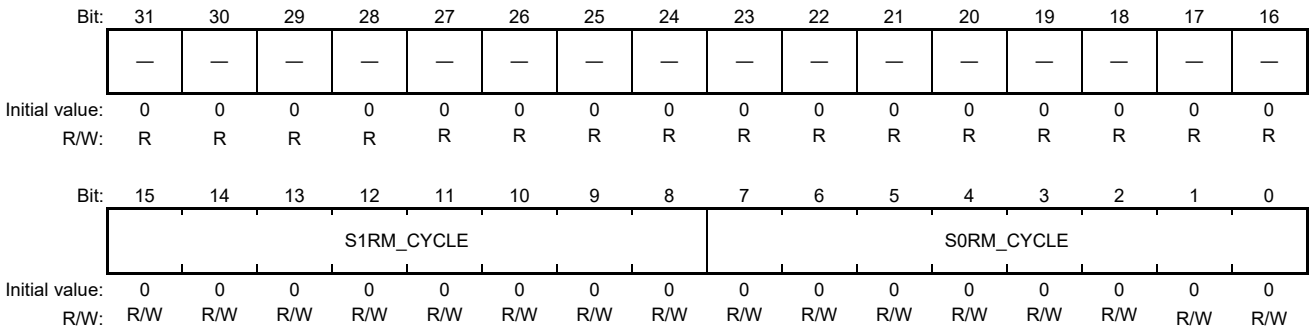
This is the register to control the SRC min wraparound address. This register is implemented for Slim-IMP DMAC only.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	WRAP_MAX_DST	All 0	R/W	Maximum address of Dst wraparound. If dst_wrap_enb of WRAPER register is 0, setting in this register is not used. Start address of destination (D0SAR) shall be in between the WRAPD_MIN and WRAPD_MAX address. WRAPD_MIN < WRAPD_MAX (WRAPD_MAX-WRAPD_MIN+1) shall be in 512-byte alignment. For ex: When wraparound between 512-byte and 1024-byte. WRAPD_MIN = 0x00000200 (512-byte). (WRAPD_MAX+1) shall be in 512 byte alignment. (WRAPD_MAX+1)= (0x000003FF+1) =0x00000400.

U30.2.43 Transaction control Register 1 (TCR1)

This controls the issue cycle of Src0,1 read request.

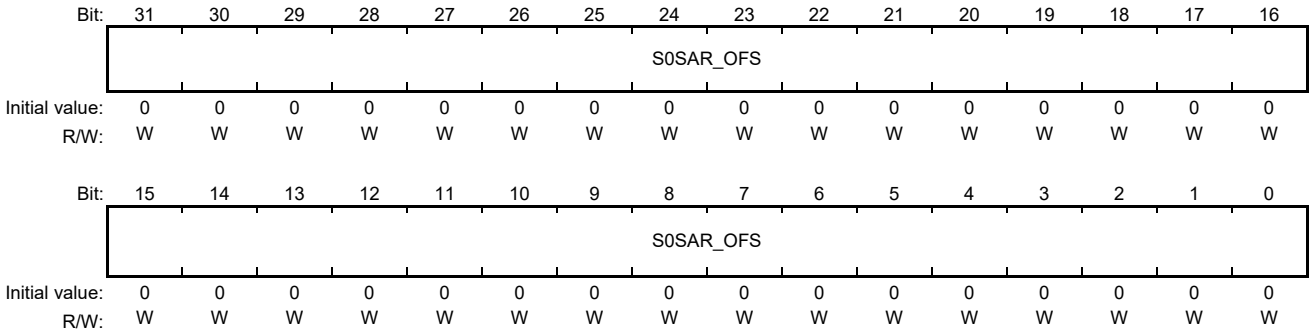


Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	S1RM_CYCLE	H'00	R/W	Setting minimum interval to issue the read request of Src1 The read request is issued with the read request issuance interval greater than the value set in this bit. When reading from the internal memory, set an appropriate value of 32 or more according to the number of IPs using internal memory. **[Slim-IMP DMAC]** Reserved. Operation cannot be guaranteed if a value other than H'00 is written here.
7 to 0	S0RM_CYCLE	H'00	R/W	Setting minimum interval to issue the read request of Src0 The read request is issued with the read request issuance interval greater than the value set in this bit. When reading from the internal memory, set an appropriate value of 32 or more according to the number of IPs using internal memory.

U30.2.44 Source0 Start Address Offset Register (S0SAR_OFS)

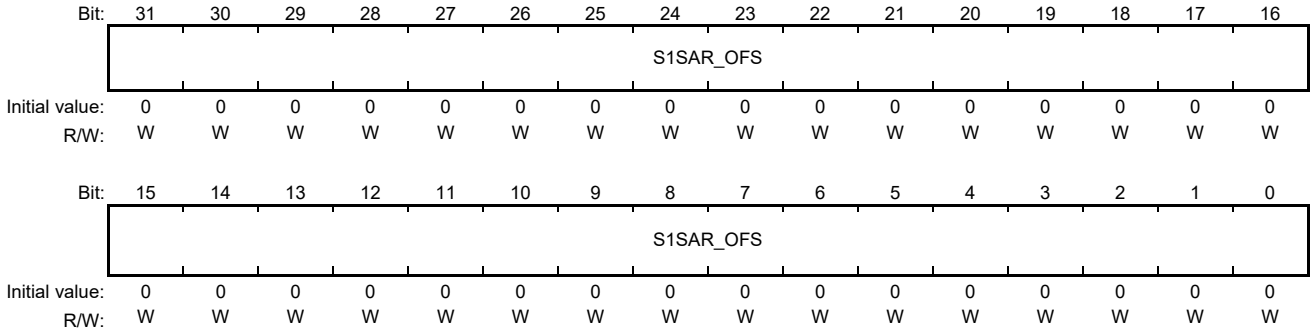
This register is used to set the offset to be added to the start address of Source0.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	S0SAR_OFS	H'0000 0000	W	Set the offset value to be added to the start address of Source0 in byte unit. When PXALIGN of FCR1 register is 0, set according to the following. ・If SRC0_TSIZE bits of TSCR register are 2, set this register in 64-byte unit. ・If SRC0_TSIZE bits of TSCR register are 3, set this register in 128-byte unit. When PXALIGN of FCR1 register is 1, set according to the following. ・If S0PF bits of S0CR register are 3, set this register in 1-byte unit. ・If S0PF bits of S0CR register are 4, set this register in 2-byte unit. ・If S0PF bits of S0CR register are 5, set this register in 4-byte unit.

U30.2.45 Source1 Start Address Offset Register (S1SAR_OFS)

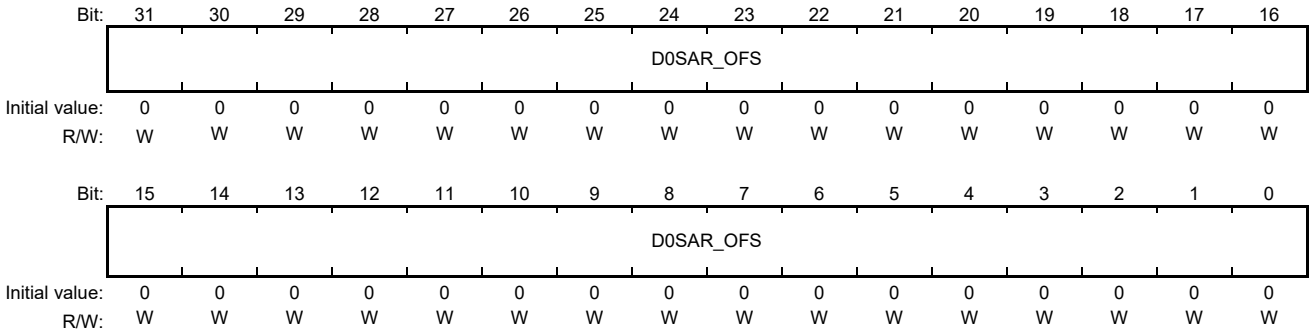
This register is used to set the offset to be added to the start address of Source1.
Note: This register is not support for Slim-IMP DMAC. Do not set this register for Slim-IMP DMAC operation.
This register is always read as 0x00000000.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	S1SAR_OFS	H'0000 0000	W	Set the offset value to be added to the start address of Source1 in byte unit. When PXALIGN of FCR1 register is 0, set according to the following. ・If SRC1_TSIZE bits of TSCR register are 2, set this register in 64-byte unit. ・If SRC1_TSIZE bits of TSCR register are 3, set this register in 128-byte unit. When PXALIGN of FCR1 register is 1, set according to the following. ・If S1PF bits of S1CR register are 3, set this register in 1-byte unit. ・If S1PF bits of S1CR register are 4, set this register in 2-byte unit. ・If S1PF bits of S1CR register are 5, set this register in 4-byte unit.

U30.2.46 Destination0 Start Address Offset Register (D0SAR_OFS)

This register is used to set the offset to be added to the start address of Destination0.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	D0SAR_OFS	H'0000 0000	W	Set the offset value to be added to the start address of Destination0 in byte unit. When PXALIGN of FCR1 register is 0, set according to the following. ・If DST0_TSIZE bits of TSCR register are 2, set this register in 64-byte unit. ・If DST0_TSIZE bits of TSCR register are 3, set this register in 128-byte unit. When PXALIGN of FCR1 register is 1, set according to the following. ・If D0PF bits of D0CR register are 3, set this register in 1-byte unit. ・If D0PF bits of D0CR register are 4, set this register in 2-byte unit. ・If D0PF bits of D0CR register are 5, set this register in 4-byte unit.

U30.2.47 CL Break Address Register (CLBRKADDRR)

This is the register to control the CL break.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CLBRKADDRR[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CLBRKADDRR[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CLBRKADDR R	All 0	R/W	CL break address. Specify the address(break point) of command list. Specify a 32 bit (4-byte) command list address. Data address is prohibited.

U30.2.48 CL Conditional GOSUB Register(CLCNDGSBR)

his is the register to control the GOSUB command.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—		—	—	—	—	—	—	—	CLCND GSBR
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.
0	CLCNDGSBR	0	R/W	Condition for conditional GOSUB instruction: 1: GOSUB is executed 0: GOSUB is not executed, NOP is instead executed (Bit 22 of the GOSUB command should be 1 for NOP operation)

U30.3 Operation

U30.3.1 Data-Path configuration

The configuration of Data-Path built in IMP DMAC is shown below.

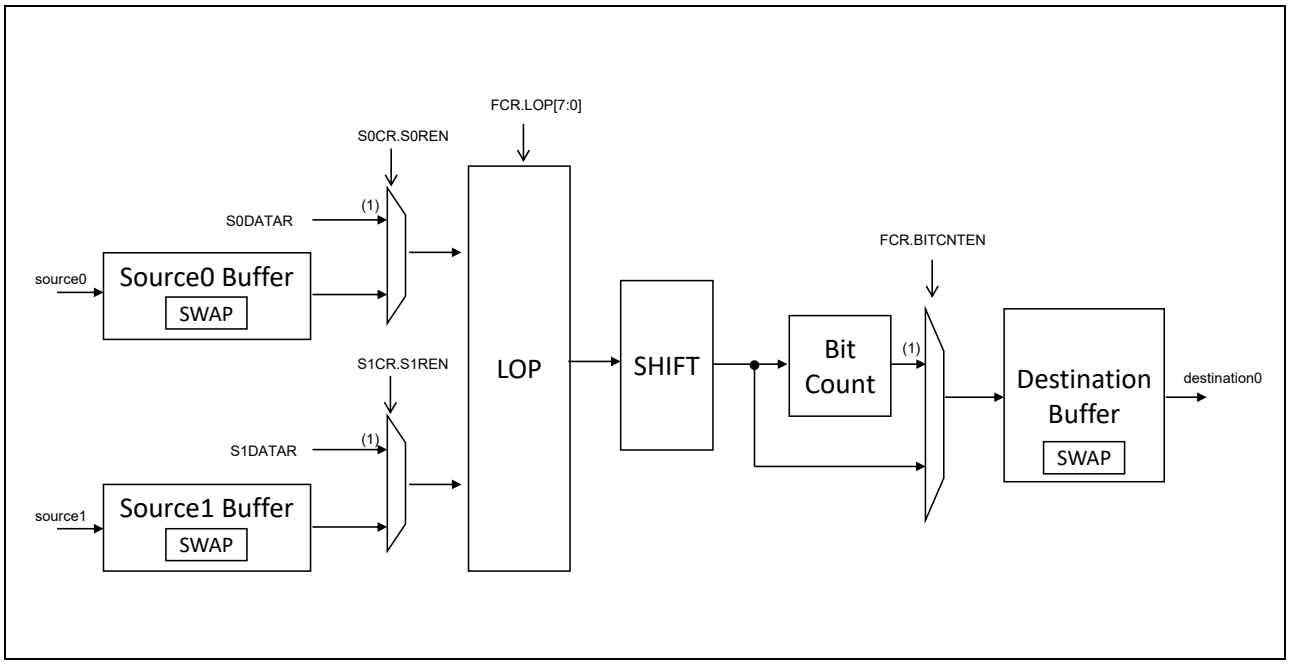


Figure U30.3 Data-Path block diagram [IMP DMAC]

[IMP DMAC]

The source input (Source0, Source1) and the register setting fixed value (S0DATAR, S1DATAR) are selected by S0REN, S1REN bits of S0CR, S1CR registers.
The data is inverted by INVS0D and INVS1D bits of FCR0 register, then Logic Operation (LOP) is performed according to the set value of LOP bits in FCR0 register. The result of LOP is shifted according to the setting of FCR1 register and then output to the destination buffer. By enabling the BITCNTEN bit of FCR0 register, it is possible to output the number of 1 resulting from the shift process to the destination buffer.

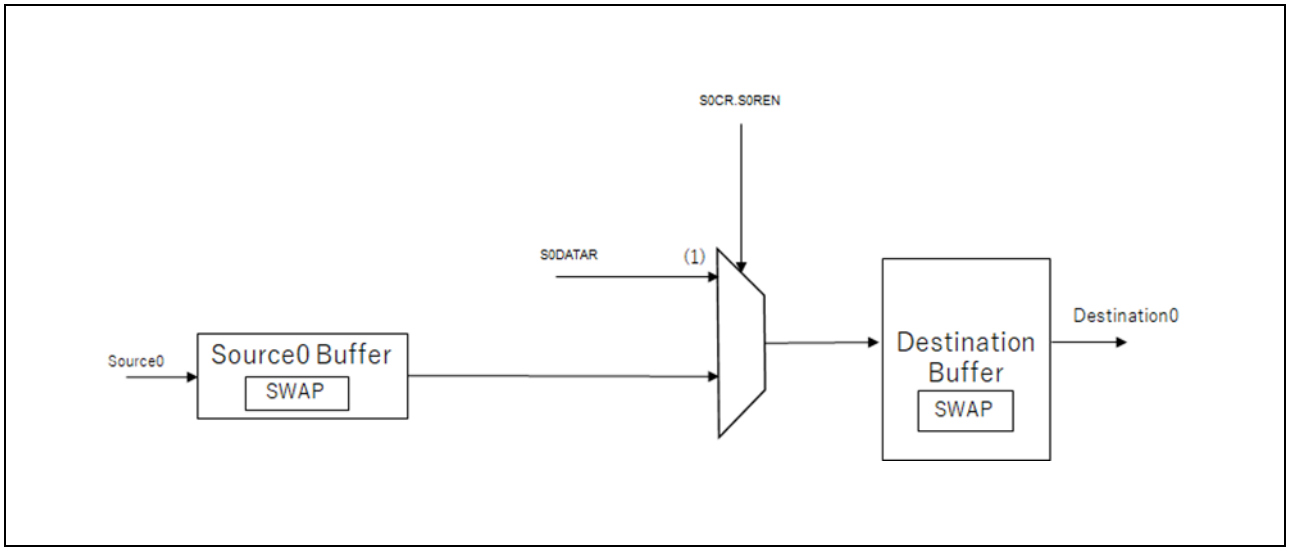

Figure U30.4 Data-Path block diagram [Slim-IMP DMAC]

[Slim-IMP DMAC]

The S0REN bits of the S0CR register is used to select whether memory or the S0DATAR is to be used as sources 0.The logical operation (LOP), BITCNTEN and shifting feature is not implemented in Slim-IMP DMAC.

U30.3.2 Shift

Note: This feature is not support for Slim-IMP DMAC.

The shift is valid when PXALIGN bit of FCR1 register = 1, S0PF bits of S0CR register = 4, S1PF bits of S1CR register = 4, and D0PF bits of D0CR register = 4. When shift is enabled, shifting, rounding, and saturation are performed for the output data of LOP according to the setting of FCR1 register.
When left shifting, 0 is put in the lower bit without holding the sign. When right shifting, the sign or 0 is put in the upper level according to the data format. When right shifting, it is possible to round the shift output.
The shift result is output in 16 bits. When rounding with right shift, the result of rounding to positive infinity is output as 16 bits. If the left shift or shift amount is 0, set the rounding mode to rounding down.
When saturation is enabled, the shifted or rounded 16 bits data is regarded as unsigned 16 bits data, and saturated to either unsigned 10 bits, unsigned 12 bits or unsigned 14 bits.
When it is saturated with unsigned 10 bits/ unsigned 12 bits/ unsigned 14 bit, the upper bits are filled with 0 to output as 16 bits.
Refer to FCR1 register for shift amount setting, rounding setting and saturation setting.

U30.3.3 Tile addressing

Note: This feature is not supported for Slim-IMP DMAC.

This module supports not only linear addressing where the two-dimensional image data is arranged in memory as a whole in raster scan order, but also a tile addressing mode where the data is arranged tile wise. In tile addressing mode, continuous data in x direction is interleaved with data from other rows, thus improving the cache-hit ratio for vertical access to the image data (e.g., for rotation of an image) and also improving processing performance.

In tile addressing mode, the data are stored with the data incremented in 16-byte units within 64-byte sections. An example where 8-bpp data are exclusively output is shown below. (x, y) in the figure below indicate the x and y coordinates of pixels.

The tile addressing mode can be set up individually for source and destination images.

To set up the tile addressing mode for the source0 image, set the S0TAMODE bit in S0CR to 1.

To set up the tile addressing mode for the destination0 image, set the D0TAMODE bit in D0CR to 1.

To set the stride in tile addressing mode, set the corresponding bits in D0STR and S0STRto a value equal to one quarter of the actual memory stride.

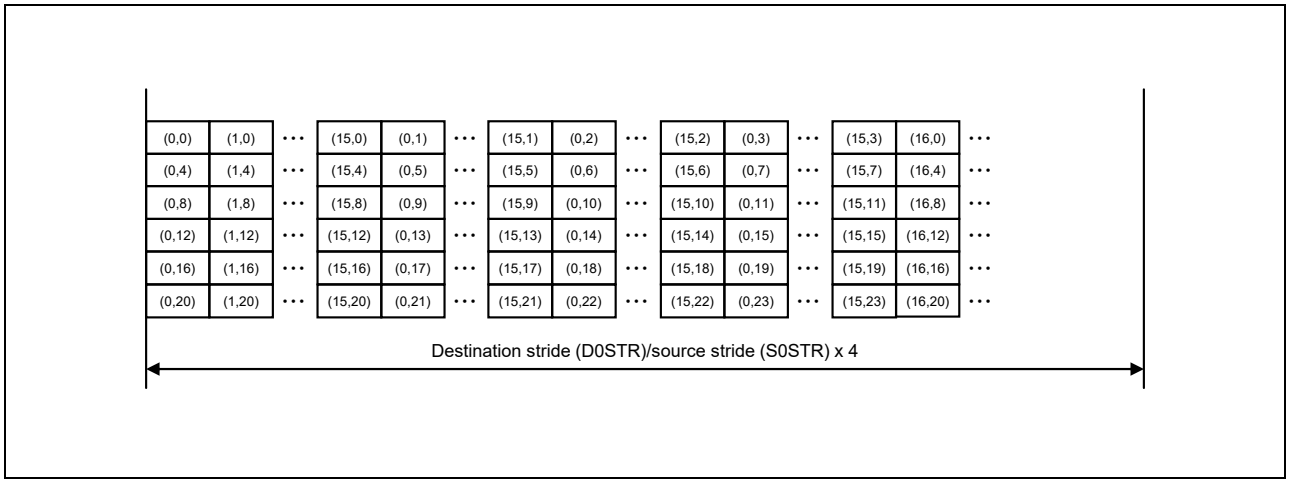

Figure U30.5 Image of data arrangement on memory in tile addressing mode

U30.3.4 Inter Module Synchronization System

The synchronization system between modules is the system that synchronizes the control of each CL Controller by specifying the target module and executing the WUP instruction and the SLP instruction for IMP core, CVe, IMP DMAC, IMP PSC, IMP CNN, slim-IMP DMAC, VDSP and IMPDTA.

For the WUP instruction and the SLP instruction in IMP DMAC, refer to “U30.4.9 WUP” and “U30.4.10 SLP”. For target module specification, refer to the next section.

U30.3.4.1 Target module specification

Refer to the **U34.IMP-X7_system, U34.10.5 Inter Module Synchronization** chapter for the details.

U30.3.5 Data compression

For the DATA compression, refer to 63. FCPR HWM for the details. Note that transmission size(TSCR register) of the IMPDMAC/Slim-IMP DMAC should be 256 byte when using DATA compression.

Note: It is prohibited to compress the Command List (CL), so place the CL only to the uncompressed region. IMPDMAC can pre-fetch the CL of maximum 640-byte. Therefore, do not use last 640-byte of uncompressed region before the compressed region.

U30.3.6 Addition of offset to start address

Note: This feature is not supported for Slim-IMP DMAC.

IMP DMAC can add an offset to the start address of Source0, Source1, Destination0.
By writing the offset value to S0SAR_OFS, S1SAR_OFS*, and D0SAR_OFS, the value obtained by adding the offset specified in S0SAR, S1SAR, and D0SAR is written. If offset is not added, write the value directly to S0SAR, S1SAR, and D0SAR. In addition, the read values of S0SAR_OFS, S1SAR_OFS*, and D0SAR_OFS are always 0.

U30.3.7 CL break

To use the CL break function, following setting is required.

1. Specify the break point address of command list. Be sure that break point is command address of command list.

2. Set CLBRKENB of SER register to 1 and if interrupt is required, set CLBRKM bit in IMR bit to use CL break function.
3. Check the CLBRK status in SR0 register.

4. To continue execution after CL break, Set the CLBRKC bit of SCR register to 1.

U30.4 Command List(CL)

It is prohibited from using instructions other than those described in this section.

Table 30.4 **Instruction list**

Instruction	OP CODE	Description
NOP	H'80	No Operation
TRAP	H'88	Close the CL
WPR	H'55	Write to register
INT	H'81	Generate an interrupt cause and wait until the interrupt is cleared
SYNCS	H'8B	Wait for the completion of DMA transmission execution
Reserved	H'8C	This instruction is not allowed to use With this instruction, no illegal instruction interrupt occurs
Reserved	H'8D	This instruction is not allowed to use With this instruction, no illegal instruction interrupt occurs
JUMP	H'90	Jump to the specified address
GOSUB	H'91	Jump to the specified address
RET	H'99	Jump to the instruction next to the GOSUB
WUP	H'A0	Release the SLP of other modules
SLP	H'A1	Wait for another module to execute WUP
Reserved	H'B0	This instruction is not allowed to use With this instruction, no illegal instruction interrupt occurs
Reserved	H'B1	This instruction is not allowed to use With this instruction, no illegal instruction interrupt occurs
Reserved	H'C0	This instruction is not allowed to use With this instruction, no illegal instruction interrupt occurs

U30.4.1 NOP (No OPeration)

(1) Function

It is No Operation instruction.
The NOP instruction causes the IMP DMAC to do nothing for the number of clock cycles specified in the N field before execution of the next instruction.

(2) Instruction format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OP CODE=1000_0000 (H'80)								Reserved (all 0)																			N (1≦N≦16)				

U30.4.2 TRAP (TRAP)

(1) Function

This is the instruction to close the CL.
It closes the CL execution. When the TRAE bit of SER register is 1, the TRA bit of SR0 register is set to 1.
However, regardless of the value of the TRAE bit in SER register, the value specified in the CODE field is set to TRAPCODE of SR1 register.

(2) Instruction format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OP CODE=1000_1000 (H'88)								Reserved (all 0)																CODE							

U30.4.3 WPR (Write PaRameter)

(1) Function

This instruction performs writing to the register.
Register write is performed only by the number of fields N from the offset address of the register, which is specified in the ADD field. The value to be written to the register is the value of the DATA N-1 field in order from the DATA 0 field.
The ADD field specifies only the offset value in 1-byte unit. (Thread0 and Thread1 have the same address specification)
Do not set the N field to 0. The Index number field specifies the number of INDEX register so that value written to the selected Index register will be added to the S0SAR, S1SAR and D0SAR specified in DATA field of this command. The range of Index Number is (0 to 7). When using WPR for registers other than above, set Index Number=0.

(2) Instruction format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OP CODE=0101_0101 (H'55)								Index Number			ADD													N(>=1)							
DATA 0																															
DATA 1																															
DATA 2																															

…

DATA N-1

U30.4.4 INT (INTerrupt)

(1) Function

This instruction generates the INT interrupt cause.
When the INTE bit of SER register is 1, the INT bit of SR0 register is set to 1.
Regardless of the value of the INTE bit in SER register, the value specified in the CODE field is set to INTCODE of SR1 register.
The next instruction is not started until the INT bit of SR0 register is cleared to 0.

(2) Instruction format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OP CODE=1000_0001 (H'81)								Reserved (all 0)																CODE							

U30.4.5 SYNCS (SYNChronize DMAC ProcesS)

(1) Function

This is the instruction to wait for the completion of DMA transmission execution.
This instruction waits for the completion of DMA transmission when there is a DMA transmission currently being executed. After waiting for the completion of DMA transmission, the next instruction is started.
If there is no DMA transmission being executed, it is the same as NOP (the next command is started).
Right after having set the DMAEN bit of SCTLR0 register to 1 by the WPR instruction, be sure to always wait for the completion of DMA transmission with the SYNCS instruction. If you do not wait for the DMA transmission to complete, the operation cannot be guaranteed.

(2) Instruction format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OP CODE=1000_1011 (H'8B)								Reserved (all 0)																							

U30.4.6 JUMP

(1) Function

This is the command to jump to the specified address.
It allows jumping to the address specified in JMPADD field. Setting 1 to RLT field uses relative address to JUMP command address and setting 0 in RLT field uses absolute address of the command list. Specify 4-byte unit command address in the JMPADD field.

(2) Instruction format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OP CODE=1001_0000(H'90)								RLT	Reserved（all 0）																						
JMPADD[31:0]																															

U30.4.7 GOSUB (Go Subroutine)

(1) Function

This is the command to save current CL address to the hardware buffer and jump to the specified address.
It allows jumping to the address specified in GSADD field and returning to the address next to the GOSUB command by RET command. Specify 4-byte unit command address in the GSADD field. Nesting from the GOSUB up to 4 level can be possible. Setting 1 to RLT field uses GSADD as relative address to GOSUB command address and setting 0 in RLT field uses absolute address of the command list. Setting 1 in CON field and 0 in CLCNDGSBR bit of CLCNDGSBR register change GOSUB command into NOP command. After the CLCNDGSBR register is set, a SYNCS command should be added before using the GOSUB command.

(2) Instruction format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OP CODE = 1001_0001 (H'91)								RLT	CON	Reserved (all 0)																					
GSADD[31:0]																															

U30.4.8 RET (RETurn)

(1) Function

This is the instruction to jump to the instruction next to the GOSUB.

RET allows jumping to the CL address next to the address at which the GOSUB instruction is executed.

(2) Instruction format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OP CODE = 1001_1001 (H'99)								Reserved (all 0)																							

U30.4.9 WUP (WakeUP)

(1) Function

This is the instruction to cancel the SLP state of the module, which is specified in the SYNCC enable field, in the intermodule synchronization system. By setting bit 'm' of SYNCC enable field to 1, WUP signal is issued to the module set in SYNCCm(m=0~15) of SYNCCRn(n=0~3) register. Be sure to insert 8 or more instructions other than the WUP instruction between two WUP instructions in the CL. For details, refer to the operation explanation of the intermodule synchronization system.

(2) Instruction format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OP CODE=1010_0000 (H'A0)								Reserved (all 0)								SYNCC enable															

U30.4.10 SLP (SLeep)

(1) Function

This is the instruction to change the own module into the SLP state in the intermodule synchronization system.

The SLP state is cancelled by the WUP instruction of the module specified in the SYNCC enable field.

By setting bit 'm' of SYNCC enable field to 1, wait for the WUP signal from the module set in SYNCCm(m=0~15) of SYNCCRn(n=0~3) register. For details, refer to the operation explanation of the intermodule synchronization system.

(2) Instruction format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OP CODE=1010_0001 (H'A1)								Reserved (all 0)								SYNCC enable															

U30.5 Usage Notes

U30.5.1 Power off

Refer to chapter 58.7 Usage Notes in IMP-X7 HW Manual for the power off.

U30.5.2 Module Standby Mode

Refer to chapter chapter 58.7 Usage Notes in IMP-X7 HW Manual for the Module Standby Mode.

U30.5.3 CPG Software reset

Refer to chapter chapter 58.7 Usage Notes in IMP-X7 HWM Manual for the software reset.

U30.6 Safety Mechanisms

Note: The suitability of the safety mechanisms referenced in this manual will finally be judged during the safety analysis and safety assessment of the SoC. Therefore, the safety documentation shall always be considered as additional requirements for the system or software derived from the results of the safety analysis.

U30.6.1 EDC protection.

EDC protection is implemented to SRAM and Bus interface in IMPDMAC/Slim-IMP DMAC. EDC check is always enabled. When using the EDC function of memory (after every power on reset or software reset by CPG or Runtime Test or POST), it is necessary to initialize the memories. Set the **U30.2.29 RAMTSTR** register for memory initialization in IMPDMAC/Slim-IMP DMAC. When using both the thread0 and thread1, set the memory initialization by only thread0.

After setting MEMINIT bit of RAMTSTR to "1", SYNCS command need to insert (waiting initialize complete) when writing from command list or CPU polling to this status bit is needed for data coherency.

Execute following steps from (1) to (3) to initialize IMP DMAC memory by CPU
< Procedure to initialize memory by CPU>

(1) Set MEMINIT bit to 1 in RAMTSTR register
(2) Read 8 times the RAMTSTR register
(3) Wait till RAMTSTR bit becomes 0 by polling further the RAMTSTR register

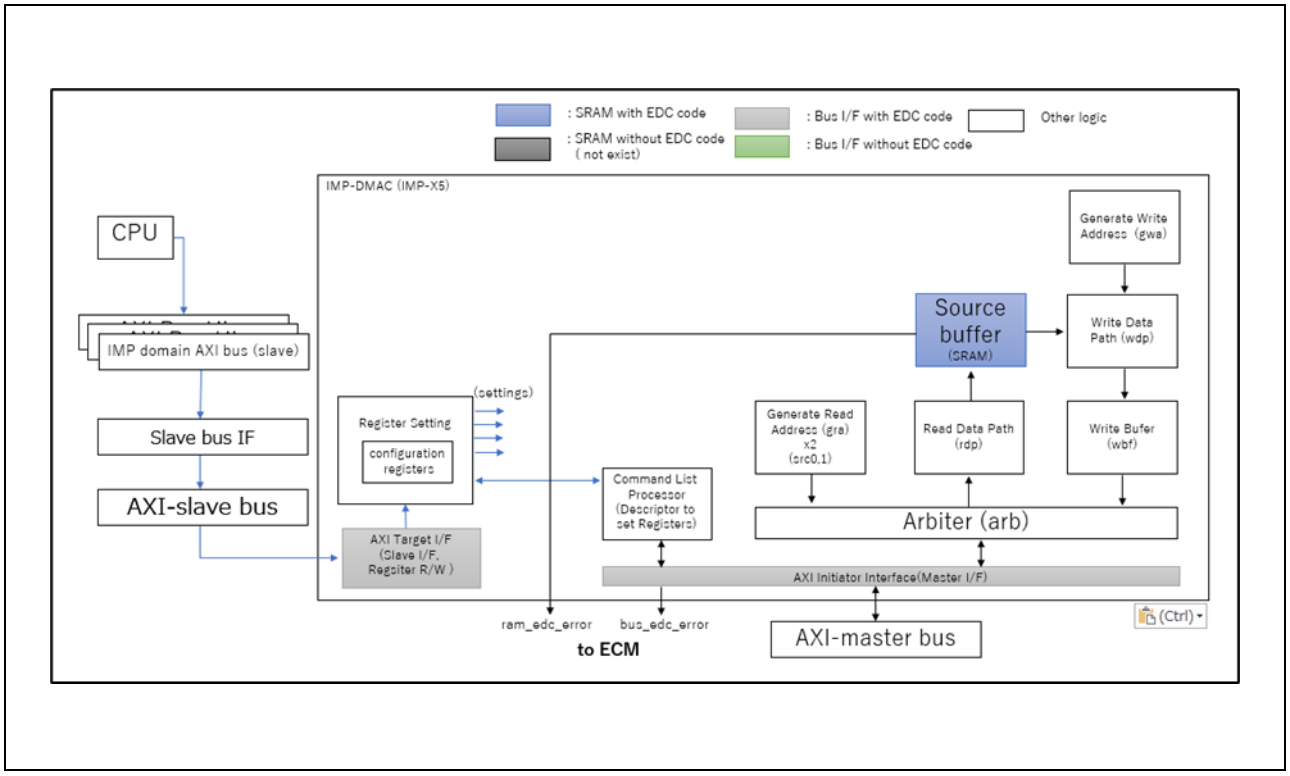

Figure U30.6 Block Diagram of FUSA

U31. IMP PSC

U31.1 Overview

The IMP PSC reads one image (hereinafter referred to as source image) from an external memory (hereinafter referred to as DDR-SDRAM) or an IMP dedicated internal memory (hereinafter referred to as "internal memory") and extracts up to four reduced images (hereinafter referred to as destination images) and writes these to DDR-SDRAM or Internal memory.

8 bpp (signed, unsigned), 10 bpp (unsigned), 12 bpp (unsigned), 16 bpp (signed) are supported as pixel format. The reduction ratio for each destination image (1 to 4), can be set between 0.5 to 1.0 for X and Y direction (step size 1/1048576). IMP PSC internal processing is done in little endian format.

The operation of IMP PSC is shown in the image below.

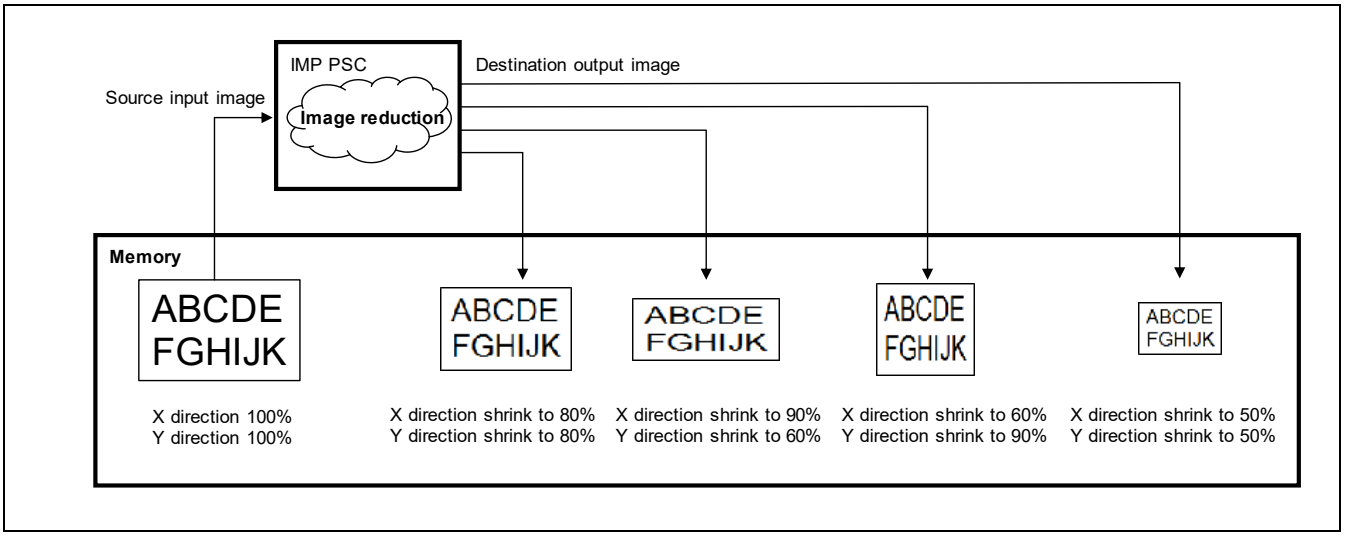

Figure U31.1 Operation of the IMP PSC

Table U31B.1 Base Address of IMP PSC

Channel	Base Address
0	H'FFA8 4000

U31.1.1 Features

- Command List (CL) system
- Register write instruction (WPR)
- Interrupt generation instruction (INT)
- Control instructions (NOP, TRAP, SYNCS, JUMP, GOSUB(stack based), RET)
- Conditional GOSUB, CL Break
- Relative and absolute addressing of JUMP and GOSUB instruction.
- Synchronization instructions (WUP, SLP) with other modules[*1]

- PSC
- Source image is input from DDR-SDRAM or from Internal memory by DMA transfer
- Reduced source image (Destination image) is output to DDR-SDRAM or Internal memory[*2] by DMA transfer
- Support of maximal 4096 pixels in the X direction and 4096 lines in the Y direction for source images and destination images[*3]
- Pixel format can be selected from unsigned 8, 10, 12 bpp or signed 8, 16 bpp[*4]
- The range setting in the X and Y directions of the reduction ratio is between 0.5 and 1.0[*5]
- Reduction operation is performed by bilinear interpolation
- IMP PSC activation with WPR instruction of CL[*6]

Notes: 1. For modules that can be synchronized with IMP PSC, see **U34.IMP-X7_system**.
2. 1 to 4 destination images can be output per source image.
3. When the pixel format is 10, 12, 16 bpp, the maximum in the X direction is 2048 pixels.
4. Please use the same pixel format for source and destination images.
5. It can be set with step size 1/1048576.
6. It is prohibited to write the EX bit of the EXCTLR register to 1 from the CPU to start the IMP PSC.

U31.1.2 Block Diagram

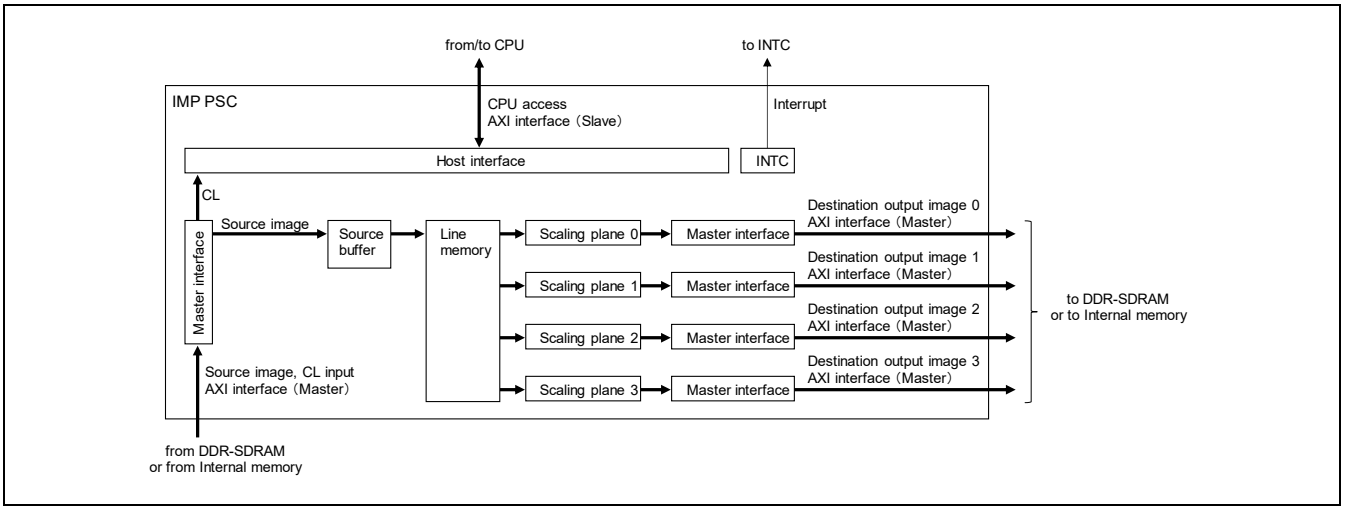

Figure U31.2 Block Diagram

— Host interface:

This is an interface module for AXI slave access. Handles AXI slave access (in 4-byte units only) set via registers.

CL is loaded from DDR-SDRAM or Internal memory by DMA transfer and executed.

— Interrupt control (INTC):

Controls output of various interrupt signals.

— Master interface:

This is an interface module for AXI master access.

— Source buffer:

Source image is input from DDR-SDRAM or Internal memory by DMA transfer and stored to Line memory.

— Line memory(LM):

This is the storage unit to realize the bilinear filtering.

— Scaling plane0-3:

According to register settings, the IMP PSC can generate 4 reduced-size destination images in parallel.

Destination image is output by DMA transfer to DDR-SDRAM or internal memory.

U31.1.3 Register Configuration

Access to addresses not listed in this register list is prohibited. Operation is not guaranteed if access is made to an address not listed. Access size is 32-bit. Operation is not guaranteed if access is made except for 32-bit. Operation is not guaranteed when writing to registers that can not be accessed during IMP PSC execution.

Table U31B.2 Register Configuration – Scaling Control Registers

Name	Symbol	R/W	Offset	CPU Write Access during IMP PSC execution[*1]	Initial value	Reset[*2]	WPR
Version Control Register	VCR	R	H'0000	—	[*3]	—	—

CL Conditinal GOSUB Register	CLCNDGSBR	R/W	H'03FC	√	H'00000000	S/H	—

Notes: 1. IMP PSC execution is the state where the EX bit in the EXCTLR register = 1 or the CLE bit in the SCTLR1 register = 1.

2. H: Power-on reset, S: Software reset by the SWRST bit of the SCTLR register.

3. The value to be read varies depending on the product. Refer register description for the initial value.

4. Initial value is varies depending on the product. Refer register description for the initial value.

Table U31B.3 Register Configuration - Memory Control Registers

Name	Symbol	R/W	Offset	CPU Write Access during IMP PSC execution[*1]	Initial value	Reset[*2]	WPR
Source Start Address Register	SSAR	R/W	H'0100	—	Undefined	—	√
Source Length Register	SLR	R/W	H'0104	—	H'0000 0000	S/H	√

Destination Address Enable-Register 3	DAER3	R/W	H'018C	—	H'FFFF FFFF	S/H	√

Notes: 1. IMP PSC execution is the state where the EX bit in the EXCTLR register = 1 or the CLE bit in the SCTLR1
register = 1.
2. H: Power-on reset
S: Software reset by the SWRST bit of the SCTLR register.

Table U31B.4 Register Configuration - Scaling Control Registers

Name	Symbol	R/W	Offset	CPU Write Access during IMP PSC execution[*1]	Initial value	Reset[*2]	WPR
Scaling Parameter Register	SPR	R/W	H'0200	—	H'0000 0000	S/H	√
Scaling Ratio Y for Destination Register 0	SRYDR0	R/W	H'0204	—	H'0000 0000	S/H	√
Scaling Ratio X for Destination Register 0	SRXDR0	R/W	H'0208	—	H'0000 0000	S/H	√
Scaling Offset Y for Destination Register 0	SOYDR0	R/W	H'020C	—	H'0000 0000	S/H	√
Scaling Offset X for Destination Register 0	SOXDR0	R/W	H'0210	—	H'0000 0000	S/H	√
Scaling Ratio Y for Destination Register 1	SRYDR1	R/W	H'021C	—	H'0000 0000	S/H	√
Scaling Ratio X for Destination Register 1	SRXDR1	R/W	H'0220	—	H'0000 0000	S/H	√
Scaling Offset Y for Destination Register 1	SOYDR1	R/W	H'0224	—	H'0000 0000	S/H	√
Scaling Offset X for Destination Register 1	SOXDR1	R/W	H'0228	—	H'0000 0000	S/H	√
Scaling Ratio Y for Destination Register 2	SRYDR2	R/W	H'0234	—	H'0000 0000	S/H	√
Scaling Ratio X for Destination Register 2	SRXDR2	R/W	H'0238	—	H'0000 0000	S/H	√
Scaling Offset Y for Destination Register 2	SOYDR2	R/W	H'023C	—	H'0000 0000	S/H	√
Scaling Offset X for Destination Register 2	SOXDR2	R/W	H'0240	—	H'0000 0000	S/H	√
Scaling Ratio Y for Destination Register 3	SRYDR3	R/W	H'024C	—	H'0000 0000	S/H	√
Scaling Ratio X for Destination Register 3	SRXDR3	R/W	H'0250	—	H'0000 0000	S/H	√
Scaling Offset Y for Destination Register 3	SOYDR3	R/W	H'0254	—	H'0000 0000	S/H	√
Scaling Offset X for Destination Register 3	SOXDR3	R/W	H'0258	—	H'0000 0000	S/H	√
Blend Mode Register0	BMDR0	R/W	H'0264	—	H'0000 0000	S/H	√
Blend Mode Register1	BMDR1	R/W	H'0268	—	H'0000 0000	S/H	√
Blend Mode Register2	BMDR2	R/W	H'026C	—	H'0000 0000	S/H	√
Blend Mode Register3	BMDR3	R/W	H'0270	—	H'0000 0000	S/H	√

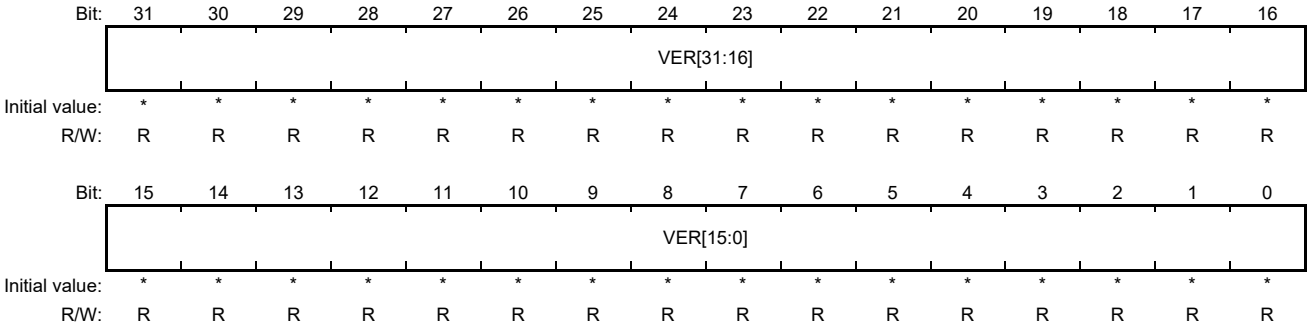
Notes: 1. IMP PSC execution is the state where the EX bit in the EXCTLR register = 1 or the CLE bit in the SCTLR1
register = 1.
2. H: Power-on reset
S: Software reset by the SWRST bit of the SCTLR register.

U31.2 Register Description

【Register description symbol】
Initial value: Register value after reset
—: Undefined value
R/W: Read and write enabled. The write value can be read.
R: Read-only. The write value should be the same as the read value. Only modify the target bit (Read Modify Write) because the initial value should not be changed.
-/W: Only write is available. The read value is undefined.

U31.2.1 Version Control Register (VCR)

This register indicates the version of this module.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	VER	H'21111616	R	Indicates the version of this module.

U31.2.2 System Control Register 0 (SCTLR0)

This register performs (software) reset control.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SWRST	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	SWRST	0	R/W	Software reset Writing 1 to this bit applies a software reset and writing 0 cancels a software reset. 0: Cancels a software reset for this module. 1: Applies a software reset to this module. When set to 1, the value of the register in which the notation of 'S' is written in the "Reset" column of Tables in section U31.1.3 Register Configuration. Setting the EX bit in the EXCTLR register to 1 or the CLE bit in the SCTLR1 register to 1 is prohibited. In that case, operation is not guaranteed. To cancel the reset, write 0 to this bit. After, read this bit to check that the value is 0.
30 to 0	—	All 0	R	Reserve The read value is always 0. When values other than 0 are written, operation is not guaranteed.

U31.2.3 Status Register (SR)

This register displays each status generated by PSC.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	WUPCOVF
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	CLBRK	—	—	—	INT	IER	TRA	—	—	—	END
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	—	All 0	R	Reserve The read value is always 0. When values other than 0 are written, operation is not guaranteed.
16	WUPCOVF	0	R	WUP counter overflow This bit indicates the overflow of WUP instruction. 0: WUP overflow has not been occured 1: WUP overflow has been occured Note: When WUPCOVFE bit in SER is 0, this bit is not set to 1 even if the WUP overflow occured. When WUPCOVFE bit in SER is 1, this bit is set to 1 if the WUP overflow occur.
15 to 11	—	All 0	R	Reserve The read value is always 0. When values other than 0 are written, operation is not guaranteed.
10	CLBRK	0	R	CL break status. 0: CL does not break 1: CL break CL break can not be usable if CLBRKE of SER register is 0. Set CLBRKE of SER register to 1 to use CL break function. Command list continue execution after clearing this bit using CLBRKC bit of SCR register.
9 to 7	—	All 0	R	Reserve The read value is always 0. When values other than 0 are written, operation is not guaranteed.

Bit	Bit Name	Initial Value	R/W	Description
6	INT	0	R	Decoding of INT instruction/ This bit indicates decoding of the INT instruction. Once this bit becomes 1, subsequent instructions are not started until this bit becomes 0. 0 : The INT instruction is not decoded 1 : The INT instruction is decoded Note: When INTE bit in SER is 0, this bit is not set to 1 even if the INT instruction is decoded. When INTE bit in SER is 1, this bit is set to 1 if the INT instruction is decoded.
5	IER	0	R	Decoding of illegal instruction or GOSUB overflow/underflow. This bit indicates the decoding of illegal instructions. Once this bit becomes 1, execution of CL is terminated. An illegal instruction is an instruction not listed in Table U31B.8. 0 : Illegal instruction is not decoded 1 : Illegal instruction is decoded Note: When IERE bit in SER is 0, this bit is not set to 1 even if illegal instructions are decoded. When IERE bit in SER is 1, this bit is set to 1 if illegal instructions are decoded. Reset IMP PSC by using SWRST bit of SCTLR0 when this bit is 1.
4	TRA	0	R	Decode TRAP instruction This bit indicates decoding of the TRAP instruction. When decoding the TRAP instruction, CL execution is terminated. 0: TRAP instruction is not decoded 1: TRAP instruction is decoded Note: When TRAE bit in SER is 0, this bit is not set to 1 even if the TRAP instruction is decoded. When TRAE bit in SER is 1, this bit is set to 1 if the TRAP instruction is decoded.
3 to1	—	All 0	R	Reserve The read value is always 0. When values other than 0 are written, operation is not guaranteed.
0	END	0	R	Image processing end of IMP PSC When the EX bit of the EXCTLR register = 1, the image processing of the IMP PSC is started and when the image processing of the IMP PSC ends, the EX bit of the EXCTLR register becomes 0 and this bit becomes 1. 0: IMP PSC is not running or image processing is in progress 1: IMP PSC image processing has ended Note: When ENDE bit in SER is 0, this bit is not set to 1 even if the image processing has ended. When ENDE bit in SER is 1, this bit is set to 1 if image processing has ended.

U31.2.4 Status Clear Register (SCR)

This register clears each status displayed in the SR register. Clearing is done by writing a 1, writing 0 is illegal.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	WUPCOVFC
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	-/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	CLBRKC	—	—	—	INTC	IERC	TRAC	—	—	—	ENDC
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	-/W	R	R	R	-/W	-/W	-/W	R	R	R	-/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	—	All 0	R	Reserve The read value is always 0. When values other than 0 are written, operation is not guaranteed.
16	WUPCOVFC	0	-/W	Clear the WUPOVF bit. By writing 1, the WUPOVF bit of the SR register is cleared to 0. When this bit is read, 0 is always read.
15 to 11	—	All 0	R	Reserve The read value is always 0. When values other than 0 are written, operation is not guaranteed.
10	CLBRKC	0	-/W	CL break status clear. By writing 1, the 0 in the CLBRK bit of SR register will be cleared. This bit is always read as 0. Command list continue execution after clearing CLBRK bit of SR register.
9 to 7	—	0	R	Reserved The read value is undefined. Operation cannot be guaranteed if a value other than the read value is written.
6	INTC	0	-/W	Clear the INT bit By writing 1, the INT bit of the SR register is cleared to 0. When this bit is read, 0 is always read.
5	IERC	0	-/W	Clear the IER bit By writing 1, the IER bit of the SR register is cleared to 0. When this bit is read, 0 is always read.
4	TRAC	0	-/W	Clear TRA bit By writing 1, the TRA bit in the SR register is cleared to 0. When this bit is read, 0 is always read.
3 to1	—	All 0	R	Reserve The read value is always 0. When values other than 0 are written, operation is not guaranteed.

Bit	Bit Name	Initial Value	R/W	Description
0	ENDC	0	-/W	Clear the END bit By writing 1, the END bit of the SR register is cleared to 0. When this bit is read, 0 is always read.

U31.2.5 Status Enable Register (SER)

The bits of this register are used to set whether to reflect the status of the corresponding SR register bit.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	WUPCOVFE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	CLBRKE	—	—	—	INTE	IERE	TRAE	—	—	—	ENDE
Initial value:	0	0	0	0	0	0	0	0	0	1	1	1	0	0	0	1
R/W:	R	R	R	R	R	R/W	R	R	R	R/W	R/W	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	—	All 0	R	Reserve The read value is always 0. When values other than 0 are written, operation is not guaranteed.
16	WUPCOVFE	0	R/W	WUPOVF bit set enable 0: Even if the WUP overflow is detected, WUPOVF bit of SR register is not set to 1. 1: When WUP overflow is detected, the WUPOVF bit of SR register is set to 1. Refer to the **U34.IMP-X7_system, U34.10.3 Inter Module Synchronization** when setting this bit.
15 to 11	—	All 0	R	Reserve The read value is always 0. When values other than 0 are written, operation is not guaranteed.
10	CLBRKE	0	R/W	CL break status/CL break enable. 0: CL break disable When CLBRK is not detected, 1 is not set to CLBRK bit of SR register. 1: CL break enable When CLBRK is detected, 1 is set to CLBRK bit of SR register. When this bit is 0, CL break operation is not be possible.
9 to 7	—	All 0	R	Reserve The read value is always 0. When values other than 0 are written, operation is not guaranteed.

Bit	Bit Name	Initial Value	R/W	Description
6	INTE	1	R/W	INT bit set enable 0: Even if the INT instruction is decoded, the INT bit of the SR register is not set to 1. 1: When the INT instruction is decoded, the INT bit of the SR register is set to 1.
5	IERE	1	R/W	Set IER bit Enable 0: Even if an illegal instruction is decoded, the IER bit of the SR register is not set to 1. 1: When an illegal instruction is decoded, the IER bit of the SR register is set to 1.
4	TRAE	1	R/W	TRA bit set enable 0: Even if the TRAP instruction is decoded, the TRA bit in the SR register is not set to 1. 1: When the TRAP instruction is decoded, the TRA bit in the SR register is set to 1.
3 to1	—	All 0	R	Reserve The read value is always 0. When values other than 0 are written, operation is not guaranteed.
0	ENDE	1	R/W	END bit set enable 0: Even after IMP PSC image processing is completed, the END bit of the SR register is not set to 1. 1: When image processing of IMP PSC is completed, END bit of the SR register is set to 1.

U31.2.6 Interrupt Mask Register (IMR)

It is a register that sets whether to generate an interrupt to CPU based on the internal interrupt cause or whether to mask the internal interrupt cause.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	WUPCOVFM
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	CLBRKM	—	—	—	INTM	IERM	TRAM	—	—	—	ENDM
Initial value:	0	0	0	0	0	1	0	0	0	1	1	1	0	0	0	1
R/W:	R	R	R	R	R	R/W	R	R	R	R/W	R/W	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	—	All 0	R	Reserve The read value is always 0. When values other than 0 are written, operation is not guaranteed.
16	WUPCOVFM	0	R/W	Interrupt mask setting by WUPOVF status 0: Interrupt generation by WUPOVF is not masked. 1: Interrupt generation by WUPOVF is masked.
15 to 11	—	All 0	R	Reserve The read value is always 0. When values other than 0 are written, operation is not guaranteed.
10	CLBRKM	1	R/W	Mask setting of interrupt by CLBRK status 0: The generation of CLBRK interrupt is not masked. 1: The generation of CLBRK interrupt is masked.
9 to 7	—	0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.
6	INTM	1	R/W	Interrupt mask setting by INT status 0: Interrupt generation by INT is not masked. 1: Interrupt generation by INT is masked.
5	IERM	1	R/W	Interrupt mask setting by IER status 0: Interrupt generation by IER is not masked. 1: Interrupt generation by IER is masked.
4	TRAM	1	R/W	Interrupt mask setting by TRA status 0: Interrupt generation by TRA is not masked. 1: Interrupt generation by TRA is masked.
3 to1	—	All 0	R	Reserve The read value is always 0. When values other than 0 are written, operation is not guaranteed.

Bit	Bit Name	Initial Value	R/W	Description
0	ENDM	1	R/W	Interrupt mask setting by END status 0: Interrupt generation by END is not masked. 1: Interrupt generation by END is masked.

U31.2.7 System Control Register 1 (SCTLR1)

It is a register that controls activation of CL.

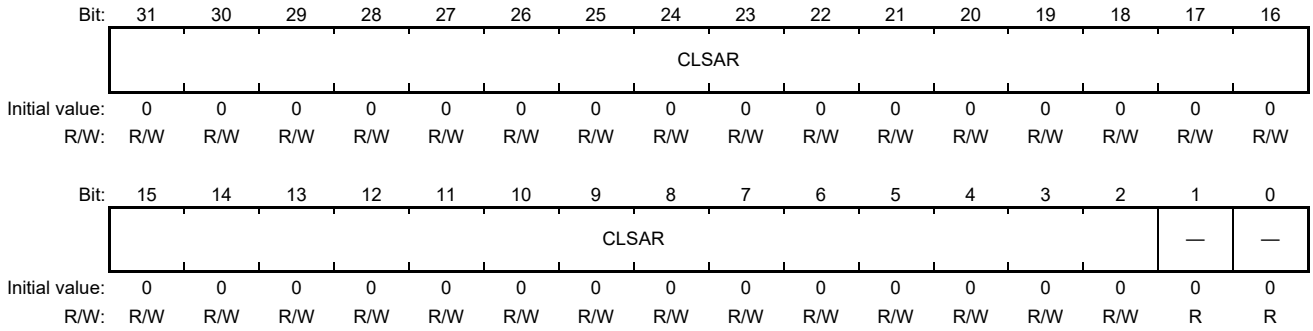
Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CLE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserve The read value is always 0. When values other than 0 are written, operation is not guaranteed.
0	CLE	0	R/W	IMP PSC CL (Command List) activation bit [writing] 0:— 1: Launch CL [reading] 0: CL is not running 1: CL is running If 1 is written to this bit, IMP PSC fetches CL from the address set in CLSAR and executes the instruction. This bit is read as 1 during CL execution and 0 is read after CL execution is completed. Writing 1 to this bit during CL execution is prohibited and operation is not guaranteed.

U31.2.8 Command List Start Address Register (CLSAR)

This register sets the start address for fetching CL.



Bit	Bit Name	Initial Value	R/W	Description
31 to 2	CLSAR	H'0000 0000	R/W	Start address of CL Set the start address of CL execution in this register. Please set it in units of 4 bytes.
1 to 0	—	All 0	R	Reserve The read value is always 0. When values other than 0 are written, operation is not guaranteed.

U31.2.9 Status Register1 (SR1)

This register displays the code value when IMP PSC executes INT and TRAP instructions.

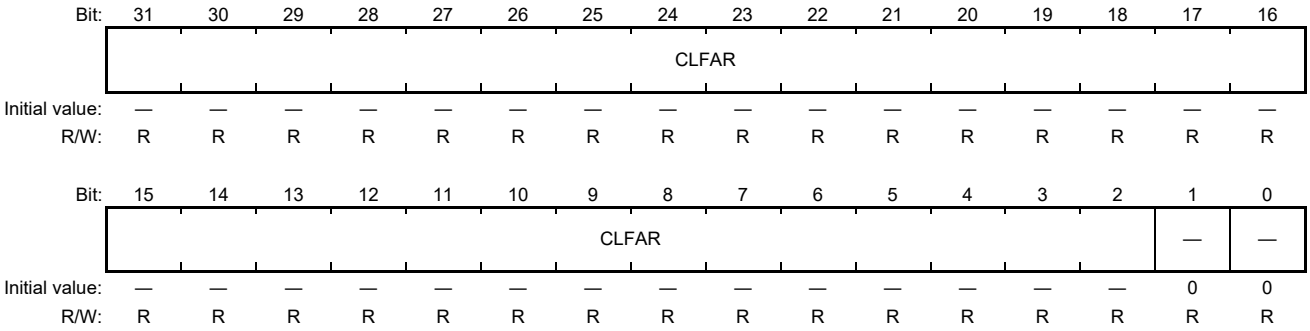
Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	INTCODE								TRAPCODE							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	INTCODE	H'00	R	INT interrupt code When the INT instruction is executed, the value specified in the CODE field (bit [7: 0]) of this instruction is reflected in these bits. These bits are updated independently of the setting of the INTE bit in the SER register.
23 to 16	TRAPCODE	H'00	R	TRAP interrupt code When the TRAP instruction is executed, the value specified in the CODE field (bit [7: 0]) of this instruction is reflected in these bits. These bits are updated independently of the setting of the TRAE bit in the SER register.
15 to 0	—	All 0	R	Reserve The read value is always 0. When values other than 0 are written, operation is not guaranteed.

U31.2.10 Command List Fetch Address Register (CLFAR)

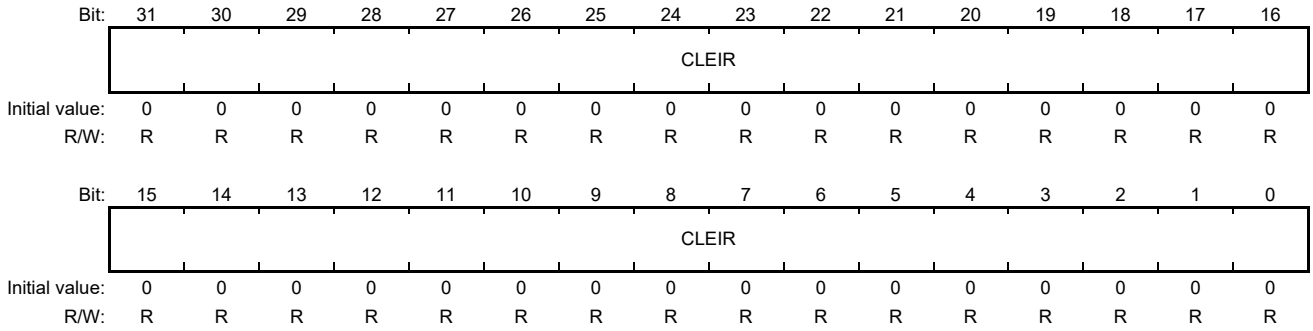
This register displays the address of the CL fetch destination (running).



Bit	Bit Name	Initial Value	R/W	Description
31 to 2	CLFAR	Undefined	R	Displays the CL fetch destination address (running). The initial value is undefined.
1 to 0	—	All 0	R	Reserve The read value is always 0. When values other than 0 are written, operation is not guaranteed.

U31.2.11 Command List Execute Instruction Register (CLEIR)

This register displays the command being executed by CL.



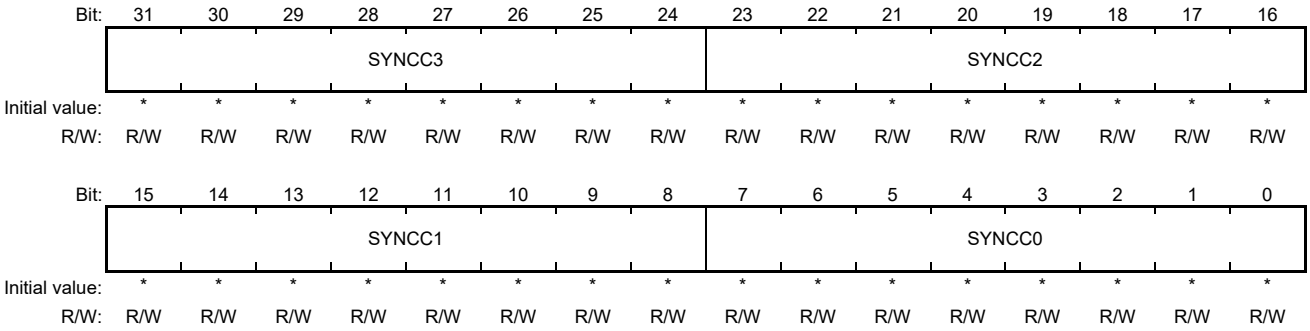
Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CLEIR	H'0000 0000	R	Display the command being executed by the CL.

U31.2.12 Synchronization Control Register 0 (SYNCCR0)

This register specifies the module corresponding to bits 0 to 3 of the SYNCC enable field of WUP or SLP instruction.

Set the module number of the module you want to specify in this register. For the module numbers, refer to U34.IMP-X7_system, U34.10.5 Inter Module Synchronization.

Set this register by the CPU before setting the CLE bit in the SCTLR1 register to 1. It is prohibited to rewrite this register while the CLE bit of the SCTLR1 register is 1.



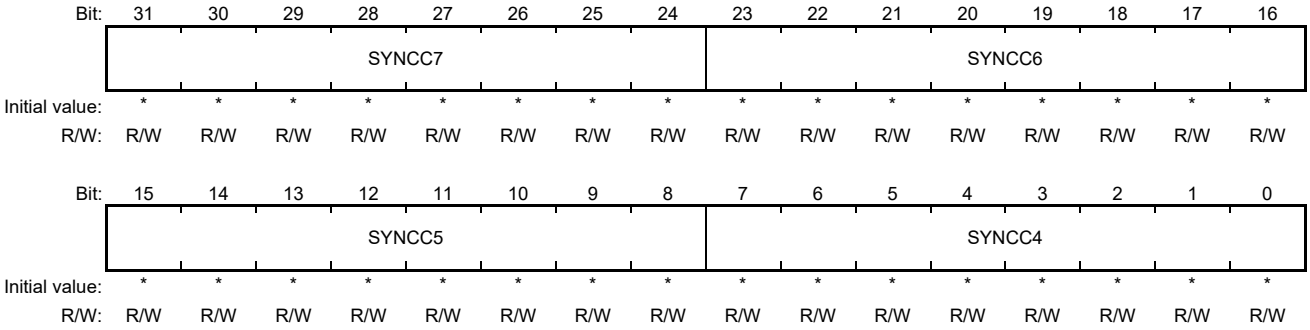
Bit	Bit Name	Initial Value	R/W	Description
31 to 24	SYNCC3	H'FF	R/W	This register is used to specify the correlated module for Bit 3 of the SYNCC enable field of the WUP, SLP instruction.
23 to 16	SYNCC2	H'FF	R/W	This register is used to specify the correlated module for Bit 2 of the SYNCC enable field of the WUP, SLP instruction.
15 to 8	SYNCC1	H'FF	R/W	This register is used to specify the correlated module for Bit 1 of the SYNCC enable field of the WUP, SLP instruction.
7 to 0	SYNCC0	H'FF	R/W	This register is used to specify the correlated module for Bit 0 of the SYNCC enable field of the WUP, SLP instruction.

U31.2.13 Synchronization Control Register 1 (SYNCCR1)

This register specifies the module corresponding to bits 4 to 7 of the SYNCC enable field of WUP or SLP instruction.

Set the module number of the module you want to specify in this register. For the module numbers, refer to U34.IMP-X7_system, U34.10.5 Inter Module Synchronization.

Set this register by the CPU before setting the CLE bit in the SCTLR1 register to 1. It is prohibited to rewrite this register while the CLE bit of the SCTLR1 register is 1.



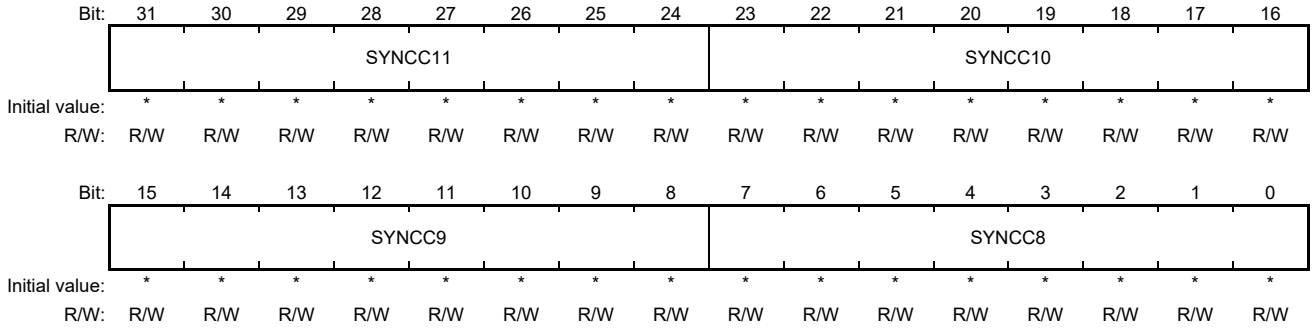
Bit	Bit Name	Initial Value	R/W	Description
31 to 24	SYNCC7	H'FF	R/W	This register is used to specify the correlated module for Bit 7 of the SYNCC enable field of the WUP, SLP instruction.
23 to 16	SYNCC6	H'FF	R/W	This register is used to specify the correlated module for Bit 6 of the SYNCC enable field of the WUP, SLP instruction.
15 to 8	SYNCC5	H'FF	R/W	This register is used to specify the correlated module for Bit 5 of the SYNCC enable field of the WUP, SLP instruction.
7 to 0	SYNCC4	H'FF	R/W	This register is used to specify the correlated module for Bit 4 of the SYNCC enable field of the WUP, SLP instruction.

U31.2.14 Synchronization Control Register 2 (SYNCCR2)

This register specifies the module corresponding to bits 8 to 11 of the SYNCC enable field of WUP or SLP instruction.

Set the module number of the module you want to specify in this register. For the module numbers, refer to U34.IMP-X7_system, U34.10.5 Inter Module Synchronization.

Set this register by the CPU before setting the CLE bit in the SCTLR1 register to 1. It is prohibited to rewrite this register while the CLE bit of the SCTLR1 register is 1.



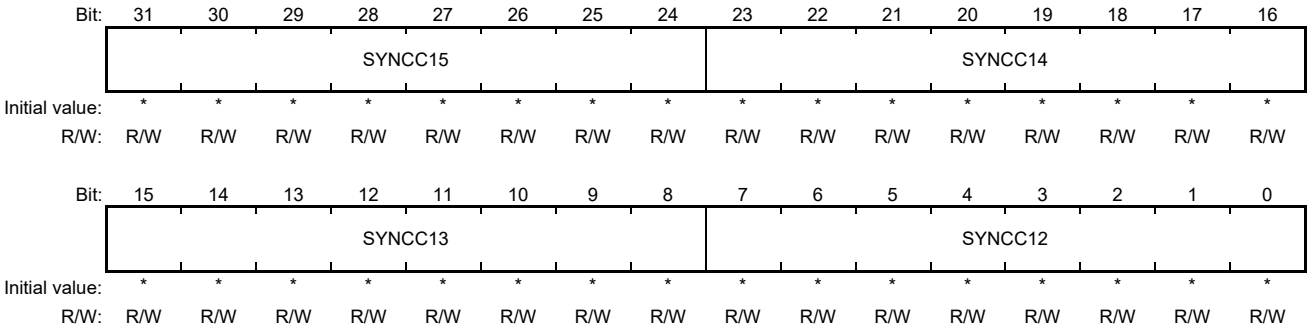
Bit	Bit Name	Initial Value	R/W	Description
31 to 24	SYNCC11	H'FF	R/W	This register is used to specify the correlated module for Bit 11 of the SYNCC enable field of the WUP, SLP instruction.
23 to 16	SYNCC10	H'FF	R/W	This register is used to specify the correlated module for Bit 10 of the SYNCC enable field of the WUP, SLP instruction.
15 to 8	SYNCC9	H'FF	R/W	This register is used to specify the correlated module for Bit 9 of the SYNCC enable field of the WUP, SLP instruction.
7 to 0	SYNCC8	H'FF	R/W	This register is used to specify the correlated module for Bit 8 of the SYNCC enable field of the WUP, SLP instruction.

U31.2.15 Synchronization Control Register 3 (SYNCCR3)

This register specifies the module corresponding to bits 12 to 15 of the SYNCC enable field of WUP or SLP instruction.

Set the module number of the module you want to specify in this register. For the module numbers, refer to U34.IMP-X7_system, U34.10.5 Inter Module Synchronization.

Set this register by the CPU before setting the CLE bit in the SCTLR1 register to 1. It is prohibited to rewrite this register while the CLE bit of the SCTLR1 register is 1.



Bit	Bit Name	Initial Value	R/W	Description
31 to 24	SYNCC15	H'FF	R/W	This register is used to specify the correlated module for Bit 15 of the SYNCC enable field of the WUP, SLP instruction.
23 to 16	SYNCC14	H'FF	R/W	This register is used to specify the correlated module for Bit 14 of the SYNCC enable field of the WUP, SLP instruction.
15 to 8	SYNCC13	H'FF	R/W	This register is used to specify the correlated module for Bit 13 of the SYNCC enable field of the WUP, SLP instruction.
7 to 0	SYNCC12	H'FF	R/W	This register is used to specify the correlated module for Bit 12 of the SYNCC enable field of the WUP, SLP instruction.

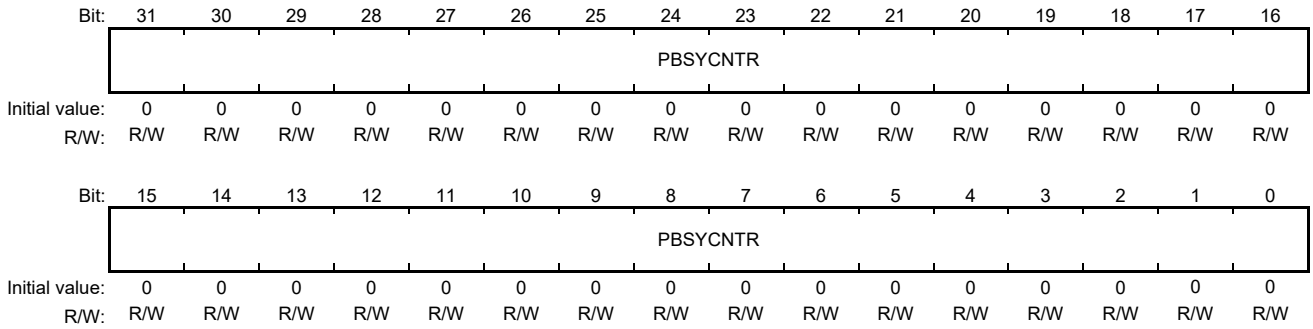
U31.2.16 Performance Control Register (PCR)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	IFBSYCNTENB	IBSYCNTENB
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

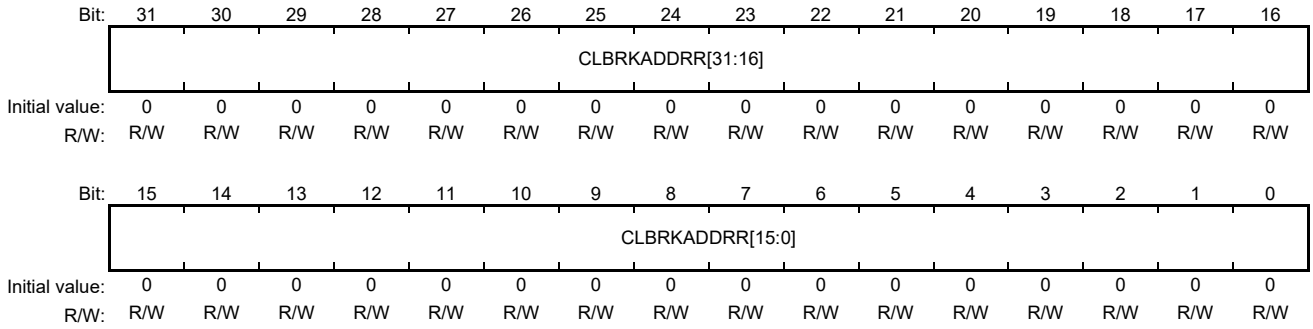
Bit	Bit Name	Initial Value	R/W	Description
31 to 2	—	All 0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.
1	IFBSYCNTENB	0	R/W	IFID operation count enable When this bit is 1, CYCLE is counted while CL is running. Write 1 in this bit during IBSYCNTENB= 1 is prohibited.
0	IBSYCNTENB	0	R/W	Image operation count enable When this bit is 1, CYCLE is counted while EX bit in EXCNTR register = 1. Write 1 in this bit during IFBSYCNTENB = 1 is prohibited.

U31.2.17 Performance Busy Counter Register (PBSYCNTR)



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	PBSYCNTR	H'0000 0000	R/W	This register count cycles during operation This reads the value counted in the condition set in Performance Control Register (PCR). Count value of this register cannot be guarenteed. When this register is written, the counter is set to the written value, and starts counts from set value onwards. Writing this register during the counting is prohibited.

U31.2.18 CL Break Address Register(CLBRKADDRR)



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CLBRKADDRR	All 0	R/W	CL break address. Specify the address(break point) of command list. Specify a 32bit command list address. Data address is prohibited.

U31.2.19 CL Conditinal GOSUB Register(CLCNDGSBR)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—		—	—	—	—	—	—	—	CLCND GSBR
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved The read value should always be 0. Operation cannot be guaranteed if a value other than 0 is written.
0	CLCNDGSBR	All 0	R/W	Condition for conditional GOSUB instruction: .1: GOSUB is executed 0: GOSUB is not executed, NOP is instead executed (Bit 22 of the GOSUB command should be 1 for NOP operation)

U31.2.20 Source Start Address Register (SSAR)

This register sets the start address of the source image to be read from DDR-SDRAM or Internal memory.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SSAR															
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SSAR															
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	SSAR	Undefined	R/W	Set the start address of the source image in byte units. When it is not 8 bpp, please set it by 2-byte unit. (The lowest 1 bit is fixed to 0) The initial value is undefined.

U31.2.21 Source Length Register (SLR)

This register sets the reading size of the source image from the DDR-SDRAM or Internal memory.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	YLNG												
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	XLNG												
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	All 0	R	Reserve The read value is always 0. When values other than 0 are written, operation is not guaranteed.
28 to 16	YLNG	H'0000	R/W	Please specify the number of lines in the Y direction of the source image. It can be specified in the range from 1 to 4096. Operation is not guaranteed if a value outside the range is set.
15 to 13	—	All 0	R	Reserve The read value is always 0. When values other than 0 are written, operation is not guaranteed.
12 to 0	XLNG	H'0000	R/W	Please specify the number of pixels in the X direction of the source image. 8 bpp: It can be specified in the range of 1 to 4096. 10, 12, 16 bpp: It can be specified in the range of 1 to 2048. Operation is not guaranteed if a value outside the range is set.

U31.2.22 Source Stride (SSTR)

This register sets the stride of the source image to be read from DDR-SDRAM or Internal memory.

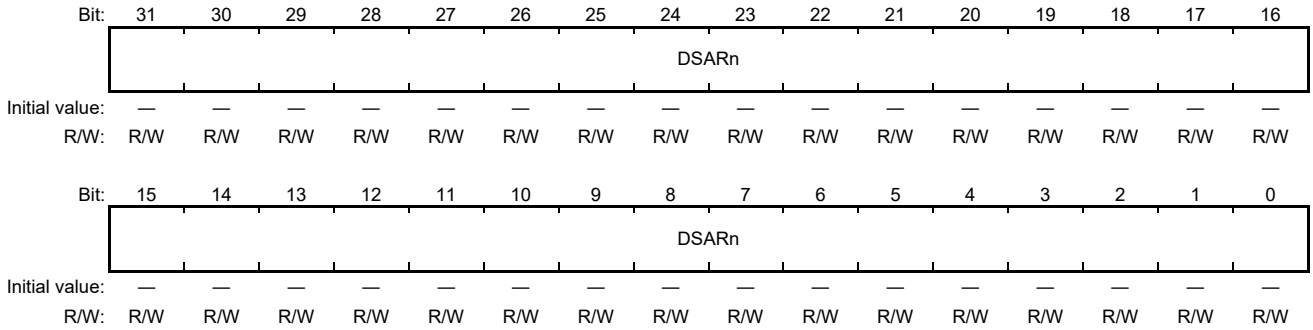
Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SSTR															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserve The read value is always 0. When values other than 0 are written, operation is not guaranteed.
15 to 0	SSTR	H'0000	R/W	Sets the stride of the source image in unsigned byte units. If it is not 8 bpp, set it in 2-byte units (the lowest 1 bit is fixed to 0). Set these bits to a value larger than or equal to the value obtained by converting the number of pixels in the X direction of the source image (set in the XLNG bit of the SLR register) to the number of bytes. In case of 8bpp, convert one pixel as one byte, otherwise, convert one pixel as 2 bytes.

U31.2.23 Destination Start Address register n (DSARn) (n=0-3)

This register sets the start address of the destination image to be written to in DDR-SDRAM or Internal memory.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DSARn	Undefined	R/W	Please set the start address of the Destination image in byte units. When it is not 8 bpp, please set it in 2-byte units. (The lowest 1 bit is fixed to 0) DSAR 0: Start address of destination image for output image 0 DSAR 1: Start address of destination image for output image 1 DSAR 2: Start address of destination image for output image 2 DSAR 3: Start address of destination image for output image 3 The initial value is undefined.

U31.2.24 Destination Stride Register n (DSTRn) (n=0-3)

This register sets the stride of the destination image to be written to in DDR-SDRAM or Internal memory.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DSTRn															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/w	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserve The read value is always 0. When values other than 0 are written, operation is not guaranteed.
15 to 0	DSTRn	H'0000	R/W	Sets the stride of the Destination image in unsigned byte units. When it is not 8 bpp, please set it in 2-byte units. (The lowest 1 bit is fixed to 0) DSTR 0: stride of destination image of output image 0 DSTR 1: stride of destination image of output image 1 DSTR 2: stride of destination image of output image 2 DSTR 3: stride of destination image of output image 3 Set this bit to a value greater than or equal to the number of pixels in the X direction of the Destinatoion image (set in the DXLNGn bit of the DLNGRn register) converted to the number of bytes. In case of 8 bpp, convert one pixel as one byte, otherwise, convert one pixel as 2 bytes.

U31.2.25 Destination Length Register n (DLNGRn) (n=0-3)

This register sets the size of the destination image to be written to in DDR-SDRAM or Internal memory.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	DYLNGn												
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	DXLNGn												
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	All 0	R	Reserve The read value is always 0. When values other than 0 are written, operation is not guaranteed.
28 to 16	DYLNGn	H'0000	R/W	Please specify the number of lines in the Y direction of the destination image. It can be specified in the range from 1 to 4096. DYLNG 0: Number of lines of destination image for output image 0 DYLNG 1: Number of lines of destination image for output image 1 DYLNG 2: Number of lines of destination image for output image 2 DYLNG 3: Number of lines of destination image for output image 3 Set these bits to a value equal or below the number of lines in the Y direction of the source image (set in the YLNG bit of the SLR register). [important point] When the value specified in these bits is less than or equal to the number of lines after reduction of the source image, the number of lines set by these bits are output. If the value specified by these bits is larger than the number of lines after reduction of the source image, the number of lines set by these bits is output by repeating the last line of the source image.
15 to 13	—	All 0	R	Reserve The read value is always 0. When values other than 0 are written, operation is not guaranteed.
12 to 0	DXLNGn	H'0000	R/W	Please specify the number of pixels in the X direction of the Destination image. 8 bpp: It can be specified in the range of 1 to 4096. 10, 12, 16 bpp: It can be specified in the range of 1 to 2048. DXLNG 0: Number of pixels of destination image for output image 0 DXLNG 1: Number of pixels of destination image for output image 1 DXLNG 2: Number of pixels of destination image for output image 2 DXLNG 3: Number of pixels of destination image for output image 3 Set these bits to a value equal or below the number of pixels in the X direction of the source image (set in the XLNG bit of the SLR register). [important point] When the value specified in these bits is less than or equal to the number of pixels after reduction of the source image, the number of pixels set by these bits is output. If the value specified by these bits is larger than the number of pixels after reduction of the source image, the number of pixels set by these bits is output by repeating the last pixel of each row of the source image.

U31.2.26 Data Control Register (DCTLR)

This register specifies the pixel format of the source image and destination images.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	PFSRC	H'0	R/W	Specify the pixel format of the source image. 0: unsigned 8 bits 1: unsigned 10 bits 2: unsigned 12 bits 8: Signed 8bit 11: Signed 16bit Other: Not defined (please do not set) Set the same value as the PFDST bit.
27 to 16	—	All 0	R	Reserve The read value is always 0. When values other than 0 are written, operation is not guaranteed.
15 to 12	PFDST	H'0	R/W	Specifies the pixel format of the destination image. 0: unsigned 8 bits 1: unsigned 10 bits 2: unsigned 12 bits 8: Signed 8bit 11: Signed 16bit Other: Not defined (please do not set) Set the same value as the PFSRC bit.
11 to 0	—	All 0	R	Reserve The read value is always 0. When values other than 0 are written, operation is not guaranteed.

U31.2.27 Execute Control Register (EXCTLR)

It is a register that controls startup of IMP PSC.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	EX	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	EX	0	R/W	IMP PSC activation bit [writing] 0: NOP 1: Start IMP PSC [reading] 0: IMP PSC is not activated 1: IMP PSC is running (during image processing) When IMP PSC is activated, and image processing is completed, this bit automatically becomes 0. At this time, if the ENDE bit of the SER register is 1, the END bit of the SR register is set to 1. Write 1 to this bit (activate IMP PSC) with CL's WPR instruction. Setting this bit to 0 or 1 while this bit is 1 is prohibited. In that case, operation is not guaranteed.
30 to 0	—	All 0	R	Reserve The read value is always 0. When values other than 0 are written, operation is not guaranteed.

U31.2.28 Execute Line Count Register (EXCNTR)

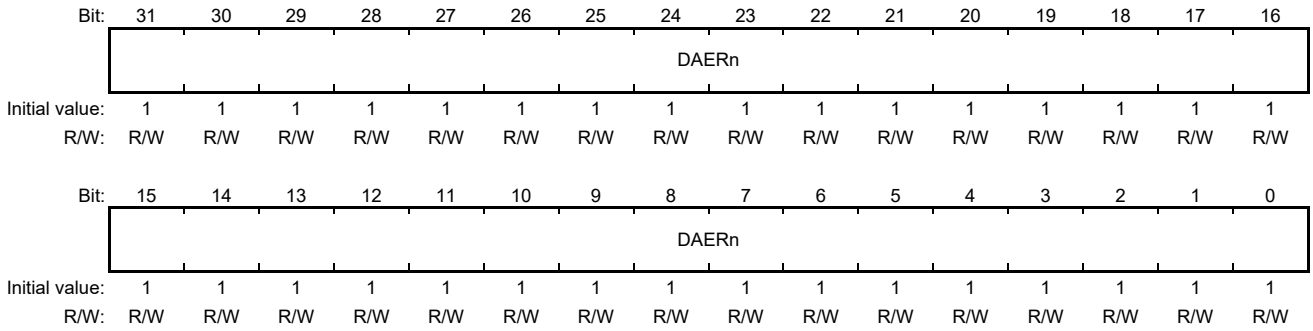
This register displays the number of output lines of the destination image。

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	EXCNT													
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 14	—	All 0	R	Reserve The read value is always 0. When values other than 0 are written, operation is not guaranteed.
13 to 0	EXCNT	H'0000	R	Displays the number of output lines of the destination image. When the destination image is output in multiple directions by setting the SURFACE bit of SPR register, the minimum number of outputted lines in output image 0-3 is displayed.

U31.2.29 Destination Address Enable-Register n (DAERn) (n=0-3)



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DAERn	H'FFFF FFFF	R/W	DAER 0: Destination address of output image 0 bit Enable DAER 1: Destination address of output image 1 bit Enable DAER 2: Destination address of output image 2 bit Enable DAER 3: Destination address of output image 3 bit Enable When outputting destination image to DDR-SDRAM or Internal memory, set H'FFFF FFFF (initial value) to this register.

U31.2.30 Scaling Parameter Register (SPR)

Scaling operation setting register of IMP PSC.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

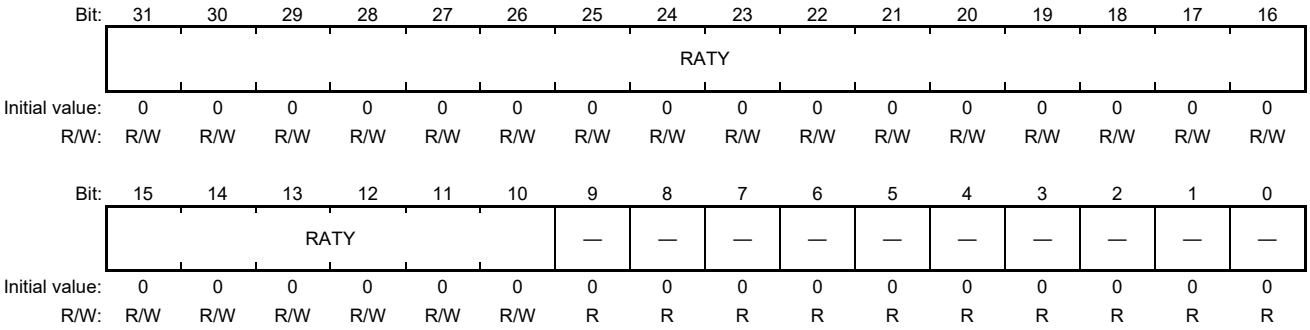
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	SURFACE[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	—	All 0	R	Reserve The read value is always 0. When values other than 0 are written, operation is not guaranteed.
3 to 0	SURFACE[3:0]	H'0	R/W	Depending on the number of destination images to be outputted, set the output image 0 to 3 to be used as follows. 0001: 1 sheet output (using only output image 0) 0011: 2 sheets output (using output image 0 to 1) 0111: 3 sheets output (using output image 0 to 2) 1111: 4 sheets output (using output image 0 to 3) It is prohibited to start IMP PSC with settings other than the above. When setting other than the above, operation is not guaranteed. Corresponding to the settings in of these bits, set the following registers accordingly. DSARn, DSTRn, DLNGRn, DAERn, SRYDRn, SRXDRn, SOYDRn, SOXDRn, BMDRn (N = 0-3) For example, when SURFACE [3: 0] = 0111, please set each register n = 0 - 2 above.

U31.2.31 Scaling Ratio Y for Destination Register n (SRYDRn) (n=0-3)

This register sets the magnification in the Y direction.

Calculate the result of source Image size / destination Image size in Y direction and multiply it by 2^{20} (binary number with 20bits), then truncate the decimal part.



Bit	Bit Name	Initial Value	R/W	Description
31 to 10	RATY	H'00 0000	R/W	Set the magnification in Y direction according to source image size / destination image size. The register area is a fixed point value with 2 bits integer and 20 bits fraction part. Since IMP PSC supports reduction ratio = 0.5 to 1.0, set the value between H '10 0000 ~ H'20 0000. For example, when reducing 480 lines to 479 lines: (480/479) x 2^{20} = H'10088D.
9 to 0	—	All 0	R	Reserve The read value is always 0. When values other than 0 are written, operation is not guaranteed.

U31.2.32 Scaling Ratio X for Destination Register n (SRXDRn) (n=0-3)

This register sets the magnification in the X direction.

Calculate the result of source Image size / destination Image size in X direction and multiply it by 2^{20} (binary number with 20bits), then truncate the decimal part.

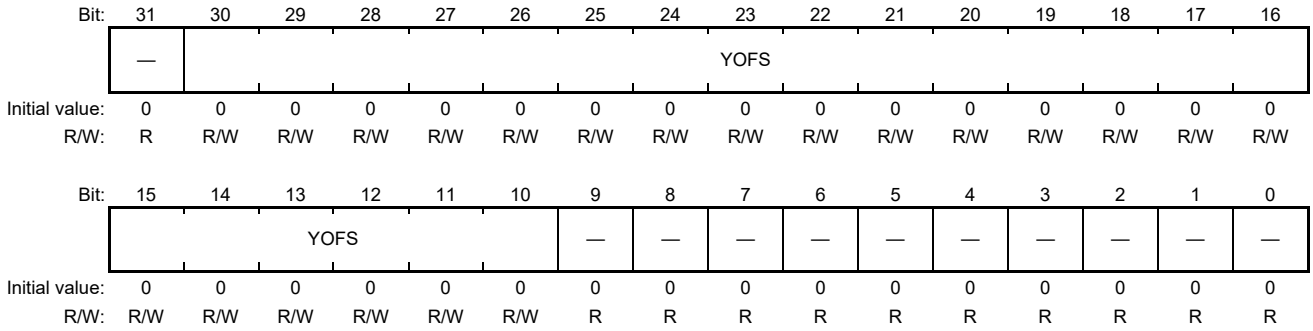
Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RATX															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RATX						—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	RATX	H'00 0000	R/W	Set the magnification in the X direction according to the source image size / destination image size. The register area is a fixed point value with 2 bits integer and 20 bits fraction part. Since IMP PSC supports reduction ratio = 0.5 to 1.0, set the value between H '10 0000 ~ H'20 0000. For example, when reducing 640 pixels to 639 pixels: (640/639) x2^{20} = H'100668.
9 to 0	—	All 0	R	Reserve The read value is always 0. When values other than 0 are written, operation is not guaranteed.

U31.2.33 Scaling Offset Y for Destination Register n (SOYDRn) (n=0-3)

This register specifies the start offset for reading the source image in the Y direction.



Bit	Bit Name	Initial Value	R/W	Description
31	—	0	R	Reserve The read value is always 0. When values other than 0 are written, operation is not guaranteed.
30 to 10	YOFS	H'00 0000	R/W	Specify the offset value in the Y direction at the start of processing. The register area is a fixed-point number of 1 integer digit and 20 decimal places, and it can set a value less than 2. For example, when adding an offset of 0.5 at the start, specify H'080000.
9 to 0	—	All 0	R	Reserve The read value is always 0. When values other than 0 are written, operation is not guaranteed.

U31.2.34 Scaling Offset X for Destination Register n (SOXDRn) (n=0-3)

This register specifies the start offset for reading the source image in the X direction.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	XOFS														
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	XOFS						—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	—	0	R	Reserve The read value is always 0. When values other than 0 are written, operation is not guaranteed.
30 to 10	XOFS	H'00 0000	R/W	Specify the offset value in the X direction at the start of processing. The register area is a fixed-point number of 1 integer digit and 20 decimal places, and it can set a value less than 2. For example, when adding an offset of 1.5 at the start, specify H'180000.
9 to 0	—	All 0	R	Reserve The read value is always 0. When values other than 0 are written, operation is not guaranteed.

U31.2.35 Blend Mode Register n (BMDRn) (n=0-3)

It is a register that controls blend of pixels (bilinear interpolation operation)。

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RNDM	BLDM
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	—	All 0	R	Reserve The read value is always 0. When values other than 0 are written, operation is not guaranteed.
1	RNDM	0	R/W	When shrinking in X direction, this bit is used for masking the rounding with bilinear interpolation calculation. 0: Perform rounding processing (do not mask). 1: Mask rounding processing. In the case of 16 bpp, the value setting value of this bit is invalid, and rounding processing is not performed.
0	BLDM	0	R/W	When shrinking in X direction, this bit is used for masking the bilinear interpolation calculation. 0: Bilinear interpolation operation is executed (not masked). 1: Mask bilinear interpolation operation. When bilinear interpolation operation is masked, the source image is reduced by thinning pixels instead of blending adjacent pixels.

U31.3 Operation

U31.3.1 Image reduction

Reduction calculation of the input image is performed by bilinear interpolation. Figure U31.3 shows an outline of the operation of bilinear interpolation calculation.

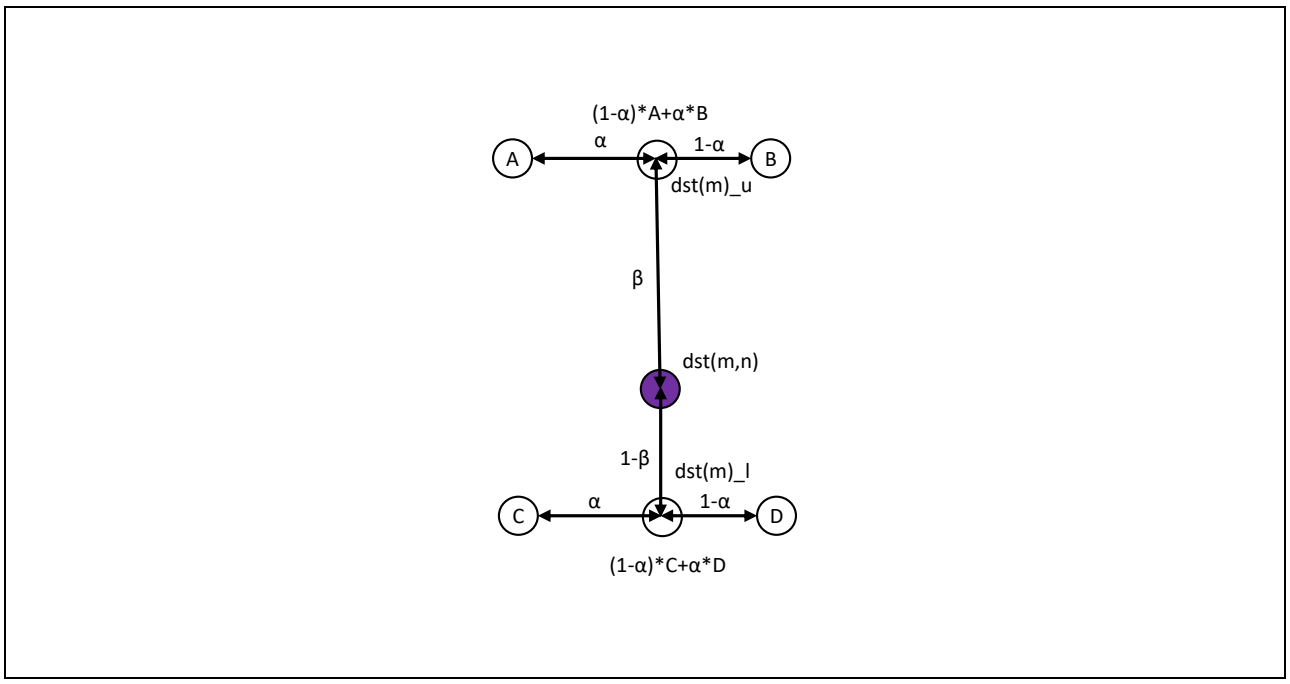


Figure U31.3 Example of bilinear interpolation calculation operation

A pixel dst (m, n) in a destination image can be found by bilinear interpolation calculation using 2 * 2 pixels (A, B, C, D) of the source image located around it. The calculation procedure at this time is as follows:

Step1：Bilinearly interpolate the pixels A and B of the source image to calculate the pixel dst(m)_u:

$$dst(m)_u = (1 - \alpha) * A + \alpha * B$$

Step2：Bilinearly interpolate the pixels C and D of the source image to calculate the pixel dst(m)_l:

$$dst(m)_l = (1 - \alpha) * C + \alpha * D$$

Step3：Bilinearly interpolate dst(m)_u and dst(m)_l obtained in Step1 and Step2 above to calculate the pixel dst (m, n):

$$dst(m,n) = (1 - \beta) * dst(m)_u + \beta * dst(m)_l$$

U31.3.2 Inter-Module Synchronization System

This functionality allows the synchronization of operations between the IMP core, CVe, IMP DMAC, Slim-IMP DMAC, IMP PSC, IMP CNN, VDSP and IMP DTA. Executing the WUP and SLP instructions with target modules specified enables synchronization of the operations of the command list (CL) controllers in each of these modules.

For details of the WUP and SLP instructions in the IMP PSC, refer to Section U31.4.9 WUP, and Section U31.4.10 SLP. For selection of target modules, refer to the following section.

U31.3.2.1 Selection of Target Modules

Refer to the **U34.IMP-X7_system, U34.10.5 Inter Module Synchronization** chapter for the details.

U31.3.3 CL break

To use the CL break function, following setting is required.

1. Specify the break point address of command list. Be sure that break point is command address of command list.

2. Set CLBRKENB of SER register to 1 and if interrupt is required, set CLBRKM bit in IMR bit to use CL break function.
3. Check the CLBRK status in SR register.

4. To continue execution after CL break, Set the CLBRKC bit of SCR register to 1.

U31.4 Command List

It is prohibited to use instructions not listed on this section.

Table U31B.8 Instruction list

Instruction	OP CODE	Description
NOP	H'80	No Operation
TRAP	H'88	Quit CL
WPR	H'55	Write register
INT	H'81	Generate an interrupt cause and wait until the interrupt is cleared.
SYNCS	H'8B	Wait for completion of DMA transfer execution
Reserved	H'8C	This OP CODE is prohibited. When this OP CODE is used, no illegal instruction interrupt occurs.
JUMP	H'90	Jump to the specified address
GOSUB	H'91	Jump to the specified address
RET	H'99	Jump to the next instruction of GOSUB
WUP	H'A0	Release SLP of other modules
SLP	H'A1	Wait for other modules to execute WUP

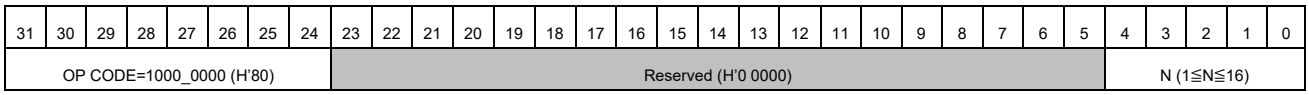
U31.4.1 NOP (No OPeration)

U31.4.1.1 Functionality

This is an instruction to do No Operation.

The NOP instruction causes the IMP PSC to do nothing for the number of clock cycles specified in the N field before execution of the next instruction.

U31.4.1.2 Instruction Format



U31.4.2 TRAP (TRAP)

U31.4.2.1 Functionality

This is an instruction to end CL execution.
TRAP terminates execution of the command list. Only when the TRAE bit of the SER register is 1, the TRA bit of the SR register is set to 1.
However, regardless of the value of the TRAE bit in the SER register, the value specified in the CODE field is set to the TRAPCODE bit of the SR1 register.

U31.4.2.2 Instruction Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OP CODE=1000_1000 (H'88)								Reserved (H'0000)																CODE							

U31.4.3 WPR (Write PaRameter)

U31.4.3.1 Functionality

This is an instruction to write data to registers.
Register write is performed for the number of fields N from the offset address specified by the ADD field. The value to be written to the register is the value of the DATA N - 1 field in order from the DATA 0 field.
Set the ADD field in 1-byte units. Setting 0 in the N field is prohibited.

U31.4.3.2 Instruction Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OP CODE=0101_0101 (H'55)								ADD																N(>=1)							
DATA 0																															
DATA 1																															
DATA 2																															

…

DATA N-1

U31.4.4 INT (INTerrupt)

U31.4.4.1 Functionality

This instruction generates an interrupt.
When the INTE bit of the SER register is 1, the INT bit of the SR register is set to 1. Regardless of the value of the INTE bit in the SER register, the value specified in the CODE field is set to the INTCODE bit of the SR1 register.
The next instruction is not started until the INT bit of the SR0 register is cleared to 0.

U31.4.4.2 Instruction Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OP CODE=1000_0001 (H'81)								Reserved (H'0000)																CODE							

U31.4.5 SYNCS (SYNChronize ProcesS)

U31.4.5.1 Functionality

Wait for completion of DMA transfer execution.
If there is image processing currently being executed, wait for completion of the image processing. After waiting for the completion of the image processing, the next instruction is started.

If image processing is not being executed, it is the same as NOP (next instructions are started).

Always wait for image processing to be completed with the SYNCS instruction immediately after setting the EX bit in the EXCTLR register to 1 with the WPR instruction. If you do not wait for image processing to complete, the operation is not guaranteed.

U31.4.5.2 Instruction Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OP CODE=1000_1011(H'8B)								Reserved (H'00 0000)																							

U31.4.6 JUMP

U30B.4.5.1 Functionality

This is the command to jump to the specified address.
It allows jumping to the address specified in JMPADD field. Setting 1 to RLT field uses relative address to JUMP command address and setting 0 in RLT field uses absolute address of the command list. Specify 4-byte unit command address in the JMPADD field.

U30B.4.5.2 Instruction format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OP CODE=1001_0000(H'90)								RLT	Reserved（all 0）																						
JMPADD																															

U31.4.7 GOSUB (GOSUB)

U31.4.7.1 Functionality

This is the command to save current CL address to the hardware buffer and jump to the specified address.

It allows jumping to the address specified in GSADD field and returning to the address next to the GOSUB command by RET command. Specify 4-byte unit command address in the GSADD field. Nesting from the GOSUB up to 4 level can be possible. Setting 1 to RLT field uses GSADD as relative address to GOSUB command address and setting 0 in RLT field uses absolute address of the command list. Setting 1 in CON field and 0 in CLCNDGSBR bit of CLCNDGSBR register change GOSUB command into NOP command. After the CLCNDGSBR register is set, a SYNCS command should be added before using the GOSUB command.

U31.4.7.2 Instruction Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OP CODE = 1001_0001 (H'91)								RLT	CON	Reserved (All 0)																					
GSADD																															

U31.4.8 RET (RETurn)

U31.4.8.1 Functionality

This instruction jumps to the next instruction of GOSUB.
RET allows jumping to the CL address next to the address at which the GOSUB instruction was executed.

U31.4.8.2 Instruction Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OP CODE=1001_1001(H'99)								Reserved (All 0)																							

U31.4.9 WUP (WakeUP)

U31.4.9.1 Functionality

This instruction releases the modules specified in the SYNCC enable field from the sleep state in inter-module synchronization.

For details, see the explanation obout the operation on the intermodule synchronization system. Be sure to insert 8 or more instructions other than the WUP instruction between two WUP instructions in the CL.

U31.4.9.2 Instruction Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OP CODE=1010_0000 (H'A0)								Reserved (H'00)								SYNCC enable															

U31.4.10 SLP (SLeeP)

U31.4.10.1 Functionality

This instruction places the current module in the sleep state in inter-module synchronization.
When the modules specified in the SYNCC enable field executes the WUP instruction, the current module is released from the sleep state.
For details, see the explanation obout the operation on the intermodule synchronization system.

U31.4.10.2 Instruction Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OP CODE=1010_0001 (H'A1)								Reserved (H'00)								SYNCC enable															

U31.5 Usage Notes

U31.5.1 Power shutdown

Refer to chapter 58.7 Usage Notes in IMP-X7 HW Manual for the power off.

U31.5.2 Module Standby Mode

Refer to chapter chapter 58.7 Usage Notes in IMP-X7 HW Manual for the Module Standby Mode.

U31.5.3 Software reset of CPG

Refer to chapter chapter 58.7 Usage Notes in IMP-X7 HWM Manual for the software reset.

U31.6 Safety mechanism

Note: The suitability of the safety mechanisms referenced in this manual will finally be judged during the safety analysis and safety assessment of the SoC. Therefore, the safety documentation shall always be considered as additional requirements for the system or software derived from the results of the safety analysis.

U31.6.1 Overview

EDC protection is implemented to SRAM and Bus interface in IMPPSC. EDC check is always enabled.

U31.6.2 Block diagram EDC protection

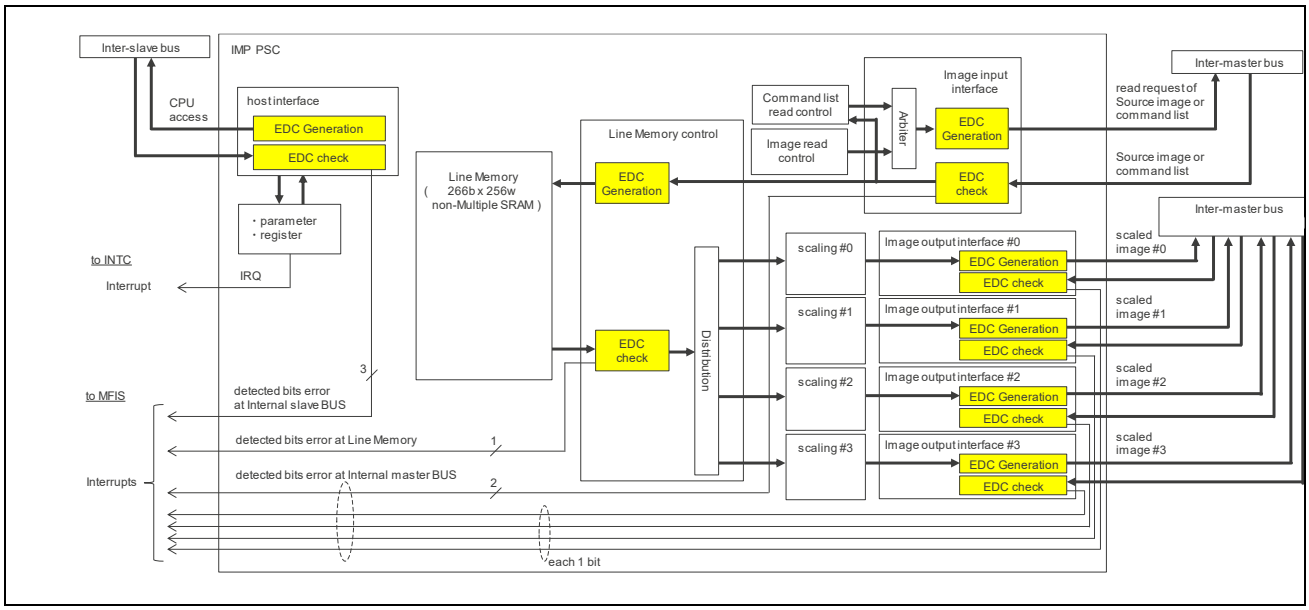


Figure U31.9 Functional safety of IMP PSC.

U32. IMP-X7 CVengine

U32.1 Overview

The IMP-X7 CVengine is a general purpose processor; its main target are algorithms of the computer vision area.

The IMP-X7 CVengine is configured of a hierarchy of three types of units referred to as the cluster, cores, and threads. Each of the units is described below.

A thread retains the thread state and is the element that executes a program based on the vertices it is assigned. As many programs as there are threads can be executed in parallel.

8 threads are collected in units called cores. The multiple threads of a core have local working memory (LWM) and Shared ArithMetic logic unit (SAM), both of which are shared among the multiple threads of the core.

Each thread in a core is configured by the command list as “master” or “slave”. The master and slave have own program area. Vertex Issue starts the master thread and slave threads are started by the master thread.

4 cores are collected in the unit called a cluster. A cluster serves as one processing unit of an IMP-X7 CVengine.

The multiple cores of a cluster have various caches (for data and instructions denoted by D$ and I$), a stream buffer output (SBO), global working memory (GWM) and a Shared Operation Unit (SOU). These are all shared among the multiple cores of the cluster.

The scratchpad memory and external memory are implemented outside of clusters.

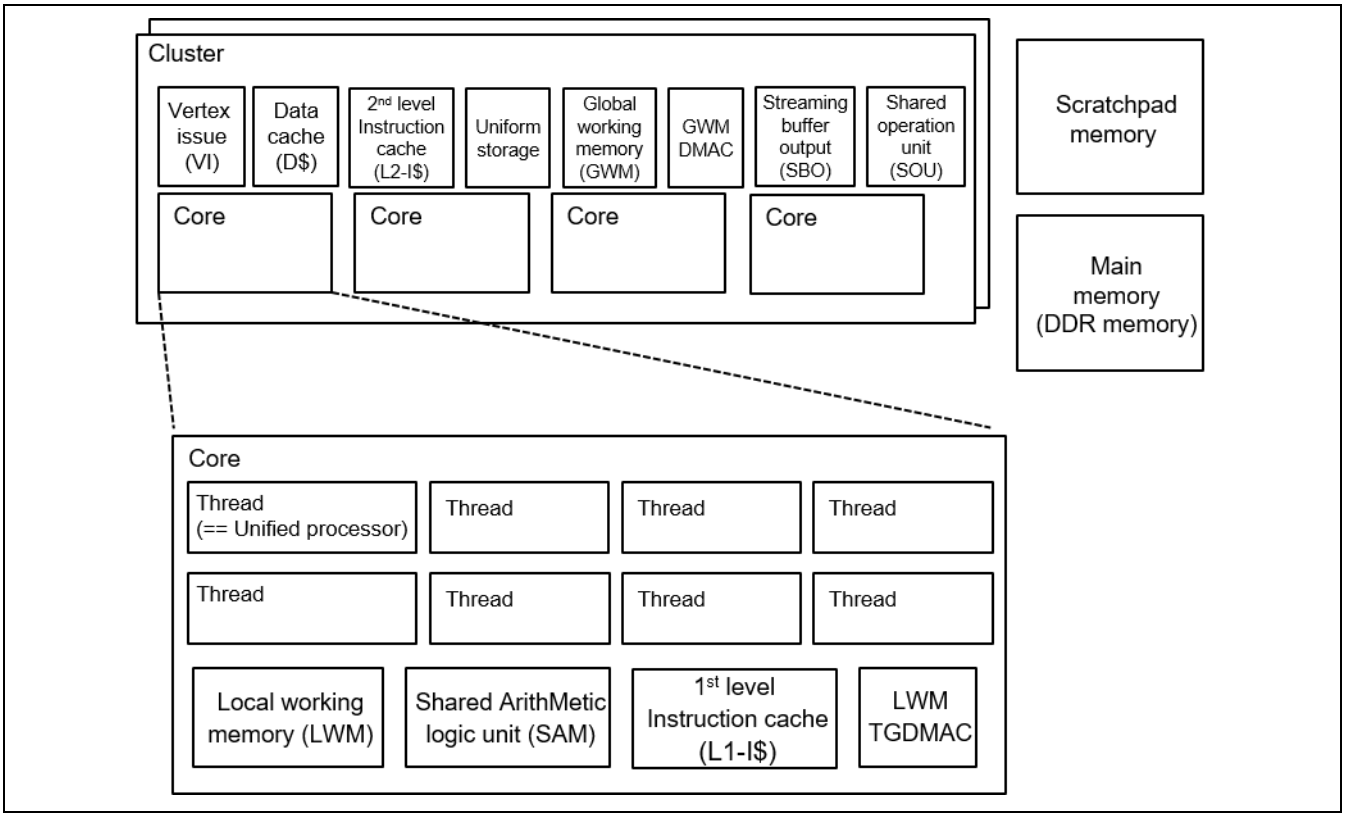

Figure U32.1.1 Block Diagram of an CVengine Cluster

The programming model focuses on the thread as the unit of operations by CVengine and its specifications are described in the remainder of this document.

The CVengine incorporates a single type of processor that is the CVengine thread. The CVengine thread is connected to the following ports or modules:

(1) Data input port (Master: Input from Vertex Issue / Slave: Input from Master thread)
(2) Data cache
(3) Instruction cache
(4) Local working memory
(5) Global working memory
(6) Uniform storage
(7) Main memory / Scratchpad memory
(8) Streaming buffer output
(9) Data output port (Master thread only)
(10) Data cache bypassing

Figure U32.1.2 shows an overview of the CVengine thread.

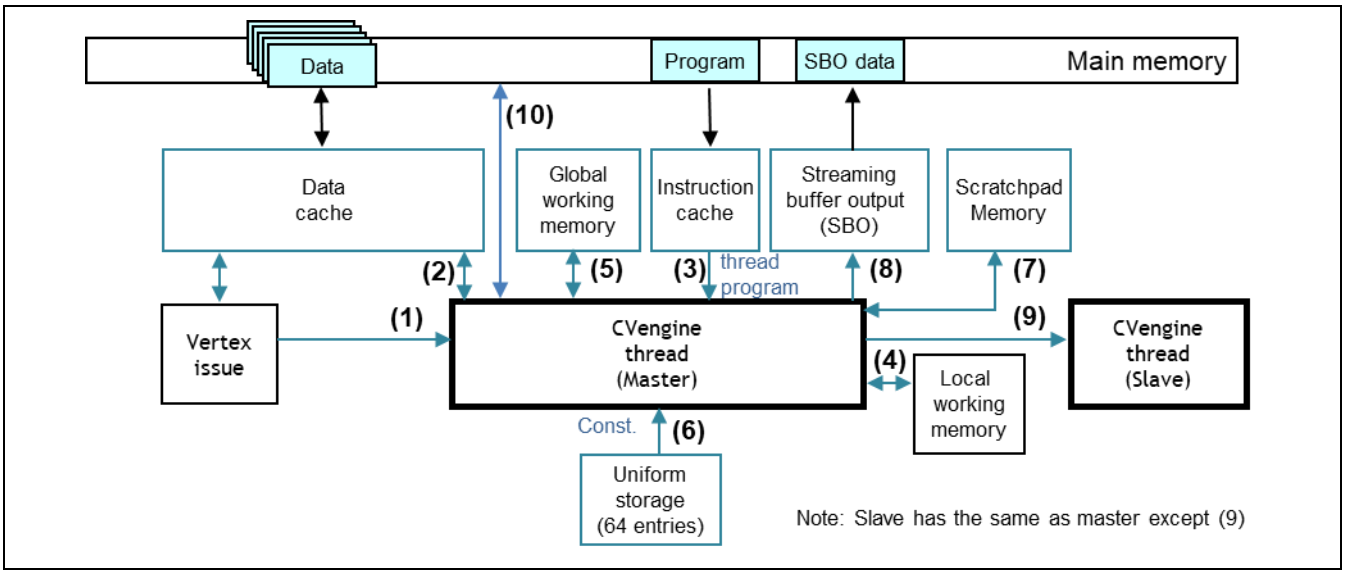

Figure U32.1.2 Connection Diagram of CVengine Thread and Peripheral Blocks

U32.1.1 Input Data

The data input from the data input port is stored in registers from which the thread can read.

U32.1.2 Cache Memory

There are data cache and instruction cache between main memory and CVengine.

Table U32.1.1 Cache Memory List

	Data Cache	L1 Instruction Cache	L2 Instruction Cache
Shared among	All threads in a cluster	All threads in a core	All cores in a cluster
Size	8kB x 1bank	8kB	16kB
Line size	128byte	←	←
Structure	4-way set associative	2-way set associative	4-way set associative
Tag	Upper 19bit of physical address	Upper 21bit of physical address	Upper 21bit of physical address
Refill	LRU(Least Recently Used)	←	←
Purging	Write-back	NA	NA
Stage	7 stages (responded at stage 6)	←	←
Remarks			

U32.1.2.1 Data Cache

A data cache memory consists of 1 bank of 8kbyte memory and is connected to CVengine for fast access to image data and variables in the external memory. The line size of the L1 data cache is128 bytes. Data is read in units of 128 bytes into L1 data cache. Output data can be written out in 32-, 64- or 128-byte unit. i.e., When in one line of 128 bytes, only 32 bytes are marked as dirty then only 32 bytes will be written out. Access to the data cache from the thread is specified by X-Y coordinates or linear address on Shader memory space. Refer to Figure U32.5.1 for this linear memory space. Addresses in the main memory are automatically calculated from the specified X-Y coordinates or linear address using the image, data format, base address, or stride. More than one base address can be handled, and they are specified by configuration registers. All threads of a cluster share the same L1 data cache. Use software to maintain data coherence between the threads if required. For bypassing this data cache, refer to section U32.8.9 .

The 0th level cache (named as “pbuf”) has a 32byte long write buffer with write-back method and a 32byte read buffer which are implemented at the data cache (D$) access port of each thread to improve data access performance at D$ conflicts. This cache is automatically flushed but not cleared at the thread end, TRAP instruction. Clearing this cache is user responsibility. A dedicated instruction SYNCP is also available to clear or flush the cache manually and it invalidates the content in pbuf. Be noticed that pbuf is only connected to D$ thus it does not work for accessing any other memory (e.g., LWM).

U32.1.2.2 Instruction Cache

The program which is executed by the thread is supplied from the instruction cache. The instruction cache consists of the level 1 cache which is 8kbyte of 2way set associative cache and shared by all 8 threads in a core. The level 2 cache is 16kbyte of 4way set associative cache which is implemented per cluster and is shared by all 32 threads.

In addition to the above, a 0th level cache is also implemented as 8 buffers with a size of 32byte. It is placed between the thread and the instruction cache allowing 64 instructions to be cached. For details on improving performance by effectively using the 0th level instruction cache, refer to section U32.14.4 .

U32.1.3 Local Working Memory

The local working memory is readable and writable memory. In non-common access mode, each thread has its own dedicated local working memory bank, and it is only accessible by the thread. In common access mode, the full local working memory address space can be accessed by any thread inside a core. The size of local working memory is 3kB per thread in non-common mode and 24kB per core in common mode, refer to U32.5.8 for more information.
Each core of a cluster has local work memory.

The local working memory can be used as space for holding temporary variables which cannot be stored in general-purpose registers.

U32.1.4 Global Working Memory

The global working memory is readable and writable and is shared by all threads of the CVengine. It can be used to hold common data which is shared by all threads. The size of global working memory is 8kB per cluster.

The global working memory has additionally two types of special storage. One storage is a semaphore register. This register is a 1-bit register that can be read from and written to by all threads. When this register is read, the register value is forcibly changed to 1 after the read operation. This allows the shared resources between the threads to be managed.

The other storage is an increment register. This register is a 32-bit register which can be read from and written to by all threads. When this register is read, the register value is incremented by 1 after the read operation. This allows the order between the threads to be controlled.

Since all threads share the global working memory, use software to maintain data coherence.

U32.1.5 Uniform Storage

The uniform storage is used to hold constants that can be used by programs. Values that were stored as source operands from specific instructions can be used. Values need to be already set in the uniform storage by the Vertex Issue through the command list before programs are started. The uniform storage comprises 64 32bit entries.

U32.1.6 Streaming Buffer Output

The streaming buffer output is used to consecutively write data to the external memory. Up to three types of data can be written. The type of data to be written can be set by the control register.

As the streaming buffer output is shared by multiple threads, the order in which data is written to the external memory cannot be guaranteed between the threads.

U32.1.7 Data Output Port

The data output port of the thread is for use in starting slave threads by issuing the ACTST instruction. The data through the port is used as arguments, provided by the master thread for the slave threads.

U32.2 Overview of Thread Hardware

The features and overview of a thread are shown in Figure U32.2.1.

Features

- Input/output interface to register file
- 32- and 16-bit signed-integer arithmetic units and floating-point arithmetic unit operating in the IEEE 754 single-precision format
- SIMD operation for multiple-accumulation with 64-bit width input.
- Data read from the constant area (uniform storage) can be used in operations.
- Conditional execution instructions are supported.
- SAM supports special arithmetic operations such as multiplying and rotating which are shared by multiple threads.
- SOU supports other special arithmetic operations (e.g., square root) which are shared by multiple cores.

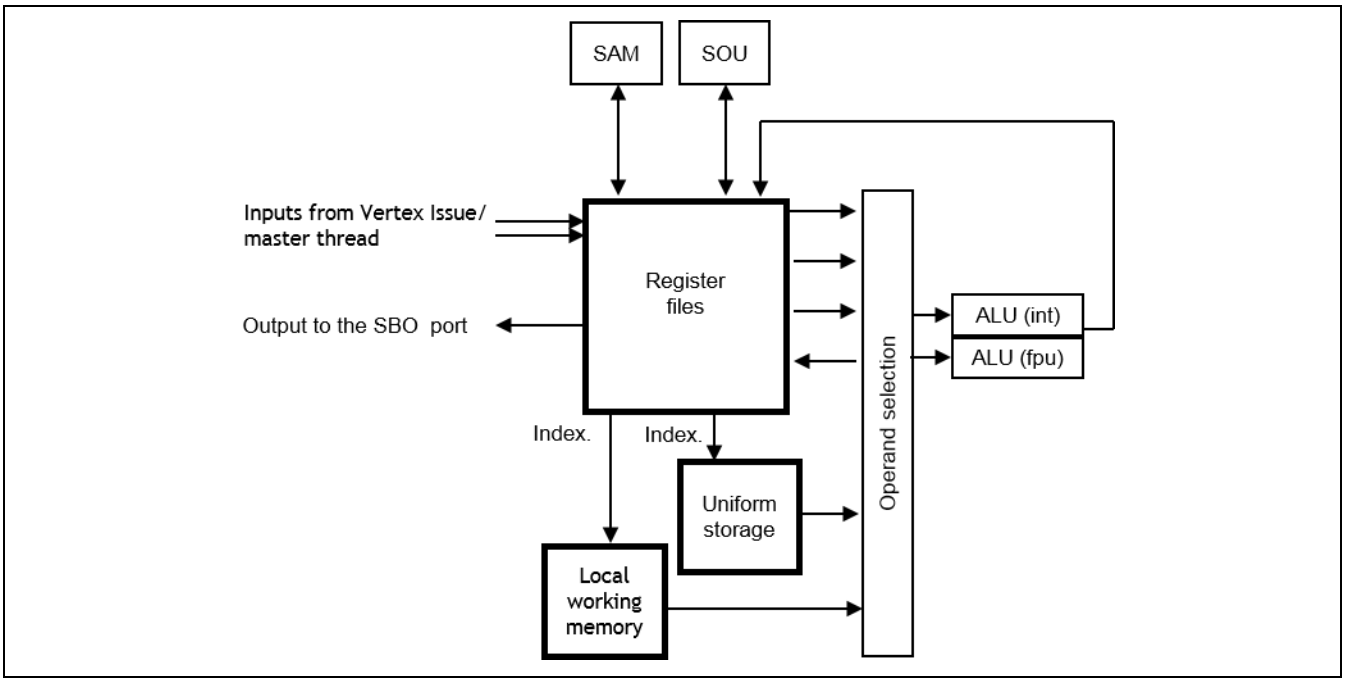

Figure U32.2.1 Data Flow in CVengine Thread

Input/output ports to interface with external modules are connected to the register files, and the thread can make access by reading from registers or writing to registers. Each register file consists of 48 32-bit registers.

U32.3 Thread State

U32.3.1 Program Start and Stop

The thread can be in one of two states: idle state or processing state. In the idle state, the PC (Program Counter) is stopped, and no operation is done. When the previous stage (vertex issue/master thread) has completed setting values to necessary input registers, an activation signal is generated. The thread loads the specified PC and transitions to processing state. To shift from the processing state back to the stopped state, execute the TRAP instruction, to bring the thread into idle state.

If a break occurs in the processing state due to a CVengine configuration register setting, the thread transits to the break state after execution of the decoded instruction has completed. Also, when an interrupt happens with the INT instruction, the thread goes to the break state. In break state, the PC is stopped, and the thread state can be read and changed by a CVengine configuration register. When the break state is released due to a CVengine configuration register setting, the thread returns to the processing state.

For information how a thread can be disabled, please refer to section U32.12.1.49 . The CVengine can also be reset by a configuration register but resetting while a thread is in running or breaking state is prohibited and behavior is not defined. For more information, please refer to section U32.12.1.2 .

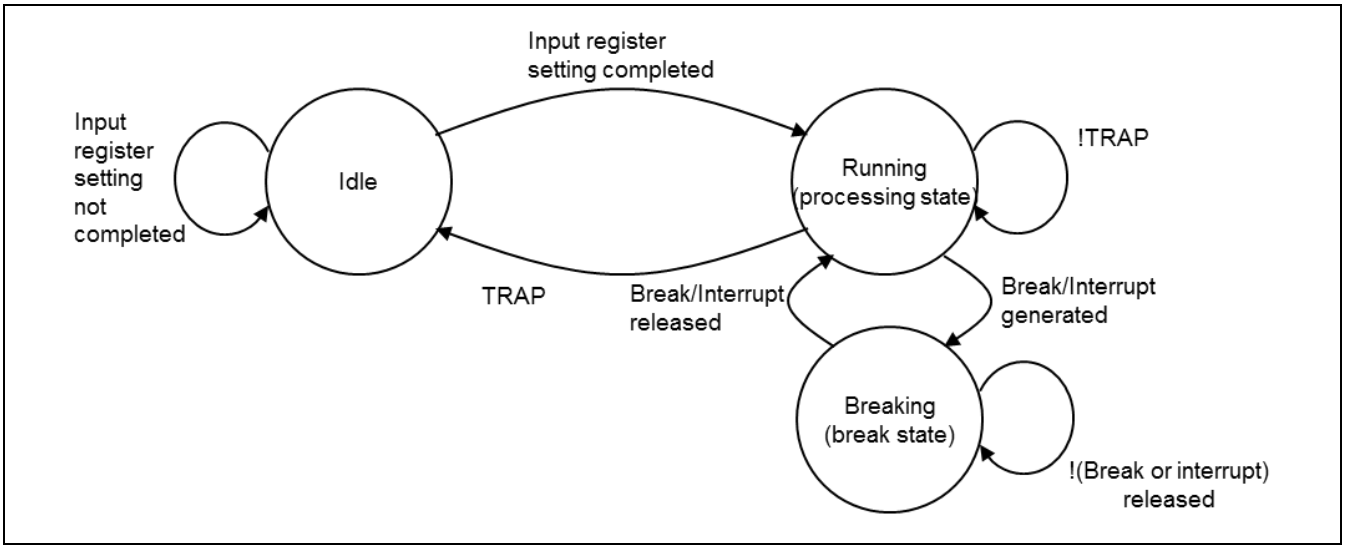

Figure U32.3.1 State Transitions of CVengine Thread

U32.3.2 Master and Slave

Each thread in CVengine can take a role as master or slave. This role is configured for each thread by TGSEN1 configuration register and fulfilled for the commands POINT, POINTS and RECT. Differences between master and slave are as follows.

- The Vertex Issue starts master threads only.
- The slave threads are only called by master threads by ACTST, which slave thread is called is assigned by the queue arbiter.
- Only the master threads can issue SYNCG and wait for completion of the slave threads.
- R2 is used as parameter transferred from master to slave (e.g., master ID or LWM base address).
- The slave thread starts from a dedicated instruction area which is specified by PPCSAR.

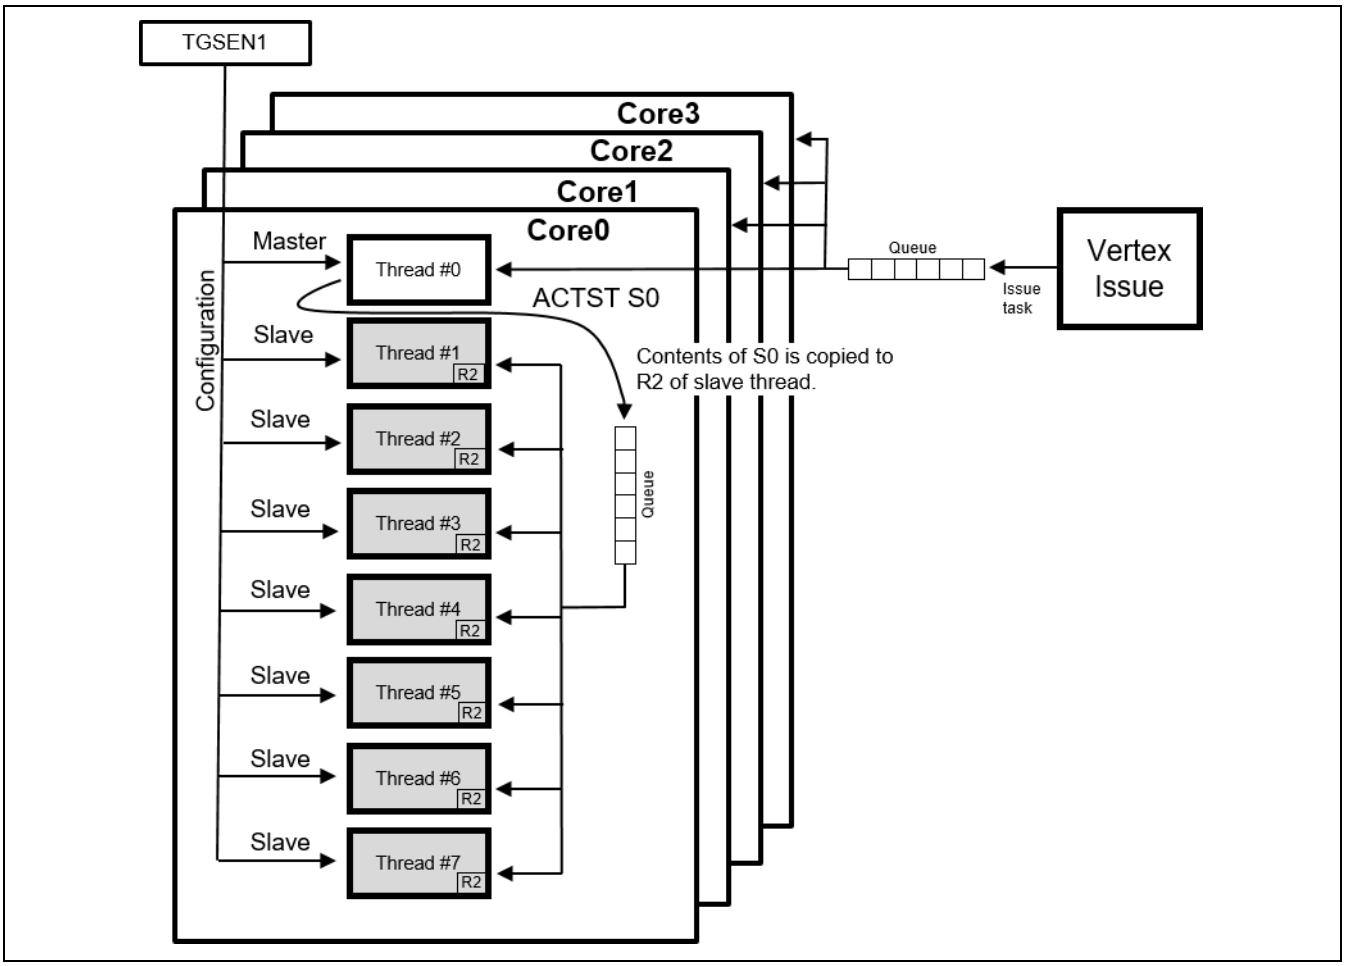

Figure U32.3.2 Master/Slave Architecture (Case of 1 Master and 7 Slaves)

Issuing SYNCG or ACTST command by a slave thread causes undefined result. Hardware is not initialized automatically when a slave thread is started. Initialize manually with SINI if necessary.

The following figure shows a typical and basic master-slave sequence in case of 1 master and 7 slaves' configuration.

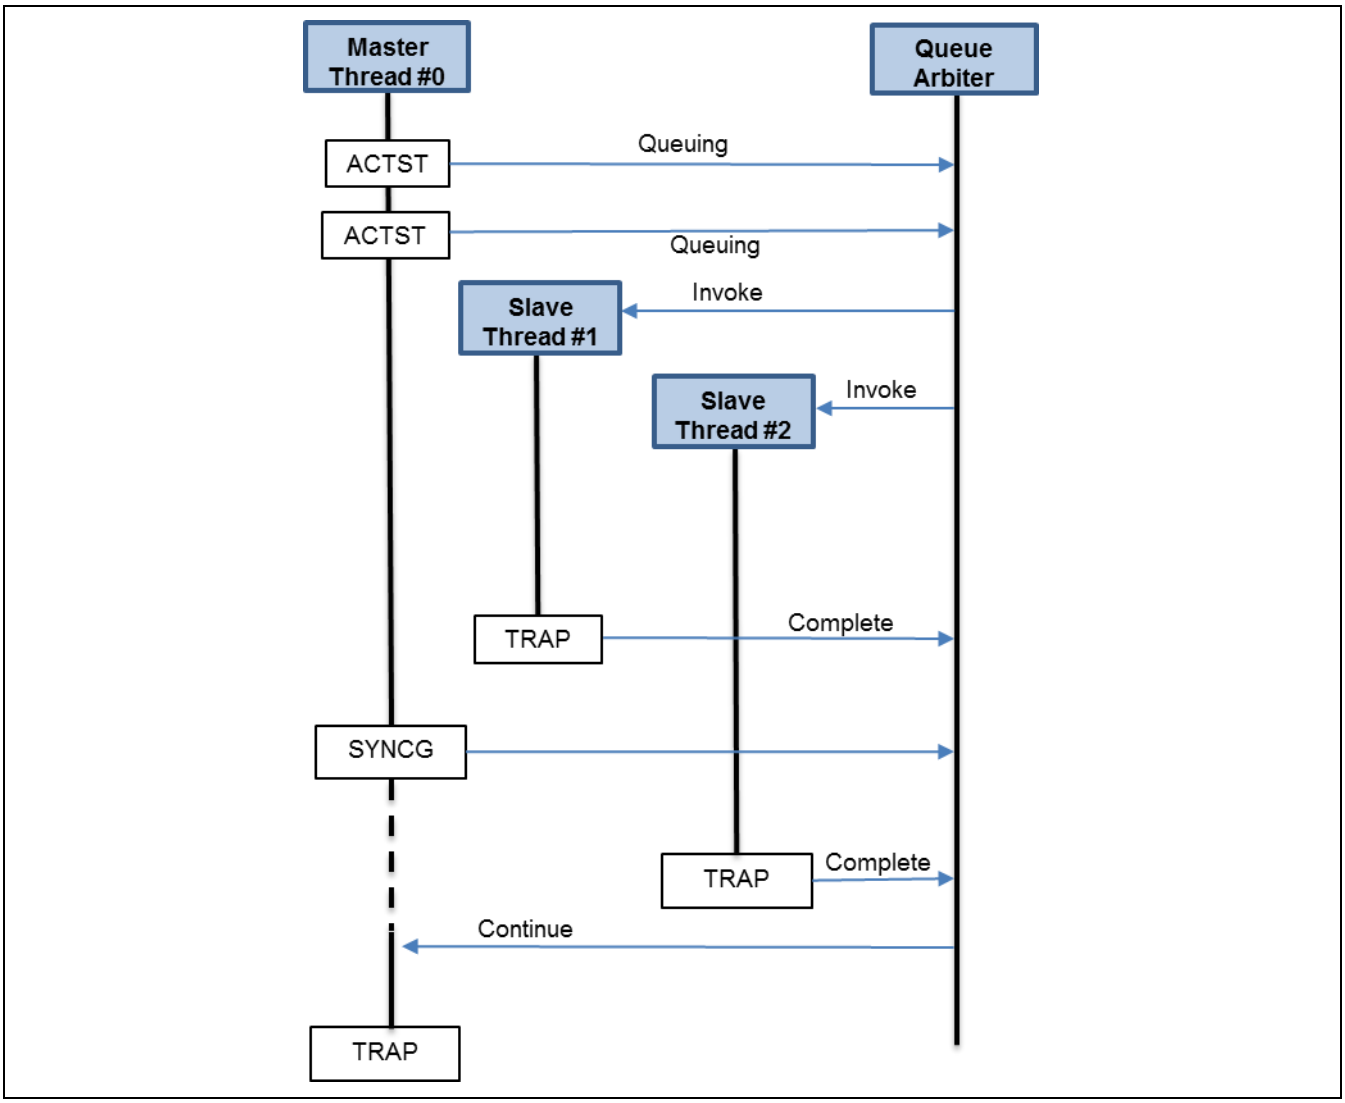

Figure U32.3.3 Typical Master/Slave Sequence

In the above figure, the master thread deploys two slave threads by issuing two ACTST via the queue arbiter, then two slave threads proceed their task. The queue arbiter detects completions (TRAP instruction) from all slaves and resumes the master thread which waits by SYNCG.

As derived cases from above:

- The master must issue SYNCG before TRAP.
- The master can issue SYNCG with no ACTST issuing. In this case, SYNCG is treated as NOP.

The master can issue ACTST at any time. If there is no vacant slave in the same core, the master stalls. SYNCG makes the master to wait for all the slave threads to finish that are invoked with ACTST by the master thread.

Only master threads can initiate an LWM-DMA transfer and only 1 DMA transfer can be active at a time.

All threads can be set to either master or slave with TGSEN1. This TGSEN1 setting is applied to all 4 cores. For more details, please refer to U32.12.1.49 . Any combination of master and slave is possible.

U32.4 Memory Space for Program and Data Planes

The CVengine has two types of memory space. One is for program and data planes. The threads access the program area as instruction fetch and the data planes indexed by coordinates of dedicated instructions like LDRXY, STRXY, etc. These memory areas are the scope of this chapter.

The other type of memory space is used for variables and IO which is described in the next chapter.

U32.4.1 Program Area

The program of the CVengine thread is located in an area allocated in the external memory.

The start address of the area allocated in the main memory needs to be set in the CVengine configuration register VIBAR before program execution starts.

The program is accessed via the instruction cache (I$). There are two types of instruction caches (I$): a 4kbyte 2way set-associative first-level (L1) cache which is shared by all threads in a core and an 8kbyte 4way set-associative second-level (L2) cache which is shared by all cores in a cluster.

The thread refers to the instruction located at the address specified by the VIBAR register as an instruction whose program counter (PC) is 0, and execution starts from the start PC set in the CVengine configuration register. When the SINI command of the vertex issue is used, execution starts from the PC set in the VSINISAR register. When other start commands are used, execution starts from the PC set in the VPCSAR register.

The main memory space that can be accessed as the program area by the thread is 64Kbytes from the start address specified by the VIBAR register.

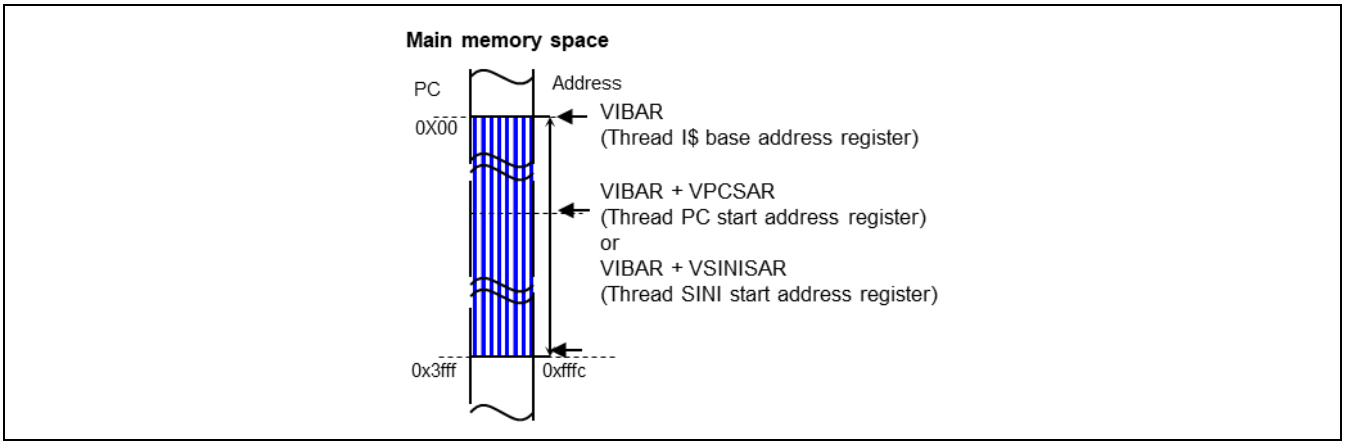

Figure U32.4.1 Memory Space for Program Area

U32.4.2 Data Planes

This external memory space holds image data or variables. Data in external memory can be in variable format and is determined by the fields PFORMAT and PFORMAT2 of the configuration register IMGC0Rn. The area that is accessed by the thread via the data cache (D$) is a two-dimensional space that is always represented by the X and Y coordinates. At the data cache, the X and Y coordinates requested by the thread are converted into a memory address used for accessing the external memory.

With instructions for loading and storing of integers using X and Y coordinates e.g., LDRXY/STRXY, if the data format of the external memory is not 32-bit signed integer, in case of loading, data from the external memory are converted into 32-bit signed integers and then provided to the thread. In case of storing, the 32-bit signed integer from the thread is converted into the data format of the external memory and written afterwards.

With instructions for loading and storing of floating-point numbers using X and Y coordinates e.g., FLDRXY/FSTRXY, if the data format of the external memory is not 32-bit floating-point number, in case of loading, data from the external memory are converted into 32-bit floating-point numbers and then provided to the thread. In case of storing, the 32-bit floating-point number from the thread is converted into the data format of the external memory and written afterwards.

With instructions for loading and storing data using linear addressing e.g., LD/ST, data format conversion is not taken place and data is loaded and stored as-is.

The D$ is composed of one bank of 8-Kbyte 4-way set associative cache.

The CVengine configuration registers (IMGBAR0 to IMGBAR11, IMGSTR0 to IMGSTR11, and IMGC0R0 to IMGC0R11) need to be set before executing the program. The CVengine can handle up to 12 planes of memory space. The n-th plane registers are described as IMGBARn, IMGSTRn, and IMGC0Rn in this document. The planes are shared by all threads. The values of Control Registers CR8 and CR9 are used to select which plane to be read or written by a thread. Refer to section U32.6.2 .

The start address of the data area of the plane should be set in the IMGBARn register. The memory width of the plane should be set in the IMGSTRn register. Both of the settings should be made based on the unit of the data format specified by the IMGC0Rn register. The external memory data format, rounding mode at conversion between integer and floating-point, and saturation specification at conversion of the plane are set in the IMGC0Rn register.

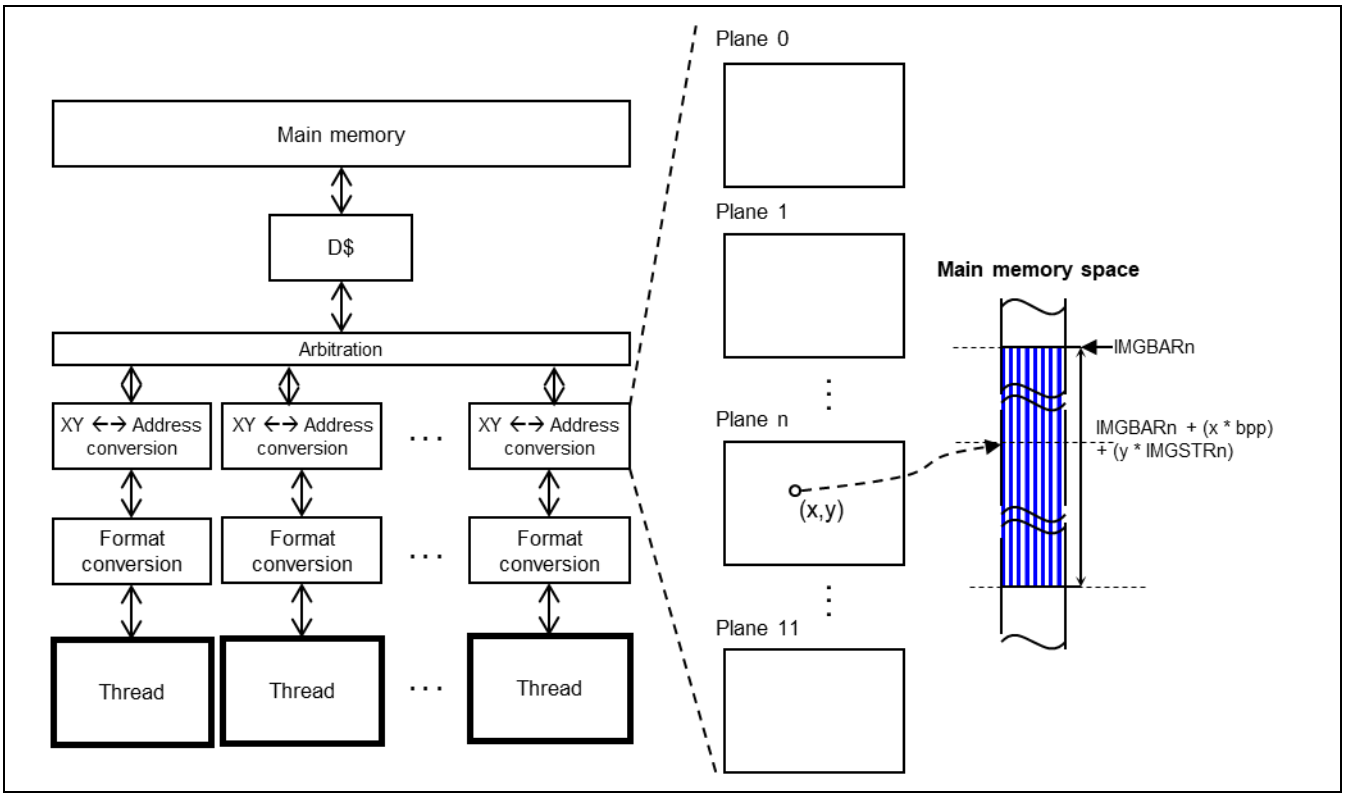

Figure U32.4.2 Memory Space for Data Cache Area

Note: Maximum size of data plane accessed by the thread

The physical address accessed by a thread is calculated with the following formula:

Physical Address = Base + (X × Format) + (Y × Stride)

Base: unsigned 32-bit, 0 ~ 4294967295 (IMGBARn)
Format: 1/2/4 (IMGC0Rn.PFORMAT/PFORMAT2)
Stride: signed 16-bit, -32768 ~ 32767 (IMGSTRn)
X: signed 32-bit, -2147483648 ~ 2147483647 (R0)
Y: signed 16-bit, -32768 ~ 32767 (R1)
(X × Format) + (Y × Stride) >= 0
Physical Address <= 0xFFFFFFFF

Since the final offset to Base cannot take a negative value, the maximum area size that can be accessed by a thread is 2147483648 × 1 byte for a one-dimensional plane. For a two-dimensional plane, maximum width is 32767 bytes since Stride is signed 16-bit, and the maximum height is 32768 lines since effective range of Y is $0 \leq Y \leq 32767$. The maximum size in pixels varies depending on the Format. (On the other hand, Vertex Issue can handle maximum 65536 × 65536 pixels regardless of the Format. (Refer to section U32.13.1 , U32.13.2 and 0.)

U32.5 Memory Space for Variables and IO

U32.5.1 Memory Map and Attributes

The CVengine has a 32-bit address space and any memory space for variables and I/O are mapped on it. It can access host memory space with the same address, which is useful to read/write directly from/to external memory. The Figure U32.5.1 shows this address space with some attributions for each memory area.

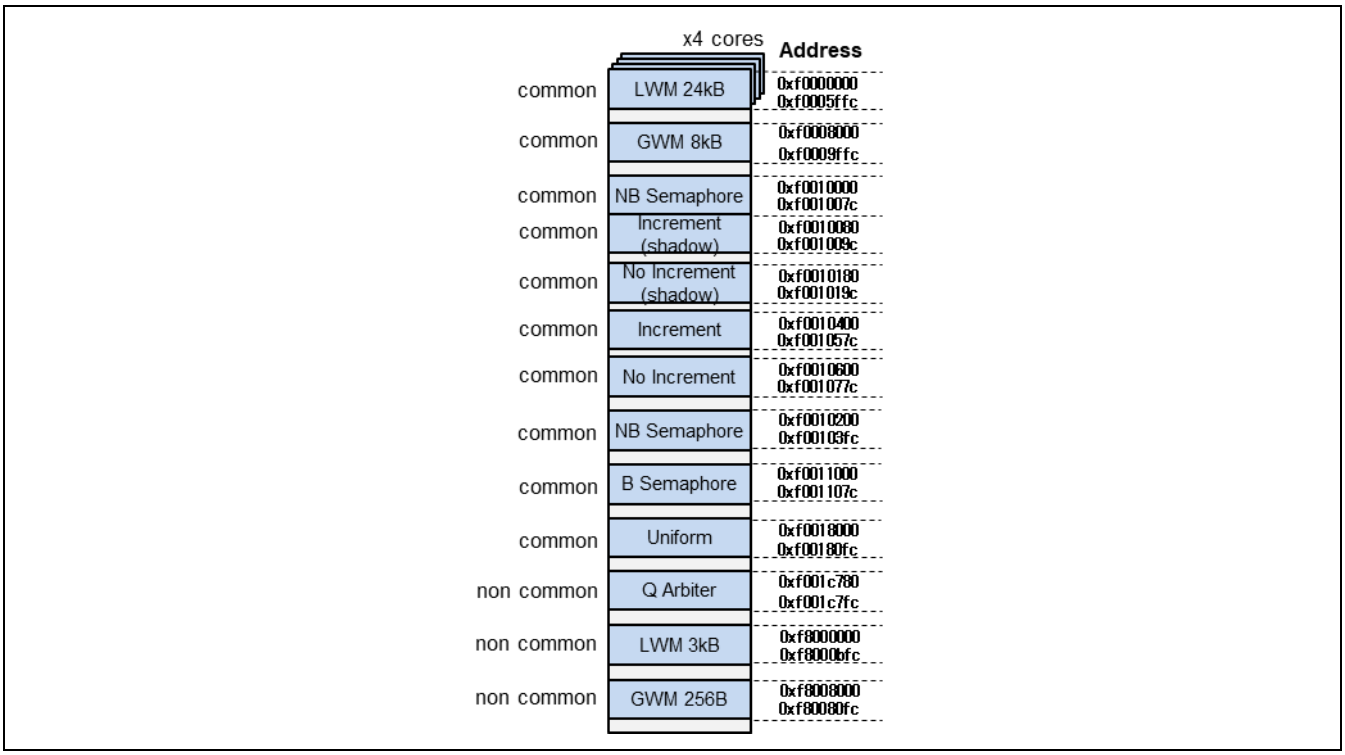

Figure U32.5.1 Memory Map for Variables and IO

For this address space, dedicated load/store instructions are used to access actual data. And these load/store instructions have variants to access memory with byte and half word size. For example, store instructions have ST (word size), STH (half word size) and STB (byte size). Any access to an area where nothing is mapped to has no effect, i.e., is dealt as NOP instruction. Regarding common area and non-common area, refer to the section U32.5.8 . Table U32.5.1 shows some attributes of each memory from each master.

Table U32.5.1 Memory Attributes

Transferred Memory / Bus Master	LWM	GWM	Scratchpad	Host Memory Space (External Memory)
Host (Arm, System DMA)	Cannot access	Cannot access	Can access	Can access

			- Mapped on virtual memory space of Arm - Non-cacheable *1	- Mapped on virtual memory space of Arm - Cacheable
CVengine Thread	Can access - Mapped on CVengine memory space - Non-cacheable, but fast. - Thread dedicated. Cannot be shared with other thread.(non-common access) - Can be shared with other thread in the same core.(common access) - Data only. CVengine instruction cannot be loaded - General CVengine load / store instructions are used. - 8-bit, 16-bit, 32-bit, 64-bit access are available	Can access - Mapped on CVengine memory space - Non-cacheable, but fast. - Thread dedicated. Cannot be shared with other thread.(non-common access) - Can be shared with other thread in the same cluster.(common access) - Data only. CVengine instruction cannot be loaded - General CVengine load / store instructions are used. - 8-bit, 16-bit, 32-bit access are available.	Can access - Mapped on CVengine memory space - Cacheable - Both data and CVengine instruction are loaded - General CVengine load / store instructions are used. - 8-bit, 16-bit, 32-bit access are available. - Dedicated instructions e.g., LDRXY/STRXY are also available to access the data. - Can be shared among threads and clusters	Can access - Mapped on CVengine memory space. - Cacheable - Both data and CVengine instruction are loaded - General CVengine load / store instructions are used. - 8-bit, 16-bit, 32-bit access are available. - Dedicated instructions e.g., LDRXY/STRXY are also available to access the data.
CVengine DMA	Can access - Master thread / program can use this DMA. - Arm cannot use this DMA. - Not through cache. Physical memory to memory.	Can access - CVengine thread / program cannot use this DMA. - Arm can use this DMA. - Not through cache. Physical memory to memory.	Can access - Not through cache. Physical memory to memory.	Can access - Not through cache. Physical memory to memory.
SBO	Cannot access	Cannot access	Can access - Write only	Can access - Write only

*1 Arm can access the scratchpad memory with 4byte width only. Accessing the scratchpad memory via data cache of Arm is not supported.

U32.5.2 Constant Memory Area

This memory area is for storing uniform storage data (constants that can be read from the CVengine threads). CVengine has 64 entries, and each entry has 32-bit long and is mapped in the memory space.

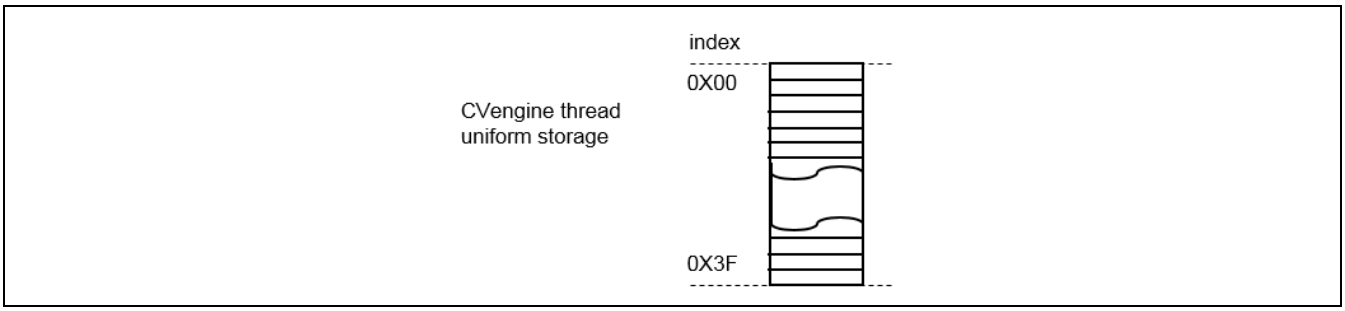

Figure U32.5.2 Address Space for Constant Memory Area

The uniform storage area can be accessed by the dedicated instructions like MOVU, ORU, ADDU using a dedicated index. The uniform storage can always be accessed by these instructions without penalty cycles.

In addition, general memory load instruction LD is available to read the uniform storage area. This general load instruction can access the constant memory area described in the section U32.5.1 by word, half word and byte unit.

To mention is, the dedicated instructions like e.g., MOVU specify an address on this area by “index”, namely address is in a word unit. However, the general load/store instructions specify an address by “byte address”, same as other memory areas.

U32.5.3 Local Working Memory Area

The local working memory size is in total 24 Kbytes for all 8 threads in a core and it has a 32-bit width. This memory is not cached. There are common and non-common accessing modes to this memory, for details refer to section U32.5.8 . In non-common mode this memory cannot be accessed from other threads, so it can be used as temporal data storage by each thread of CVengine. Each thread can access this local working memory via same memory window, but actual

physical memory is dedicated to each thread. See Figure U32.5.3 for this mapping. In common-access mode, all the threads in a core share one memory space. Accessing LWM in another core is impossible.

The local working memory can be accessed by general load/store instructions like LD/ST.

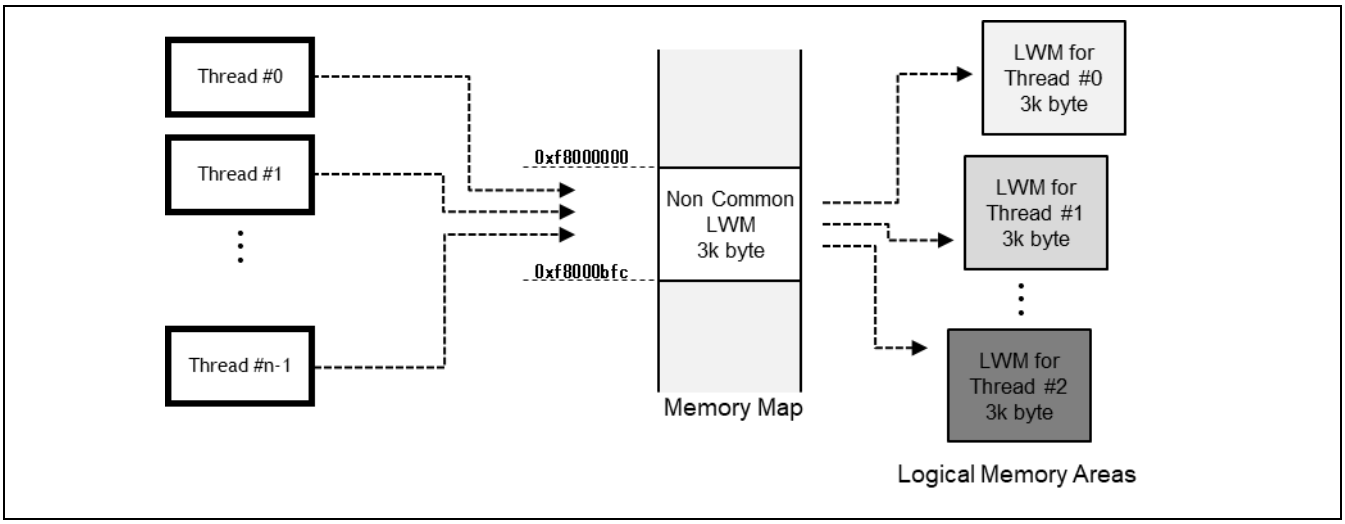

Figure U32.5.3 Local Working Memory Space

U32.5.4 Global Working Memory Area

The global working memory is an area that can be accessed by all threads of the CVengine. This memory is not cached. There are common and non-common accessing modes to this memory, for details, refer to section U32.5.8 . The global working memory of the CVengine is composed of an 8 Kbyte data area and two types of special registers (semaphore register and increment register).

The data area is a 32-bit width memory area to which values can be read from or written to freely. When data coherency needs to be guaranteed, synchronization by the executed program is necessary.

The global working memory can be accessed by general load/store instructions like LD/ST.

U32.5.5 Semaphore and Increment Register Area

This common area is divided into 2 parts: semaphore and increment part. These register areas must be accessed with a word (32-bit) access instruction. Accessing these areas with instructions in 16-bit or 8-bit length is prohibited.

U32.5.5.1 Semaphore Register Area

The semaphore register area is from 0xF0010200 to 0xF00103FC. There are 128 32-bit long semaphore registers. There is also another semaphore register area from 0xF0010000 to 0xF001007C, which is the mirror of the first 32 of the 128 semaphores.

The semaphore register holds only 0 or 1 and it can be read from and written to by all threads. When the semaphore register is read, the register value is forcibly changed to 1 after the read operation.

This feature can be used to control accesses to shared resources. Each register is assigned the state of a resource. 0 indicates that the resource is available, whereas 1 indicates that the resource is not available. During program execution, as long as the relevant semaphore register value is 1, a wait routine to wait for the semaphore register value to become 0 shall be executed. When the value has changed to 0 and is read, perform the processing using that resource and write 0 to the relevant semaphore register at the end. This allows another thread that was waiting to use that resource to get exclusive access.

Operation is not guaranteed when a value other than 0 or 0.0f is written to the semaphore register.

The non-blocking (read without blocking) semaphore register area is from 0xF0010200 to 0xF00103FC, the blocking (read with blocking) semaphore area is available from 0xF0011000 till 0xF001107C.

Same as the non-blocking semaphore register, the blocking semaphore register also holds only 0 or 1. Each blocking semaphore register is assigned the state of a resource. 0 indicates that the resource is available, whereas 1 indicates that the resource is not available. When the blocking semaphore register is read, the register value is forcibly changed to 1 after the read operation. Only 1 thread is able to read the blocking semaphore register at one time. While the register value is 1, any thread trying to read the blocking semaphore register stalls so that the read value of the blocking semaphore is always 0. When the register value is changed from 1 to 0, the stalling thread restarts and read the register value again. Only 0 can be written to the blocking semaphore register regardless of the value stored in the register. Unlike the non-blocking semaphore registers explained above, waiting loop is not needed to wait for the register value becoming 0 to control resources. The round robin arbitration scheme is used to control the threads accessing to the blocking semaphore register. Writing access has higher priority than reading access.

After a load instruction reading a blocking register, an instruction reading the loaded value must be inserted. For example, instruction sequence below is valid.

```
LD      R26, R13, R3; R13 points to the blocking semaphore register
MOV R3, R26; an instruction reading the loaded value
```

Note that there is no need to insert the read instruction just after the load instruction. Instructions that do not access resources protected by the semaphore can be scheduled in between. Generally, compiler for CVengine does not support this insertion automatically, insertion is user responsibility.

Note: For non-blocking semaphore, value is returned regardless of successful acquisition of a semaphore. Because of the hardware implementation, a semaphore may not be acquired forever depending on access timings from threads. This is an example case of deadlock. When the value of a shared variable is changed after acquisition of a semaphore, and if both reading and writing from/to the shared variable use the same semaphore, reading from the shared variable by a thread can disturb writing to the shared variable from another thread so that deadlock can happen. To avoid this kind of deadlock, logic must be designed carefully. For example, only the thread writing to the shared variable uses the semaphore.

U32.5.5.2 Increment Register Area

The increment register area is from 0xF0010400 to 0xF001057C. There are 96 32-bit long increment registers.

The increment register is a 32-bit register in the integer format, and it can be read from and written to by all threads.

When the increment register is read, the register value is incremented by 1 after the read operation. This feature can be used by each thread to acquire unique serial numbers that are consecutive.

The default value of the increment register is 0. User can write 0 to reset the increment register. Any other value can also be written to the increment register.

A second access area for the increment registers exists for read access from 0xF0010600 to 0xF001077C. When using this access area for a read access, the register value is read without incrementing the value by 1. A write to this access area is not allowed.

For the first 8 increment register, a shadow area exists from 0xF0010080 to 0xF001009C for an access with incrementation and from 0xF0010180 to 0xF001019C for an access without incrementation.

U32.5.6 Scratchpad Memory Area

CVengine can access to a 16MB scratchpad memory area. Scratchpad memory is formerly called “IMPC”. This memory is accessible by all threads of all clusters. This is useful to exchange data with any external core like IMP Core or Arm without using DDR memory. There are common and non-common accessing modes to this memory.

The CVengine memory map prepares 16MB area for scratchpad, but the mapping to the physical memory is decided by the bus system which is outside of the scope of CVengine. For the used address map, refer to User's Manual: Hardware, section U34.1.3, Address map.

U32.5.7 Queue Arbiter Register Area

This area has some configuration registers which are read/written by each thread to control its behavior. TGDMCR0, TGDMEXTMEMOFSADDR, TGDMLWMBADDR, TGDMLWMSTRR, TGLNGR, TGSBOCNTR0 are implemented to configure TGDMAC “Thread Group DMAC” and start/stop DMA transfer between external memory and local working memories.

The start address of this area is 0xf001c780 and the end address is 0xf001c7fc.

These registers are so called “non-common”, namely, each thread has his own register set which cannot be directly accessed by other threads. And they must be accessed by word (32-bit) unit. Half word (16-bit) and byte access are prohibited.

U32.5.8 Common and Non Common Area

In the following, the relation between common and non-common address will be shown. For LWM and GWM, common and non-common base addresses can be taken from Figure U32.5.1. For scratchpad memory, the common base address can be taken from the User's Manual: Hardware, section U34.1.3, Address map, the non-common base address can be calculated as follows:

non-common base address = 0xee000000 + (common base address - 0xed000000) / 32

After, each address can be converted between common and non-common style. In the case of common address calculation from non-common address, do as follows:

1.) Calculate non-common offset from non-common address by subtracting non-common base address from non-common address as follows:

2.) Calculate common offset from non-common offset as follows:

common offset = non-common offset * (32 + thread #x)

3.) Calculate common address from common offset by adding common base address to common offset.

In the case of non-common address calculation from common address, do as follows:

1.) Calculate common offset from common address by subtracting common base address from common address.

2.) Calculate non-common offset from common offset as follows:

non-common offset = (common offset / 32) for thread ((common offset / 4) % 32)

3.) Calculate non-common address from non-common offset by adding non-common base address to non-common offset.

U32.5.8.1 Non-Common Access to LWM

Some memory areas have two memory regions, one is for non-common area and the other is for common area. The non-common area provides one virtual area on the memory map. Through this area, each thread can access a physical memory “bank” dedicated to each thread. This non-common access is typically used in the case of local working memory.

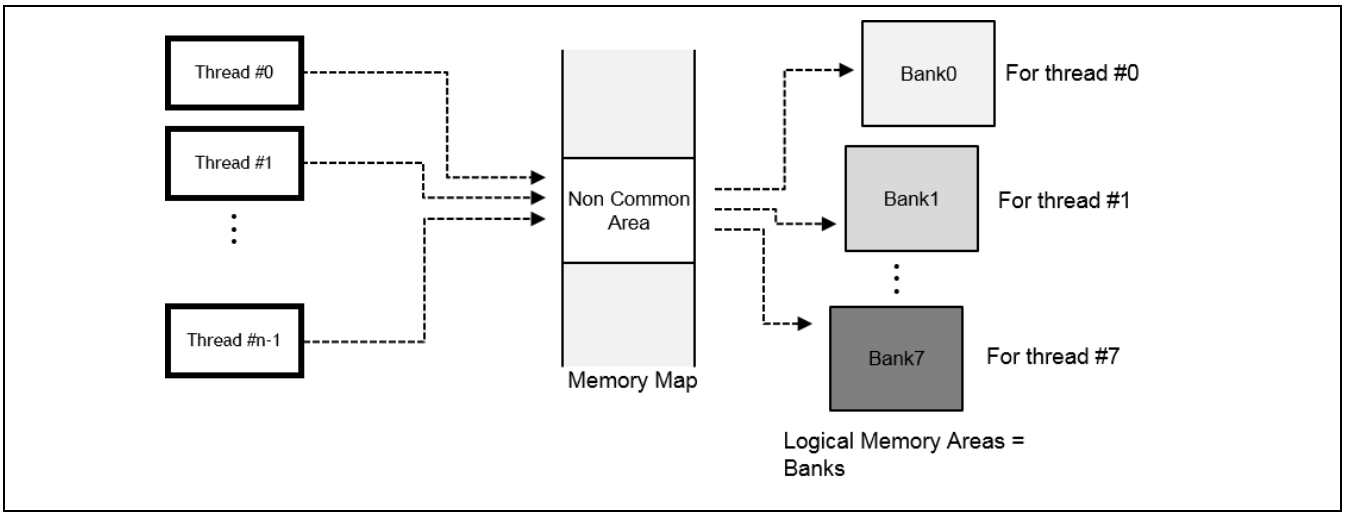

Figure U32.5.4 Non-common Access to LWM

U32.5.8.2 Common Access to LWM

The common access provides capability to access all banks from any thread. For example, through common area, a thread can access the LWM owned by other threads. However, each bank is not mapped on this common area continuously. A bank appears on the common area every 64 byte (8byte × 8threads), because of the 64-bit access instructions to LWM. This 8 byte access is only to LWM. Access to other memories is in 4 bytes. Figure U32.5.5 shows this mapping for LWM case. A thread can access any bank of other threads, but software should have responsible to manage memory consistency among all threads.

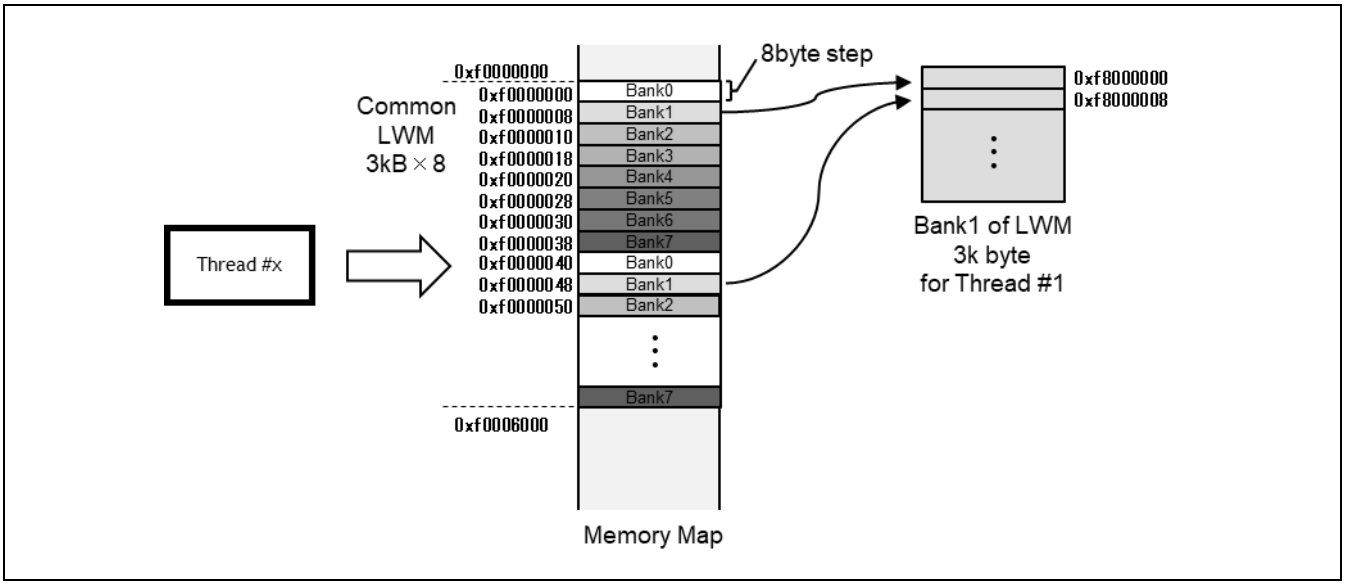

Figure U32.5.5 Common Access to LWM

U32.5.8.3 Access Collision to LWM Common Area

When multiple threads access to the same LWM bank at the same time in common mode, lower prioritized thread stalls until access is ready. The priority is: TGDMAC > thread 0 > thread 1 > … > thread 7. This stall happens for both, reading and writing accesses. For the LWM bank structure in detail, refer to section U32.5.8.2 .

For 8bit, 16bit, 32bit and 64bit LD read accesses to LWM in common mode, a data sharing is implemented so that if multiple threads are reading the same memory address in the same clock cycle, the read data is sent to all these requesting threads. For reading access no stall happens. For writing access stall still happens.

U32.5.8.4 Common and Non-Common Access to GWM

GWM can be also accessed in either common or non-common mode. GWM is designed to be used in common mode access in general, so that threads can share one global memory area. But, if necessary, GWM can be accessed in non-common mode, so that threads can have a slightly larger dedicated memory than only using LWM.

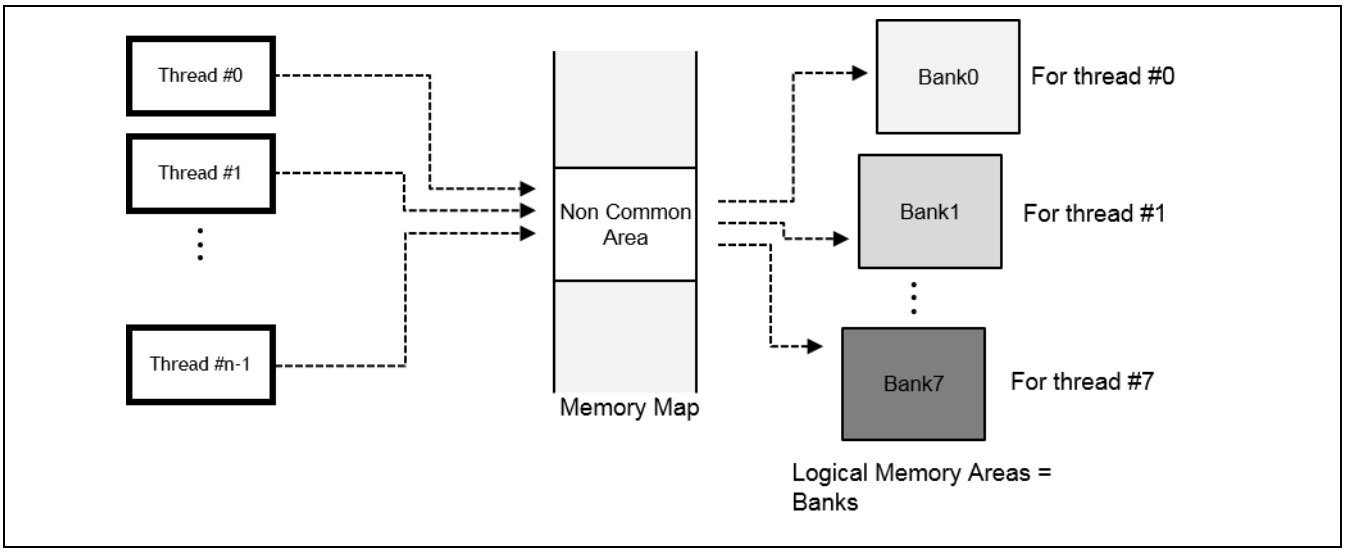

Figure U32.5.6 Non-common Access to GWM

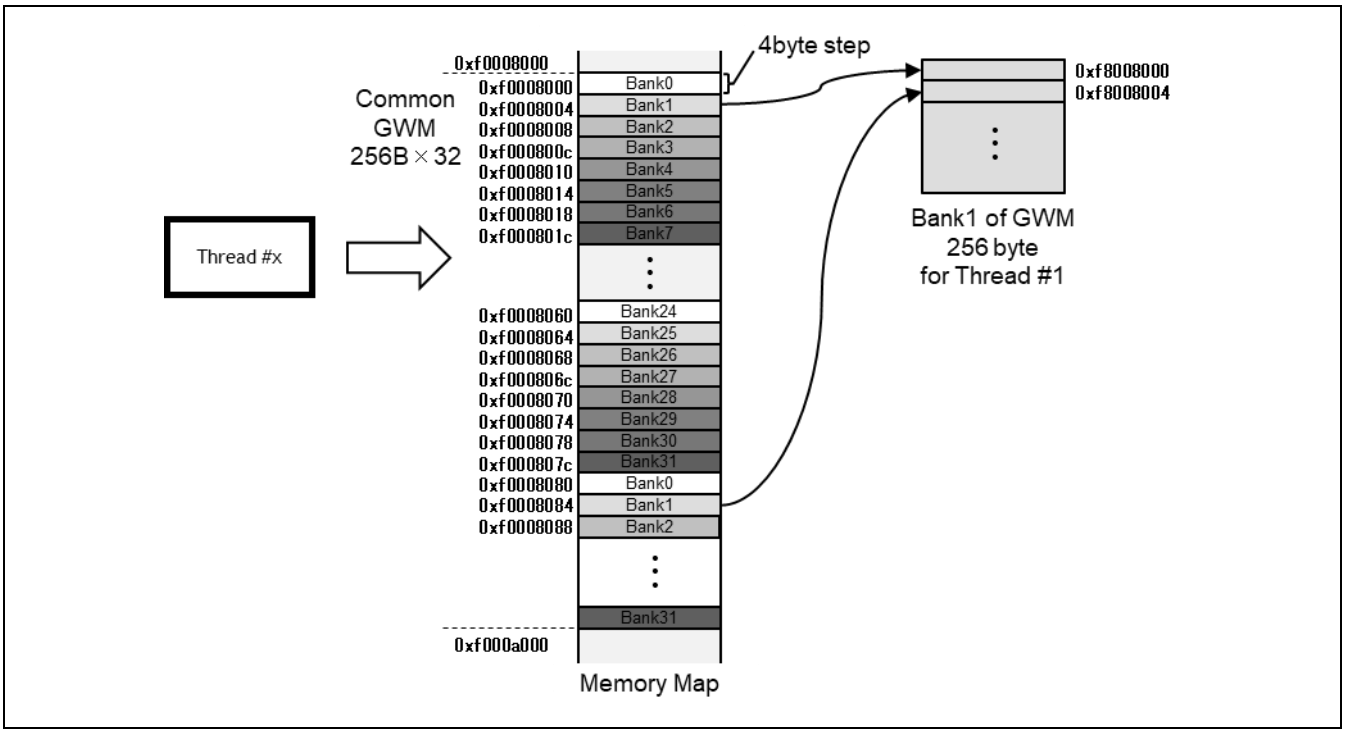

Figure U32.5.7 Common Access to GWM

U32.5.8.5 Common and Non-Common Access to Scratchpad

Scratchpad can be also accessed either in common or non-common mode. Note that Scratchpad memory is shared among clusters even in non-common access mode. Maintain data coherence is user responsibility.

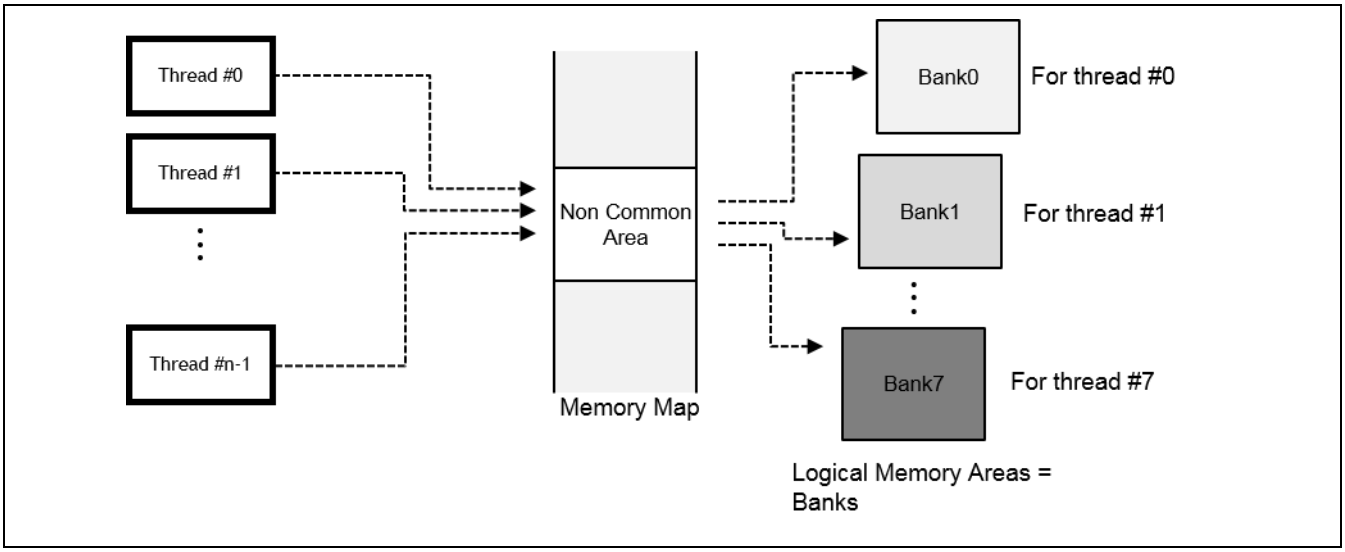

Figure U32.5.8 Non-common Access to Scratchpad

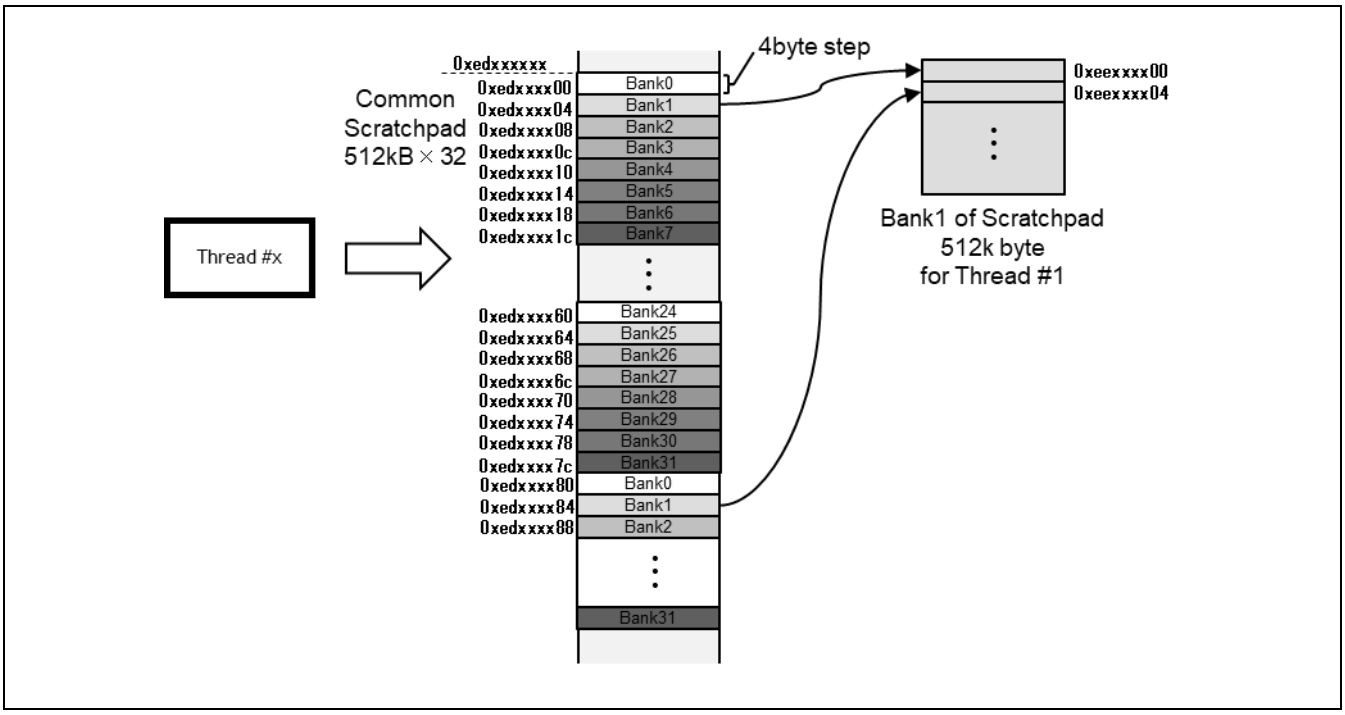

Figure U32.5.9 Common Access to Scratchpad

U32.6 Register Description: CVengine Thread

U32.6.1 List of CVengine Thread Registers

The CVengine thread has 48 registers with 32-bit width. All these registers are read/write able from thread and at the beginning uninitialized, they are not used as control registers but as data registers to hold e.g., temporary processed data from the thread instructions of U32.9 .

Registers are classified into input registers, output registers, address registers, and constant registers, each of which has special features. Also, there is one status register (SR) which has flags that are set to 1 or 0 depending on the results of compare instructions.

R0 and R1	Input registers in which X and Y coordinate information is set
R2	Inter-Thread-Register to pass a value by ACTST from master thread to slave thread
R3	ZERO register, reading this register returns always zero
R4/R5	General purpose registers.
R6	The register is used either to specify an index address for use in access to the uniform storage, or as a general purpose register. For detail, refer to Note 4 in U32.9 .
R7	General purpose register
R8	Register to calculate the sine of the written value / General purpose register
R9	Register to calculate the cosine of the written value / General purpose register
R10	Register to calculate the inverse of square root of the written value / General purpose register
R11	Register to calculate the exponent of the written value with 2 as the base / General purpose register
R12	Register to calculate the logarithm of the written value with 2 as the base / General purpose register
R13	Register to calculate the square root of the written value / General purpose register
R14 and R15	Registers to calculate the reciprocal of the written value. Independent values can be written in these two registers, and the reciprocal operations are executed in pipeline. / General purpose registers
R16 to R47	General purpose registers
SR	Status register, which stores the results of compare instructions

About R8 to R15 registers, refer to Section U32.6.2 for SOU/GP switching. Also refer to section U32.7.2 for exception handlings.

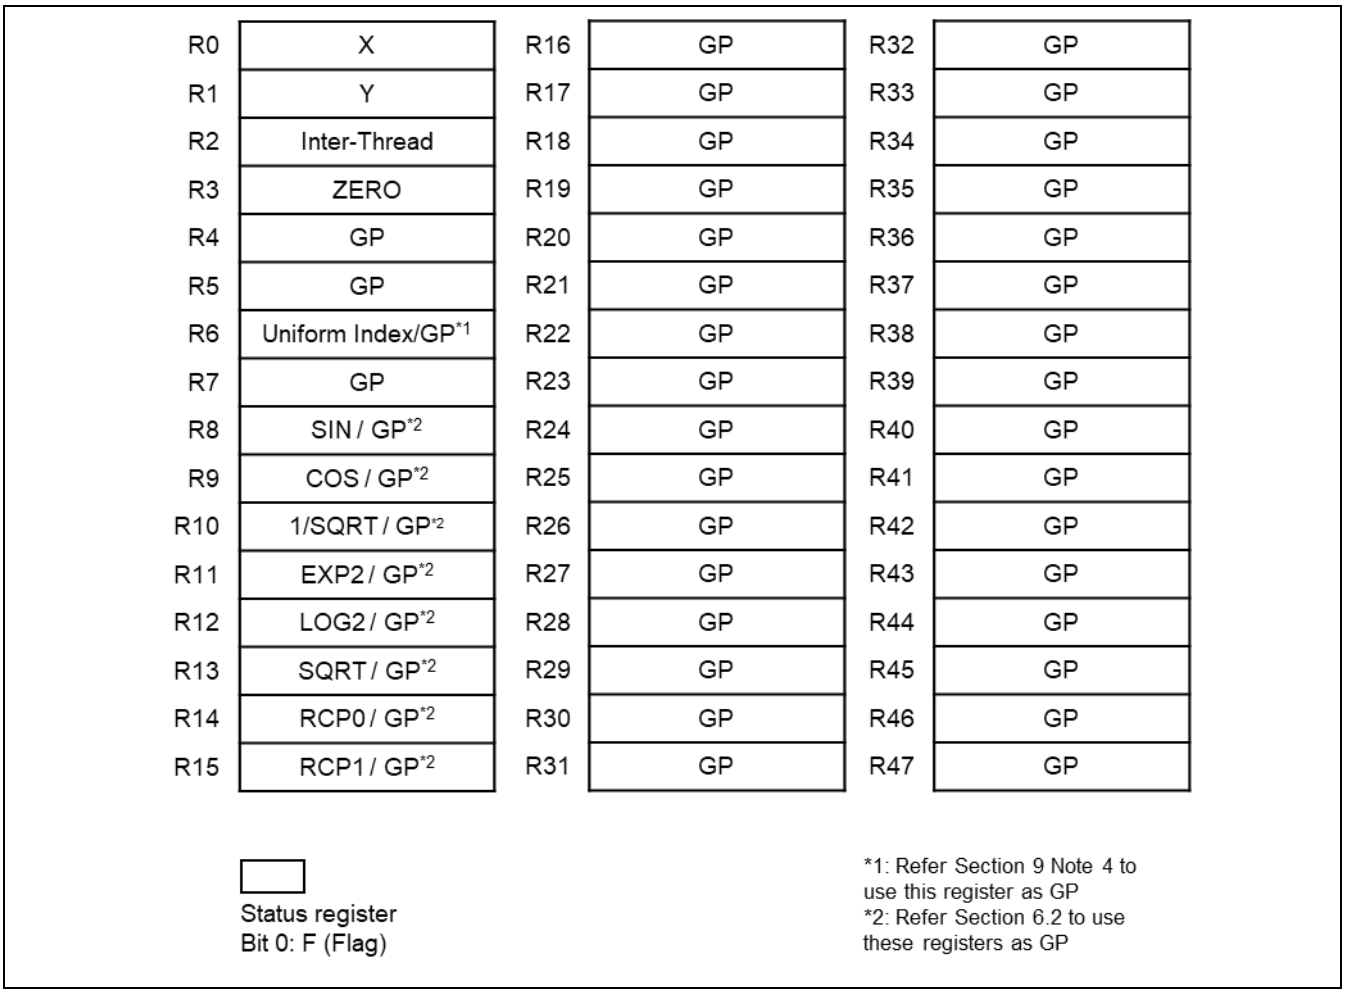

Figure U32.6.1 Register Files of CVengine Thread

The following subsections show details of the CVengine thread registers

U32.6.1.1 Coordinate Input Registers (R0 and R1)

These are 32bit registers to which the coordinates are input. The X coordinate is input to R0, and the Y coordinate is input to R1. These coordinate values are used when the coordinates are output to the SBO port. The coordinate information can be read as well as changed by the thread.

The coordinates to be input are the values of the X and Y coordinates issued by the vertex issue.

U32.6.1.2 Inter-Thread Register (R2)

This register is for a slave thread to receive a 32-bit small information from a master thread. The master thread specifies the register having the value in an operand of ACTST. The slave thread can get the value in its register R2.

Software can use this register as one of general purpose register, if conflict by ACTST writing is managed by software accordingly.

U32.6.1.3 Zero Register (R3)

When CVengine program reads this register, 0 “zero” is always returned. Writing any value to this register is ignored.

U32.6.1.4 Uniform Index Register (R6)

This register is used to specify an index (address offset in word unit) for use in access to uniform storage.

An instruction uses the value obtained by adding the index specified in this register to the address specified in the instruction as the address for access.

The value of this register is automatically cleared to 0 each time a thread is started.

This register can be used as a general purpose register. Refer to Section U32.9 Note 4 for detail.

U32.6.1.5 Sine Operation Register (R8)

This is a register to calculate the sine.

When a value (floating point) is written to this register, input value is multiplied by pi automatically in the hardware, then sine is calculated from the value, namely compute sin(pi*x). Upon completion of operation, the result is written back to this register.

If this register is read from an instruction as a source operand before operation has completed, the thread stalls.

If this register is read before being written, the result is undefined.

This register can be used as a general purpose register. Refer to Section U32.6.2 for detail.

U32.6.1.6 Cosine Operation Register (R9)

This is a register to calculate the cosine.

When a value (floating point) is written to this register, input value is multiplied by pi automatically in the hardware, then cosine is calculated from the value, namely compute cos(pi*x). Upon completion of operation, the result is written back to this register.

If this register is read from an instruction as a source operand before operation has completed, the thread stalls.

If this register is read before being written, the result is undefined.

This register can be used as a general purpose register. Refer to Section U32.6.2 for detail.

U32.6.1.7 Inverse of Square Root Operation Register (R10)

This is a register to calculate the inverse of square root.

When a value (floating point) is written to this register, square root and inverse operation are executed with the value used as an operand. Upon completion of operation, the result is written back to this register. If a negative value is specified as an input, NaN (exponent=0xff, fraction!=0) is returned.

If this register is read from an instruction as a source operand before operation has completed, the thread stalls.

If this register is read before being written, the result is undefined.

This register can be used as a general purpose register. Refer to Section U32.6.2 for detail.

U32.6.1.8 Exponent Operation Register (R11)

This is a register to calculate the exponent with 2 as the base.

When a value (floating point) is written to this register, exponent operation with base 2 is executed with the value used as an operand. Upon completion of operation, the result is written back to this register.

If this register is read from an instruction as a source operand before operation has completed, the thread stalls.

If this register is read before being written, the result is undefined.

This register can be used as a general purpose register. Refer to Section U32.6.2 for detail.

U32.6.1.9 Logarithm Operation Register (R12)

This is a register to calculate the logarithm with 2 as the base.

When a value (floating point) is written to this register, logarithm operation with base 2 is executed with the value used as an operand. Upon completion of operation, the result is written back to this register.

If this register is read from an instruction as a source operand before operation has completed, the thread stalls.

If this register is read before being written, the result is undefined.

This register can be used as a general purpose register. Refer to Section U32.6.2 for detail.

U32.6.1.10Square Root Register (R13)

This is a register to calculate the square root.

When a value (floating point) is written to this register, square root operation is executed with the value used as an operand. Upon completion of operation, the result is written back to this register. If a negative value is specified as an input, NaN (exponent=0xff, fraction≠0) is returned.

If this register is read from an instruction as a source operand before operation has completed, the thread stalls.

If this register is read before being written, the result is undefined.

This register can be used as a general purpose register. Refer to Section U32.6.2 for detail.

U32.6.1.11Reciprocal Operation Registers (R14 and R15)

These are registers to calculate the reciprocal.

When a value (floating point) is written to either of these registers, reciprocal operation is executed with the value used as an operand. Upon completion of operation, the result is written back to that register.

If the register is read from an instruction as a source operand before operation has completed, the thread stalls.

If these registers are read before being written, the result is undefined.

RCP0 (R14) and RCP1 (R15) are both registers to calculate reciprocal in the same manner. Since parallel processing of these registers is possible, the required number of cycles can be hidden by operating them in parallel when two reciprocals are needed.

Rounding mode of the registers is fixed to “Round to the nearest, ties to even”.

These registers can be used as a general purpose register. Refer to Section U32.6.2 for detail.

Note: RCP0 and RCP1 share the same reciprocal arithmetic unit. Therefore, if it is used frequently by multiple threads, contention will occur frequently, and it may not be possible to successfully hide the number of cycles.

U32.6.1.12R4, R5, R7, R16 to R31/R47 and 64-bit Pair Register

These are general-purpose and temporary registers (readable and writable) with 32-bit width. Initial value of these registers is undefined.

In addition, some instructions, which are handling 64-bit width data, utilize two consecutive general purpose registers in little endian, with the lower register being at an even index. For example, "MULLS R16, R30, R31" means lower 32-bit of 64-bit result is stored in R16, and upper 32-bit is stored in R17. And when specify an odd register as 64-bit register, result of execution is not guaranteed. Only R16(R17) to R46(R47) can be used for the 64-bit pair registers.

Further, the new small register block load/store instructions to local work memory LDSRB, STSRB, LDSRBI, STSRBI, LDSRBC and STSRBC have the possibility to access the registers R16 to R23 by specifying R16, R24 to R31 by specifying R24, R32 to R39 by specifying R32 and R40 to R47 by specifying R40, while the new large register block load/store instructions to local work memory LDLRB, STLRB, LDLRBI, STLRBI, LDLRBC and STLRBC have the possibility to access the registers R16 to R31 by specifying R16 and the registers R32 to R47 by specifying R32.

U32.6.1.13Status Register

This register has bits that are set to 0 or 1 by the results of compare instructions. This register is used to determine whether to branch or conditionally execute instructions, for details refer to section U32.9.1 . This register cannot be read as an operand by instructions.

U32.6.2 Control Registers of CVengine Thread

The CVengine thread has control registers (CR) to control operation.

The control registers can be changed by the STC instruction or STCI instruction and read by the LDC instruction.

An integer value has to be set to the control registers.

These registers are initialized only upon a software reset. Refer to section U32.12.1.2 .

CR0	When read, the core number (ID) is read. This register cannot be rewritten.
CR1	When read, the thread number (ID) is read. This register cannot be rewritten.
CR2 to CR7	Reserved. Writing these registers is prohibited.
CR8	This register specifies the data plane number to be read via the D$. The initial value is undefined.
CR9	This register specifies the data plane number to be written via the D$. The initial value is undefined.
CR10	This register specifies the output mask for each element of SBO. Bit 2, bit 1 and bit 0 correspond to R0 (X coordinate), R1 (Y coordinate) and D0 (data) respectively. When each bit is set to 1, the corresponding element is not output. For example, when bit 2 = 0, bit 1 = 1, and bit 0 = 1, only R0 (X coordinate) is output from the SBO port.
CR11	Reserved. Writing this register is prohibited.
CR12	This register holds offset number from thread's own TGDMAC configuration register. When this register holds value m, thread #n accesses TGDMAC configuration register for thread #((n+m)%8), for details refer to section U32.8.3 . User can change the value of this register freely but avoiding resource conflict is user responsibility.
CR13 to CR15	Control registers that have not been implemented. Rewriting these registers is prohibited.
CR16	This register specifies the rounding mode of floating-point operations. The initial value is 0. 0: Round to the nearest, ties to even 1: Round toward zero This setting specifies the behavior of addition or multiplication performed by an instruction and also the behavior of conversion performed by the I2F instruction. When changing value of this register, 4 or more cycles must have passed from the last floating-point operation. Alternatively, insert 4 NOPs to clear pipeline before changing its value.
CR17	This register specifies the rounding mode of conversion between floating-point and integer. The initial value is 1. 0: Round to the nearest, ties to even 1: Round toward zero This setting specifies the behavior of conversion performed by the F2I instruction. When changing value of this register, 4 or more cycles must have passed from the last F2I instruction. Or insert 4 NOPs to clear pipeline before changing its value.
CR18	This register specifies the rounding mode to be used in casting by the FFRC and FFLR instructions. The initial value is 1. Changing the value from the initial value leads to the instruction not operating in the manner of the operating model. Accordingly, do not change the value unless this is essential. 0: Round to the nearest, ties to even 1: Round toward zero When changing value of this register, 4 or more cycles must have passed from the last FFRC or FFLR instruction. Or insert 4 NOPs to clear pipeline before changing its value.

CR19 Writing 1 to bit-n of this register turns Rn to the general purpose register (n=8-15).
Reading this register shows current mode of each of R8 to R15. The default mode is SOU for all the registers.
0: SOU
1: General purpose register
When changing each bit of this register, 4 or more cycles must have passed from the last corresponding SOU operation to the bit. Or the result of SOU operation must be used as an operand of an instruction before changing the corresponding bit. (Because pipeline stalls until result of SOU operation becomes ready.) Or insert 4 NOPs to clear pipeline before changing a bit.

CR20 Writing 1 to bit-n of this register turns Rn to the SOU register (n=8-15).
This register is write-only. Behavior of reading this register is undefined.
When value of this register is changed, corresponding SOU operation must be executed 4 or more cycles after the changing instruction. Or insert 4 NOPs to clear pipeline after changing its value.

U32.7 Operation: Floating-Point

U32.7.1 Floating-Point Data Format

The CVengine thread handles 32-bit floating-point values. The floating-point data format is shown below.

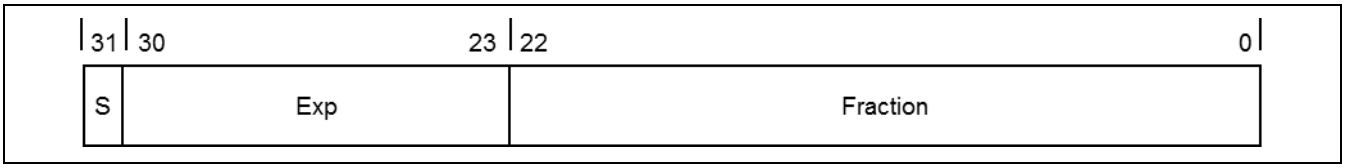

Figure U32.7.1 32-bit Floating-Point Data Format

— S (sign): Indicates the sign.
0: positive value or 0/1: negative value or 0

— Exp (exponent): Indicates the N-th power of 2 as a bias.
H'7F is the 0th power of 2, H'80 is the 1st power of 2, H'7E is the −1st power of 2,
H'FF is infinite and H'00 is 0.

Fraction: Indicates the fraction (a total of 24 bits with an implicit one bit added is regarded as the fraction part).

U32.7.2 IEEE754 Conformance

The CVengine is partially conformant to IEEE754-1985 in floating-point number calculation accuracy.

Table U32.7.1 IEEE754 Conformance

Operation	Bit Accuracy Compliancy to IEEE754, i.e., < 0.5ulp	IEEE754 Compliancy except accuracy, e.g., handling NaN, denormal, exception, etc.
Float to Integer (F2I)	Comply	Comply
Integer to Float (I2F)	Comply	Comply
Addition, Subtraction (FADD, etc.)	Comply	Comply
Multiplication (FMUL, etc.)	Comply	Comply

Sine (R8)	maximum 2^(-23)	Comply
Cosine (R9)	maximum 2^(-23)	Comply
Inverse Square Root (R10)	1ulp	Comply
Exponent (R11)	1ulp	Comply
Logarithm (R12)	maximum 2^(-23)	Comply
Square Root (R13)	1ulp	Comply
Reciprocal (R14, R15)	1ulp	Comply
Comparison (FCMP, etc.)	N/A	Comply

U32.8 Peripheral Functions

U32.8.1 Streaming Buffer Output (SBO)

Executing SBOCRD instructions leads to the writing of an X coordinate, Y coordinate, and value of a specified register to consecutive areas of the main memory via the streaming buffer output (SBO) port. Masking can be specified individually for the output of the X coordinate, Y coordinate, and specified register value. When masking is specified, only unmasked data is written to consecutive areas. The X and Y coordinates to be output are the X and Y coordinates specified in R0 and R1 with the #IMM1 value added to X and the #IMM2 value added to Y and the data format converted into the integer format. The register value is output as the 32-bit bit string without any change.

The CVengine configuration register SBOBAR0 is used to specify the start address of each SBO. The SBOMMSR0 register is used to specify the maximum size of the sum of data output from each SBO port. When the sum of the output data exceeds this setting, data output is stopped, and an interrupt is generated.

Control register CR10 is used to specify whether to mask the output of the X coordinate, Y coordinate, and specified register value. Setting examples and the output results after the SBOCRD instruction is executed for n times are shown in the figure below. The CVengine has multiple threads, and thus data output via the SBO port are in the same order as that in which the SBOCRD instructions are issued. Note that the output of data through the SBO is not in the order of activation of the threads.

Note:

SBO buffer size is 128 bytes. So SBO transmits data in 128-byte long each time. User must maintain the data size to be transmitted via SBO in multiple of 128-byte.

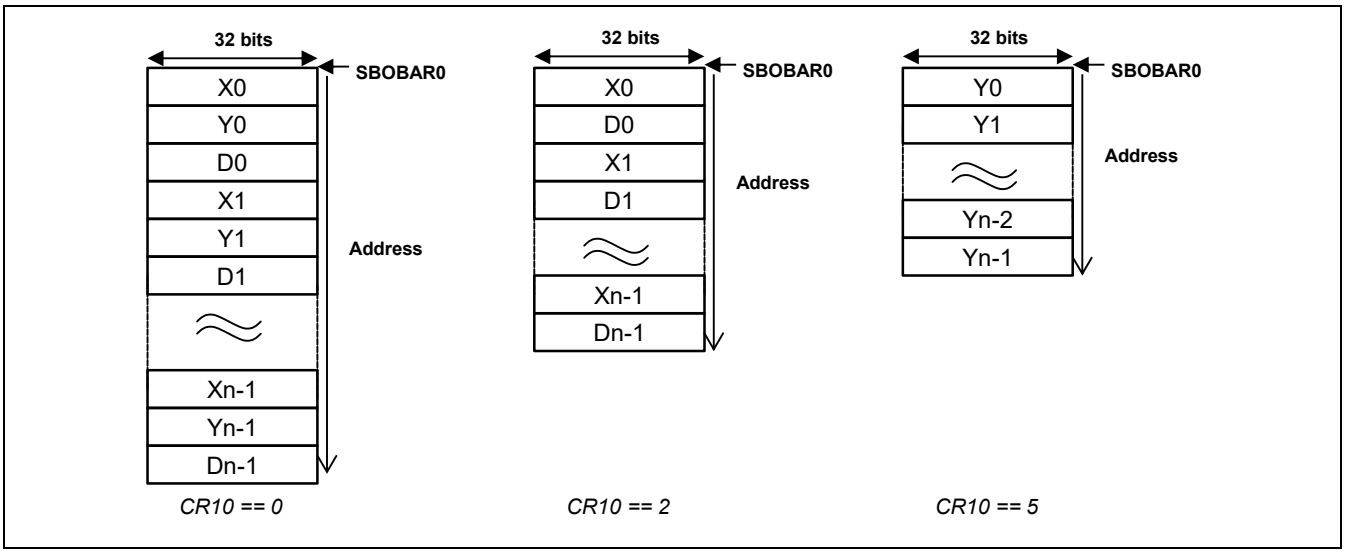

Figure U32.8.1 Examples of Data Format Output from the SBO Port (XYPCK=0)

The X coordinate and Y coordinate output can be controlled by the CVengine configuration registers SBOCR0. When the XYPCK bit is set to 1, the lower 16 bits of the X coordinate and Y coordinate which are used when the XYPCK bit is 0 are packed to form 32 bits, then output as the X and Y coordinates. The order of the X coordinate and Y coordinate can be swapped by changing the PCKMODE bit to 0 or 1. When the XYPCK bit is 1 and no mask is specified, the 32 bits output as the X coordinate and the 32 bits output as the Y coordinate are the same value. Setting examples and the output results with those settings are shown in the figure below.

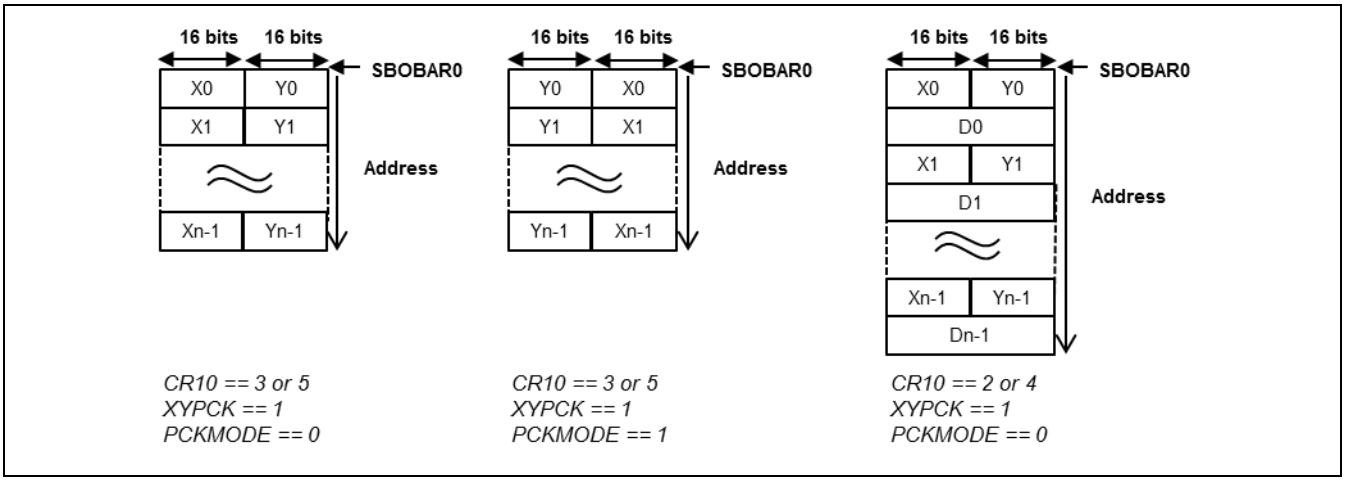

Figure U32.8.2 Examples of X and Y Coordinate Packs Output from the SBO Port

U32.8.2 SOU and SAM

CVengine has some shared logic among threads or cores to consider trade-off between chip size and calculation efficiency. The Shared ArithMetic logic unit (SAM) is implemented for each core, and it is shared by threads belonging to a core. This SAM is further divided in SAM2, SAM4 and SAM8. The SAM8 unit is shared among all 8 threads of a core. The SAM4 unit consists of SAM4E unit and SAM4O unit. The SAM4E is shared among even threads of a core and the SAM4O is shared odd threads. The SAM2 unit consists of SAM2A to SAM2D units. Each SAM2 unit is shared by two threads. The following figure shows how these units are shared by the threads.

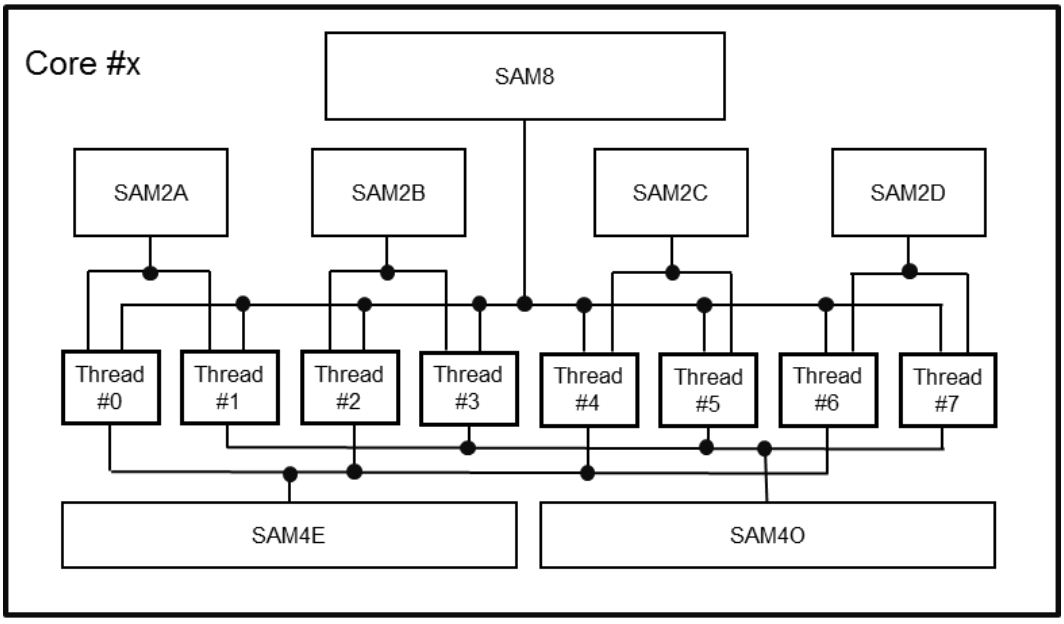

Figure U32.8.3 SAM Sharing among Threads

The instructions using the SAM unit are clarified in the Table U32.10.2.

On the other hand, the shared operation unit (SOU) is implemented for each cluster, and it is shared by all threads in the cluster. The SOU is used through special registers, namely EXP2(R11), LOG2(R12), SQRT(R13), RCP(R14 and R15), 1/SQRT(R10), SIN(R8), COS(R9).

For both SAM and SOU case, the sharing is done by hardware automatically. A thread waits for availability of a SAM/SOU operation if the SAM/SOU operation is already used by another thread.

U32.8.3 DMA

CVengine supports DMA transfer from/to the common memory regions of LWM/GWM to/from the data plane on the external memory by utilizing TGDMAC “Thread Group DMAC” which can be initiated in CVengine program of any master thread. DMA transfer between LWM and GWM is not supported.

The TGDMAC for transfer to/from LWM is named LWM-TGDMAC and it is implemented one in a core. The LWM DMA supports line size units of 32, 64 and 128 bytes to SPMC and 128-byte units to DDR, while on internal side to LWM, 32-byte units are used. The GWM-DMAC is for transfer from/to GWM which is implemented one time in a cluster. It transfers data in 128-byte units to DDR/SPMC and 32-byte units to GWM.

There is one LWM DMA channel per core so there are 4 LWM DMA channels per cluster. Only one DMA channel can transfer data at a time slot.

Each DMA transfer from/to LWM is configured by TGDMAC configuration registers. This bunch of registers is implemented for each thread and mapped on the queue arbiter register area, so a thread can transfer any data with certain configuration. TGDMCR0 specifies transfer direction, data plane and has control bits to start/stop DMA transfer. Offset or X/Y coordinates of transferred data on the data plane are decided by TGDMEXTMEMOFSADDR. The LWM region is specified by TGDMLWMBADDR as a base address and TGDMLWMSTRR as an image stride. TGLNGR is used to indicate lengths for X and Y direction. See chapter U32.12.1 for detail description of each register.

Only master thread can read/write LWM-TGDMAC configuration registers and manage DMA transfer. This means only master thread initiate DMA transfer and issue WAITDMA instruction to wait for completion of transfer. If those DMA operations are done by slave threads, behavior is undefined. When multiple master threads issue DMA transfers, requests are prioritized by an arbiter which has a fair arbitration policy.

Due to the fact that only master threads can initiate a DMA transfer, CVengine has the function that enables master thread to control slave thread’s LWM-TGDMAC. The master thread can also access to the slave threads’ LWM-TGDMAC configuration registers to be able to control up to 8 different DMA transfers. To achieve this, CR12 register and DMAWAITS instruction were added to specify DMA transfer for which slave thread to control. For details, refer to section U32.6.2 and section U32.9 .

To transfer any data from/to GWM, the GWM-DMAC must be used. GWM-DMAC has the same bunch of registers as LWM-TGDMAC, but these registers are implemented in CVengine configuration register area which can be accessed while in processing state by a command list only, while Arm or thread cannot access these registers.

The following is a typical DMA procedure for LWM-TGDMAC and the Figure U32.8.4 is for better understanding of this transfer.

1. Master thread configures DMA through his LWM-TGDMAC configuration registers.
2. Master thread starts DMA transfer by writing 1 to DMACEX bit of TGDMCR0.
3. After starting DMA, the master thread issues WAITDMA instruction, then waits for completion of DMA.

4. After DMA completion, the master thread resumes from WAITDMA, then proceeds next steps like invoking slave threads.

Considering use cases, DMA transfer and thread accessing to LWM should be executed via LWM common area to simplify splitting image area to each thread.

A typical procedure for GWM-DMAC is as follows.

1. Configure GWM-DMAC registers by a command list.
2. A command list starts DMA transfer by writing 1 to DMACEX bit of DMCR0.
3. After starting DMA, the command list issues SYNCS command, then waits for completion of DMA.
4. After DMA completion, the command list resumes from SYNCS, then proceeds next steps like invoking RECT command.

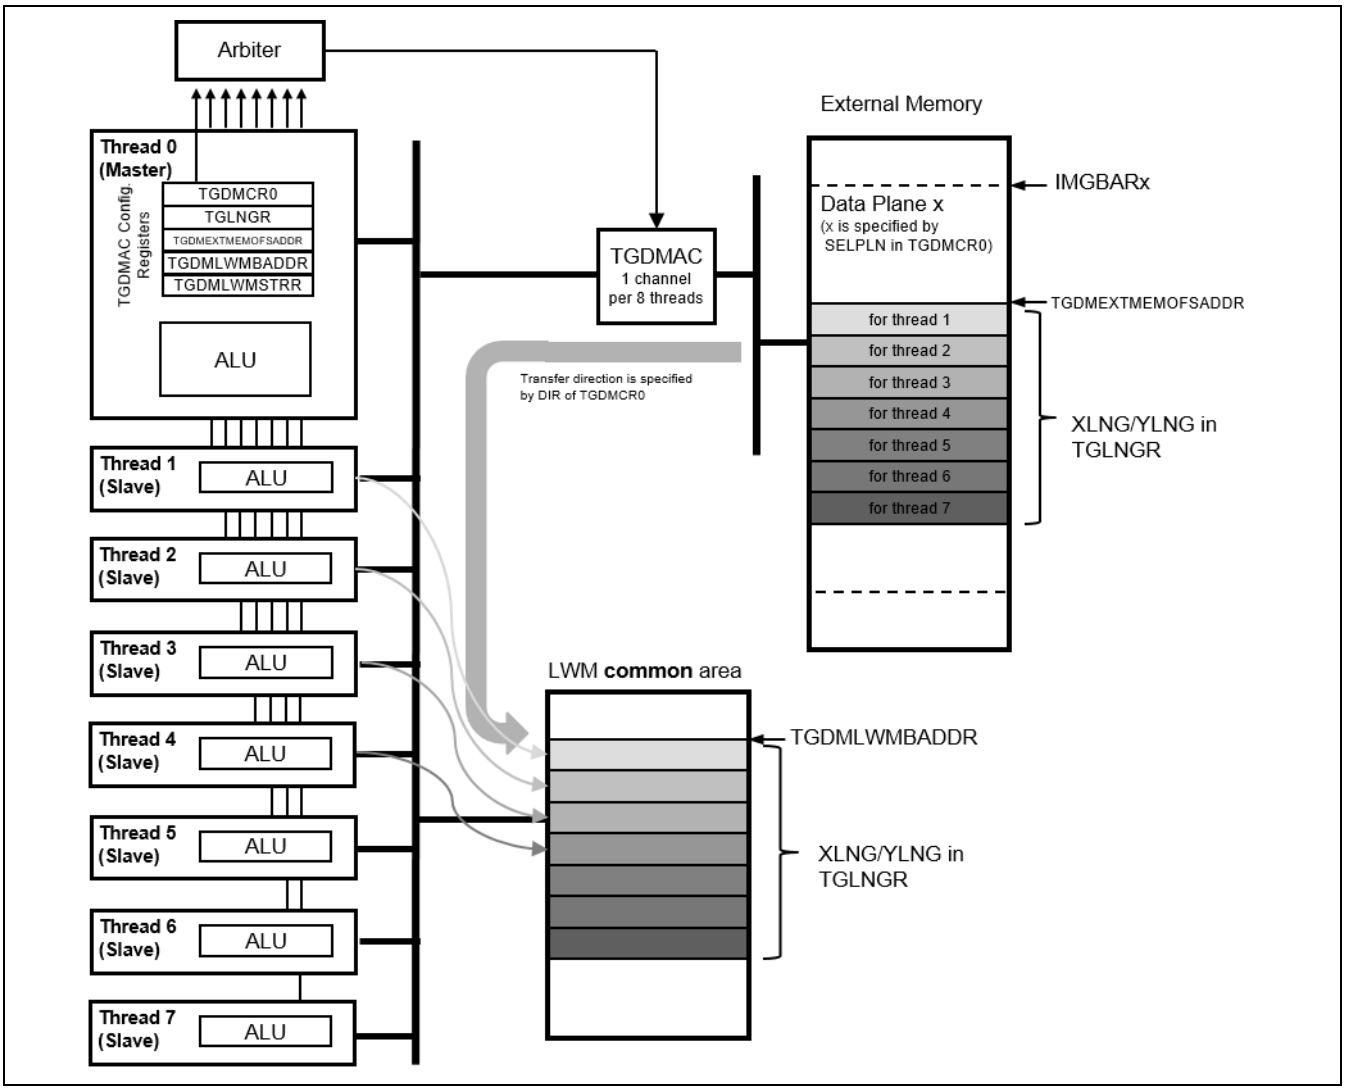

Figure U32.8.4 Data Transfer by TGDMAC between LWM and External DDR Memory

U32.8.4 Debug Support

On the CVengine, a debug resource is available with limitations described below. This debug resource is only available to a dedicated debugger.

1. All clusters have the same debug resources.
2. Only core 0 of each cluster has the debug resource. Other cores do not.
3. Only thread 0 and thread 1 have the debug resource. Other threads do not.
4. The two threads of point 3 are intended for debugging master/slave behavior. Thread 0 can be debugged only as master and thread 1 only as slave.

U32.8.5 Interrupt

Each thread is able to issue an interrupt to the host processor by the INT instruction. After issuing interrupt, the corresponding bit of status register SR2 configuration register is set to 1. The thread completes execution of the current instruction and updates the thread internal program counters with the address of the next instruction to be executed. If the corresponding bit of interrupt control register ICR2 is unmasked, the bit13 of SR1 is set to 1. Finally, the host processor is interrupted if it is not masked by interrupt mask register IMR1.After the host processor received an interrupt, the host can check which thread is interrupted via two status registers SR1 and SR2. The host can resume the interrupted thread by writing 0 to two status clear register SCR1 and SCR2.

See the Figure U32.8.5 for better understanding of this interrupt routing. And some remarks should be described as follows:

Remarks:

- A corresponding bit of SR2 is set to 1 after previous instruction including load/store and SOU calculation is completed.
- If INT instruction and status clearing take place at the same time, the clearing is prioritized.
- Clearing SR1 does not affect SR2, i.e., the interrupt is retained.
- DMA operation is not affected by the INT instruction, as it works independently. Software must take care data synchronization transferred by DMA.
- The thread internal program counters are for debugging purpose only. Refer to section U32.8.4 .

This interrupt and its handshake with the host processor have detrimental effects on performance and seamless thread processing. Therefore, this INT should be used for debugging purpose only.

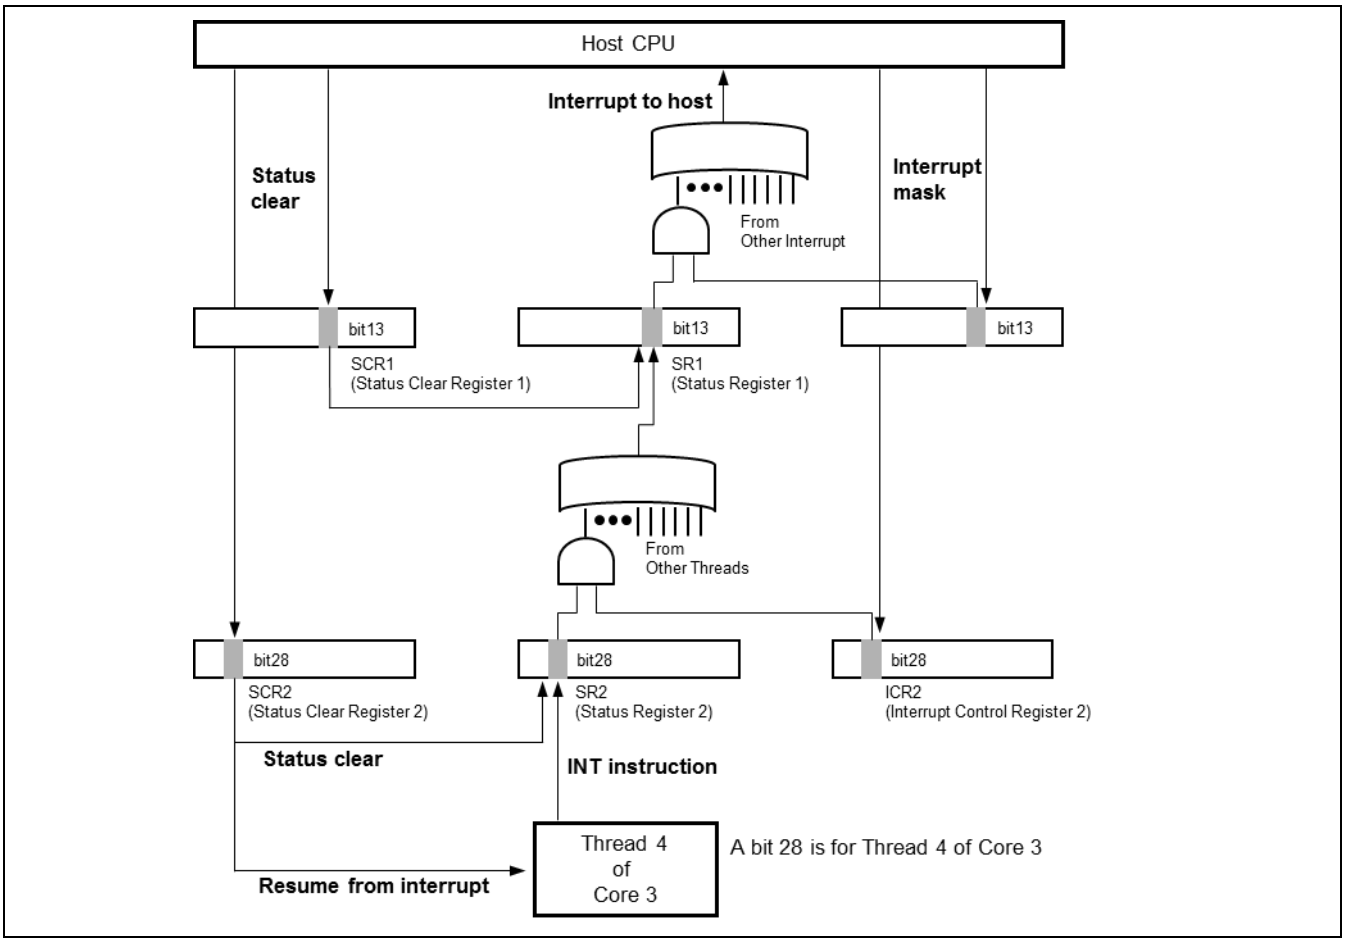

Figure U32.8.5 Interrupt from Thread to Host

U32.8.6 Performance Counter

There are two kinds of hardware counters ready to measure performance.

One kind is a hardware counter is available in a cluster to measure performance of the cluster. It counts the clock cycles while CVengine is active (while CL is running). This counter can be enabled or disabled by the settings of configuration registers, SPCR and SPBSYCNTR. This counter does not take care for overflow. Refer to sections U32.12.1.19 and U32.12.1.20 for the details of the configuration registers for this counter.

The other kind is to measure performance of each thread. This counter can count stalled cycles of a thread. To use this counter, corresponding configuration registers must be set before invocation of CVengine. The configuration registers TGCR0, USPFCCTLR and PFCTOTALR0 are available for this counter. Refer to sections U32.12.1.14 , U32.12.1.50 and U32.12.1.51 . By checking the overflow bit, this counter can detect whether overflow happened or not. This counter can count only one thread in a cluster per execution.

Note:

Counter values are just for your information. These counters could be useful to improve software performance in some cases, but any relationship between counter values and actual processing time is not guaranteed. Also, any detailed condition of counting will not be opened.

U32.8.7 Image Clipping

CVengine supports the image clipping feature. This feature allows user to clip the entire image into some necessary parts of the image to process. Refer to Figure U32.8.6.

To clip the image, CLPMINR and CLPMAXR configuration registers of the CVengine are used. Refer to section U32.12.1.17 and section U32.12.1.18 .

To enable this image clipping feature, set 1 to the clip bit in POINT/POINTS/RECT command. Refer to section U32.13.1 , section U32.13.2 and section U32.13.3 .

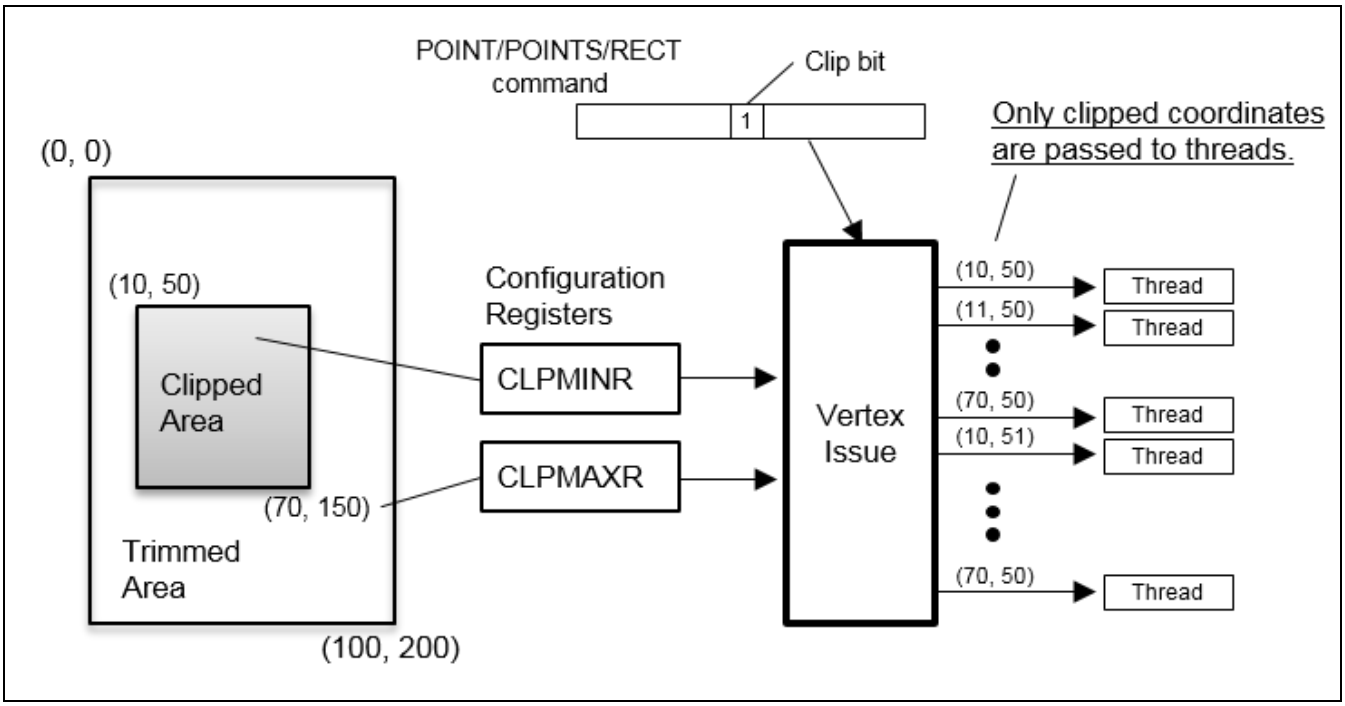

Figure U32.8.6 Image Clipping Feature

U32.8.8 Guard Timer

The guard timer function is to check if CVengine processing time exceeds expected time. The guard timer is an additional function of the performance counter. Refer to section U32.8.6 .

To show the processing time has exceeded the threshold, this function can set two types of flags, SR1.PBCOVF and SR1.INT. SR1.PBCOVF flag is automatically set at the moment when SPBSYCNTR exceeds SPBCTHRR while threads are running. To utilize SR1.INT flag, an INT command with INT_PBCOVF bit enabled is needed after a CVengine operation command (e.g., RECT) in the Command List. When the INT command in Command List is executed, and if INT.INT_PBCOVF and SR1.PBCOVF are both 1, SR1.INT flag is set so that the execution of command list is halted, and the host CPU can recognize an overflow interrupt has happened. Thus, the host CPU can take some action for the processing time overflow like rewriting commands in the Command List. When the INT command in Command List is executed, and if INT.INT_PBCOVF is set to 1 but SR1.PBCOVF is 0, so no overflow happened, then instead of the INT a NOP is executed.

When SCR1.PBCOVFCLR is set to 1, SR1.PBCOVF and SPBSYCNTR are both cleared. Figure U32.8.7shows flowchart of this function. Also refer to section U32.12.1.5 , U32.12.1.6 , U32.12.1.21 and U32.13.7 .

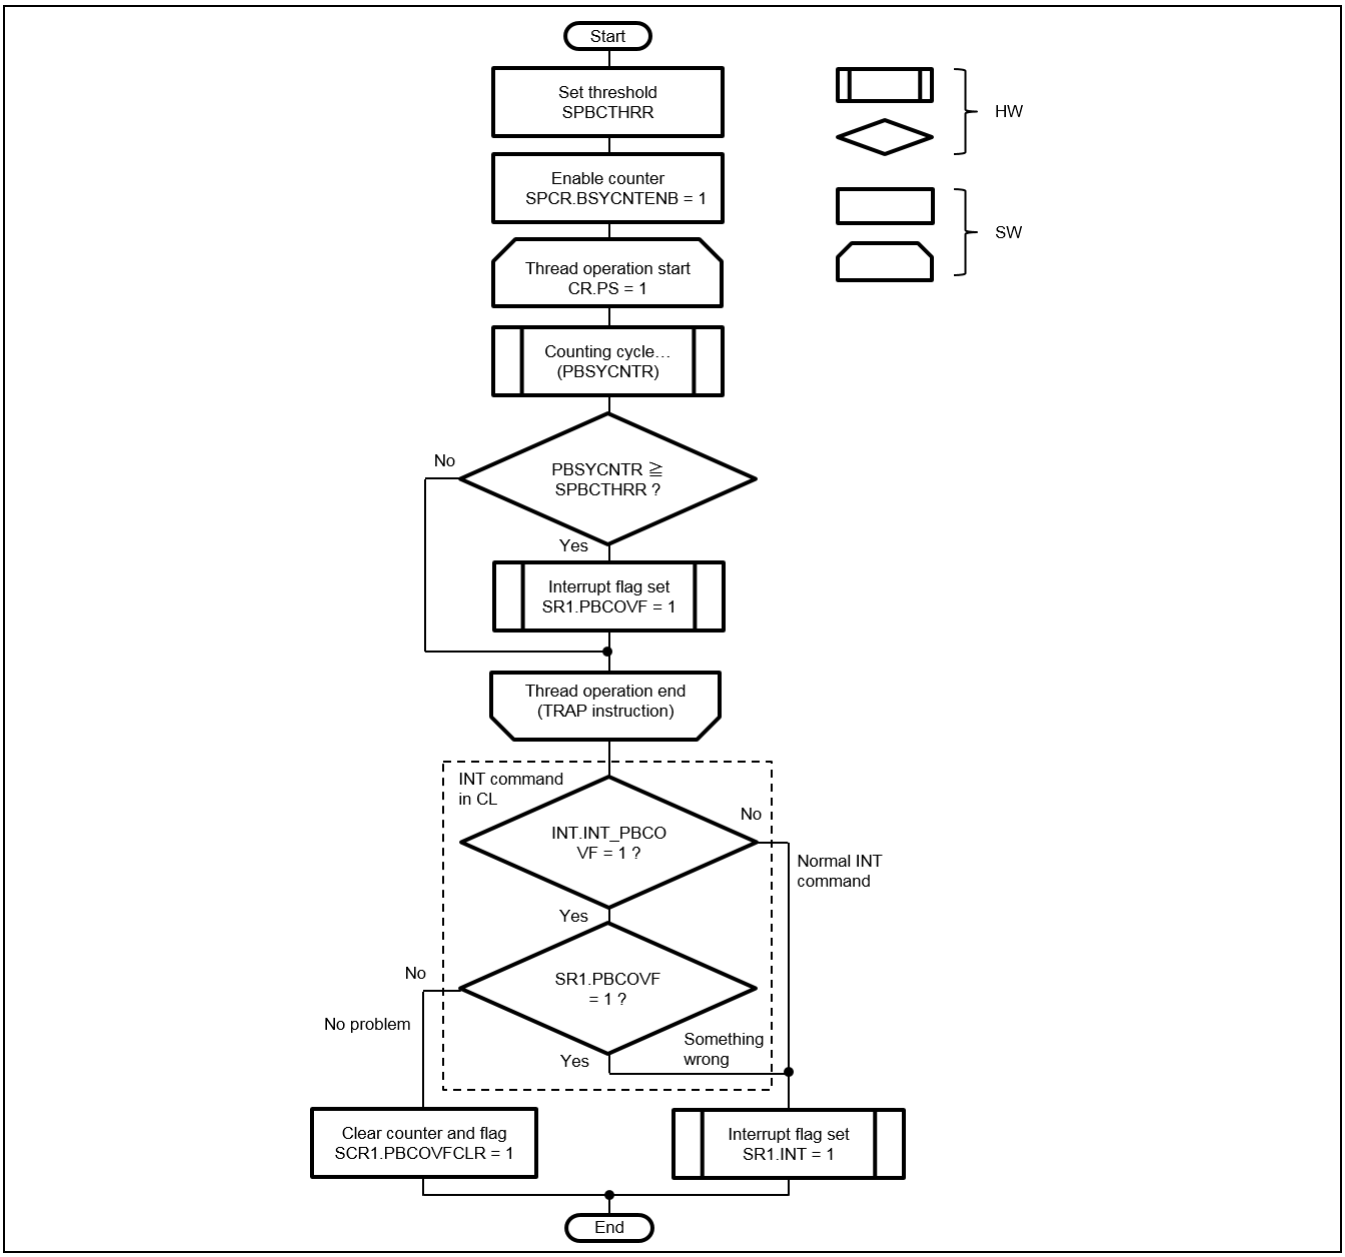

Figure U32.8.7 Guard Timer Flow Chart

Figure U32.8.8 shows a use case of the Guard Timer. In this case IMR1.PBCOVFMSK is set to 1 so the interrupt during RECT command, SR1.PBCOVF is masked. When counter value exceeds threshold value at the end of the 1st RECT command, the INT command in CL signals the CPU that a processing time overflow happened. So, the host CPU alters the threshold value set by WPR command in CL to the new value.

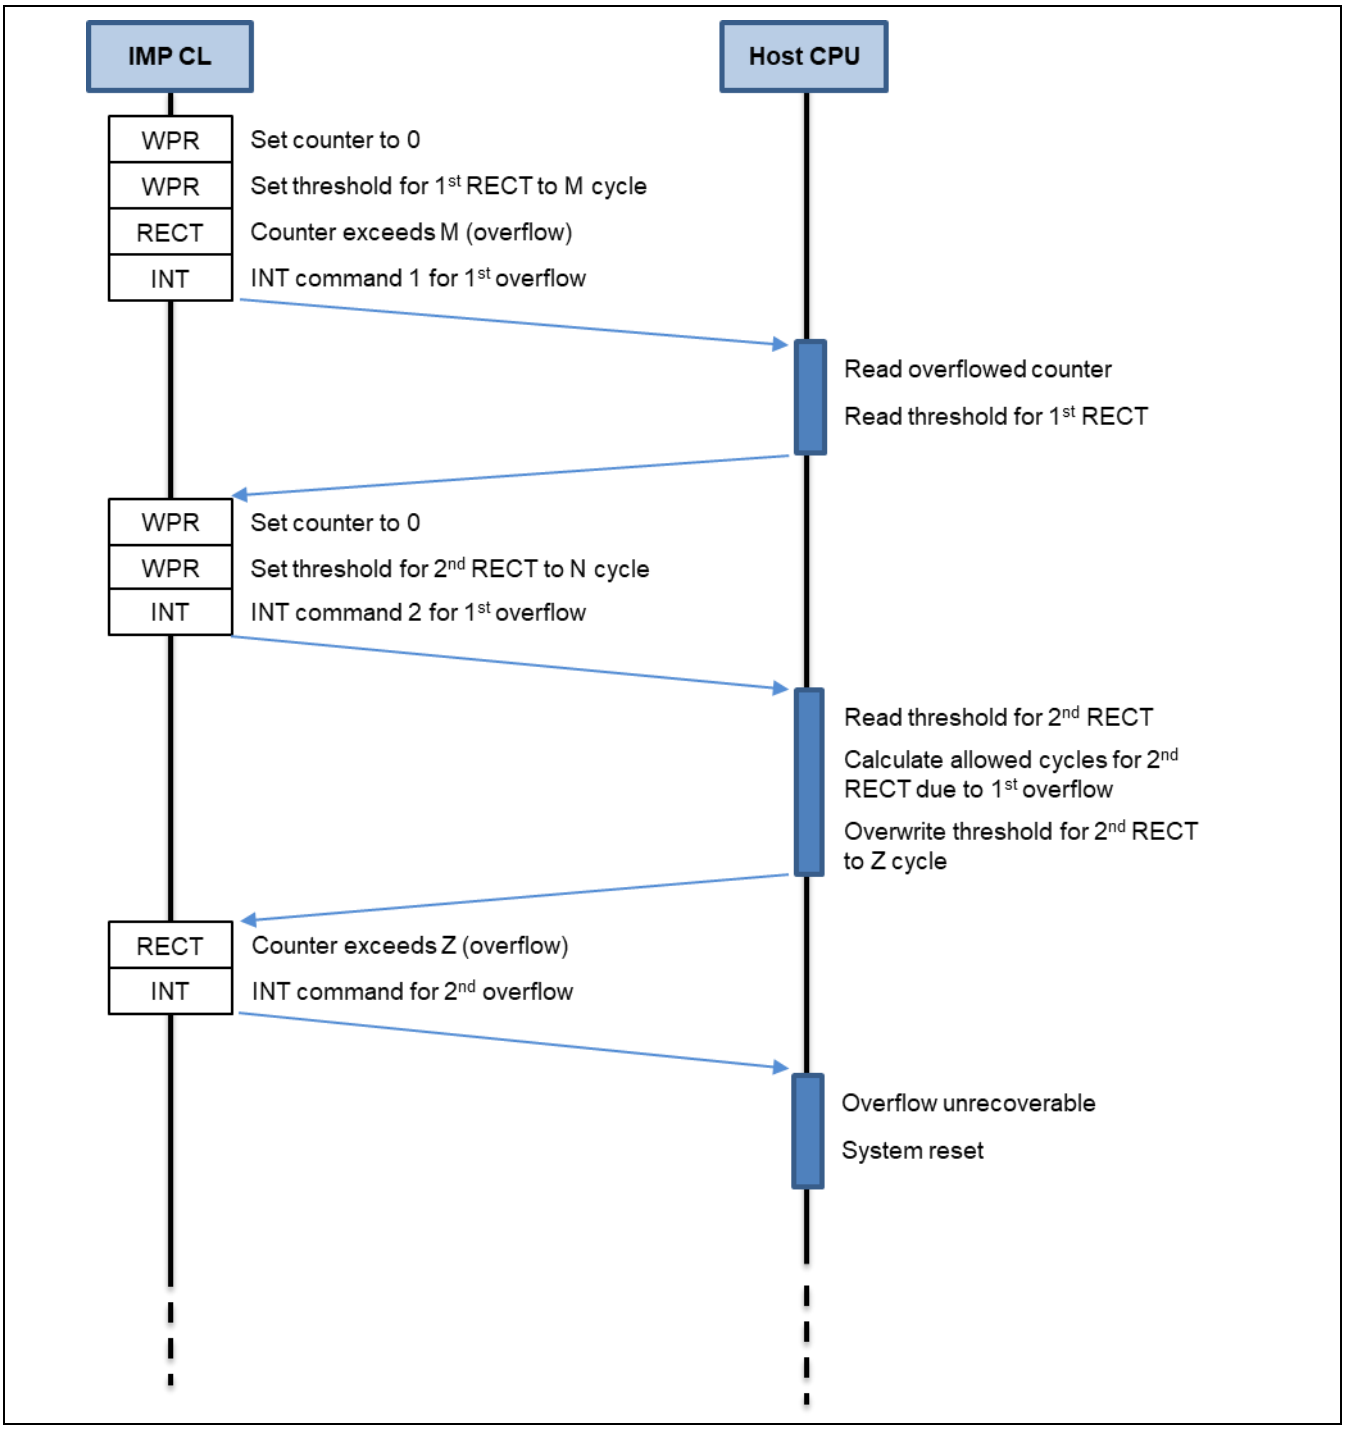

Figure U32.8.8 Guard Timer Use Case

U32.8.9 Data Cache Bypassing

Data cache bypassing area can be set with configuration registers DCBYPA0MIN and DCBYPA0MAX. The default values of the registers are 0xFFFFFFFF and 0x00000000 respectively, so no bypassing area is set. Only 4-byte access is supported for D$ bypassing. This feature can be enabled and disabled for each thread with DCBYPEN register. Refer to sections U32.12.1.22 , U32.12.1.23 , and U32.12.1.24 .

Additionally, store data replacement feature is implemented. When both DCBYPEN and DCBYPCTRL are enabled for a thread, upper 16 bits of writing data with bypassing D$ by the thread are replaced with Core# (bits 24 and 25) and Thread# (bits 16 till 18), which can be utilized for debugging purpose.

The D$ bypassing function is available for reading and writing data of all threads in a cluster, but it is recommended to use only thread 0 of each core, total 4 threads in a cluster to prevent large performance degradation. Only Arm and Command List can change the values of the configuration registers for this function. When changing the register values from CL, insert SYNCM just before it.

Through the D$ bypassing, registers for IMP Core, IMP DMAC, PSC, CNN and CoreSight can be accessed from a thread. Also registers for CVengine clusters can be accessed, except for the cluster to which the thread belongs. Scratchpad cannot be accessed via D$ bypassing.

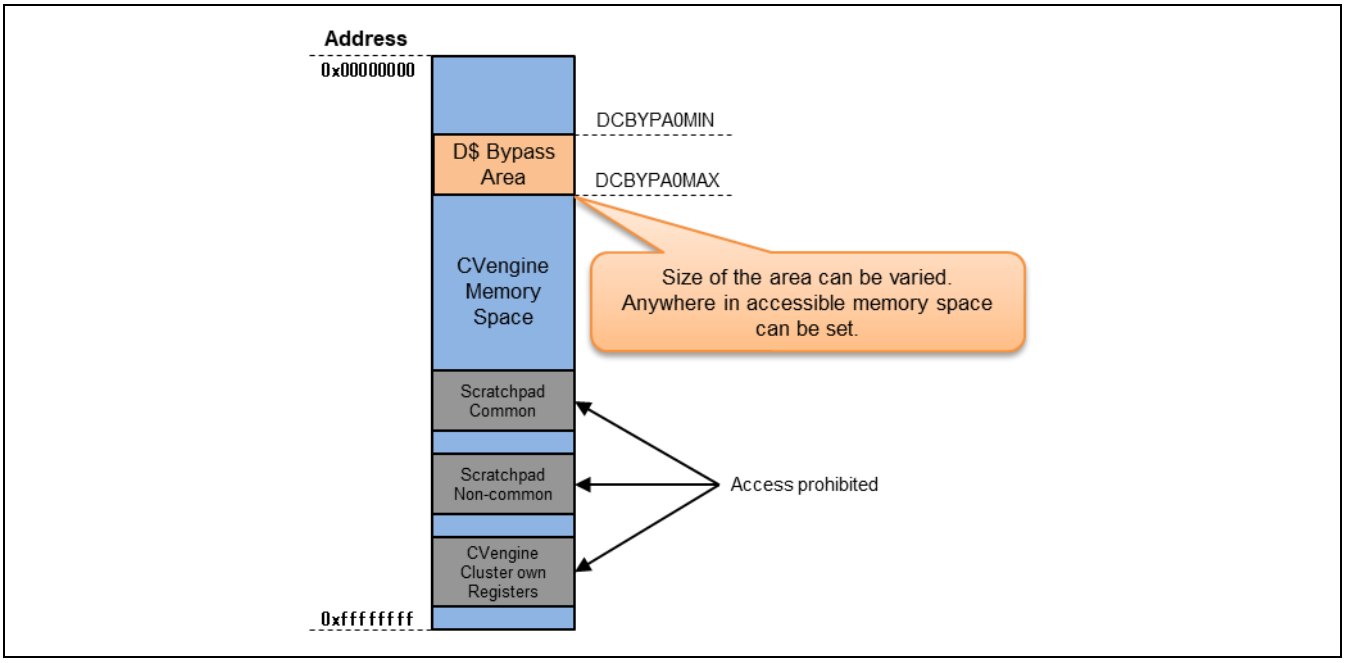

Figure U32.8.9 Data Cache Bypassing Area

U32.9 Instruction Set

The CVengine thread instructions are classified into the following three types of instructions.

(1) Flow control instructions
- Branch instructions
- Compare instructions to generate the branch conditions
- Instructions to control the stop of program execution

(2) Data transfer instructions

(3) Operation instructions

All of the instructions can be executed conditionally with the condition of the status register value being 0 or 1.

Note 1:

Division instructions are not implemented in the CVengine threads of the CVengine.

Note 2:
#ASMIMM is the immediate description for the CVengine Assembler. This #ASMIMM is interpreted by the assembler and is translated to #IMM which is the immediate used in an actual instruction code defined in Section U32.10.1 .
The translation from #ASMIMM to #IMM is defined instruction-by-instruction in the following description.

Note 3:

For 8-bit and 16-bit group instructions such as GADDxx, GMADxx, GSADxx or GSUBxx, s0 and s1 are treated as 64-bit pair registers. Refer to Section U32.6.1.12 . A pair register contains 4 16-bit data or 8 8-bit data as a data array. For 16-bit group instructions, S0[0] means S0(n)[15:0] and S0[3] means S0(n+1)[31:16]. For 8-bit group instructions, S0[0] means S0(n)[7:0] and S0[7] means S0(n+1)[31:24].

Note 4:

R6 register can be used either as offset base for Uniform storage immediate value indexing, or as a general purpose register. Refer to section U32.10.1 about the R6 bit of instruction format. To use R6 as the offset base with the CVengine Assembler, add '$' mark to the 3rd operand for the RU type instructions. See the examples below.

ADDU R16, R17, 1 → R16 = R17 + Uniform[1];
ADDU R16, R17, $1 → R16 = R17 + Uniform[R6+1];

#R6IMM is used at behavior model in the description of the RU type instructions. If R6 is used as the offset base, the value of #R6IMM is R6 + #IMM. If R6 is used as a general purpose register, the value of #R6IMM is equal to #IMM.

#IMM: 7-bit signed integer
R6: 8-bit signed integer

If the value of R6 + #IMM exceeds the area of uniform storage, result is undefined.

U32.9.1 Conditional instruction execution

For all instructions, it is possible to control the execution/non-execution of the instruction by referencing the status register SR. By writing "SR" at the end of an operand, the instruction is executed if the status register is true, and the instruction is regarded as the NOP instruction if the status register is false. By writing "!SR" at the end of an operand, the instruction is executed if the status register is false, and the instruction is regarded as the NOP instruction if the status register is true.

Examples:

```
CMP.EQ   R3,   R16,   R17
ADD      R20,  R21,   R22,   SR      # When R16 == R17, execute ADD.
SUB      R20,  R21,   R22,   !SR     # When R16 != R17, execute SUB.
```

ABS	ABSolute
Usage	ABS D0, S0
Function	Stores the absolute value of S0 in D0. The value of S0 is handled as an integer in the operation.
Behavior model	D0 = |(int)S0|;

ABS8	ABSolute 8-bit values
Usage	ABS8 D0, S0
Function	This is an instruction to get the absolute value from 8 signed 8-bit input values from source S0.
Behavior model	D0[n] = ABS(S0[n]), n = 0...7;
Operand type	D0: 8 times 8-bit unsigned integer S0: 8 times 8-bit signed integer

ABS16	ABSolute 16-bit values
Usage	ABS16 D0, S0
Function	This is an instruction to get the absolute value from 4 signed 16-bit input values from source S0.
Behavior model	D0[n] = ABS(S0[n]), n = 0...3;
Operand type	D0: 4 times 16-bit unsigned integer S0: 4 times 16-bit signed integer

ACTST	ACTivate Shader Thread
Usage	ACTST S0
Function	Master thread activates slave thread. Which slave is going to be activated is determined by the queue arbiter. The values of R0 and R1 are sent as the X and Y coordinates. In addition, the register value specified by S0 is sent to R2 of the slave thread. This instruction must not be executed by the slave thread and must not be executed by threads started by the SINI CL command .
Behavior model	-
Operand type	S0: -(32-bit array)

ADD	ADD
Usage	ADD D0, S0, S1
Function	Adds S0 and S1, then stores the result in D0. S0 and S1 are handled as integers in the operation.
Behavior model	D0 = (int)S0 + (int)S1;

ADDS	ADD with Saturation
Usage	ADDS D0, S0, S1
Function	This is an instruction to add 2 signed 32-bit values from source S0 and source S1 with saturation. Mapped on Thread.
Behavior model	D0 = SAT(S0 + S1, 32);
Operand type	D0: 32-bit signed integer S0: 32-bit signed integer S1: 32-bit signed integer

ADDSS8	**ADD Signed with Saturation 8-bit values**
Usage	ADDSS8 D0, S0, S1
Function	This is an instruction to add 8 times 2 signed 8-bit values from source S0 and source S1 with saturation.
Behavior model	D0[n] = SAT(S0[n] + S1[n], 8), n = 0...7;
Operand type	D0: 8 times 8-bit signed integer S0: 8 times 8-bit signed integer S1: 8 times 8-bit signed integer

ADDSS16	**ADD Signed with Saturation 16-bit values**
Usage	ADDSS16 D0, S0, S1
Function	This is an instruction to add 4 times 2 signed 16-bit values from source S0 and source S1 with saturation.
Behavior model	D0[n] = SAT(S0[n] + S1[n], 16), n = 0...3;
Operand type	D0: 4 times 16-bit signed integer S0: 4 times 16-bit signed integer S1: 4 times 16-bit signed integer

ADDSU	**ADD with Saturation signed Uniform value**
Usage	ADDSU D0, S0, #IMM
Function	This is an instruction to add 2 signed 32-bit values from source S0 and Uniform value indexed by #IMM with saturation. Mapped on Thread.
Behavior model	D0 = SAT(S0 + Uniform[#R6IMM], 32);
Operand type	D0: 32-bit signed integer S0: 32-bit signed integer

ADDSI	**ADD with Saturation signed Immediate value**
Usage	ADDSI D0, S0, #IMM
Function	This is an instruction to add a signed 32-bit values from source S0 and the immediate 8-bit value #IMM with saturation. Mapped on Thread.
Behavior model	D0 = SAT(S0 + #IMM, 32);
Operand type	D0: 32-bit signed integer S0: 32-bit signed integer #IMM: 8-bit signed integer

ADDDBL	ADD DouBL
Usage	ADDDBL D0, S0, S1
Function	This instruction treats S0 as two 32-bit integers, upper and lower, and S1 as two 15bit integers, upper and lower. And adds those integers respectively. Then stores the result to D0. Typical use case of this instruction is to increment two pointers in a loop with one instruction. D0 and S0 are 64-bit pair registers, always the lower even register is specified, which holds the lower 32-bit. S1 is a 32-bit register.
Behavior model	D0[63:32] = {S0[63:48], (16-bit unsign extended(S0[46:32])+16-bit unsign extended(S1[30:16]))} D0[31:0] = {S0[31:16], (16-bit unsign extended(S0[14:0])+16-bit unsign extended(S1[14:0]))}
Operand type	D0: Concatenated two 32-bit unsigned integers S0: Concatenated two 32-bit unsigned integers. S1: Concatenated two 15-bit unsigned integers (16-bit aligned)

ADDDBLU	ADD DouBL with Uniform
Usage	ADDDBLU D0, S0, #IMM
Function	This instruction treats S0 as two 32-bit integers, upper and lower, and the uniform value indexed by #IMM as two 15bit integers, upper and lower. And adds those integers respectively. Then stores the result to D0. Typical use case of this instruction is to increment two pointers in a loop with one instruction. D0 and S0 are 64-bit pair registers, always the lower even register is specified, which holds the lower 32-bit. S1 is a 32-bit register.
Behavior model	D0[63:32] = {S0[63:48], (16-bit unsign extended(S0[46:32]) + 16-bit unsign extended(Uniform[#R6IMM][30:16]))}; D0[31:0] = {S0[31:16], (16-bit unsign extended(S0[14:0]) + 16-bit unsign extended(Uniform[#R6IMM][14:0]))};
Operand type	D0: Concatenated two 32-bit unsigned integers S0: Concatenated two 32-bit unsigned integers Uniform: Concatenated two 15-bit unsigned integers (16-bit aligned)

ADDI	ADD to Immediate value
Usage	ADDI D0, S0, #IMM
Function	Adds S0 and #IMM, then stores the result in D0. S0 and #IMM are handled as integers in the operation.
Behavior model	D0 = (int)S0 + (char)#IMM;

ADDU	ADD to Uniform
Usage	ADDU D0, S0, #IMM
Function	Adds S0 and the uniform value indexed by #IMM, then stores the result in D0. S0 is handled as an integer in the operation.
Behavior model	D0 = S0 + (int)Uniform[#R6IMM];

ADDUS8	ADD Unsigned with Saturation 8-bit values
Usage	ADDUS8 D0, S0, S1
Function	This is an instruction to add 8 times 2 unsigned 8-bit values from source S0 and source S1 with saturation.
Behavior model	D0[n] = SAT(S0[n] + S1[n], 8), n = 0...7;
Operand type	D0: 8 times 8-bit unsigned integer S0: 8 times 8-bit unsigned integer S1: 8 times 8-bit unsigned integer

ADDUS16	ADD Unsigned with Saturation 16-bit values
Usage	ADDUS16 D0, S0, S1
Function	This is an instruction to add 4 times 2 unsigned 16-bit values from source S0 and source S1 with saturation.
Behavior model	D0[n] = SAT(S0[n] + S1[n], 16), n = 0...3;
Operand type	D0: 4 times 16-bit unsigned integer S0: 4 times 16-bit unsigned integer S1: 4 times 16-bit unsigned integer

AND	AND
Usage	AND D0, S0, S1
Function	Performs the logical AND operation between S0 and S1, then stores the result in D0.
Behavior model	D0 = S0 & S1;

AND64	AND 64-bit values
Usage	AND64 D0, S0, S1
Function	This is an instruction to AND 2 64-bit (8 times 8-bit or 4 times 16-bit) values.
Behavior model	D0[n] = S0[n] AND S1[n], n = 0...63;
Operand type	D0: 64-bit integer S0: 64-bit integer S1: 64-bit integer

ANDU	AND with Uniform
Usage	ANDU D0, S0, #IMM
Function	Performs the logical AND operation between S0 and the uniform value indexed by #IMM, then stores the result in D0.
Behavior model	D0 = S0 & Uniform[#R6IMM];

ASM	Add and Sub, then each Multiplied
Usage	ASM D0, S0, S1
Function	This instruction is assumed to be used in Haar Wavelet or FFT butterfly. D0, S0, S1 has 64-bit width which is concatenated by two 32-bit signed integers. Calculate summation and subtraction between higher 32-bit and lower 32-bit of S0. Then each summation and subtraction are multiplied by higher 32-bit and lower 32-bit of S1 respectively. Finally, these two values are concatenated into 64-bit width D0. Hardware does not take care any overflow handlings, so software must take care of it.

Behavior model	D0[63:32] = (S0[63:32] + S0[31:0]) * S1[63:32]; // Each 32-bit is “signed”.
	D0[31:0] = (S0[63:32] - S0[31:0]) * S1[31:0]; // Each 32-bit is “signed”.

Operand type	D0: Concatenated two 32-bit signed integers S0: Concatenated two 32-bit signed integers S1: Concatenated two 32-bit signed integers

ASMU	Add and Sub, then each Multiplied by Uniform
Usage	ASMU D0, S0, #IMM
Function	This instruction is assumed to be used in Haar Wavelet or FFT butterfly. D0, S0 has 64-bit width which is concatenated by two 32-bit signed integers. Calculate summation and subtraction between higher 32-bit and lower 32-bit of S0. Then each summation and subtraction are multiplied by a constant in uniform value indexed by #IMM. Finally, there two values are concatenated into 64-bit width D0. Hardware does not take care any overflow handlings, so software must take care of it.
Behavior model	D0[63:32] = (S0[63:32] + S0[31:0]) * Uniform[#R6IMM]; D0[31:0] = (S0[63:32] - S0[31:0]) * Uniform[#R6IMM];
Operand type	D0: Concatenated two 32-bit signed integers S0: Concatenated two 32-bit signed integers Uniform: 32-bit signed integer

BRA	BRAnch
Usage	BRA #LABEL
Function	Branches to #LABEL.
Behavior model	PC=#LABEL;
Operand type	#LABEL: 16-bit unsigned integer

BRAR	BRAnch (Register)
Usage	BRAR S0
Function	Branches to the register value specified by S0. The 16 lower-order bits of S0 are handled as an unsigned integer.
Behavior model	PC= (ushort)(S0&0xffff);
Operand type	S0: 16-bit unsigned integer

BRCID	BRanch based on Core ID
Usage	BRCID #IMM
Function	Jump to new PC which is defined as the sum of by 1 incremented old PC address and the product of the own core ID times the specified 8-bit signed immediate value. The address is a word address.
Behavior model	PC=PC+(core ID * #IMM)+1;

BRTID	**BRanch based on Thread ID**
Usage	BRTID #IMM
Function	Jump to new PC which is defined as the sum of by 1 incremented old PC address and the product of the own thread ID times the specified 8-bit signed immediate value. The address is a word address.
Behavior model	PC=PC+(thread ID * #IMM)+1;

BTST	**Bit TeST**
Usage	BTST D0, S0, S1
Function	This instruction copies the S1th bit from S0 to D0, in case D0 is R3, SR is set with this bit. Mapped on each Thread.
Behavior model	D0 = (S0 >> S1) & 1
Operand type	D0: 1bit integer S0: 32-bit integer S1: 5bit unsigned integer

BTSTU	**Bit TeST with S0th bit from UNI[#IMM]**
Usage	BTSTU D0, S0, #IMM
Function	This instruction copies the S0th bit from UNI[#IMM] to D0, in case D0 is R3, SR is set with this bit. Mapped on each Thread.
Behavior model	D0 = (UNI[#IMM] >> S0) & 1
Operand type	D0: 1bit integer S0: 5bit unsigned integer #IMM: 6bit unsigned integer

BTSTI	**Bit TeST with Immediate bit selection**
Usage	BTSTI D0, S0, #IMM
Function	This instruction copies the #IMMth bit from S0 to D0, in case D0 is R3, SR is set with this bit. Mapped on each Thread.
Behavior model	D0 = (S0 >> #IMM) & 1
Operand type	D0: 1bit integer S0: 32-bit integer #IMM: 5bit unsigned integer

CALL	**sub routine CALL**
Usage	CALL D0, #LABEL
Function	PC+1 is saved to D0, and branch to #LABEL.
Behavior model	D0 = (PC+1); PC=#LABEL;

CALLA	**sub routine CALL Alternative**
Usage	CALLA D0, #LABEL
Function	Saves PC+1 to the temporary-storage PC register specified by D0 and branches to #LABEL. Although this temporary-storage PC register is not described in the list of registers, but it is implicitly implemented. The register to be specified by D0 is not the general-purpose register number, but the CALLA/RETA dedicated temporary-storage PC register number. There are eight registers for this purpose and 0 to 7 can be specified. The 3 lower-order bits of D0 are handled as an unsigned integer. For example, to save the return address to the 3rd PC register, let D0 to have the value 3 before CALLA instruction.
Behavior model	PCR[(D0&0x7)]=PC+1; PC=#LABEL;
Operand type	D0: 3-bit unsigned integer #LABEL: 16-bit unsigned integer

CALLR	**sub routine CALL(Register)**
Usage	CALLR D0, S0
Function	PC+1 is saved to D0, and branch to the PC specified by S0.
Behavior model	D0 = (PC+1); PC=S0;

CMP.EQ	**EQual**
Usage	CMP.EQ D0, S0, S1
Function	D0 == R3 (zero register): If S0 is equal to S1, sets the SR.F bit to 1, otherwise sets it to 0. D0 != R3 (zero register): If S0 is equal to S1, D0 is set to 1, else it is set to 0. In this case, SR.F is not updated. Both operands S0 and S1 are handled as 32-bit signed integers in the comparison.
Behavior model	SR.F = (S0 == S1); (D0 == R3) D0 = (S0 == S1); (D0 != R3)
Operand type	S0: 32-bit signed integer S1: 32-bit signed integer

CMP.EQ8	**CoMPare EQual 8-bit values**
Usage	CMP.EQ8 D0, S0, S1
Function	This is an instruction to compare (equal) 8 8-bit values with 8 8-bit value. The result of the nth compare is stored in the nth byte of D0.
Behavior model	D0[n] = S0[n] == S1[n], n = 0...7;
Operand type	D0: 8 times 8-bit unsigned integer, only lowest bit in each byte used S0: 8 times 8-bit integer S1: 8 times 8-bit integer

CMP.EQ16	CoMPare EQual 16-bit values
Usage	CMP.EQ16 D0, S0, S1
Function	This is an instruction to compare (equal) 4 16-bit values with 4 16-bit value. The result of the nth compare is stored in the nth 16-bit word of D0.
Behavior model	D0[n] = S0[n] == S1[n], n = 0...3;
Operand type	D0: 4 times 16-bit unsigned integer, only lowest bit in each 16-bit word used S0: 4 times 16-bit integer S1: 4 times 16-bit integer

CMP.NEQ	Not EQual
Usage	CMP.NEQ D0, S0, S1
Function	D0 == R3 (zero register): If S0 is not equal to S1, sets the SR.F bit to 1, otherwise sets it to 0. D0 != R3 (zero register): If S0 is not equal to S1, D0 is set to 1, else it is set to 0. In this case, SR.F is not updated. Both operands S0 and S1 are handled as 32-bit signed integers in the comparison.
Behavior model	SR.F = (S0 != S1); (D0 == R3) D0 = (S0 != S1); (D0 != R3)
Operand type	S0: 32-bit signed integer S1: 32-bit signed integer

CMP.NEQ8	CoMPare Not EQual 8-bit values
Usage	CMP.NEQ8 D0, S0, S1
Function	This is an instruction to compare (not equal) 8 8-bit values with 8 8-bit value. The result of the nth compare is stored in the nth byte of D0.
Behavior model	D0[n] = S0[n] != S1[n] , n = 0...7;
Operand type	D0: 8 times 8-bit unsigned integer, only lowest bit in each byte used S0: 8 times 8-bit integer S1: 8 times 8-bit integer

CMP.NEQ16	CoMPare Not EQual 16-bit values
Usage	CMP.NEQ16 D0, S0, S1
Function	This is an instruction to compare (not equal) 4 16-bit values with 4 16-bit value. The result of the nth compare is stored in the nth 16-bit word of D0.
Behavior model	D0[n] = S0[n] != S1[n], n = 0...3;
Operand type	D0: 4 times 16-bit unsigned integer, only lowest bit in each 16-bit word used S0: 4 times 16-bit integer S1: 4 times 16-bit integer

CMP.SGE	Greater than or Equal
Usage	CMP.SGE D0, S0, S1
Function	D0 == R3 (zero register): If S0 is greater than or equal to S1, sets the SR.F bit to 1, otherwise sets it to 0. D0 != R3 (zero register): If S0 is greater than or equal to S1, D0 is set to 1, else it is set to 0. In this case, SR.F is not updated. Both operands S0 and S1 are handled as 32-bit signed integers in the comparison.
Behavior model	SR.F = (S0 >= S1); (D0 == R3) D0 = (S0 >= S1); (D0 != R3)
Operand type	S0: 32-bit signed integer S1: 32-bit signed integer

CMP.SGT	Greater Than
Usage	CMP.SGT D0, S0, S1
Function	D0 == R3 (zero register): If S0 is greater than S1, sets the SR.F bit to 1, otherwise sets it to 0. D0 != R3 (zero register): If S0 is greater than S1, D0 is set to 1, else it is set to 0. In this case, SR.F is not updated. Both operands S0 and S1 are handled as 32-bit signed integers in the comparison.
Behavior model	SR.F = (S0 > S1); (D0 == R3) D0 = (S0 > S1); (D0 != R3)
Operand type	S0: 32-bit signed integer S1: 32-bit signed integer

CMP.SLE	Less than or Equal
Usage	CMP.SLE D0, S0, S1
Function	D0 == R3 (zero register): If S0 is smaller than or equal to S1, sets the SR.F bit to 1, otherwise sets it to 0. D0 != R3 (zero register): If S0 is smaller than or equal to S1, D0 is set to 1, else it is set to 0. In this case, SR.F is not updated. Both operands are handled as 32-bit signed integers in the comparison.
Behavior model	SR.F = (S0 <= S1); (D0 == R3) D0 = (S0 <= S1); (D0 != R3)
Operand type	S0: 32-bit signed integer S1: 32-bit signed integer

CMP.SLE8	CoMPare Signed Less than or Equal 8-bit values
Usage	CMP.SLE8 D0, S0, S1
Function	This is an instruction to compare (lower or equal than) 8 signed 8-bit values with 8 signed 8-bit value. The result of the nth compare is stored in the nth byte of D0. Implemented in SAM4.
Behavior model	D0[n] = S0[n] <= S1[n] , n = 0...7;
Operand type	D0: 8 times 8-bit unsigned integer, only lowest bit in each byte used S0: 8 times 8-bit signed integer S1: 8 times 8-bit signed integer

CMP.SLE16	CoMPare Signed Less than or Equal 16-bit values
Usage	CMP.SLE16 D0, S0, S1
Function	This is an instruction to compare (lower or equal than) 4 signed 16-bit values with 4 signed 16-bit value. The result of the nth compare is stored in the nth 16-bit word of D0.
Behavior model	D0[n] = S0[n] <= S1[n] , n = 0...3;
Operand type	D0: 4 times 16-bit unsigned integer, only lowest bit in each 16-bit word used S0: 4 times 16-bit signed integer S1: 4 times 16-bit signed integer

CMP.SLT	Less than
Usage	CMP.SLT D0, S0, S1
Function	D0 == R3 (zero register): If S0 is smaller than S1, sets the SR.F bit to 1, otherwise sets it to 0. D0 != R3 (zero register): If S0 is smaller than S1, D0 is set to 1, else it is set to 0. In this case, SR.F is not updated. Both operands are handled as 32-bit signed integers in the comparison.
Behavior model	SR.F = (S0 < S1); (D0 == R3) D0 = (S0 < S1); (D0 != R3)
Operand type	S0: 32-bit signed integer S1: 32-bit signed integer

CMP.SLT8	CoMPare Signed Less than 8-bit values
Usage	CMP.SLT8 D0, S0, S1
Function	This is an instruction to compare (lower than) 8 signed 8-bit values with 8 signed 8-bit value. The result of the nth compare is stored in the nth byte of D0.
Behavior model	D0[n] = S0[n] < S1[n] , n = 0...7;
Operand type	D0: 8 times 8-bit unsigned integer, only lowest bit in each byte used S0: 8 times 8-bit signed integer S1: 8 times 8-bit signed integer

CMP.SLT16	CoMPare Signed Less than 16-bit values
Usage	CMP.SLT16 D0, S0, S1
Function	This is an instruction to compare (lower than) 4 signed 16-bit values with 4 signed 16-bit value. The result of the nth compare is stored in the nth 16-bit word of D0.
Behavior model	D0[n] = S0[n] < S1[n] , n = 0...3;
Operand type	D0: 4 times 16-bit unsigned integer, only lowest bit in each 16-bit word used S0: 4 times 16-bit signed integer S1: 4 times 16-bit signed integer

CMP.ULE8	CoMPare Unsigned Less than or Equal 8-bit values
Usage	CMP.ULE8 D0, S0, S1
Function	This is an instruction to compare (lower or equal than) 8 unsigned 8-bit values with 8 unsigned 8-bit value. The result of the nth compare is stored in the nth byte of D0.
Behavior model	D0[n] = S0[n] <= S1[n] , n = 0...7;
Operand type	D0: 8 times 8-bit unsigned integer, only lowest bit in each byte used S0: 8 times 8-bit unsigned integer S1: 8 times 8-bit unsigned integer

CMP.ULE16	CoMPare Unsigned Less than or Equal 16-bit values
Usage	CMP.ULE16 D0, S0, S1
Function	This is an instruction to compare (lower or equal than) 4 unsigned 16-bit values with 4 unsigned 16-bit value. The result of the nth compare is stored in the nth 16-bit word of D0.
Behavior model	D0[n] = S0[n] <= S1[n] , n = 0...3;
Operand type	D0: 4 times 16-bit unsigned integer, only lowest bit in each 16-bit word used S0: 4 times 16-bit unsigned integer S1: 4 times 16-bit unsigned integer

CMP.ULT8	CoMPare Unsigned Less than 8-bit values
Usage	CMP.ULT8 D0, S0, S1
Function	This is an instruction to compare (lower than) 8 unsigned 8-bit values with 8 unsigned 8-bit value. The result of the nth compare is stored in the nth byte of D0.
Behavior model	D0[n] = S0[n] < S1[n] , n = 0...7;
Operand type	D0: 8 times 8-bit unsigned integer, only lowest bit in each byte used S0: 8 times 8-bit unsigned integer S1: 8 times 8-bit unsigned integer

CMP.ULT16	CoMPare Unsigned Less than 16-bit values
Usage	CMP.ULT16 D0, S0, S1
Function	This is an instruction to compare (lower than) 4 unsigned 16-bit values with 4 unsigned 16-bit value. The result of the nth compare is stored in the nth 16-bit word of D0.
Behavior model	D0[n] = S0[n] < S1[n] , n = 0...3;
Operand type	D0: 4 times 16-bit unsigned integer, only lowest bit in each 16-bit word used S0: 4 times 16-bit unsigned integer S1: 4 times 16-bit unsigned integer

CMPU.EQ	EQual to Uniform
Usage	CMPU.EQ D0, S0, #IMM
Function	D0 == R3 (zero register): If S0 is equal to the uniform value indexed by #IMM, sets the SR.F bit to 1, otherwise sets it to 0. D0 != R3 (zero register): If S0 is equal to the uniform value indexed by #IMM, D0 is set to 1, else it is set to 0. In this case, SR.F is not updated. Both operands are handled as signed integers in the comparison.
Behavior model	SR.F = (S0 == Uniform[#R6IMM]); (D0 == R3) D0 = (S0 == Uniform[#R6IMM]); (D0 != R3)
Operand type	S0: 32-bit signed integer R6: 8-bit unsigned integer Uniform: 32-bit signed integer

CMPU.NEQ	Not EQual to Uniform
Usage	CMPU.NEQ D0, S0, #IMM
Function	D0 == R3 (zero register): If S0 is not equal to the uniform value indexed by #IMM, sets the SR.F bit to 1, otherwise sets it to 0. D0 != R3 (zero register): If S0 is not equal to the uniform value indexed by #IMM, D0 is set to 1, else it is set to 0. In this case, SR.F is not updated. Both operands are handled as signed integers in the comparison.
Behavior model	SR.F = (S0 != Uniform [#R6IMM]); (D0 == R3) D0 = (S0 != Uniform [#R6IMM]); (D0 != R3)
Operand type	S0: 32-bit signed integer R6: 8-bit unsigned integer Uniform: 32-bit signed integer

CMPU.SGE	Greater than or Equal to Uniform
Usage	CMPU.SGE D0, S0, #IMM
Function	D0 == R3 (zero register): If S0 is greater than or equal to the uniform value indexed by #IMM, sets the SR.F bit to 1, otherwise sets it to 0. D0 != R3 (zero register): If S0 is greater than or equal to the uniform value indexed by #IMM, D0 is set to 1, else it is set to 0. In this case, SR.F is not updated. Both operands are handled as signed integers in the comparison.
Behavior model	SR.F = (S0 >= Uniform[#R6IMM]); (D0 == R3) D0 = (S0 >= Uniform[#R6IMM]); (D0 != R3)
Operand type	S0: 32-bit signed integer R6: 8-bit unsigned integer Uniform: 32-bit signed integer

CMPU.SGT	Greater Than to Uniform
Usage	CMPU.SGT D0, S0, #IMM
Function	D0 == R3 (zero register): If S0 is greater than the uniform value indexed by #IMM, sets the SR.F bit to 1, otherwise sets it to 0. D0 != R3 (zero register): If S0 is greater than the uniform value indexed by #IMM, D0 is set to 1, else it is set to 0. In this case, SR.F is not updated. Both operands are handled as signed integers in the comparison.
Behavior model	SR.F = (S0 > Uniform[#R6IMM]); (D0 == R3) D0 = (S0 > Uniform[#R6IMM]); (D0 != R3)
Operand type	S0: 32-bit signed integer R6: 8-bit unsigned integer Uniform: 32-bit signed integer

CMPU.SLE	Less than or Equal to Uniform
Usage	CMPU.SLE D0, S0, #IMM
Function	D0 == R3 (zero register): If S0 is smaller than or equal to the uniform value indexed by #IMM, sets the SR.F bit to 1, otherwise sets it to 0. D0 != R3 (zero register): If S0 is smaller than or equal to the uniform value indexed by #IMM, D0 is set to 1, else it is set to 0. In this case, SR.F is not updated. Both operands are handled as signed integers in the comparison.
Behavior model	SR.F = (S0 <= Uniform[#R6IMM]); (D0 == R3) D0 = (S0 <= Uniform[#R6IMM]); (D0 != R3)
Operand type	S0: 32-bit signed integer R6: 8-bit unsigned integer Uniform: 32-bit signed integer

CMPU.SLT	Less Than Uniform
Usage	CMPU.SLT D0, S0, #IMM
Function	D0 == R3 (zero register): If S0 is smaller than the uniform value indexed by #IMM, sets the SR.F bit to 1, otherwise sets it to 0. D0 != R3 (zero register): If S0 is smaller than the uniform value indexed by #IMM, D0 is set to 1, else it is set to 0. In this case, SR.F is not updated. Both operands are handled as signed integers in the comparison.
Behavior model	SR.F = (S0 < Uniform[#R6IMM]); (D0 == R3) D0 = (S0 < Uniform[#R6IMM); (D0 != R3)
Operand type	S0: 32-bit signed integer R6: 8-bit unsigned integer Uniform: 32-bit signed integer

CMV8	Conditional MoVe of 8-bit values
Usage	CMV8 D0, S0, S1
Function	This is an instruction to copy dependent on 2 condition bits stored in S0[n] and S0[32+n] the value from S1[7:0] to D0[(n+1)*8-1:n*8]. The values of other bits are retained.
Behavior model	if (S0[n] && (S0[32+n]) then D0[(n+1)*8-1:n*8] = S1[7:0], n=0...7
Operand type	D0: 8 times 8-bit value (=64-bit) S0: 64-bit value (only bits 0...7 and 32...39 used) S1: 8-bit value in lower 8-bit

CMV16	**Conditional MoVe of 16-bit values**
Usage	CMV16 D0, S0, S1
Function	This is an instruction to copy dependent on 2 condition bits stored in S0[n] and S0[32+n] the value from S1[15:0] to D0[(n+1)*16-1:n*16]. The values of other bits are retained.
Behavior model	if (S0[n] && (S0[32+n]) then D0[(n+1)*16-1:n*16] = S1[15:0], n=0...3
Operand type	D0: 4 times 16-bit value (=64-bit) S0: 64-bit value (only bits 0...3 and 32...35 used) S1: 16-bit value in lower 16-bit

CNT0	**Count 0**
Usage	CNT0 D0, S0
Function	Treats S0 as a 32-bit array, counts the number of zero-valued bits in this array, and stores the result in D0.
Behavior model	D0 = {number of zero-valued bits in S0}

CNT1	**Count 1**
Usage	CNT1 D0, S0
Function	Treats S0 as a 32-bit array, counts the number of one-valued bits in this array, and stores the result in D0.
Behavior model	D0 = {number of one-valued bits in S0}

CSUSS	**Signed census**
Usage	CSUSS D0, S0, S1
Function	D0 = (S0[23:16] < D0[15:8]) << 31 | (D0[23:16] < D0[15:8]) << 30 | (S1[23:16] < D0[15:8]) << 29 | (S0[15:8] < D0[15:8]) << 28 | (S1[15:8] < D0[15:8]) << 27 | (S0[7:0] < D0[15:8]) << 26 | (D0[7:0] < D0[15:8]) << 25 | (S1[7:0] < D0[15:8]) << 24 | D0[23:0]; S0, S1 and D0 are 3 24bit vectors with each holding 3 8-bit signed elements. The instruction is calculating the census operation by comparing the center byte stored in D0[15:8] with each of the other 8 bytes. Each comparison delivers a 0 or 1 depending on the result of the comparison. These 8 comparison results are stored into D0[31:24] before D0 is stored back to the register file.
Behavior model	D0 = (S0[23:16] < D0[15:8]) << 31 | (D0[23:16] < D0[15:8]) << 30 | (S1[23:16] < D0[15:8]) << 29 | (S0[15:8] < D0[15:8]) << 28 | (S1[15:8] < D0[15:8]) << 27 | (S0[7:0] < D0[15:8]) << 26 | (D0[7:0] < D0[15:8]) << 25 | (S1[7:0] < D0[15:8]) << 24 | D0[23:0];

CSUSU	Unsigned census
Usage	CSUSU D0, S0, S1
Function	D0 = (S0[23:16] < D0[15:8]) << 31 | (D0[23:16] < D0[15:8]) << 30 | (S1[23:16] < D0[15:8]) << 29 | (S0[15:8] < D0[15:8]) << 28 | (S1[15:8] < D0[15:8]) << 27 | (S0[7:0] < D0[15:8]) << 26 | (D0[7:0] < D0[15:8]) << 25 | (S1[7:0] < D0[15:8]) << 24 | D0[23:0]; S0, S1 and D0 are 3 24bit vectors with each holding 3 8-bit unsigned elements. The instruction is calculating the census operation by comparing the center byte stored in D0[15:8] with each of the other 8 bytes. Each comparison delivers a 0 or 1 depending on the result of the comparison. These 8 comparison results are stored into D0[31:24] before D0 is stored back to the register file.
Behavior model	D0 = (S0[23:16] < D0[15:8]) << 31 | (D0[23:16] < D0[15:8]) << 30 | (S1[23:16] < D0[15:8]) << 29 | (S0[15:8] < D0[15:8]) << 28 | (S1[15:8] < D0[15:8]) << 27 | (S0[7:0] < D0[15:8]) << 26 | (D0[7:0] < D0[15:8]) << 25 | (S1[7:0] < D0[15:8]) << 24 | D0[23:0];

DMAWAITS	Wait for the specified DMA
Usage	DMAWAITS #IMM
Function	This is a command to wait for the finish of DMA transfers. With #IMM you are specifying the thread of the core. For thread #n, each k-th bit of #IMM corresponds to TGDMAC for thread #((n+k)%8), which the master thread should wait for. Refer to section U32.8.3 .
Behavior model	#IMM[k] == 1 ? Wait for finishing DMA for thread #(n+k)%8.
Operand type	#IMM: 8-bit unsigned integer

EOR	Exclusive OR
Usage	EOR D0, S0, S1
Function	Treats S0 and S1 as 32-bit arrays, takes the exclusive OR (XOR) of S0 and S1, and stores the result in D0.
Behavior model	D0 =S0 ^ S1;

EOR64	Exclusive OR 64-bit values
Usage	EOR64 D0, S0, S1
Function	This is an instruction to XOR 2 64-bit (8 times 8-bit or 4 times 16-bit) values.
Behavior model	D0[n] = S0[n] XOR S1[n], n = 0...63;
Operand type	D0: 64-bit integer S0: 64-bit integer S1: 64-bit integer

EORU	Exclusive OR with Uniform
Usage	EORU D0, S0, #IMM
Function	Treats S0 and the uniform value indexed by #IMM as 32-bit arrays, takes the exclusive OR (XOR) of S0 and the uniform value, and stores the result in D0.
Behavior model	D0 =S0 ^ Uniform[#R6IMM];

F2I	Float to Integer
Usage	F2I D0, S0
Function	Assumes the S0 value is an IEEE754 single-precision floating-point number, converts it into a 32-bit signed integer, then stores the result in D0. The rounding method can be changed by the control register.
Behavior model	D0 =int((float)S0);

FABS	Float ABSolute
Usage	FABS D0, S0
Function	Stores the absolute value of S0 in D0. S0 is handled as a floating-point number in the operation.
Behavior model	D0 = |(float)S0|;

FADD	Float ADD
Usage	FADD D0, S0, S1
Function	Adds S0 and S1, then stores the result in D0. S0 and S1 are handled as floating-point numbers in the operation.
Behavior model	D0 = (float)S0 + (float)S1;

FADDU	Float ADD to Uniform
Usage	FADDU D0, S0, #IMM
Function	Adds S0 and the uniform value indexed by #IMM, then stores the result in D0. S0 and the uniform value are handled as floating-point numbers in the operation.
Behavior model	D0 = (float)S0 + (float)Uniform[#R6IMM];

FCMP.O	Ordered Floating point
Usage	FCMP.O D0, S0, S1
Function	D0 == R3 (zero register): If S0 and S1 are not NaN, status register flag (SR.F) is set to 1, else it is set to 0. D0 != R3 (zero register): If S0 and S1 are not NaN, D0 is set to 1, else it is set to 0.
Behavior model	SR.F = S0 != NaN and S1 != NaN; (D0 == R3) D0 = S0 != NaN and S1 != NaN; (D0 != R3)

FCMP.OEQ	Ordered Floating point equal
Usage	FCMP.OEQ D0, S0, S1
Function	D0 == R3 (zero register): If S0 and S1 are not NaN and S0 is equal to S1, status register flag (SR.F) is set to 1, else it is set to 0. D0 != R3 (zero register): If S0 and S1 are not NaN and S0 is equal to S1, D0 is set to 1, else it is set to 0.
Behavior model	SR.F = (S0 == S1) and S0 != NaN and S1 != NaN; (D0 == R3) D0 = (S0 == S1) and S0 != NaN and S1 != NaN; (D0 != R3)

FCMP.OGE	Ordered Floating point greater than or equal
Usage	FCMP.OGE D0, S0, S1
Function	D0 == R3 (zero register): If S0 and S1 are not NaN and S0 is greater than or equal S1, status register flag (SR.F) is set to 1, else it is set to 0. D0 != R3 (zero register): If S0 and S1 are not NaN and S0 is greater than or equal S1, D0 is set to 1, else it is set to 0.
Behavior model	SR.F = (S0 >= S1) and S0 != NaN and S1 != NaN; (D0 == R3) D0 = (S0 >= S1) and S0 != NaN and S1 != NaN; (D0 != R3)

FCMP.OGT	Ordered Floating point greater than
Usage	FCMP.OGT D0, S0, S1
Function	D0 == R3 (zero register): If S0 and S1 are not NaN and S0 is greater than S1, status register flag (SR.F) is set to 1, else it is set to 0. D0 != R3 (zero register): If S0 and S1 are not NaN and S0 is greater than S1, D0 is set to 1, else it is set to 0.
Behavior model	SR.F = (S0 > S1) and S0 != NaN and S1 != NaN; (D0 == R3) D0 = (S0 > S1) and S0 != NaN and S1 != NaN; (D0 != R3)

FCMP.OLE	Ordered Floating point less than or equal
Usage	FCMP.OLE D0, S0, S1
Function	D0 == R3 (zero register): If S0 and S1 are not NaN and S0 is less than or equal S1, status register flag (SR.F) is set to 1, else it is set to 0. D0 != R3 (zero register): If S0 and S1 are not NaN and S0 is less than or equal S1, D0 is set to 1, else it is set to 0.
Behavior model	SR.F = (S0 <= S1) and S0 != NaN and S1 != NaN; (D0 == R3) D0 = (S0 <= S1) and S0 != NaN and S1 != NaN; (D0 != R3)

FCMP.OLT	Ordered Floating point less than
Usage	FCMP.OLT D0, S0, S1
Function	D0 == R3 (zero register): If S0 and S1 are not NaN and S0 is less than S1, status register flag (SR.F) is set to 1, else it is set to 0. D0 != R3 (zero register): If S0 and S1 are not NaN and S0 is less than S1, D0 is set to 1, else it is set to 0.
Behavior model	SR.F = (S0 < S1) and S0 != NaN and S1 != NaN; (D0 == R3) D0 = (S0 < S1) and S0 != NaN and S1 != NaN; (D0 != R3)

FCMP.ONE	Ordered Floating point not equal
Usage	FCMP.ONE D0, S0, S1
Function	D0 == R3 (zero register): If S0 and S1 are not NaN and S0 is not equal S1, status register flag (SR.F) is set to 1, else it is set to 0. D0 != R3 (zero register): If S0 and S1 are not NaN and S0 is not equal S1, D0 is set to 1, else it is set to 0.
Behavior model	SR.F = (S0 != S1) and S0 != NaN and S1 != NaN; (D0 == R3) D0 = (S0 != S1) and S0 != NaN and S1 != NaN; (D0 != R3)

FCMP.UEQ	Unordered Floating point equal
Usage	FCMP.UEQ D0, S0, S1
Function	D0 == R3 (zero register): If S0 is NaN or S1 is NaN or S0 is equal to S1, status register flag (SR.F) is set to 1, else it is set to 0. D0 != R3 (zero register): If S0 is NaN or S1 is NaN or S0 is equal to S1, D0 is set to 1, else it is set to 0.
Behavior model	SR.F = (S0 == S1) or S0 == NaN or S1 == NaN; (D0 == R3) D0 = (S0 == S1) or S0 == NaN or S1 == NaN; (D0 != R3)

FCMP.UGE	Unordered Floating point greater than or equal
Usage	FCMP.UGE D0, S0, S1
Function	D0 == R3 (zero register): If S0 is NaN or S1 is NaN or S0 is greater than or equal S1, status register flag (SR.F) is set to 1, else it is set to 0. D0 != R3 (zero register): If S0 is NaN or S1 is NaN or S0 is greater than or equal S1, D0 is set to 1, else it is set to 0.
Behavior model	SR.F = (S0 >= S1) or S0 == NaN or S1 == NaN; (D0 == R3) D0 = (S0 >= S1) or S0 == NaN or S1 == NaN; (D0 != R3)

FCMP.UGT	Unordered Floating point greater than
Usage	FCMP.UGT D0, S0, S1
Function	D0 == R3 (zero register): If S0 is NaN or S1 is NaN or S0 is greater than S1, status register flag (SR.F) is set to 1, else it is set to 0. D0 != R3 (zero register): If S0 is NaN or S1 is NaN or S0 is greater than S1, D0 is set to 1, else it is set to 0.
Behavior model	SR.F = (S0 > S1) or S0 == NaN or S1 == NaN; (D0 == R3) D0 = (S0 > S1) or S0 == NaN or S1 == NaN; (D0 != R3)

FCMP.ULE	Unordered Floating point less than or equal
Usage	FCMP.ULE D0, S0, S1
Function	D0 == R3 (zero register): If S0 is NaN or S1 is NaN or S0 is less than or equal S1, status register flag (SR.F) is set to 1, else it is set to 0. D0 != R3 (zero register): If S0 is NaN or S1 is NaN or S0 is less than or equal S1, D0 is set to 1, else it is set to 0.
Behavior model	SR.F = (S0 <= S1) or S0 == NaN or S1 == NaN; (D0 == R3) D0 = (S0 <= S1) or S0 == NaN or S1 == NaN; (D0 != R3)

FCMP.ULT	Unordered Floating point less than
Usage	FCMP.ULT D0, S0, S1
Function	D0 == R3 (zero register): If S0 is NaN or S1 is NaN or S0 is less than S1, status register flag (SR.F) is set to 1, else it is set to 0. D0 != R3 (zero register): If S0 is NaN or S1 is NaN or S0 is less than S1, D0 is set to 1, else it is set to 0.
Behavior model	SR.F = (S0 < S1) or S0 == NaN or S1 == NaN; (D0 == R3) D0 = (S0 < S1) or S0 == NaN or S1 == NaN; (D0 != R3)

FCMP.UNE	Unordered Floating not equal
Usage	FCMP.UNE D0, S0, S1
Function	D0 == R3 (zero register): If S0 is NaN or S1 is NaN or S0 is not equal S1, status register flag (SR.F) is set to 1, else it is set to 0. D0 != R3 (zero register): If S0 is NaN or S1 is NaN or S0 is not equal S1, D0 is set to 1, else it is set to 0.
Behavior model	SR.F = (S0 != S1) or S0 == NaN or S1 == NaN; (D0 == R3) D0 = (S0 != S1) or S0 == NaN or S1 == NaN; (D0 != R3)

FCMP.UO	Unordered Floating point
Usage	FCMP.UO D0, S0, S1
Function	D0 == R3 (zero register): If S0 is NaN or S1 is NaN, status register flag (SR.F) is set to 1, else it is set to 0. D0 != R3 (zero register): If S0 is NaN or S1 is NaN, D0 is set to 1, else it is set to 0.
Behavior model	SR.F = S0 == NaN or S1 == NaN; (D0 == R3) D0 = S0 == NaN or S1 == NaN; (D0 != R3)

FCMPU.O	Ordered Floating point with Uniform
Usage	FCMPU.O D0, S0, #IMM
Function	D0 == R3 (zero register): If S0 and the uniform value indexed by #IMM are not NaN, status register flag (SR.F) is set to 1, else it is set to 0. D0 != R3 (zero register): If S0 and the uniform value indexed by #IMM, are not NaN, D0 is set to 1, else it is set to 0.
Behavior model	SR.F = S0 != NaN and Uniform[#R6IMM] != NaN; (D0 == R3) D0 = S0 != NaN and Uniform[#R6IMM] != NaN; (D0 != R3)

FCMPU.OEQ	Ordered Floating point equal to Uniform
Usage	FCMPU.OEQ D0, S0, #IMM
Function	D0 == R3 (zero register): If S0 and the uniform value indexed by #IMM are not NaN and S0 is equal to the uniform value indexed by #IMM, status register flag (SR.F) is set to 1, else it is set to 0. D0 != R3 (zero register): If S0 and Uniform[R6+#IMM] are not NaN and S0 is equal to the uniform value indexed by #IMM, D0 is set to 1, else it is set to 0.
Behavior model	SR.F = (S0 == Uniform[#R6IMM]) and S0 != NaN and Uniform[#R6IMM] != NaN; (D0 == R3) D0 = (S0 == Uniform[#R6IMM]) and S0 != NaN and Uniform[#R6IMM] != NaN; (D0 != R3)

FCMPU.OGE	Ordered Floating point greater than or equal to Uniform
Usage	FCMPU.OGE D0, S0, #IMM
Function	D0 == R3 (zero register): If S0 and the uniform value indexed by #IMM are not NaN and S0 is greater than or equal to the uniform value indexed by #IMM, status register flag (SR.F) is set to 1, else it is set to 0. D0 != R3 (zero register): If S0 and the uniform value indexed by #IMM are not NaN and S0 is greater than or equal to the uniform value indexed by #IMM, D0 is set to 1, else it is set to 0.
Behavior model	SR.F = (S0 >= Uniform[#R6IMM]) and S0 != NaN and Uniform[#R6IMM] != NaN; (D0 == R3) D0 = (S0 >= Uniform[#R6IMM]) and S0 != NaN and Uniform[#R6IMM] != NaN; (D0 != R3)

FCMPU.OGT	Ordered Floating point greater than Uniform
Usage	FCMPU.OGT D0, S0, #IMM
Function	D0 == R3 (zero register): If S0 and the uniform value indexed by #IMM are not NaN and S0 is greater than the uniform value indexed by #IMM, status register flag (SR.F) is set to 1, else it is set to 0. D0 != R3 (zero register): If S0 and the uniform value indexed by #IMM are not NaN and S0 is greater than the uniform value indexed by #IMM, D0 is set to 1, else it is set to 0.
Behavior model	SR.F = (S0 > Uniform[#R6IMM]) and S0 != NaN and Uniform[#R6IMM] != NaN; (D0 == R3) D0 = (S0 > Uniform[#R6IMM]) and S0 != NaN and Uniform[#R6IMM] != NaN; (D0 != R3)

FCMPU.OLE	Ordered Floating point less than or equal to Uniform
Usage	FCMPU.OLE D0, S0, #IMM
Function	D0 == R3 (zero register): If S0 and the uniform value indexed by #IMM are not NaN and S0 is less than or equal to the uniform value indexed by #IMM, status register flag (SR.F) is set to 1, else it is set to 0. D0 != R3 (zero register): If S0 and the uniform value indexed by #IMM are not NaN and S0 is less than or equal to the uniform value indexed by #IMM, D0 is set to 1, else it is set to 0.
Behavior model	SR.F = (S0 <= Uniform[#R6IMM]) and S0 != NaN and Uniform[#R6IMM] != NaN; (D0 == R3) D0 = (S0 <= Uniform[#R6IMM]) and S0 != NaN and Uniform[#R6IMM] != NaN; (D0 != R3)

FCMPU.OLT	Ordered Floating point less than Uniform
Usage	FCMPU.OLT D0, S0, #IMM
Function	D0 == R3 (zero register): If S0 and the uniform value indexed by #IMM are not NaN and S0 is less than the uniform value indexed by #IMM, status register flag (SR.F) is set to 1, else it is set to 0. D0 != R3 (zero register): If S0 and the uniform value indexed by #IMM are not NaN and S0 is less than the uniform value indexed by #IMM, D0 is set to 1, else it is set to 0.
Behavior model	SR.F = (S0 < Uniform[#R6IMM]) and S0 != NaN and Uniform[#R6IMM] != NaN; (D0 == R3) D0 = (S0 < Uniform[#R6IMM]) and S0 != NaN and Uniform[#R6IMM] != NaN; (D0 != R3)

FCMPU.ONE	Ordered Floating point not equal to Uniform
Usage	FCMPU.ONE D0, S0, #IMM
Function	D0 == R3 (zero register): If S0 and the uniform value indexed by #IMM are not NaN and S0 is not equal the uniform value indexed by #IMM, status register flag (SR.F) is set to 1, else it is set to 0. D0 != R3 (zero register): If S0 and the uniform value indexed by #IMM are not NaN and S0 is not equal the uniform value indexed by #IMM, D0 is set to 1, else it is set to 0.
Behavior model	SR.F = (S0 != Uniform[#R6IMM]) and S0 != NaN and Uniform[#R6IMM] != NaN; (D0 == R3) D0 = (S0 != Uniform[#R6IMM]) and S0 != NaN and Uniform[#R6IMM] != NaN; (D0 != R3)

FCMPU.UEQ	**Unordered Floating point equal to Uniform**
Usage	FCMPU.UEQ D0, S0, #IMM
Function	D0 == R3 (zero register): If S0 is NaN or the uniform value indexed by #IMM is NaN or S0 is equal to the uniform value indexed by #IMM, status register flag (SR.F) is set to 1, else it is set to 0. D0 != R3 (zero register): If S0 is NaN or the uniform value indexed by #IMM is NaN or S0 is equal to the uniform value indexed by #IMM, D0 is set to 1, else it is set to 0.
Behavior model	SR.F = (S0 == Uniform[#R6IMM]) or S0 == NaN or Uniform[#R6IMM] == NaN; (D0 == R3) D0 = (S0 == Uniform[#R6IMM]) or S0 == NaN or Uniform[#R6IMM] == NaN; (D0 != R3)

FCMPU.UGE	**Unordered Floating point greater than or equal to Uniform**
Usage	FCMPU.UGE D0, S0, #IMM
Function	D0 == R3 (zero register): If S0 is NaN or the uniform value indexed by #IMM is NaN or S0 is greater than or equal the uniform value indexed by #IMM, status register flag (SR.F) is set to 1, else it is set to 0. D0 != R3 (zero register): If S0 is NaN or the uniform value indexed by #IMM is NaN or S0 is greater than or equal the uniform value indexed by #IMM, D0 is set to 1, else it is set to 0.
Behavior model	SR.F = (S0 >= Uniform[#R6IMM]) or S0 == NaN or Uniform[#R6IMM] == NaN; (D0 == R3) D0 = (S0 >= Uniform[#R6IMM]) or S0 == NaN or Uniform[#R6IMM] == NaN; (D0 != R3)

FCMPU.UGT	**Unordered Floating point greater than Uniform**
Usage	FCMPU.UGT D0, S0, #IMM
Function	D0 == R3 (zero register): If S0 is NaN or the uniform value indexed by #IMM is NaN or S0 is greater than the uniform value indexed by #IMM, status register flag (SR.F) is set to 1, else it is set to 0. D0 != R3 (zero register): If S0 is NaN or the uniform value indexed by #IMM is NaN or S0 is greater than the uniform value indexed by #IMM, D0 is set to 1, else it is set to 0.
Behavior model	SR.F = (S0 > Uniform[#R6IMM]) or S0 == NaN or Uniform[#R6IMM] == NaN; (D0 == R3) D0 = (S0 > Uniform[#R6IMM]) or S0 == NaN or Uniform[#R6IMM] == NaN; (D0 != R3)

FCMPU.ULE	**Unordered Floating point less than or equal to Uniform**
Usage	FCMPU.ULE D0, S0, #IMM
Function	D0 == R3 (zero register): If S0 is NaN or the uniform value indexed by #IMM is NaN or S0 is less than or equal to the uniform value indexed by #IMM, status register flag (SR.F) is set to 1, else it is set to 0. D0 != R3 (zero register): If S0 is NaN or the uniform value indexed by #IMM is NaN or S0 is less than or equal to the uniform value indexed by #IMM, D0 is set to 1, else it is set to 0.
Behavior model	SR.F = (S0 <= Uniform[#R6IMM]) or S0 == NaN or Uniform[#R6IMM] == NaN; (D0 == R3) D0 = (S0 <= Uniform[#R6IMM]) or S0 == NaN or Uniform[#R6IMM] == NaN; (D0 != R3)

FCMPU.ULT	Unordered Floating point less than Uniform
Usage	FCMPU.ULT D0, S0, #IMM
Function	D0 == R3 (zero register): If S0 is NaN or the uniform value indexed by #IMM is NaN or S0 is less than the uniform value indexed by #IMM, status register flag (SR.F) is set to 1, else it is set to 0. D0 != R3 (zero register): If S0 is NaN or the uniform value indexed by #IMM is NaN or S0 is less than the uniform value indexed by #IMM, D0 is set to 1, else it is set to 0.
Behavior model	SR.F = (S0 < Uniform[#R6IMM]) or S0 == NaN or Uniform[#R6IMM] == NaN; (D0 == R3) D0 = (S0 < Uniform[#R6IMM]) or S0 == NaN or Uniform[#R6IMM] == NaN; (D0 != R3)

FCMPU.UNE	Unordered Floating not equal to Uniform
Usage	FCMPU.UNE Do, S0, #IMM
Function	D0 == R3 (zero register): If S0 is NaN or the uniform value indexed by #IMM is NaN or S0 is not equal the uniform value indexed by #IMM, status register flag (SR.F) is set to 1, else it is set to 0. D0 != R3 (zero register): If S0 is NaN or the uniform value indexed by #IMM is NaN or S0 is not equal the uniform value indexed by #IMM, D0 is set to 1, else it is set to 0.
Behavior model	SR.F = (S0 != Uniform[#R6IMM]) or S0 == NaN or Uniform[#R6IMM] == NaN; (D0 == R3) D0 = (S0 != Uniform[#R6IMM]) or S0 == NaN or Uniform[#R6IMM] == NaN; (D0 != R3)

FCMPU.UO	Unordered Floating point with Uniform
Usage	FCMPU.UO D0, S0, #IMM
Function	D0 == R3 (zero register): If S0 is NaN or the uniform value indexed by #IMM is NaN, status register flag (SR.F) is set to 1, else it is set to 0. D0 != R3 (zero register): If S0 is NaN or the uniform value indexed by #IMM is NaN, D0 is set to 1, else it is set to 0.
Behavior model	SR.F = S0 == NaN or Uniform[#R6IMM] == NaN; (D0 == R3) D0 = S0 == NaN or Uniform[#R6IMM] == NaN; (D0 != R3)

FFLR	Float FLooR
Usage	FFLR D0, S0
Function	Stores the integer part of S0 in D0. This integer part is calculated according to a configuration of CR18. The default value of CR 18 is 1 and the logic is integer part of floating value (round towards zero). When CR18 is 0 floating value is rounded to "nearest" integer. The result is stored to D0 and S0 is handled as a floating-point number in the operation.
Behavior model	D0=floor ((float)S0);

FFRC	Float FRaCtion
Usage	FFRC D0, S0
Function	Subtracts the integer part of S0 from S0. This integer part is calculated according to a configuration of CR18. value of CR 18 is 1 and the logic is integer part of floating value (round towards zero). When CR18 is 0 floating value is rounded to "nearest" integer. The result is stored to D0 and S0 is handled as a floating-point number in the operation.
Behavior model	D0=S0 - floor ((float)S0);

FLDCI	Float Load from Control Register
Usage	FLDCI D0, #IMM
Function	This is an instruction for loading data from a control register. Writes the data read from the control register at the address specified by #IMM to D0. The value written to D0 is floating-point. Specifying #IMM as the number of a control register that does not exist is prohibited.
Behavior model	D0 = (float)ControlRegister[#IMM];

FLDRCI	Float Load from Relative Coordinate XY with Immediate offset
Usage	FLDRCI D0, #IMM1, #IMM2
Function	This is an instruction for data transfer from memory to a register. X and Y coordinates are specified in R0 and R1 respectively. Reads the value from memory at the coordinates obtained by adding the #IMM1 value to X and the #IMM2 value to Y and stores the value in D0. The full 32 bits of R0 and the 16 lower-order bits of R1 are handled as signed integers. #IMM1 and #IMM2 need to be specified with 8-bit signed integers. Operation cannot be guaranteed if the calculated offset is negative to the base address or obtained address is outside from the range handled by the CVengine. The value stored in D0 is floating-point.
Behavior model	D0 = (float) *(R0+(char)#IMM1, (short)((short)(R1&0xffff)+(char)#IMM2));
Operand type	D0: 32-bit signed floating-point #IMM1: 8-bit signed integer #IMM2: 8-bit signed integer R0: 32-bit signed integer R1: 16-bit signed integer

FLDRCIU	Float Load from Relative Coordinate XY with Immediate offset, then source Updated
Usage	FLDRCIU D0, #IMM1, #IMM2
Function	This is an instruction for data transfer from memory to a register. X and Y coordinates are specified in R0 and R1 respectively. Reads the value from memory at the coordinates obtained by adding the #IMM1 value to X and the #IMM2 value to Y and stores the value in D0. The full 32 bits of R0 and the 16 lower-order bits of R1 are handled as signed integers. #IMM1 and #IMM2 need to be specified with 8-bit signed integers. After operation, X(R0) and Y(R1) are updated by adding #IMM1 and #IMM2 respectively. Operation cannot be guaranteed if the calculated offset is negative to the base address or obtained address is outside from the range handled by the CVengine. The value stored in D0 is floating-point.

Behavior model	D0 = (float) *(R0+(char)#IMM1, (short)((short)(R1&0xffff)+(char)#IMM2));
	R0 = R0+(char)#IMM1; R1 = R1+ (char)#IMM2;

Operand type	D0: 32-bit signed floating-point #IMM1: 8-bit signed integer #IMM2: 8-bit signed integer R0: 32-bit signed integer R1: 16-bit signed integer

FLDRXY	Float Load from Relative Coordinate XY with register offset
Usage	FLDRXY D0, S0, S1
Function	This is an instruction for data transfer from memory to a register. X and Y coordinates are specified in R0 and R1 respectively. Reads the value from memory at the coordinates obtained by adding the S0 value to X and the S1 value to Y and stores the value in D0. The full 32 bits of R0 and S0 and the 16 lower-order bits of R1 and S1 are handled as signed integers. Operation cannot be guaranteed if the calculated offset is negative to the base address or obtained address is outside from the range handled by the CVengine. The value stored in D0 is floating-point.
Behavior model	D0 = (float) *(R0+S0, (short)((short)(R1&0xffff)+(short)(S1&0xffff)));
Operand type	D0: 32-bit signed floating-point S0: 32-bit signed integer S1: 16-bit signed integer R0: 32-bit signed integer R1: 16-bit signed integer

FLDRXYU	Float Load from Relative Coordinate XY with register offset, then source Updated
Usage	FLDRXYU D0, S0, S1
Function	This is an instruction for data transfer from memory to a register. X and Y coordinates are specified in R0 and R1 respectively. Reads the value from memory at the coordinates obtained by adding the S0 value to X and the S1 value to Y and stores the value in D0. The full 32 bits of R0 and S0 and the 16 lower-order bits of R1 and S1 are handled as signed integers. After operation, X(R0) and Y(R1) are updated by adding S0 and S1 respectively. Operation cannot be guaranteed if the calculated offset is negative to the base address or obtained address is outside from the range handled by the CVengine. The value stored in D0 is floating-point.
Behavior model	D0 = (float) *(R0+S0, (short)((short)(R1&0xffff)+(short)(S1&0xffff))); R0 = R0+S0; R1 = (short)((short)(R1&0xffff)+(short)(S1&0xffff));
Operand type	D0: 32-bit signed floating-point S0: 32-bit signed integer S1: 16-bit signed integer R0: 32-bit signed integer R1: 16-bit signed integer

FMAD	Float Multiply and ADd
Usage	FMAD D0, S0, S1
Function	Adds D0 and the product of S0 and S1, then stores the result in D0. D0, S0 and S1 are handled as floating-point numbers in the operation. The result of this instruction matches that of the similar operation obtained by combining the FMUL and FADD instructions.
Behavior model	D0 = S0*S1 + D0;

FMADU	Float Multiply and Add Uniform
Usage	FMADU D0, S0, #IMM
Function	Adds D0 and the product of S0 and the uniform value indexed by #IMM, then stores the result in D0. D0, S0 and S1 are handled as floating-point numbers in the operation. The result of this instruction matches that of the similar operation obtained by combining the FMULU and FADD instructions.
Behavior model	D0 = S0*Uniform[#R6IMM] + D0;

FMAX	Float MAXimum
Usage	FMAX D0, S0, S1
Function	Selects the larger value between S0 and S1, then stores the result in D0. S0 and S1 are handled as floating-point numbers in the operation.
Behavior model	D0 = (S0 > S1) ? S0 : S1;

FMAXU	Float MAXimum compared to Uniform
Usage	FMAXU D0, S0, #IMM
Function	Selects the larger value between S0 and the uniform value indexed by #IMM, then stores the result in D0. S0 and the uniform value are handled as floating-point numbers in the operation.
Behavior model	D0 = (S0 > Uniform[#R6IMM]) ? S0 : Uniform[#R6IMM]);

FMIN	Float MINimum
Usage	FMIN D0, S0, S1
Function	Selects the smaller value between S0 and S1, then stores the result in D0. S0 and S1 are handled as floating-point numbers in the operation.
Behavior model	D0 = (S0 > S1) ? S1 : S0;

FMINU	Float MINimum compared to Uniform
Usage	FMINU D0, S0, #IMM
Function	Selects the smaller value between S0 and the uniform value indexed by #IMM, then stores the result in D0. S0 and the uniform value are handled as floating-point numbers in the operation.
Behavior model	D0 = (S0 > Uniform[#R6IMM]) ? Uniform[#R6IMM]) : S0;

FMP	Float Middle Point
Usage	FMP D0, S0, S1
Function	Divides the sum of S0 and S1 by 2.0, then stores the result in D0. S0 and S1 are handled as floating-point numbers in the operation.
Behavior model	D0 = (S0 + S1) / 2.0;

FMSU	Float Multiply and Sub
Usage	FMSU D0, S0, S1
Function	Subtracts the product of S0 and S1 from D0, then stores the result in D0. D0, S0 and S1 are handled as floating-point numbers in the operation. The result of this instruction matches that of the similar operation obtained by combining the FMUL and FSUB instructions.
Behavior model	D0 = -S0*S1 + D0;

FMSUU	Float Multiply and Sub Uniform
Usage	FMSUU D0, S0, #IMM
Function	Subtracts the product of S0 and the uniform value indexed by #IMM from D0, then stores the result in D0. D0, S0 and S1 are handled as floating-point numbers in the operation. The result of this instruction matches that of the similar operation obtained by combining the FMULU and FSUB instructions.
Behavior model	D0 = -S0*Uniform[#R6IMM] + D0;

FMUL	Float MULtiply
Usage	FMUL D0, S0, S1
Function	Multiplies S0 and S1, then stores the result in D0. S0 and S1 are handled as floating-point numbers in the operation.
Behavior model	D0 = S0 * S1;

FMULU	Float MULtiply by Uniform
Usage	FMULU D0, S0, #IMM
Function	Multiplies S0 and the uniform value indexed by #IMM, then stores the result in D0. S0 and the uniform value are handled as floating-point numbers in the operation.
Behavior model	D0 = S0 * Uniform[#R6IMM];

FSTC	Float STore to Control Register
Usage	FSTC D0, S0
Function	This is an instruction for storing data in a control register. The S0 value is converted to integer and written to the control register D0. Specifying D0 as a control register that does not exist is prohibited.
Behavior model	ControlRegisterD0 = (int)S0;

FSTRCI	Float STore to Relative Coordinate with Immediate offset
Usage	FSTRCI D0, #IMM1, #IMM2
Function	This is an instruction for data transfer from a register to memory. Stores the D0 value in memory at X and Y coordinates which are specified in R0 and R1 respectively, with the #IMM1 value added to X and the #IMM2 value added to Y. The full 32 bits of R0 and the 16 lower-order bits of R1 are handled as signed integers. #IMM1 and #IMM2 need to be specified with 8-bit signed integers. Operation cannot be guaranteed if the calculated offset is negative to the base address or obtained address is outside from the range handled by the CVengine. D0 is handled as a floating-point number.
Behavior model	@(R0+(char)#IMM1, (short)((short)(R1&0xffff)+(char)#IMM2))= D0
Operand type	D0: 32-bit signed floating-point #IMM1: 8-bit signed integer #IMM2: 8-bit signed integer R0: 32-bit signed integer R1: 16-bit signed integer

FSTRCIU	Float STore to Relative Coordinate with Immediate offset, then source Updated
Usage	FSTRCIU D0, #IMM1, #IMM2
Function	This is an instruction for data transfer from a register to memory. Stores the D0 value in memory at X and Y coordinates which are specified in R0 and R1 respectively, with the #IMM1 value added to X and the #IMM2 value added to Y. The full 32 bits of R0 and the 16 lower-order bits of R1 are handled as signed integers. #IMM1 and #IMM2 need to be specified with 8-bit signed integers. After operation, X(R0) and Y(R1) are updated by adding #IMM1 and #IMM2 respectively. Operation cannot be guaranteed if the calculated offset is negative to the base address or obtained address is outside from the range handled by the CVengine. D0 is handled as a floating-point number.

Behavior model	@(R0+(char)#IMM1, (short)((short)(R1&0xffff)+(char)#IMM2)) = D0;
	R0 = R0+(char)#IMM1; R1 = R1+ (char)#IMM2;

Operand type	D0: 32-bit signed floating-point #IMM1: 8-bit signed integer #IMM2: 8-bit signed integer R0: 32-bit signed integer R1: 16-bit signed integer

FSTRXY	Float STore to Relative Coordinate XY with register offset
Usage	FSTRXY D0, S0, S1
Function	This is an instruction for data transfer from a register to memory. Stores the D0 value in memory at X and Y coordinates which are specified in R0 and R1 respectively, with the S0 value added to X and the S1 value added to Y. The full 32 bits of R0 and S0 and the 16 lower-order bits of R1 and S1 are handled as signed integers. Operation cannot be guaranteed if the calculated offset is negative to the base address or obtained address is outside from the range handled by the CVengine. D0 is handled as a floating-point number.
Behavior model	@(R0+S0, (short)((short)(R1&0xffff)+(short)(S1&0xffff))) = D0;
Operand type	D0: 32-bit signed floating-point S0: 32-bit signed integer S1: 16-bit signed integer R0: 32-bit signed integer R1: 16-bit signed integer

FSTRXYU	Float STore to Relative Coordinate XY with register offset, then source Updated
Usage	FSTRXYU D0, S0, S1
Function	This is an instruction for data transfer from a register to memory. Stores the D0 value in memory at X and Y coordinates which are specified in R0 and R1 respectively, with the S0 value added to X and the S1 value added to Y. The full 32 bits of R0 and S0 and the 16 lower-order bits of R1 and S1 are handled as signed integers. After operation, X(R0) and Y(R1) are updated by adding S0 and S1 respectively. Operation cannot be guaranteed if the calculated offset is negative to the base address or obtained address is outside from the range handled by the CVengine. D0 is handled as a floating-point number.
Behavior model	@(R0+S0, (short)((short)(R1&0xffff)+(short)(S1&0xffff))) = D0; R0 = R0+S0; R1 = (short)((short)(R1&0xffff)+(short)(S1&0xffff));
Operand type	D0: 32-bit signed floating-point S0: 32-bit signed integer S1: 16-bit signed integer R0: 32-bit signed integer R1: 16-bit signed integer

FSUB	Float SUB
Usage	FSUB D0, S0, S1
Function	Subtracts S1 from S0, then stores the result in D0. S0 and S1 are handled as floating-point numbers in the operation.
Behavior model	D0 = S0 - S1;

FSUBU	Float SUB Uniform from
Usage	FSUBU D0, S0, #IMM
Function	Subtracts the uniform value indexed by #IMM from S0, then stores the result in D0. S0 and the uniform value are handled as floating-point numbers in the operation.
Behavior model	D0 = S0 - Uniform[#R6IMM];

GADDBS	Group add and sum up for 8-bit signed input data
Usage	GADDBS D0, S0, S1
Function	D0 = D0+S0[0]+S1[0]+S0[1]+S1[1]+S0[2]+S1[2]+S0[3]+S1[3]+S0[4]+S1[4]+S0[5]+S1[5]+S0[6]+S1[6] +S0[7]+S1[7] S0 and S1 are signed 8-bit vectors with each 8 elements. The instruction is performing an addition of each element between the vectors S0 and S1 and adding all results to the input D0 before storing back the result to D0. D0 is a 32-bit signed value. S0 and S1 are 64-bit vectors, which are specified by the even of 2 consecutive 32-bit registers. Hardware does not take care any overflow handlings, so software must take care of it.
Behavior model	D0 = D0+S0[0]+S1[0]+S0[1]+S1[1]+S0[2]+S1[2]+S0[3]+S1[3]+S0[4]+S1[4]+S0[5]+S1[5]+S0[6] +S1[6]+S0[7]+S1[7]
Operand type	D0: 32-bit signed integer S0: 8 * 8-bit signed integer S1: 8 * 8-bit signed integer

GADDBU	Group add and sum up for 8-bit unsigned input data
Usage	GADDBU D0, S0, S1
Function	D0 = D0+S0[0]+S1[0]+S0[1]+S1[1]+S0[2]+S1[2]+S0[3]+S1[3]+S0[4]+S1[4]+S0[5]+S1[5]+S0[6]+S1[6] +S0[7]+S1[7] S0 and S1 are unsigned 8-bit vectors with each 8 elements. The instruction is performing an addition of each element between the vectors S0 and S1 and adding all results to the input D0 before storing back the result to D0. D0 is a 32-bit signed value. S0 and S1 are 64-bit vectors, which are specified by the even of 2 consecutive 32-bit registers. Hardware does not take care any overflow handlings, so software must take care of it.
Behavior model	D0 = D0+S0[0]+S1[0]+S0[1]+S1[1]+S0[2]+S1[2]+S0[3]+S1[3]+S0[4]+S1[4]+S0[5]+S1[5]+S0[6] +S1[6]+S0[7]+S1[7]
Operand type	D0: 32-bit signed integer S0: 8 * 8-bit unsigned integer S1: 8 * 8-bit unsigned integer

GADDHS	Group add and sum up for 16-bit signed input data
Usage	GADDHS D0, S0, S1
Function	D0 = D0+S0[0]+S1[0]+S0[1]+S1[1]+S0[2]+S1[2]+S0[3]+S1[3] S0 and S1 are signed 16-bit vectors with each 4 elements. The instruction is performing an addition of each element between the vectors S0 and S1 and adding all results to the input D0 before storing back the result to D0.D0 is a 32-bit signed value.S0 and S1 are 64-bit vectors, which are specified by the even of 2 consecutive 32-bit registers. Hardware does not take care any overflow handlings, so software must take care of it.
Behavior model	D0 = D0+S0[0]+S1[0]+S0[1]+S1[1]+S0[2]+S1[2]+S0[3]+S1[3]
Operand type	D0: 32-bit signed integer S0: 4 * 16-bit signed integer S1: 4 * 16-bit signed integer

GADDHU	Group add and sum up for 16-bit unsigned input data
Usage	GADDHU D0, S0, S1
Function	D0 = D0+S0[0]+S1[0]+S0[1]+S1[1]+S0[2]+S1[2]+S0[3]+S1[3] S0 and S1 are unsigned 16-bit vectors with each 4 elements. The instruction is performing an addition of each element between the vectors S0 and S1 and adding all results to the input D0 before storing back the result to D0.D0 is a 32-bit signed value. S0 and S1 are 64-bit vectors, which are specified by the even of 2 consecutive 32-bit registers. Hardware does not take care any overflow handlings, so software must take care of it.
Behavior model	D0 = D0+S0[0]+S1[0]+S0[1]+S1[1]+S0[2]+S1[2]+S0[3]+S1[3]
Operand type	D0: 32-bit signed integer S0: 4 * 16-bit unsigned integer S1: 4 * 16-bit unsigned integer

GMADBS	Group multiply and add for 8-bit signed input data
Usage	GMADBS D0, S0, S1
Function	D0 = D0+S0[0]*S1[0]+S0[1]*S1[1]+S0[2]*S1[2]+S0[3]*S1[3]+S0[4]*S1[4]+S0[5]*S1[5]+S0[6]*S1[6]+S0[7]*S1[7] S0 and S1 are signed 8-bit vectors with each 8 elements. The instruction is performing a multiplication of each element between the vectors S0 and S1 and adding all results to the input D0 before storing back the result to D0. D0 is a 32-bit signed value. S0 and S1 are 64-bit vectors, which are specified by the even of 2 consecutive 32-bit registers. Hardware does not take care any overflow handlings, so software must take care of it.
Behavior model	D0 = D0+S0[0]*S1[0]+S0[1]*S1[1]+S0[2]*S1[2]+S0[3]*S1[3]+S0[4]*S1[4]+S0[5]*S1[5]+S0[6]*S1[6]+S0[7]*S1[7]
Operand type	D0: 32-bit signed integer S0: 8 * 8-bit signed integer S1: 8 * 8-bit signed integer

GMADBSL	Group multiply and add for 8-bit signed input data long
Usage	GMADBSL D0, S0, S1
Function	D0 = D0+S0[0]*S1[0]+S0[1]*S1[1]+S0[2]*S1[2]+S0[3]*S1[3]+S0[4]*S1[4]+S0[5]*S1[5]+S0[6]*S1[6]+S0[7]*S1[7] S0 and S1 are signed 8-bit vectors with each 8 elements. The instruction is performing a multiplication of each element between the vectors S0 and S1 and adding all results to the input D0 before storing back the result to D0. D0 is a 64-bit signed value. S0 and S1 are 64-bit vectors, which are specified by the even of 2 consecutive 32-bit registers. Hardware does not take care any overflow handlings, so software must take care of it.
Behavior model	D0 = D0+S0[0]*S1[0]+S0[1]*S1[1]+S0[2]*S1[2]+S0[3]*S1[3]+S0[4]*S1[4]+S0[5]*S1[5]+S0[6]*S1[6]+S0[7]*S1[7]
Operand type	D0: 64-bit signed integer S0: 8 * 8-bit signed integer S1: 8 * 8-bit signed integer

GMADBU	**Group multiply and add for 8-bit unsigned input data**
Usage	GMADBU D0, S0, S1
Function	D0 = D0+S0[0]*S1[0]+S0[1]*S1[1]+S0[2]*S1[2]+S0[3]*S1[3]+S0[4]*S1[4]+S0[5]*S1[5]+S0[6]*S1[6]+S0[7]*S1[7] S0 and S1 are unsigned 8-bit vectors with each 8 elements. The instruction is performing a multiplication of each element between the vectors S0 and S1 and adding all results to the input D0 before storing back the result to D0. D0 is a 32-bit signed value. S0 and S1 are 64-bit vectors, which are specified by the even of 2 consecutive 32-bit registers. Hardware does not take care any overflow handlings, so software must take care of it.
Behavior model	D0 = D0+S0[0]*S1[0]+S0[1]*S1[1]+S0[2]*S1[2]+S0[3]*S1[3]+S0[4]*S1[4]+S0[5]*S1[5]+S0[6]*S1[6]+S0[7]*S1[7]
Operand type	D0: 32-bit signed integer S0: 8 * 8-bit unsigned integer S1: 8 * 8-bit unsigned integer

GMADBUL	**Group multiply and add for 8-bit unsigned input data long**
Usage	GMADBUL D0, S0, S1
Function	D0 = D0+S0[0]*S1[0]+S0[1]*S1[1]+S0[2]*S1[2]+S0[3]*S1[3]+S0[4]*S1[4]+S0[5]*S1[5]+S0[6]*S1[6]+S0[7]*S1[7] S0 and S1 are unsigned 8-bit vectors with each 8 elements. The instruction is performing a multiplication of each element between the vectors S0 and S1 and adding all results to the input D0 before storing back the result to D0. D0 is a 64-bit signed value. S0 and S1 are 64-bit vectors, which are specified by the even of 2 consecutive 32-bit registers. Hardware does not take care any overflow handlings, so software must take care of it.
Behavior model	D0 = D0+S0[0]*S1[0]+S0[1]*S1[1]+S0[2]*S1[2]+S0[3]*S1[3]+S0[4]*S1[4]+S0[5]*S1[5]+S0[6]*S1[6]+S0[7]*S1[7]
Operand type	D0: 64-bit unsigned integer S0: 8 * 8-bit unsigned integer S1: 8 * 8-bit unsigned integer

GMADHS	**Group multiply and add for 16-bit signed input data**
Usage	GMADHS D0, S0, S1
Function	D0 = D0+S0[0]*S1[0]+S0[1]*S1[1]+S0[2]*S1[2]+S0[3]*S1[3] S0 and S1 are signed 16-bit vectors with each 4 elements. The instruction is performing a multiplication of each element between the vectors S0 and S1 and adding all results to the input D0 before storing back the result to D0. D0 is a 32-bit signed value. S0 and S1 are 64-bit vectors, which are specified by the even of 2 consecutive 32-bit registers. Hardware does not take care any overflow handlings, so software must take care of it.
Behavior model	D0 = D0+S0[0]*S1[0]+S0[1]*S1[1]+S0[2]*S1[2]+S0[3]*S1[3]
Operand type	D0: 32-bit signed integer S0: 4 * 16-bit signed integer S1: 4 * 16-bit signed integer

GMADHSL	Group multiply and add for 16-bit signed input data long
Usage	GMADHSL D0, S0, S1
Function	D0 = D0+S0[0]*S1[0]+S0[1]*S1[1]+S0[2]*S1[2]+S0[3]*S1[3] S0 and S1 are signed 16-bit vectors with each 4 elements. The instruction is performing a multiplication of each element between the vectors S0 and S1 and adding all results to the input D0 before storing back the result to D0. D0 is a 64-bit signed value. S0 and S1 are 64-bit vectors, which are specified by the even of 2 consecutive 32-bit registers. Hardware does not take care any overflow handlings, so software must take care of it.
Behavior model	D0 = D0+S0[0]*S1[0]+S0[1]*S1[1]+S0[2]*S1[2]+S0[3]*S1[3]
Operand type	D0: 64-bit signed integer S0: 4 * 16-bit signed integer S1: 4 * 16-bit signed integer

GMADHU	Group multiply and add for 16-bit unsigned input data
Usage	GMADHU D0, S0, S1
Function	D0 = D0+S0[0]*S1[0]+S0[1]*S1[1]+S0[2]*S1[2]+S0[3]*S1[3] S0 and S1 are unsigned 16-bit vectors with each 4 elements. The instruction is performing a multiplication of each element between the vectors S0 and S1 and adding all results to the input D0 before storing back the result to D0. D0 is a 32-bit unsigned value. S0 and S1 are 64-bit vectors, which are specified by the even of 2 consecutive 32-bit registers. Hardware does not take care any overflow handlings, so software must take care of it.
Behavior model	D0 = D0+S0[0]*S1[0]+S0[1]*S1[1]+S0[2]*S1[2]+S0[3]*S1[3]
Operand type	D0: 32-bit unsigned integer S0: 4 * 16-bit unsigned integer S1: 4 * 16-bit unsigned integer

GMADHUL	Group multiply and add for 16-bit unsigned input data long
Usage	GMADHUL D0, S0, S1
Function	D0 = D0+S0[0]*S1[0]+S0[1]*S1[1]+S0[2]*S1[2]+S0[3]*S1[3] S0 and S1 are unsigned 16-bit vectors with each 4 elements. The instruction is performing a multiplication of each element between the vectors S0 and S1 and adding all results to the input D0 before storing back the result to D0. D0 is a 64-bit unsigned value. S0 and S1 are 64-bit vectors, which are specified by the even of 2 consecutive 32-bit registers. Hardware does not take care any overflow handlings, so software must take care of it.
Behavior model	D0 = D0+S0[0]*S1[0]+S0[1]*S1[1]+S0[2]*S1[2]+S0[3]*S1[3]
Operand type	D0: 64-bit unsigned integer S0: 4 * 16-bit unsigned integer S1: 4 * 16-bit unsigned integer

GSADBS	Group SAD and sum up for 8-bit signed input data
Usage	GSADBS D0, S0, S1
Function	D0 = D0+|S0[0]-S1[0]|+|S0[1]-S1[1]|+|S0[2]-S1[2]|+|S0[3]-S1[3]|+|S0[4]-S1[4]|+|S0[5]-S1[5]|+|S0[6]-S1[6]|+|S0[7]-S1[7]| S0 and S1 are signed 8-bit vectors with each 8 elements. The instruction is performing difference calculation of each element of vector S1 from vector S0 and adding all results to the input D0 before storing back the result to D0. D0 is a 32-bit signed value. S0 and S1 are 64-bit vectors, which are specified by the even of 2 consecutive 32-bit registers.
Behavior model	D0 = D0+|S0[0]-S1[0]|+|S0[1]-S1[1]|+|S0[2]-S1[2]|+|S0[3]-S1[3]|+|S0[4]-S1[4]|+|S0[5]-S1[5]|+|S0[6]-S1[6]|+|S0[7]-S1[7]|
Operand type	D0: 32-bit signed integer S0: 8 * 8-bit signed integer S1: 8 * 8-bit signed integer

GSADBU	Group SAD and sum up for 8-bit unsigned input data
Usage	GSADBU D0, S0, S1
Function	D0 = D0+|S0[0]-S1[0]|+|S0[1]-S1[1]|+|S0[2]-S1[2]|+|S0[3]-S1[3]|+|S0[4]-S1[4]|+|S0[5]-S1[5]|+|S0[6]-S1[6]|+|S0[7]-S1[7]| S0 and S1 are unsigned 8-bit vectors with each 8 elements. The instruction is performing a difference calculation of each element of vector S1 from vector S0 and adding all results to the input D0 before storing back the result to D0. D0 is a 32-bit unsigned value. S0 and S1 are 64-bit vectors, which are specified by the even of 2 consecutive 32-bit registers.
Behavior model	D0 = D0+|S0[0]-S1[0]|+|S0[1]-S1[1]|+|S0[2]-S1[2]|+|S0[3]-S1[3]|+|S0[4]-S1[4]|+|S0[5]-S1[5]|+|S0[6]-S1[6]|+|S0[7]-S1[7]|
Operand type	D0: 32-bit unsigned integer S0: 8 * 8-bit unsigned integer S1: 8 * 8-bit unsigned integer

GSADHS	Group SAD and sum up for 16-bit signed input data
Usage	GSADHS D0, S0, S1
Function	D0 = D0+|S0[0]-S1[0]|+|S0[1]-S1[1]|+|S0[2]-S1[2]|+|S0[3]-S1[3]| S0 and S1 are signed 16-bit vectors with each 4 elements. The instruction is performing a difference calculation of each element of vector S1 from vector S0 and adding all results to the input D0 before storing back the result to D0.D0 is a 32-bit signed value. S0 and S1 are 64-bit vectors, which are specified by the even of 2 consecutive 32-bit registers.
Behavior model	D0 = D0+|S0[0]-S1[0]|+|S0[1]-S1[1]|+|S0[2]-S1[2]|+|S0[3]-S1[3]|
Operand type	D0: 32-bit signed integer S0: 4 * 16-bit signed integer S1: 4 * 16-bit signed integer

GSADHU	Group SAD and sum up for 16-bit unsigned input data
Usage	GSADHU D0, S0, S1
Function	D0 = D0+|S0[0]-S1[0]|+|S0[1]-S1[1]|+|S0[2]-S1[2]|+|S0[3]-S1[3]|
	S0 and S1 are unsigned 16-bit vectors with each 4 elements. The instruction is performing difference calculation of each element of vector S1 from vector S0 and adding all results to the input D0 before storing back the result to D0.D0 is a 32-bit signed value. S0 and S1 are 64-bit vectors, which are specified by the even of 2 consecutive 32-bit registers.
Behavior model	D0 = D0+|S0[0]-S1[0]|+|S0[1]-S1[1]|+|S0[2]-S1[2]|+|S0[3]-S1[3]|
Operand type	D0: 32-bit signed integer
	S0: 4 * 16-bit unsigned integer
	S1: 4 * 16-bit unsigned integer

GSUBBS	Group sub and sum up for 8-bit signed input data
Usage	GSUBBS D0, S0, S1
Function	D0 = D0+(S0[0]-S1[0])+(S0[1]-S1[1])+(S0[2]-S1[2])+(S0[3]-S1[3])+(S0[4]-S1[4])+(S0[5]-S1[5])+(S0[6]-S1[6])+(S0[7]-S1[7])
	S0 and S1 are signed 8-bit vectors with each 8 elements. The instruction is performing a subtraction of each element of vector S1 from vector S0 and adding all results to the input D0 before storing back the result to D0. D0 is a 32-bit signed value. S0 and S1 are 64-bit vectors, which are specified by the even of 2 consecutive 32-bit registers.
Behavior model	D0 = D0+(S0[0]-S1[0])+(S0[1]-S1[1])+(S0[2]-S1[2])+(S0[3]-S1[3])+(S0[4]-S1[4])+(S0[5]-S1[5])+(S0[6]-S1[6])+(S0[7]-S1[7])
Operand type	D0: 32-bit signed integer
	S0: 8 * 8-bit signed integer
	S1: 8 * 8-bit signed integer

GSUBBU	Group sub and sum up for 8-bit unsigned input data
Usage	GSUBBU D0, S0, S1
Function	D0 = D0+(S0[0]-S1[0])+(S0[1]-S1[1])+(S0[2]-S1[2])+(S0[3]-S1[3])+(S0[4]-S1[4])+(S0[5]-S1[5])+(S0[6]-S1[6])+(S0[7]-S1[7])
	S0 and S1 are unsigned 8-bit vectors with each 8 elements. The instruction is performing a subtraction of each element of vector S1 from vector S0 and adding all results to the input D0 before storing back the result to D0. D0 is a 32-bit signed value. S0 and S1 are 64-bit vectors, which are specified by the even of 2 consecutive 32-bit registers.
Behavior model	D0 = D0+(S0[0]-S1[0])+(S0[1]-S1[1])+(S0[2]-S1[2])+(S0[3]-S1[3])+(S0[4]-S1[4])+(S0[5]-S1[5])+(S0[6]-S1[6])+(S0[7]-S1[7])
Operand type	D0: 32-bit signed integer
	S0: 8 * 8-bit unsigned integer
	S1: 8 * 8-bit unsigned integer

GSUBHS	Group sub and sum up for 16-bit signed input data
Usage	GSUBHS D0, S0, S1
Function	D0 = D0+(S0[0]-S1[0])+(S0[1]-S1[1])+(S0[2]-S1[2])+(S0[3]-S1[3]) S0 and S1 are signed 16-bit vectors with each 4 elements. The instruction is performing a subtraction of each element of vector S1 from vector S0 and adding all results to the input D0 before storing back the result to D0.D0 is a 32-bit signed value.S0 and S1 are 64-bit vectors, which are specified by the even of 2 consecutive 32-bit registers.
Behavior model	D0 = D0+(S0[0]-S1[0])+(S0[1]-S1[1])+(S0[2]-S1[2])+(S0[3]-S1[3])
Operand type	D0: 32-bit signed integer S0: 4 * 16-bit signed integer S1: 4 * 16-bit signed integer

GSUBHU	Group sub and sum up for 16-bit unsigned input data
Usage	GSUBHU D0, S0, S1
Function	D0 = D0+(S0[0]-S1[0])+(S0[1]-S1[1])+(S0[2]-S1[2])+(S0[3]-S1[3]) S0 and S1 are unsigned 16-bit vectors with each 4 elements. The instruction is performing a subtraction of each element of vector S1 from vector S0 and adding all results to the input D0 before storing back the result to D0.D0 is a 32-bit signed value.S0 and S1 are 64-bit vectors, which are specified by the even of 2 consecutive 32-bit registers.
Behavior model	D0 = D0+(S0[0]-S1[0])+(S0[1]-S1[1])+(S0[2]-S1[2])+(S0[3]-S1[3])
Operand type	D0: 32-bit signed integer S0: 4 * 16-bit unsigned integer S1: 4 * 16-bit unsigned integer

I2F	Integer to Float
Usage	I2F D0, S0
Function	Assumes the S0 value is an integer, converts it into an IEEE754 single-precision floating-point number, then stores the result in D0. The rounding method can be changed by the control register.
Behavior model	D0 = float((int)S0);

INT	Interrupt
Usage	INT
Function	Interrupts current processing in a thread and waits for resuming by host.
Behavior model	-

INV	INVerse
Usage	INV D0, S0
Function	Treats S0 as a 32-bit array, inverts all bits of this array, and stores the result in D0.
Behavior model	D0 = ~S0;

INV64	INVerse 64-bit values
Usage	INV64 D0, S0
Function	This is an instruction to invert a 64-bit (8 times 8-bit or 4 times 16-bit) value.
Behavior model	D0[n] = !S0[n], n = 0...63;
Operand type	D0: 64-bit integer S0: 64-bit integer

L2F	Long to Float
Usage	L2F D0, S0
Function	Convert 64-bit value stored in register pair specified by even register S0 to IEEE754 single floating point format, then store the result to register D0. The rounding method is specified by the control register.
Behavior model	D0 = float(S0);

LD	Load word
Usage	LD D0, S0, S1
Function	It is a data transfer instruction from memory to the register. The 32-bit data is loaded to register D0 from the 32-bit aligned address specified by the sum of the values S0 and S1*4. S1 is specifying a 32-bit word offset. The value of S0 must be a multiple of 4 (word aligned) otherwise behavior is undefined.
Behavior model	D0 = *(S0+S1*4);

LDBS	Load byte with signed extension
Usage	LDBS D0, S0, S1
Function	It is a data transfer instruction from memory to the register. The 8-bit data is loaded and signed 32-bit extended to register D0 from the 8-bit aligned address specified by the sum of the values S0 and S1. S1 is specifying a signed byte offset.
Behavior model	D0 = (signed int)*(S0+S1);

LDBSI	Load byte with signed extension and immediate offset
Usage	LDBSI D0, S0, #IMM
Function	It is a data transfer instruction from memory to the register. The 8-bit data is loaded and signed 32-bit extended to register D0 from the 8-bit aligned address specified by the sum of the values S0 and #IMM. The 8-bit signed immediate value is specifying a byte offset.
Behavior model	D0 = (signed int)*(S0+#IMM);

LDBU	Load byte with unsigned extension
Usage	LDBU D0, S0, S1
Function	It is a data transfer instruction from memory to the register. The 8-bit data is loaded, and unsigned 32-bit extended to register D0 from the 8-bit aligned address specified by the sum of the values S0 and S1. S1 is specifying a signed byte offset.
Behavior model	D0 = (unsigned int)*(S0+S1);

LDBUI	Load byte with unsigned extension and immediate offset
Usage	LDBUI D0, S0, #IMM
Function	It is a data transfer instruction from memory to the register. The 8-bit data is loaded, and unsigned 32-bit extended to register D0 from the 8-bit aligned address specified by the sum of the values S0 and #IMM. The 8-bit signed immediate value is specifying a byte offset.
Behavior model	D0 = (unsigned int)*(S0+#IMM);

LDCI	Load from Control Register
Usage	LDCI D0, #IMM
Function	This is an instruction for loading data from a control register. Writes the data read from the control register specified by #IMM to the general purpose register D0. The value written to D0 is an integer. Specifying #IMM as the number of a control register that does not exist is prohibited.
Behavior model	D0 = ControlRegister[#IMM];
Operand type	D0: General purpose register #IMM: 8-bit unsigned integer

LDHS	Load half word with signed extension
Usage	LDHS D0, S0, S1
Function	It is a data transfer instruction from memory to the register. The 16-bit data is loaded and signed 32-bit extended to register D0 from the 16-bit aligned address specified by the sum of the values S0 and S1*2. S1 is specifying a 16-bit short offset. The value of S0 must be a multiple of 2 (half word aligned) otherwise behavior is undefined.
Behavior model	D0 = (signed int)*(S0+S1*2);

LDHSI	Load half word with signed extension and immediate offset
Usage	LDHSI D0, S0, #ASMIMM
Function	It is a data transfer instruction from memory to the register. The 16-bit data is loaded and signed 32-bit extended to register D0 from the 16-bit aligned address specified by the sum of the values S0 and #ASMIMM. The 8-bit signed immediate value is specifying a byte offset. The value of S0 must be a multiple of 2 (half word aligned) otherwise behavior is undefined.

Behavior model	#IMM = #ASMIMM>>1
	D0 = (signed int)*(S0+#IMM*2);

LDHU	Load half word with unsigned extension
Usage	LDHU D0, S0, S1
Function	It is a data transfer instruction from memory to the register. The 16-bit data is loaded, and unsigned 32-bit extended to register D0 from the 16-bit aligned address specified by the sum of the values S0 and S1*2. S1 is specifying a 16-bit short offset. The value of S0 must be a multiple of 2 (half word aligned) otherwise behavior is undefined.
Behavior model	D0 = (unsigned int)*(S0+S1*2);

LDHUI	Load half word with unsigned extension and immediate offset
Usage	LDHUI D0, S0, #ASMIMM
Function	It is a data transfer instruction from memory to the register. The 16-bit data is loaded, and unsigned 32-bit extended to register D0 from the 16-bit aligned address specified by the sum of the values S0 and #ASMIMM. The 8-bit signed immediate value is specifying a byte offset. The value of S0 must be a multiple of 2 (half word aligned) otherwise behavior is undefined.

Behavior model	#IMM = #ASMIMM>>1
	D0 = (unsigned int)*(S0+#IMM*2);

LDI	Load word with immediate offset
Usage	LDI D0, S0, #ASMIMM
Function	It is a data transfer instruction from memory to the register. The 32-bit data is loaded to register D0 from the 32-bit aligned address specified by the sum of the values S0 and #ASMIMM. The 8-bit signed immediate value is specifying a byte offset. The value of S0 must be a multiple of 4 (word aligned) otherwise behavior is undefined.

Behavior model	#IMM = #ASMIMM>>2
	D0 = *(S0+#IMM*4);

LDLL	Load Long from Local working memory
Usage	LDLL D0, S0, S1
Function	This is an instruction to transfer 64-bit data from local working memory to a 64-bit pair register. This instruction supports the common and non-common address space. Writes the data read from the address specified by adding the S1×8 value to address S0 of local working memory to D0. When this instruction is used for other memory accesses, this instruction transfer 32-bit from the specified memory address into the even register and set the odd register to 0. The 64-bit access to LWM must be aligned, when unaligned, function is prohibited. D0 is a 64-bit pair register, always the lower even register is specified, which holds the lower 32-bit. S0 and S1 are 32-bit registers. The value of S0 must be a multiple of 8 (long word aligned) otherwise behavior is undefined.
Behavior model	D0 = *(S0 + S1*8);
Operand type	D0: 64-bit unsigned integer S0: 32-bit unsigned integer (Multiples of 8) S1: 32-bit signed integer

LDLLI	Load Long from Local working memory with Immediate offset
Usage	LDLLI D0, S0, #ASMIMM
Function	This is an instruction to transfer 64-bit data from local working memory to a 64-bit pair register. This instruction supports the common and non-common address space. Writes the data read from the address specified by adding the #IMM×8 value to address S0 of local working memory to D0. When this instruction is used for other memory accesses, this instruction transfer 32-bit from the specified memory address into the even register and set the odd register to 0. The 64-bit access to LWM must be aligned, when unaligned, function is prohibited. D0 is a 64-bit pair register, always the lower even register is specified, which holds the lower 32-bit. S0 is a 32-bit register. The value of S0 must be a multiple of 8 (long word aligned) otherwise behavior is undefined.

Behavior model	#IMM = #ASMIMM>>3
	D0 = *(S0 + (char)#IMM*8);

Operand type	D0: 64-bit unsigned integer S0: 32-bit unsigned integer (Multiples of 8) #IMM: 8-bit signed integer

LDLRB	LoaD Large Register Block
Usage	LDLRB D0, S0, S1
Function	This is an instruction to transfer 512-bit data from local working memory to a 512-bit large register block. This instruction supports only the common address space. Writes the data read from the address specified by adding S1*64 to address S0 of local working memory to D0. The access to LWM must be 64-bit aligned, when unaligned, function is prohibited. D0 is specifying the lowest register of the register block. Allowed values are 16 (for register block R16-R31) and 32 (for register block R32-R47)
Behavior model	D0 = *(S0 + S1*64);
Operand type	D0: 512-bit unsigned integer S0: 32-bit unsigned integer (Multiples of 8) S1: 16-bit signed integer

LDLRBI	LoaD Large Register Block with Immediate offset
Usage	LDLRBI D0, S0, #IMM
Function	This is an instruction to transfer 512-bit data from local working memory to a 512-bit large register block. This instruction supports only the common address space. Writes the data read from the address specified by adding #IMM*64 to address S0 of local working memory to D0. The access to LWM must be 64-bit aligned, when unaligned, function is prohibited. D0 is specifying the lowest register of the register block. Allowed values are 16 (for register block R16-R31) and 32 (for register block R32-R47)
Behavior model	D0 = *(S0 + #IMM*64);
Operand type	D0: 512-bit unsigned integer S0: 32-bit unsigned integer (Multiples of 8) #IMM: 8-bit signed integer

LDLRBC	LoaD Large Register Block with LPC offset
Usage	LDLRBC D0, S0
Function	This is an instruction to transfer 512-bit data from local working memory to a 512-bit large register block. This instruction supports only the common address space. Writes the data read from the address specified by adding LPC (loop counter)*64 to address S0 of local working memory to D0. The access to LWM must be 64-bit aligned, when unaligned, function is prohibited. D0 is specifying the lowest register of the register block. Allowed values are 16 (for register block R16-R31) and 32 (for register block R32-R47)
Behavior model	D0 = *(S0 + LPC*64);
Operand type	D0: 512-bit unsigned integer S0: 32-bit unsigned integer (Multiples of 8) LPC: 9-bit signed integer

LDRCI	Load from Relative Coordinate XY with Immediate offset
Usage	LDRCI D0, #IMM1, #IMM2
Function	This is an instruction for data transfer from memory to a register. X and Y coordinates are specified in R0 and R1 respectively. Reads the value from memory at the coordinates obtained by adding the #IMM1 value to X and the #IMM2 value to Y and stores the value in D0. The full 32 bits of R0 and the 16 lower-order bits of R1 are handled as signed integers. #IMM1 and #IMM2 need to be specified with 8-bit signed integers. Operation cannot be guaranteed if the calculated offset is negative to the base address or obtained address is outside from the range handled by the CVengine. The value stored in D0 is an integer.
Behavior model	D0 = (int)* (R0+(char)#IMM1, (short)((short)(R1&0xffff)+(char)#IMM2));
Operand type	D0: 32-bit signed integer #IMM1: 8-bit signed integer #IMM2: 8-bit signed integer R0: 32-bit signed integer R1: 16-bit signed integer

LDRCIU	Load from Relative Coordinate XY with Immediate offset, then source Updated
Usage	LDRCIU D0, #IMM1, #IMM2
Function	This is an instruction for data transfer from memory to a register. X and Y coordinates are specified in R0 and R1 respectively. Reads the value from memory at the coordinates obtained by adding the #IMM1 value to X and the #IMM2 value to Y and stores the value in D0. The full 32 bits of R0 and the 16 lower-order bits of R1 are handled as signed integers. #IMM1 and #IMM2 need to be specified with 8-bit signed integers. After operation, X(R0) and Y(R1) are updated by adding #IMM1 and #IMM2 respectively. Operation cannot be guaranteed if the calculated offset is negative to the base address or obtained address is outside from the range handled by the CVengine. The value stored in D0 is an integer.

Behavior model	D0 = (int)* (R0+(char)#IMM1, (short)((short)(R1&0xffff)+(char)#IMM2));
	R0 = R0+(char)#IMM1; R1 = (short)(R1+(char)#IMM2);

Operand type	D0: 32-bit signed integer #IMM1: 8-bit signed integer #IMM2: 8-bit signed integer R0: 32-bit signed integer R1: 16-bit signed integer

LDRXY	Load from Relative Coordinate XY with register offset
Usage	LDRXY D0, S0, S1
Function	This is an instruction for data transfer from memory to a register. X and Y coordinates are specified in R0 and R1 respectively. Reads the value from memory at the coordinates obtained by adding the S0 value to X and the S1 value to Y and stores the value in D0. The full 32 bits of R0 and S0 and the 16 lower-order bits of R1 and S1 are handled as signed integers. Operation cannot be guaranteed if the calculated offset is negative to the base address or obtained address is outside from the range handled by the CVengine. The value stored in D0 is an integer.
Behavior model	D0 = (int) *(R0+S0, (short)((short)(R1&0xffff)+(short)(S1&0xffff)));
Operand type	D0: 32-bit signed integer S0: 32-bit signed integer S1: 16-bit signed integer R0: 32-bit signed integer R1: 16-bit signed integer

LDRXYU	Load from Relative Coordinate XY with register offset, then source Updated
Usage	LDRXYU D0, S0, S1
Function	This is an instruction for data transfer from memory to a register. X and Y coordinates are specified in R0 and R1 respectively. Reads the value from memory at the coordinates obtained by adding the S0 value to X and the S1 value to Y and stores the value in D0. The full 32 bits of R0 and S0 and the 16 lower-order bits of R1 and S1 are handled as signed integers. After operation, X(R0) and Y(R1) are updated by adding S0 and S1 respectively. Operation cannot be guaranteed if the calculated offset is negative to the base address or obtained address is outside from the range handled by the CVengine. The value stored in D0 is an integer.
Behavior model	D0 = (int) *(R0+S0, (short)((short)(R1&0xffff)+(short)(S1&0xffff))); R0 = R0+S0; R1 = (short)((short)(R1&0xffff)+(short)(S1&0xffff));
Operand type	D0: 32-bit signed integer S0: 32-bit signed integer S1: 16-bit signed integer R0: 32-bit signed integer R1: 16-bit signed integer

LDSRB	LoaD Small Register Block
Usage	LDSRB D0, S0, S1
Function	This is an instruction to transfer 256-bit data from local working memory to a 256-bit large register block. This instruction supports only the common address space. Writes the data read from the address specified by adding S1*32 to address S0 of local working memory to D0. The access to LWM must be 64-bit aligned, when unaligned, function is prohibited. D0 is specifying the lowest register of the register block. Allowed values are 16 (for register block R16-R23), 24 (for register block R24-R31), 32 (for register block R32-R39) and 40 (for register block R40-R47)
Behavior model	D0 = *(S0 + S1*32);
Operand type	D0: 256-bit unsigned integer S0: 32-bit unsigned integer (Multiples of 8) S1: 16-bit signed integer

LDSRBI	LoaD Small Register Block with Immediate offset
Usage	LDSRBI D0, S0, #IMM
Function	This is an instruction to transfer 256-bit data from local working memory to a 256-bit large register block. This instruction supports only the common address space. Writes the data read from the address specified by adding #IMM*32 to address S0 of local working memory to D0. The access to LWM must be 64-bit aligned, when unaligned, function is prohibited. D0 is specifying the lowest register of the register block. Allowed values are 16 (for register block R16-R23), 24 (for register block R24-R31), 32 (for register block R32-R39) and 40 (for register block R40-R47)
Behavior model	D0 = *(S0 + #IMM*32);
Operand type	D0: 256-bit unsigned integer S0: 32-bit unsigned integer (Multiples of 8) #IMM: 8-bit signed integer

LDSRBC	LoaD Small Register Block with LPC offset
Usage	LDSRBC D0, S0
Function	This is an instruction to transfer 256-bit data from local working memory to a 256-bit large register block. This instruction supports only the common address space. Writes the data read from the address specified by adding LPC*32 to address S0 of local working memory to D0. The access to LWM must be 64-bit aligned, when unaligned, function is prohibited. D0 is specifying the lowest register of the register block. Allowed values are 16 (for register block R16-R23), 24 (for register block R24-R31), 32 (for register block R32-R39) and 40 (for register block R40-R47)
Behavior model	D0 = *(S0 + LPC*32);
Operand type	D0: 256-bit unsigned integer S0: 32-bit unsigned integer (Multiples of 8) LPC: 9-bit signed integer

LLROT	Long left rotate
Usage	LLROT D0, S0, S1
Function	D0 = (S0 << S1) | (S0 >> (64-(S1&0x3f)))
	S0 is a 64-bit vector and S1 is a 32-bit vector. The instruction is left rotating the 64-bit source S0 by an unsigned value specified in the lower 6bits of source S1. D0 and S0 are 64-bit values stored in 2 consecutive 32-bit registers, which are specified by the even of 2 consecutive 32-bit registers.
Behavior model	D0 = (S0 << S1) | (S0 >> (64-S1))

LMBD	Left Most Bit Detection
Usage	LMBD D0, S0
Function	This is an instruction which searches the first "1" from left side inside S0 and gives back the position in D0. Position counting from left side. Output == 0x80000000 if "1" is not available. Implemented in SAM4.
Behavior model	S0[31] == "1"?D0=0: (S0[30] == "1"?D0=1: (S0[29] == "1"?D0=2:(.... S0[1] == "1"?D0=30: (S0[0] == "1"?D0=31:D0=0x80000000)))
Operand type	D0: 32bit unsigned integer (6bit used)
	S0: 32bit unsigned integer

LPE	LooP End
Usage	LPE
Function	LPC = LPC - LPC_DEC
	(LPC >=0)? PC = LPC_ADD : PC = PC+1
	This is an instruction to subtract the content from the internal register LPC_DEC from LPC and depending on the result, jump back to the address stored in the internal register LPC_ADD (in case LPC is positive) without 1 cycle delay or continue with the instruction flow (1 cycle delay will appear).
Behavior model	LPC = LPC - LPC_DEC
	(LPC >=0)? PC = LPC_ADD : PC = PC+1

LPS	LooP Start
Usage	LPS S0, #IMM
Function	This is an instruction to fast set up a most inner loop with loop counter and loop decrement value. The value specified in S0 is written to the internal loop counter register LPC that can have a 9-bit signed integer. The loop counter decrement LPC_DEC is initialized with the immediate value #IMM. The word address following the LPS instruction is saved into an internal register LPC_ADD.
Behavior model	LPC = S0;
	LPC_DEC = #IMM;
	LPC_ADD = PC+1;
Operand type	S0: 8-bit unsigned integer
	#IMM: 5-bit unsigned integer

MACS	Multiply and ACcumulate
Usage	MACS D0, S0, S1
Function	D0 = D0 + S0 * S1 S0 and S1 are 2 32-bit signed values and D0 is a 64-bit signed element. The instruction is multiplying the 2 32-bit elements and the result is added to the 64-bit signed element D0. After, the 64-bit are stored back to the register file. D0 is a register pair specified by its even register number.
Behavior model	D0 = D0 + S0 * S1

MACSS	Multiply and Accumulate Short
Usage	MACSS D0, S0, S1
Function	D0 = D0 + S0 * S1 D0, S0 and S1 are 3 32-bit signed values. The instruction is multiplying the 2 32-bit source elements S0 and S1 and the result is added to the 32-bit signed element D0. After, the lower 32-bit are stored back to D0 in the register file. The upper 32bit is getting discarded, no overflow handling is implemented.
Behavior model	D0 = D0 + S0 * S1

MACSSRE	Multiply and Accumulate Short with Register Exchange
Usage	MACSS D0, S0, S1
Function	D0 = S0 + D0 * S1 D0, S0 and S1 are 3 32-bit signed values. The instruction is multiplying D0 times S1 and the result is added to S0. After, the lower 32-bit are stored back to D0 in the register file. The upper 32bit is getting discarded, no overflow handling is implemented.
Behavior model	D0 = S0 + D0 * S1

MAXS	MAXimum
Usage	MAXS D0, S0,S1
Function	Selects the larger value between S0 and S1, then stores the result in D0. S0 and S1 are handled as integers in the operation.
Behavior model	D0 = ((int)S0 > (int)S1) ? S0 : S1;

MAXS8	MAXimum Signed 8-bit value
Usage	MAXS8 D0, S0, S1
Function	This is an instruction to get the maximum value from 8 times 2 signed 8-bit input values from source S0 and S1. Implemented in SAM4.
Behavior model	D0[n] = MAX(S0[n], S1[n]), n = 0...7;
Operand type	D0: 8 times 8-bit signed integer S0: 8 times 8-bit signed integer S1: 8 times 8-bit signed integer

MAXS16	MAXimum Signed 16-bit value
Usage	MAXS16 D0, S0, S1
Function	This is an instruction to get the maximum value from 4 times 2 signed 16-bit input values from source S0 and S1. Implemented in SAM4.
Behavior model	D0[n] = MAX(S0[n], S1[n]), n = 0...3;
Operand type	D0: 4 times 16-bit signed integer S0: 4 times 16-bit signed integer S1: 4 times 16-bit signed integer

MAXSU	MAXimum compared to Uniform
Usage	MAXSU D0, S0,#IMM
Function	Selects the larger value between S0 and the uniform value indexed by #IMM, then stores the result in D0. S0 and the uniform value are handled as integers in the operation.
Behavior model	D0 = ((int)S0 > (int)Uniform[#R6IMM] ? S0 : (int)Uniform[#R6IMM];

MAXU8	MAXimum Unsigned 8-bit value
Usage	MAXU8 D0, S0, S1
Function	This is an instruction to get the maximum value from 8 times 2 unsigned 8-bit input values from source S0 and S1. Implemented in SAM4.
Behavior model	D0[n] = MAX(S0[n], S1[n]), n = 0...7;
Operand type	D0: 8 times 8-bit unsigned integer S0: 8 times 8-bit unsigned integer S1: 8 times 8-bit unsigned integer

MAXU16	MAXimum Unsigned 16-bit value
Usage	MAXU16 D0, S0, S1
Function	This is an instruction to get the maximum value from 4 times 2 unsigned 16-bit input values from source S0 and S1. Implemented in SAM4.
Behavior model	D0[n] = MAX(S0[n], S1[n]), n = 0...3;
Operand type	D0: 4 times 16-bit unsigned integer S0: 4 times 16-bit unsigned integer S1: 4 times 16-bit unsigned integer

MINS	MINimum
Usage	MINS D0, S0,S1
Function	Selects the smaller value between S0 and S1, then stores the result in D0. S0 and S1 are handled as integers in the operation.
Behavior model	D0 = ((int)S0 > (int)S1) ? S1 : S0;

MINS8	MINimum Signed 8-bit value
Usage	MINS8 D0, S0, S1
Function	This is an instruction to get the minimum value from 8 times 2 signed 8-bit input values from source S0 and S1. Implemented in SAM4.
Behavior model	D0[n] = MIN(S0[n], S1[n]), n = 0...7;
Operand type	D0: 8 times 8-bit signed integer S0: 8 times 8-bit signed integer S1: 8 times 8-bit signed integer

MINS16	MINimum Signed 16-bit value
Usage	MINS16 D0, S0, S1
Function	This is an instruction to get the minimum value from 4 times 2 signed 16-bit input values from source S0 and S1. Implemented in SAM4.
Behavior model	D0[n] = MIN(S0[n], S1[n]), n = 0...3;
Operand type	D0: 4 times 16-bit signed integer S0: 4 times 16-bit signed integer S1: 4 times 16-bit signed integer

MINSU	MINimum compared to Uniform
Usage	MINSU D0, S0,#IMM
Function	Selects the smaller value between S0 and the uniform value indexed by #IMM, then stores the result in D0. S0 and the uniform value are handled as integers in the operation.
Behavior model	D0 = ((int)S0 > (int)Uniform[#R6IMM] ? (int)Uniform[#R6IMM] : S0;

MINU8	MINimum Unsigned 8-bit value
Usage	MINU8 D0, S0, S1
Function	This is an instruction to get the minimum value from 8 times 2 unsigned 8-bit input values from source S0 and S1. Implemented in SAM4.
Behavior model	D0[n] = MIN(S0[n], S1[n]), n = 0...7;
Operand type	D0: 8 times 8-bit unsigned integer S0: 8 times 8-bit unsigned integer S1: 8 times 8-bit unsigned integer

MINU16	MINimum Unsigned 16-bit value
Usage	MINU16 D0, S0, S1
Function	This is an instruction to get the minimum value from 4 times 2 unsigned 16-bit input values from source S0 and S1. Implemented in SAM4.
Behavior model	D0[n] = MIN(S0[n], S1[n]), n = 0...3;
Operand type	D0: 4 times 16-bit unsigned integer S0: 4 times 16-bit unsigned integer S1: 4 times 16-bit unsigned integer

MOV	MOVe
Usage	MOV D0, S0
Function	This is an instruction for data transfer between registers. Stores the S0 value in D0.
Behavior model	D0 = S0;
Operand type	D0: -(32-bit array) S0: -(32-bit array)

MOVI	MOVe Immediate value
Usage	MOVI D0, #IMM
Function	The #IMM value is handled as a 16-bit signed integer, then sign-extended into a 32-bit signed integer, and the result is stored in D0.
Behavior model	D0 = (int)(#IMM & 0x0000ffff);
Operand type	D0: Signed integer #IMM: 16-bit Signed integer

MOVU	MOVe Uniform
Usage	MOVU D0, #IMM
Function	Stores the index value in Uniform specified by #IMM in D0.
Behavior model	D0 = Uniform[#R6IMM];
Operand type	D0: -(32-bit array) Uniform value: -(32-bit array)

MUL	MULtiply
Usage	MUL D0, S0, S1
Function	Multiply the 32-bit signed input values S0 and S1 and store the lower 32-bit of the result to D0.
Behavior model	D0 = S0 * S1;

MULS	MULtiply with Saturation
Usage	MULS D0, S0, S1
Function	This is an instruction to multiply 2 signed 32-bit values from source S0 and source S1 with saturation.
Behavior model	D0 = SAT(S0 * S1, 32);
Operand type	D0: 32-bit signed integer S0: 32-bit signed integer S1: 32-bit signed integer

MULSS8	MULtiply with Saturation Signed 8-bit values
Usage	MULSS8 D0, S0, S1
Function	This is an instruction to multiply 8 times 2 signed 8-bit values from source S0 and source S1 with saturation.
Behavior model	D0[n] = SAT(S0[n] * S1[n], 8), n = 0...7;
Operand type	D0: 8 times 8-bit signed integer S0: 8 times 8-bit signed integer S1: 8 times 8-bit signed integer

MULSS16	MULtiply with Saturation Signed 16-bit values
Usage	MULSS16 D0, S0, S1
Function	This is an instruction to multiply 4 times 2 signed 16-bit values from source S0 and source S1 with saturation.
Behavior model	D0[n] = SAT(S0[n] * S1[n], 16), n = 0...3;
Operand type	D0: 4 times 16-bit signed integer S0: 4 times 16-bit signed integer S1: 4 times 16-bit signed integer

MULSU	MULtiply Saturation with Uniform
Usage	MULSU D0, S0, #IMM
Function	This is an instruction to multiply 2 signed 32-bit values from source S0 and Uniform storage indexed by #IMM with saturation.
Behavior model	D0 = SAT(S0 * Uniform[#R6IMM], 32);
Operand type	D0: 32-bit signed integer S0: 32-bit signed integer

MULLS	MULtiply long signed
Usage	MULLS D0, S0, S1
Function	Multiply the 32-bit signed input values S0 and S1 and store the 64-bit result to D0.
Behavior model	D0 = S0 * S1;

MULLS8	MULtiply Long Signed 8-bit values
Usage	MULLS8 D0, S0, S1
Function	This is an instruction to multiply 4 times 2 signed 8-bit values from source S0 and source S1 with storage of 16-bit result.
Behavior model	D0[n] = S0[n] * S1[n], n = 0...3;
Operand type	D0: 4 times 16-bit signed integer S0: 4 times 8-bit signed integer S1: 4 times 8-bit signed integer

MULLS16	MULtiply Long Signed 16-bit values
Usage	MULLS16 D0, S0, S1
Function	This is an instruction to multiply 2 times 2 signed 16-bit values from source S0 and source S1 with storage of 32-bit result.
Behavior model	D0[n] = S0[n] * S1[n], n = 0...1;
Operand type	D0: 2 times 32-bit signed integer S0: 2 times 16-bit signed integer S1: 2 times 16-bit signed integer

MULLSU	MULtiply long signed by Uniform
Usage	MULLSU D0, S0, #IMM
Function	Multiply the 32-bit signed input values S0 with the 32-bit signed input value read from uniform storage indexed by #IMM and store the 64-bit result to D0.
Behavior model	D0 = S0 * Uniform[#R6IMM];

MULLU8	MULtiply Long Unsigned 8-bit values
Usage	MULLU8 D0, S0, S1
Function	This is an instruction to multiply 4 times 2 unsigned 8-bit values from source S0 and source S1 with storage of 16-bit result.
Behavior model	D0[n] = S0[n] * S1[n], n = 0..3;
Operand type	D0: 4 times 16-bit unsigned integer S0: 4 times 8-bit unsigned integer S1: 4 times 8-bit unsigned integer

MULLU16	MULtiply Long Unsigned 16-bit values
Usage	MULLU16 D0, S0, S1
Function	This is an instruction to multiply 2 times 2 unsigned 16-bit values from source S0 and source S1 with storage of 32-bit result.
Behavior model	D0[n] = S0[n] * S1[n], n = 0..1;
Operand type	D0: 2 times 32-bit unsigned integer S0: 2 times 16-bit unsigned integer S1: 2 times 16-bit unsigned integer

MULU	MULtiply by Uniform
Usage	MULU D0, S0, #IMM
Function	Multiply the 32-bit signed input value S0 with the 32-bit signed input value read from uniform storage indexed by #IMM and store the lower 32-bit of the result to D0.
Behavior model	D0 = S0 * Uniform[#R6IMM];

MULUS8	MULtiply Unsigned with Saturation 8-bit values
Usage	MULUS8 D0, S0, S1
Function	This is an instruction to multiply 8 times 2 unsigned 8-bit values from source S0 and source S1 with saturation.
Behavior model	D0[n] = SAT(S0[n] * S1[n], 8), n = 0..7;
Operand type	D0: 8 times 8-bit unsigned integer S0: 8 times 8-bit unsigned integer S1: 8 times 8-bit unsigned integer

MULUS16	MULtiply Unsigned with Saturation 16-bit values
Usage	MULUS16 D0, S0, S1
Function	This is an instruction to multiply 4 times 2 unsigned 16-bit values from source S0 and source S1 with saturation.
Behavior model	D0[n] = SAT(S0[n] * S1[n], 16), n = 0..3;
Operand type	D0: 4 times 16-bit unsigned integer S0: 4 times 16-bit unsigned integer S1: 4 times 16-bit unsigned integer

NCSCS	Non-symmetric Census Signature Calculation Step
Usage	NCSCS D0, S0, S1
Function	S0 is compared against S1 and -S1 as signed values. Each comparison is adding a 1 or 0 depending on whether the result is true (==1) or false (==0) to the earlier by 2 bits to the left shifted D0. The result is again stored to D0.
Behavior model	D0 = (D0 << 2) + (S0 > S1) + (S0 > -S1)

NOP	No OPeration
Usage	NOP
Function	No operation is executed. One cycle of bubble is inserted in the thread operation pipeline.
Behavior model	; // empty statement

OR	OR
Usage	OR D0, S0, S1
Function	Treats S0 and S1 as 32-bit arrays, takes the logical OR of S0 and S1, and stores the result in D0.
Behavior model	D0 = S0 | S1;

OR64	OR 64-bit values
Usage	OR64 D0, S0, S1
Function	This is an instruction to OR 2 64-bit (8 times 8-bit or 4 times 16-bit) values.
Behavior model	D0[n] = S0[n] OR S1[n], n = 0...63;
Operand type	D0: 64-bit integer S0: 64-bit integer S1: 64-bit integer

ORU	OR with Uniform
Usage	ORU D0, S0, #IMM
Function	Treats S0 and the uniform value indexed by #IMM as 32-bit arrays, takes the logical OR of S0 and the uniform value, and stores the result in D0.
Behavior model	D0 = S0 | Uniform[#R6IMM];

PACKB0	**PACK byte 0**
Usage	PACKB0 D0, S0, S1
Function	D0 = (S0[39:32] << 24) | (S0[7:0] << 16) | (S1[39:32] << 8) | (S1[7:0]) S0 and S1 are 64-bit vectors with each 2 32-bit elements, which are specified by the even of 2 consecutive 32-bit registers. The instruction is taking from each of the four 32-bit elements the lowest 8-bit part and packing them together in D0. D0 is handled as a 32-bit signed value.
Behavior model	D0 = (S0[39:32] << 24) | (S0[7:0] << 16) | (S1[39:32] << 8) | (S1[7:0])

PACKB1	**PACK byte 1**
Usage	PACKB1 D0, S0, S1
Function	D0 = (S0[47:40] << 24) | (S0[15:8] << 16) | (S1[47:40] << 8) | (S1[15:8]) S0 and S1 are 64-bit vectors with each 2 32-bit elements, which are specified by the even of 2 consecutive 32-bit registers. The instruction is taking from each of the four 32-bit elements the second lowest 8-bit part and packing them together in D0. D0 is handled as a 32-bit signed value.
Behavior model	D0 = (S0[47:40] << 24) | (S0[15:8] << 16) | (S1[47:40] << 8) | (S1[15:8])

PACKB2	**PACK byte 2**
Usage	PACKB2 D0, S0, S1
Function	D0 = (S0[55:48] << 24) | (S0[23:16] << 16) | (S1[55:48] << 8) | (S1[23:16]) S0 and S1 are 64-bit vectors with each 2 32-bit elements, which are specified by the even of 2 consecutive 32-bit registers. The instruction is taking from each of the four 32-bit elements the second highest 8-bit part and packing them together in D0. D0 is handled as a 32-bit signed value.
Behavior model	D0 = (S0[55:48] << 24) | (S0[23:16] << 16) | (S1[55:48] << 8) | (S1[23:16])

PACKB3	**PACK byte 3**
Usage	PACKB3 D0, S0, S1
Function	D0 = (S0[63:56] << 24) | (S0[31:24] << 16) | (S1[63:56] << 8) | (S1[31:24]) S0 and S1 are 64-bit vectors with each 2 32-bit elements, which are specified by the even of 2 consecutive 32-bit registers. The instruction is taking from each of the four 32-bit elements the highest 8-bit part and packing them together in D0. D0 is handled as a 32-bit signed value.
Behavior model	D0 = (S0[63:56] << 24) | (S0[31:24] << 16) | (S1[63:56] << 8) | (S1[31:24])

PACKH0	**PACK half word 0**
Usage	PACKH0 D0, S0, S1
Function	D0 = (S0[15:0] << 16) | (S1[15:0]) S0 and S1 are 32-bit vectors with each 1 32-bit element. The instruction is taking from each 32-bit element the lowest 16-bit part and packing them together in D0. D0 is handled as a 32-bit signed value.
Behavior model	D0 = (S0[15:0] << 16) | (S1[15:0])

PACKH1	PACK half word 1
Usage	PACKH1 D0, S0, S1
Function	D0 = (S0[31:16] << 16) | (S1[31:16])
	S0 and S1 are 32-bit vectors with each 1 32-bit element. The instruction is taking from each 32-bit element the highest 16-bit part and packing them together in D0. D0 is handled as a 32-bit signed value.
Behavior model	D0 = (S0[31:16] << 16) | (S1[31:16])

PCMPAGT	Parallel CoMPare Anded Greater Than
Usage	PCMPAGT D0, S0, S1
Function	This instruction compares (greater) in parallel the upper and lower halves of S0 and S1 and writes the ANDed comparison result to D0, in case D0 is R3, SR is set with this bit. Mapped on each Thread.
Behavior model	SR.F = (S0[31:0] > S1[31:0]) && (S0[63:32] > S1[63:32]); (D0 == R3)
	D0 = (S0[31:0] > S1[31:0]) && (S0[63:32] > S1[63:32]); (D0 != R3)
Operand type	D0: 1bit integer
	S0: 2 32-bit signed integer
	S1: 2 32-bit signed integer

PCMPALT	Parallel CoMPare Anded Less Than
Usage	PCMPALT D0, S0, S1
Function	This instruction compares (smaller) in parallel the upper and lower halves of S0 and S1 and writes the ANDed comparison result to D0, in case D0 is R3, SR is set with this bit. Mapped on each Thread.
Behavior model	SR.F = (S0[31:0] < S1[31:0]) && (S0[63:32] < S1[63:32]) ; (D0 == R3)
	D0 = (S0[31:0] < S1[31:0]) && (S0[63:32] < S1[63:32]) ; (D0 != R3)
Operand type	D0: 1bit integer
	S0: 2 32-bit signed integer
	S1: 2 32-bit signed integer

PCMPAEQ	Parallel CoMPare Anded EQual
Usage	PCMPAEQ D0, S0, S1
Function	This instruction compares (equal) in parallel the upper and lower halves of S0 and S1 and writes the ANDed comparison result to D0, in case D0 is R3, SR is set with this bit. Mapped on each Thread.
Behavior model	SR.F = (S0[31:0] == S1[31:0]) && (S0[63:32] == S1[63:32]) ; (D0 == R3)
	D0 = (S0[31:0] == S1[31:0]) && (S0[63:32] == S1[63:32]) ; (D0 != R3)
Operand type	D0: 1bit integer
	S0: 2 32-bit signed integer
	S1: 2 32-bit signed integer

PCMPOGT	Parallel CoMPare Ored Greater Than
Usage	PCMPOGT D0, S0, S1
Function	This instruction compares (greater) in parallel the upper and lower halves of S0 and S1 and writes the ORed comparison result to D0, in case D0 is R3, SR is set with this bit. Mapped on each Thread.
Behavior model	SR.F = (S0[31:0] > S1[31:0]) || (S0[63:32] > S1[63:32]) ; (D0 == R3) D0 = (S0[31:0] > S1[31:0]) || (S0[63:32] > S1[63:32]) ; (D0 != R3)
Operand type	D0: 1bit integer S0: 2 32-bit signed integer S1: 2 32-bit signed integer

PCMPOLT	Parallel CoMPare Ored Less Than
Usage	PCMPOLT D0, S0, S1
Function	This instruction compares (smaller) in parallel the upper and lower halves of S0 and S1 and writes the ORed comparison result to D0, in case D0 is R3, SR is set with this bit. Mapped on each Thread.
Behavior model	SR.F = (S0[31:0] < S1[31:0]) || (S0[63:32] < S1[63:32]) ; (D0 == R3) D0 = (S0[31:0] < S1[31:0]) || (S0[63:32] < S1[63:32]) ; (D0 != R3)
Operand type	D0: 1bit integer S0: 2 32-bit signed integer S1: 2 32-bit signed integer

PCMPOEQ	Parallel CoMPare Ored EQual
Usage	PCMPOEQ D0, S0, S1
Function	This instruction compares (equal) in parallel the upper and lower halves of S0 and S1 and writes the ORed comparison result to D0, in case D0 is R3, SR is set with this bit. Mapped on each Thread.
Behavior model	SR.F = (S0[31:0] == S1[31:0]) || (S0[63:32] == S1[63:32]); (D0 == R3) D0 = (S0[31:0] == S1[31:0]) || (S0[63:32] == S1[63:32]); (D0 != R3)
Operand type	D0: 1bit integer S0: 2 32-bit signed integer S1: 2 32-bit signed integer

PLSB8	Pack the LSB's of 4 8-bit values into the 4 lowest bits of dst
Usage	PLSB8 D0, S0, S1
Function	This is an instruction to take the LSB's of 4 8-bit values in SRC0 and concatenate them to the 4-bit left shifted value of SRC1 and store the result to D0. Implemented in each thread.
Behavior model	D0[31:4] = S1[27:0]; D0[0] = S0[0]; D0[1] = S0[8]; D0[2] = S0[16]; D0[3] = S0[24];
Operand type	D0: 32-bit unsigned integer S0: 32-bit unsigned integer S1: 32-bit unsigned integer

PLSB16	Pack the LSB's of 2 16-bit values into the 2 lowest bits of dst
Usage	PLSB16 D0, S0, S1
Function	This is an instruction to take the LSB's of 2 16-bit values in SRC0 and concatenate them to the 2-bit left shifted value of SRC1 and store the result to D0. Implemented in each thread.
Behavior model	D0[31:2] = S1[29:0]; D0[0] = S0[0]; D0[1] = S0[16];
Operand type	D0: 32-bit unsigned integer S0: 32-bit unsigned integer S1: 32-bit unsigned integer

RETA	RETurn from subroutine Alternative
Usage	RETA D0
Function	Returns to the PC stored in the temporary-storage PC register specified by D0. The register to be specified by D0 is not the general-purpose register number, but the CALLA/RETA dedicated temporary-storage PC register number. There are eight registers for this purpose and 0 to 7 can be specified. When a number not written by the CALLA instruction is specified, operation is undefined. The 3 lower-order bits of D0 are handled as an unsigned integer.
Behavior model	PC=PCR[(D0&0x7)]
Operand type	D0: 3-bit unsigned integer

RMBD	Right Most Bit Detection
Usage	RMBD D0, S0
Function	This is an instruction which searches the first "1" from right side inside S0 and gives back the position in D0. Position counting from right side. Output == 0x80000000 if "1" is not available. Implemented in SAM4.
Behavior model	S0[0] == "1"?D0=0: (S0[1] == "1"?D0=1: (S0[2] == "1"?D0=2: (.... S0[30] == "1"?D0=30: (S0[31] == "1"?D0=31:D0=0x80000000)))))
Operand type	D0: 32bit unsigned integer (6bit used) S0: 32bit unsigned integer

RXCH	Register eXCHange
Usage	RXCH D0, S0
Function	This instruction exchanges the content of 2 registers of a register pair. Mapped on each Thread.
Behavior model	D0[31:0] = S0[63:32]; D0[63:32] = S0[31:0];
Operand type	D0: 2 32-bit signed integer S0: 2 32-bit signed integer

SBOCRD	SBO of CooRDinate
Usage	SBOCRD D0, #IMM1, #IMM2
Function	This is an instruction for outputting the X coordinate, Y coordinate, and D0 (data) to memory via the SBO port. The X and Y coordinates to be output are X and Y coordinates which are specified in R0 and R1 respectively, with the #IMM1 value added to X and the #IMM2 value added to Y. The 16 lower-order bits of R0 and R1 are handled as integers. #IMM1 and #IMM2 need to be specified with 8-bit signed integers. The output mask can be specified by control register CR10. Refer to section U32.6.2 . The X and Y data to be output can be packed or expanded by configuration register SBOCR0. Refer to section U32.12.1.34 .
Behavior model	SBO((ushort((ushort)(R0&0xffff)+(char)#IMM1), (ushort)((ushort)(R1&0xffff)+#IMM2), D0);
Operand type	D0: -(32-bit array) #IMM1: 8-bit signed integer #IMM2: 8-bit signed integer R0: 16-bit signed integer R1: 16-bit signed integer

SCSCS	Symmetric Census Signature Calculation Step
Usage	SCSCS D0, S0, S1
Function	S0 is compared against S1 and INV(S1) as signed values. Each comparison is adding a 1 or 0 depending on whether the result is true (==1) or false (==0) to the earlier by 2 bits to the left shifted D0. The result is again stored to D0.
Behavior model	D0 = (D0 << 2) + (S0 > S1) + (S0 > INV(S1))

SETHI	Set HIgher bits
Usage	SETHI D0, #ASMIMM
Function	Higher 16 bits of #ASMIMM replaces the 16 higher-order bits of D0, and the result is retained by D0.

Behavior model	#IMM = (#ASMIMM & 0xffff0000)>>16
	D0 = (D0 & 0x0000ffff) | #IMM<<16;

Operand type	D0: -(32-bit array) #ASMIMM: -(32-bit array) #IMM: -(16-bit array)

SHA8	SHift Arithmetic left of signed 8-bit values
Usage	SHA8 D0, S0, S1
Function	This is an instruction to arithmetic shift 8 signed 8-bit values by 8 signed 4-bit values stored in S1 as 8 signed 8-bit values. Implemented in SAM4.
Behavior model	D0[n] = S0[n] <<< S1[n], n = 0...7; (S1[n]>0) D0[n] = S0[n] >>> S1[n], n = 0...7; (S1[n]<0) D0[n] = S0[n], n = 0...7; (S1[n]==0)
operand type	D0: 8 times 8-bit signed integer S0: 8 times 8-bit signed integer S1: 8 times 8-bit signed integer, only lower 4 bits are used

SHA16	SHift Arithmetic of signed 16-bit values
Usage	SHA16 D0, S0, S1
Function	This is an instruction to arithmetic shift 4 signed 16-bit values by 4 signed 5-bit values stored in S1 as 4 signed 16-bit values. Implemented in SAM4.
Behavior model	D0[n] = S0[n] <<< S1[n], n = 0...3; (S1[n]>0) D0[n] = S0[n] >>> S1[n], n = 0...3; (S1[n]<0) D0[n] = S0[n], n = 0...3; (S1[n]==0)
Operand type	D0: 4 times 16-bit signed integer S0: 4 times 16-bit signed integer S1: 4 times 16-bit signed integer, only lower 5 bits are used

SHAI8	SHift Arithmetic by signed Immediate value signed 8-bit values
Usage	SHAI8 D0, S0, #IMM
Function	This is an instruction to shift 8 signed 8-bit values by 1 signed 4-bit value stored as 1 signed 8-bit immediate value. Implemented in SAM4.

Behavior model	D0[n] = S0[n] <<< #IMM, n = 0...7; (#IMM>0)
	D0[n] = S0[n] >>> #IMM, n = 0...7; (#IMM<0)
	D0[n] = S0[n], n = 0...7; (#IMM==0)

Operand type	D0: 8 times 8-bit signed integer S0: 8 times 8-bit signed integer #IMM: 1 8-bit signed integer, only lower 4 bits are used

SHAI16	SHift Arithmetic by signed Immediate value signed 16-bit values
Usage	SHAI16 D0, S0, #IMM
Function	This is an instruction to shift 4 signed 16-bit values by 1 signed 5-bit value stored as 1 signed 8-bit immediate value. Implemented in SAM4.

Behavior model	D0[n] = S0[n] <<< #IMM, n = 0...3; (#IMM>0)
	D0[n] = S0[n] >>> #IMM, n = 0...3; (#IMM<0)
	D0[n] = S0[n] , n = 0...3; (#IMM==0)

Operand type	D0: 4 times 16-bit signed integer S0: 4 times 16-bit signed integer #IMM: 1 8-bit signed integer, only lower 5 bits are used

SHL	SHift Left
Usage	SHL D0, S0, S1
Function	Shifts S0 to the left by the number of bits given by the value of S1 and stores the result in D0. The lower 5bits of S1 are used to decide shift size.
Behavior model	D0 = S0 << (S1 & 0x1f);

SHL8	SHift Logical of unsigned 8-bit values
Usage	SHL8 D0, S0, S1
Function	This is an instruction to shift 8 unsigned 8-bit values by 8 signed 4-bit values stored in S1 as 8 signed 8-bit values. Implemented in SAM4.
Behavior model	D0[n] = S0[n] << S1[n] , n = 0...7; (S1[n]>0) D0[n] = S0[n] >> S1[n] , n = 0...7; (S1[n]<0) D0[n] = S0[n] , n = 0...7; (S1[n]==0)
Operand type	D0: 8 times 8-bit unsigned integer S0: 8 times 8-bit unsigned integer S1: 8 times 8-bit signed integer, only lower 4 bits are used

SHL16	SHift Logical of unsigned 16-bit values
Usage	SHL16 D0, S0, S1
Function	This is an instruction to shift 4 unsigned 16-bit values by 4 signed 5-bit values stored in S1 as 4 signed 16-bit values. Implemented in SAM4.
Behavior model	D0[n] = S0[n] << S1[n] , n = 0...3; (S1[n]>0) D0[n] = S0[n] >> S1[n] , n = 0...3; (S1[n]<0) D0[n] = S0[n] , n = 0...3; (S1[n]==0)
Operand type	D0: 4 times 16-bit unsigned integer S0: 4 times 16-bit unsigned integer S1: 4 times 16-bit signed integer, only lower 5 bits are used

SHLI	SHift Left with Immediate value
Usage	SHLI D0, S0, #IMM
Function	Shifts S0 to the left by the number of bits given by the value of #IMM and stores the result in D0. The lower 5bits of #IMM are used to decide shift size.
Behavior model	D0 = S0 << (#IMM & 0x1f);

SHLI8	SHift Logical by signed Immediate value unsigned 8-bit values
Usage	SHLI8 D0, S0, #IMM
Function	This is an instruction to shift 8 unsigned 8-bit values by 1 signed 4-bit value stored as 1 signed 8-bit immediate value (sign bit expanded). Implemented in SAM4.

Behavior model	D0[n] = S0[n] << #IMM, n = 0...7; (#IMM>0)
	D0[n] = S0[n] >> #IMM, n = 0...7; (#IMM<0)
	D0[n] = S0[n], n = 0...7; (#IMM==0)

Operand type	D0: 8 times 8-bit unsigned integer S0: 8 times 8-bit unsigned integer #IMM: 1 8-bit signed integer, only lower 4 bits are used

SHLI16	SHift Logical by signed Immediate value unsigned 16-bit values
Usage	SHLI16 D0, S0, #IMM
Function	This is an instruction to shift 4 unsigned 16-bit values by 1 signed 5-bit value stored as 1 signed 8-bit immediate value (sign bit expanded). Implemented in SAM4.

Behavior model	D0[n] = S0[n] << #IMM, n = 0...3; (#IMM>0)
	D0[n] = S0[n] >> #IMM, n = 0...3; (#IMM<0)
	D0[n] = S0[n] , n = 0...3; (#IMM==0)

Operand type	D0: 4 times 16-bit unsigned integer S0: 4 times 16-bit unsigned integer #IMM: 1 8-bit signed integer, only lower 5 bits are used

SHRA	SHift Right Arithmetically
Usage	SHRA D0, S0, S1
Function	Treats S0 as a 32-bit signed integer, arithmetically shifts S0 to the right by the number of bits given by the value of S1 and stores the result in D0. The lower 5bits of S1 are used to decide sift size.
Behavior model	D0 = (signed int)S0 >> (S1 & 0x1f);

SHRAI	SHift Right Arithmetically with Immediate value
Usage	SHRAI D0, S0, #IMM
Function	Treats S0 as a 32-bit signed integer, arithmetically shifts S0 to the right by the number of bits given by the value of #IMM and stores the result in D0. The lower 5bits of #IMM are used to decide shift size.
Behavior model	D0 = (signed int)S0 >> (#IMM & 0x1f);

SHRL	SHift Right Logically
Usage	SHRL D0, S0, S1
Function	Treats S0 as a 32-bit unsigned integer, logically shifts S0 to the right by the number of bits given by the value of S1 and stores the result in D0. The lower 5bits of S1 are used to decide sift size.
Behavior model	D0 = (unsigned int)S0 >> (S1 & 0x1f);

SHRLI	SHift Right Logically with Immediate value
Usage	SHRLI D0, S0, #IMM
Function	Treats S0 as a 32-bit unsigned integer, logically shifts S0 to the right by the number of bits given by the value of #IMM and stores the result in D0. The lower 5bits of #IMM are used to decide shift size.
Behavior model	D0 = (unsigned int)S0 >> (#IMM & 0x1f);

SHUF	SHUFfle
Usage	SHUF D0, S0, S1
Function	This shuffle instruction is shuffling the data in S0 based on the given parameters in S1 and overwrites dependent on the parameter setting in S1 the whole or parts of the destination register. The instruction can be used to set specific bytes of an 8-byte sequence to zero, to shuffle bytes inside an 8-byte sequence, to reverse bits inside the bytes of an 8-byte sequence or to combine the operations mentioned before. By combining the operations, the user can achieve e.g., bit reversal operations in 32-bit values.
Behavior model	if (S1[n*8+3] == 1) then D0[(n+1)*8-1:n*8] = D0[(n+1)*8-1:n*8] else if (S1[n*8+4] == 1) then D0[(n+1)*8-1:n*8] = 8'b0 else if (S1[n*8+5] == 1) then D0[(n+1)*8-1:n*8] = S0[S1[n*8+2:n*8]*8 : (S1[n*8+2:n*8]+1)*8-1] else D0[(n+1)*8-1:n*8] = S0[(S1[n*8+2:n*8]+1)*8-1 : S1[n*8+2:n*8]*8]
Operand type	D0: 64bit unsigned integer S0: 64bit unsigned integer S1: 64bit unsigned integer

ST	Store word
Usage	ST D0, S0, S1
Function	It is a data transfer instruction from register to memory. The 32-bit data from register D0 is stored to the 32-bit aligned address specified by the sum of the values S0 and S1*4. S1 is specifying a 32-bit word offset. The value of S0 must be a multiple of 4 (word aligned) otherwise behavior is undefined.
Behavior model	*(S0+S1*4) = D0;

STB	Store byte
Usage	STB D0, S0, S1
Function	It is a data transfer instruction from register to memory. The lower 8-bit data from register D0 is stored to the 8-bit aligned address specified by the sum of the values S0 and S1. S1 is specifying a byte offset.
Behavior model	*(S0+S1) = D0;

STBI	Store byte with immediate offset
Usage	STBI D0, S0, #IMM
Function	It is a data transfer instruction from register to memory. The lower 8-bit data from register D0 is stored to the 8-bit aligned address specified by the sum of the values S0 and #IMM. The 8-bit signed immediate value is specifying a byte offset.
Behavior model	*(S0+#IMM) = D0;

STC	STore to Control Register
Usage	STC D0, S0
Function	This is an instruction for storing data in a control register. Writes the lower 16 bits of the data in the general purpose register S0 value to the control register D0. Specifying D0 as a control register that does not exist is prohibited.
Behavior model	ControlRegisterD0 = S0&0xffff;
Operand type	D0: Control Register. S0: 16-bit array

STCI	STore Immediate to Control Register
Usage	STCI D0 , #IMM
Function	This is an instruction for storing data in a control register. Writes the #IMM value to the control register D0. Specifying D0 as a control register that does not exist is prohibited.
Behavior model	ControlRegisterD0 = #IMM;
Operand type	D0: Control Register #IMM: 16-bit array

STH	Store half word
Usage	STH D0, S0, S1
Function	It is a data transfer instruction from register to memory. The lower 16-bit data from register D0 is stored to the 16-bit aligned address specified by the sum of the values S0 and S1*2. S1 is specifying a 16-bit short offset. The value of S0 must be a multiple of 2 (half word aligned) otherwise behavior is undefined.
Behavior model	*(S0+S1*2) = D0;

STHI	Store half word with immediate offset
Usage	STHI D0, S0, #ASMIMM
Function	It is a data transfer instruction from register to memory. The lower 16-bit data from register D0 is stored to the 16-bit aligned address specified by the sum of the values S0 and #ASMIMM. The 8-bit signed immediate value is specifying a byte offset. The value of S0 must be a multiple of 2 (half word aligned) otherwise behavior is undefined.
Behavior model	#IMM = #ASMIMM>>1 *(S0+#IMM*2) = D0;

STI	Store word with immediate offset
Usage	STI D0, S0, #ASMIMM
Function	It is a data transfer instruction from register to memory. The 32-bit data from register D0 is stored to the 32-bit aligned address specified by the sum of the values S0 and #ASMIMM. The 8-bit signed immediate value is specifying a byte offset. The value of S0 must be a multiple of 4 (word aligned) otherwise behavior is undefined.
Behavior model	#IMM = #ASMIMM>>2 *(S0+#IMM*4) = D0;

STLL	STore Long to Local working memory
Usage	STLL D0, S0, S1
Function	This is an instruction to transfer 64-bit data from a 64-bit pair register to local working memory. This instruction supports the common and non-common address space. Writes the D0 data to the address specified by adding the S1×8 value to address S0 of local working memory. When this instruction is used for other memory accesses, this instruction transfer 32-bit from the specified even register to the specified memory address. The 64-bit access to LWM must be aligned, when unaligned, function is prohibited. D0 is a 64-bit pair register, always the lower even register is specified, which holds the lower 32-bit. S0 and S1 are 32-bit registers. The value of S0 must be a multiple of 8 (long word aligned) otherwise behavior is undefined.
Behavior model	*(S0 + S1*8) = D0;
Operand type	D0: 64-bit unsigned integer S0: 32-bit unsigned integer (Multiples of 8) S1: 32-bit signed integer

STLLI	STore Long to Local working memory with Immediate offset
Usage	STLLI D0, S0, #ASMIMM
Function	This is an instruction to transfer 64-bit data from a 64-bit pair register to local working memory. This instruction supports the common and non-common address space. Writes the D0 data to the address specified by adding the #IMM×8 value to address S0 of local working memory. When this instruction is used for other memory accesses, this instruction transfer 32-bit from the specified even register to the specified memory address. The 64-bit access to LWM must be aligned, when unaligned, function is prohibited. D0 is a 64-bit pair register, always the lower even register is specified, which holds the lower 32-bit. S0 is a 32-bit register. The value of S0 must be a multiple of 8 (long word aligned) otherwise behavior is undefined.
Behavior model	#IMM = #ASMIMM>>3 *(S0 + (char)#IMM*8) = D0;
Operand type	D0: 64-bit unsigned integer S0: 32-bit unsigned integer (Multiples of 8) #IMM: 8-bit signed integer

STLRB	STore Large Register Block
Usage	STLRB D0, S0, S1
Function	This is an instruction to transfer 512-bit data from 512-bit large register block to local working memory. This instruction supports only the common address space. Writes the data read from D0 to the address specified by adding S1*64 to address S0 of local working memory. The access to LWM must be 64-bit aligned, when unaligned, function is prohibited. D0 is specifying the lowest register of the register block. Allowed values are 16 (for register block R16-R31) and 32 (for register block R32-R47)
Behavior model	*(S0 + S1*64) = D0;
Operand type	D0: 512-bit unsigned integer S0: 32-bit unsigned integer (Multiples of 8) S1: 16-bit signed integer

STore Large Register Block with Immediate offset

STLRBI

Usage	STLRBI D0, S0, #IMM
Function	This is an instruction to transfer 512-bit data from 512-bit large register block to local working memory. This instruction supports only the common address space. Writes the data read from D0 to the address specified by adding #IMM*64 to address S0 of local working memory. The access to LWM must be 64-bit aligned, when unaligned, function is prohibited. D0 is specifying the lowest register of the register block. Allowed values are 16 (for register block R16-R31) and 32 (for register block R32-R47)
Behavior model	*(S0 +#IMM*64) = D0;
Operand type	D0: 512-bit unsigned integer S0: 32-bit unsigned integer (Multiples of 8) #IMM: 8-bit signed integer

STLRBC **STore Large Register Block with LPC offset**

Usage	STLRBC D0, S0
Function	This is an instruction to transfer 512-bit data from 512-bit large register block to local working memory. This instruction supports only the common address space. Writes the data read from D0 to the address specified by adding LPC*64 to address S0 of local working memory. The access to LWM must be 64-bit aligned, when unaligned, function is prohibited. D0 is specifying the lowest register of the register block. Allowed values are 16 (for register block R16-R31) and 32 (for register block R32-R47)
Behavior model	*(S0 + LPC*64) = D0;
Operand type	D0: 512-bit unsigned integer S0: 32-bit unsigned integer (Multiples of 8) LPC: 9-bit signed integer

STRCI **STore to Relative Coordinate with Immediate offset**

Usage	STRCI D0, #IMM1, #IMM2
Function	This is an instruction for data transfer from a register to memory. Stores the D0 value in memory at X and Y coordinates which are specified in R0 and R1 respectively, with the #IMM1 value added to X and the #IMM2 value added to Y. The full 32 bits of R0 and the 16 lower-order bits of R1 are handled as signed integers. #IMM1 and #IMM2 need to be specified with 8-bit signed integers. Operation cannot be guaranteed if the calculated offset is negative to the base address or obtained address is outside from the range handled by the CVengine. D0 is handled as an integer.
Behavior model	@(R0+(char)#IMM1, (short)((short)(R1&0xffff)+(char)#IMM2)) = D0;
Operand type	D0: 32-bit signed integer #IMM1: 8-bit signed integer #IMM2: 8-bit signed integer R0: 32-bit signed integer R1: 16-bit signed integer

STRCIU	STore to Relative Coordinate with Immediate offset, then source Updated
Usage	STRCIU D0, #IMM1, #IMM2
Function	This is an instruction for data transfer from a register to memory. Stores the D0 value in memory at X and Y coordinates which are specified in R0 and R1 respectively, with the #IMM1 value added to X and the #IMM2 value added to Y. The full 32 bits of R0 and the 16 lower-order bits of R1 are handled as signed integers. #IMM1 and #IMM2 need to be specified with 8-bit signed integers. After operation, X(R0) and Y(R1) are updated by adding #IMM1 and #IMM2 respectively. Operation cannot be guaranteed if the calculated offset is negative to the base address or obtained address is outside from the range handled by the CVengine. D0 is handled as an integer.

Behavior model	@(R0+(char)#IMM1, (short)((short)(R1&0xffff)+(char)#IMM2)) = D0;
	R0 = R0+(char)#IMM1; R1 = (short)(R1+(char)#IMM2);

Operand type	D0: 32-bit signed integer #IMM1: 8-bit signed integer #IMM2: 8-bit signed integer R0: 32-bit signed integer R1: 16-bit signed integer

STRXY	STore to Relative Coordinate XY with register offset
Usage	STRXY D0, S0, S1
Function	This is an instruction for data transfer from a register to memory. Stores the D0 value in memory at X and Y coordinates which are specified in R0 and R1 respectively, with the S0 value added to X and the S1 value added to Y. The full 32 bits of R0 and S0 and the 16 lower-order bits of R1 and S1 are handled as signed integers. Operation cannot be guaranteed if the calculated offset is negative to the base address or obtained address is outside from the range handled by the CVengine.
Behavior model	@(R0+S0, (short)((short)(R1&0xffff)+(short)(S1&0xffff))) = D0;
Operand type	D0: 32-bit signed integer S0: 32-bit signed integer S1: 16-bit signed integer R0: 32-bit signed integer R1: 16-bit signed integer

STRXYU	STore to Relative Coordinate XY with register offset, then source Updated
Usage	STRXYU D0, S0, S1
Function	This is an instruction for data transfer from a register to memory. Stores the D0 value in memory at X and Y coordinates which are specified in R0 and R1 respectively, with the S0 value added to X and the S1 value added to Y. The full 32 bits of R0 and S0 and the 16 lower-order bits of R1 and S1 are handled as signed integers. After operation, X(R0) and Y(R1) are updated by adding S0 and S1 respectively. Operation cannot be guaranteed if the calculated offset is negative to the base address or obtained address is outside from the range handled by the CVengine.
Behavior model	@(R0+S0, (short)((short)(R1&0xffff)+(short)(S1&0xffff))) = D0; R0 = R0+S0; R1 = (short)((short)(R1&0xffff)+(short)(S1&0xffff));
Operand type	D0: 32-bit signed integer S0: 32-bit signed integer S1: 16-bit signed integer R0: 32-bit signed integer R1: 16-bit signed integer

STSRB	STore Small Register Block
Usage	STSRB D0, S0, S1
Function	This is an instruction to transfer 256-bit data from 256-bit large register block to local working memory. This instruction supports only the common address space. Writes the data read from D0 to the address specified by adding S1*32 to address S0 of local working memory. The access to LWM must be 64-bit aligned, when unaligned, function is prohibited. D0 is specifying the lowest register of the register block. Allowed values are 16 (for register block R16-R23), 24 (for register block R24-R31), 32 (for register block R32-R39) and 40 (for register block R40-R47)
Behavior model	*(S0 + S1*32) = D0;
Operand type	D0: 256-bit unsigned integer S0: 32-bit unsigned integer (Multiples of 8) S1: 16-bit signed integer

STSRBI	STore Small Register Block with Immediate offset
Usage	STSRBI D0, S0, #IMM
Function	This is an instruction to transfer 256-bit data from 256-bit large register block to local working memory. This instruction supports only the common address space. Writes the data read from D0 to the address specified by adding #IMM*32 to address S0 of local working memory. The access to LWM must be 64-bit aligned, when unaligned, function is prohibited. D0 is specifying the lowest register of the register block. Allowed values are 16 (for register block R16-R23), 24 (for register block R24-R31), 32 (for register block R32-R39) and 40 (for register block R40-R47)
Behavior model	*(S0 +#IMM*32) = D0;
Operand type	D0: 256-bit unsigned integer S0: 32-bit unsigned integer (Multiples of 8) #IMM: 8-bit signed integer

STore Small Register Block with LPC offset

STSRBC

Usage	STSRBC D0, S0
Function	This is an instruction to transfer 256-bit data from 256-bit large register block to local working memory. This instruction supports only the common address space. Writes the data read from D0 to the address specified by adding LPC*32 to address S0 of local working memory. The access to LWM must be 64-bit aligned, when unaligned, function is prohibited. D0 is specifying the lowest register of the register block. Allowed values are 16 (for register block R16-R23), 24 (for register block R24-R31), 32 (for register block R32-R39) and 40 (for register block R40-R47)
Behavior model	*(S0 + LPC*32) = D0;
Operand type	D0: 256-bit unsigned integer S0: 32-bit unsigned integer (Multiples of 8) LPC: 9-bit signed integer

SUB **SUB**

Usage	SUB D0, S0, S1
Function	Subtracts S1 from S0, then stores the result in D0. S0 and S1 are handled as integers in the operation.
Behavior model	D0 = S0 - S1;

SUBS **SUBtract with Saturation**

Usage	SUBS D0, S0, S1
Function	This is an instruction to subtract a signed 32-bit source value S1 from a signed 32-bit source value S0 with saturation. Mapped on Thread.
Behavior model	D0 = SAT(S0 - S1, 32);
Operand type	D0: 32-bit signed integer S0: 32-bit signed integer S1: 32-bit signed integer

SUBSS8 **SUBtract Signed with Saturation 8-bit values**

Usage	SUBSS8 D0, S0, S1
Function	This is an instruction to subtract 8 times signed 8-bit value source S1 from signed 8-bit value source S0 with saturation.
Behavior model	D0[n] = SAT(S0[n] - S1[n], 8), n = 0...7;
Operand type	D0: 8 times 8-bit signed integer S0: 8 times 8-bit signed integer S1: 8 times 8-bit signed integer

SUBSS16	SUBtract Signed with Saturation 16-bit values
Usage	SUBSS16 D0, S0, S1
Function	This is an instruction to subtract 4 times signed 16-bit value source S1 from signed 16-bit value source S0 with saturation.
Behavior model	D0[n] = SAT(S0[n] - S1[n], 16), n = 0...3;
Operand type	D0: 4 times 16-bit signed integer S0: 4 times 16-bit signed integer S1: 4 times 16-bit signed integer

SUBRU	SUB Uniform from Register
Usage	SUBRU D0, S0, #IMM
Function	Subtracts the uniform value indexed by #IMM from S0, then stores the result in D0. S0 and the uniform value are handled as integers in the operation.
Behavior model	D0 = S0 - Uniform[#R6IMM];

SUBSRU	SUBtract with Saturation from Register value a Unified memory value
Usage	SUBSRU D0, S0, #IMM
Function	This is an instruction to subtract a signed 32-bit value specified by a Uniform index #IMM from a signed 32-bit source value S0 with saturation. Mapped on Thread.
Behavior model	D0 = SAT(S0 - Uniform[#R6IMM], 32);
Operand type	D0: 32-bit signed integer S0: 32-bit signed integer

SUBSUR	SUBtract with Saturation from Unified memory value a Register value
Usage	SUBSUR D0, S0, #IMM
Function	This is an instruction to subtract a signed 32-bit source value S0 from a signed 32-bit value specified by a Uniform index #IMM with saturation. Mapped on Thread.
Behavior model	D0 = SAT(Uniform[#R6IMM] - S0, 32);
Operand type	D0: 32-bit signed integer S0: 32-bit signed integer

SUBUR	SUB Register from Uniform
Usage	SUBUR D0, S0, #IMM
Function	Subtracts S0 from the uniform value indexed by #IMM, then stores the result in D0. S0 and the uniform value are handled as integers in the operation.
Behavior model	D0 = Uniform[#R6IMM] - S0;

SUBUS8	SUBtract Unsigned with Saturation 8-bit values
Usage	SUBUS8 D0, S0, S1
Function	This is an instruction to subtract 8 times unsigned 8-bit value source S1 from unsigned 8-bit value source S0 with saturation.
Behavior model	D0[n] = SAT(S0[n] - S1[n], 8), n = 0..7;
Operand type	D0: 8 times 8-bit unsigned integer S0: 8 times 8-bit unsigned integer S1: 8 times 8-bit unsigned integer

SUBUS16	SUBtract Unsigned with Saturation 16-bit values
Usage	SUBUS16 D0, S0, S1
Function	This is an instruction to subtract 4 times unsigned 16-bit value source S1 from unsigned 16-bit value source S0 with saturation.
Behavior model	D0[n] = SAT(S0[n] - S1[n], 16), n = 0..3;
Operand type	D0: 4 times 16-bit unsigned integer S0: 4 times 16-bit unsigned integer S1: 4 times 16-bit unsigned integer

SYNCG	SYNC Group
Usage	SYNCG
Function	Synchronize all threads inside a master-slave group. A SYNCG inside a thread causes the queue arbiter to set the bit for this thread inside the SYNCG register and the thread is waiting till a continue is received from the queue arbiter, After all bits from a master-slave group are set in the SYNCG register, the queue arbiter is sending the continue signal and the bits are cleared inside the SYNCG register. A master thread can issue this instruction.
Behavior model	-

SYNCP	SYNC PBUF
Usage	SYNCP #IMM
Function	Clear or flush pbuf. The behavior of the instruction is configured as follows. 1: Clear read buffer 2: Flush write buffer 3: Clear read buffer and flush write buffer. Other immediate value is prohibited. The “pbuf” is an alias of 0^{th} data cache associated with each thread.
Behavior model	-

TRAP	TRAP program
Usage	TRAP (no operand)
Function	Stops the program and transits the thread to the idle state.
Behavior model	-

UPLSB8	Unpack the 4 lowest bits of S0 into the LSB's of 4 8-bit values stored in D0
Usage	UPLSB8 D0, S0
Function	This is an instruction to unpack the 4 lowest bits of S0 into the LSB's of 4 8-bit values stored in D0. The values of other bits are retained. Implemented in each thread.
Behavior model	D0[0] = S0[0]; D0[8] = S0[1]; D0[16] = S0[2]; D0[24] = S0[3];
Operand type	D0: 32bit unsigned integer S0: 32bit unsigned integer (4bit used)

UPLSB16	Unpack the 2 lowest bits of S0 into the LSB's of 2 16-bit values stored in D0
Usage	UPLSB16 D0, S0
Function	This is an instruction to unpack the 2 lowest bits of S0 into the LSB's of 2 16-bit values stored in D0. The values of other bits are retained. Implemented in each thread.
Behavior model	D0[0] = S0[0]; D0[16] = S0[1];
Operand type	D0: 32bit unsigned integer S0: 32bit unsigned integer (2bit used)

VPEBS	Variable Position Extract Byte Signed extension
Usage	VPEBS D0, S0, #IMM
Function	The byte value stored at a position defined by #IMM in S0 gets sign extended to 32-bit and stored into D0. #IMM can take values 0 till 24.
Behavior model	D0 = ((S0 >> #IMM) << 24) >> 24

VPEBU	Variable Position Extract Byte Unsigned extension
Usage	VPEBU D0, S0, #IMM
Function	The byte value stored at a position defined by #IMM in S0 gets unsigned extended to 32-bit and stored into D0. #IMM can take values 0 till 24.
Behavior model	D0 = ((S0 >> #IMM) << 24) >>> 24

VPEHS	Variable Position Extract Half word Signed extension
Usage	VPEHS D0, S0, #IMM
Function	The half word value stored at a position defined by #IMM in S0 gets sign extended to 32-bit and stored into D0. #IMM can take values 0 till 16.
Behavior model	D0 = ((S0 >> #IMM) << 16) >> 16

VPEHU	Variable Position Extract Half word Unsigned extension
Usage	VPEHU D0, S0, #IMM
Function	The half word value stored at a position defined by #IMM in S0 gets unsigned extended to 32-bit and stored into D0. #IMM can take values 0 till 16.
Behavior model	D0 = ((S0 >> #IMM) << 16) >>> 16

WAITDMA	Wait for DMA
Usage	WAITDMA
Function	Wait till the queue arbiter sends continue signal which happens after the DMA transfer is finished.
Behavior model	-

U32.10 Instruction Format, Code and Pipeline Operation

Instructions have a fixed length of 32 bits and are classified into the following six instruction types: NI, TypeI16, TypeI8(xy), TypeI8(i), TypeRI/TypeRU and TypeR. The bit format of each instruction type is described in section U32.10.1 .

All instructions have the F1 bit and F0 bit to conditionally execute the instruction depending on the status register value. If the F0 and F1 bits are both 0, then the instruction is always executed regardless of the status register value. If the F1 bit is 1, then the instruction is executed when the status register is 1, whereas if the status register is 0, the instruction is regarded as NOP. If the F0 bit is 0, then the instruction is executed when the status register is 0, whereas if the status register is 1, the instruction is regarded as NOP. If the F1 and F0 bits are both 1, operation is not guaranteed.

The opcode of each instruction is listed in section U32.10.2 . The instruction group to which the instruction belongs to is also described in section U32.10.2 .

The pipeline operation of each instruction group is described in section U32.10.3 . Since the pipeline is stalled depending on the combination of the instructions, the conditions described in section U32.10.3 must be considered during programming.

U32.10.1 Instruction Format

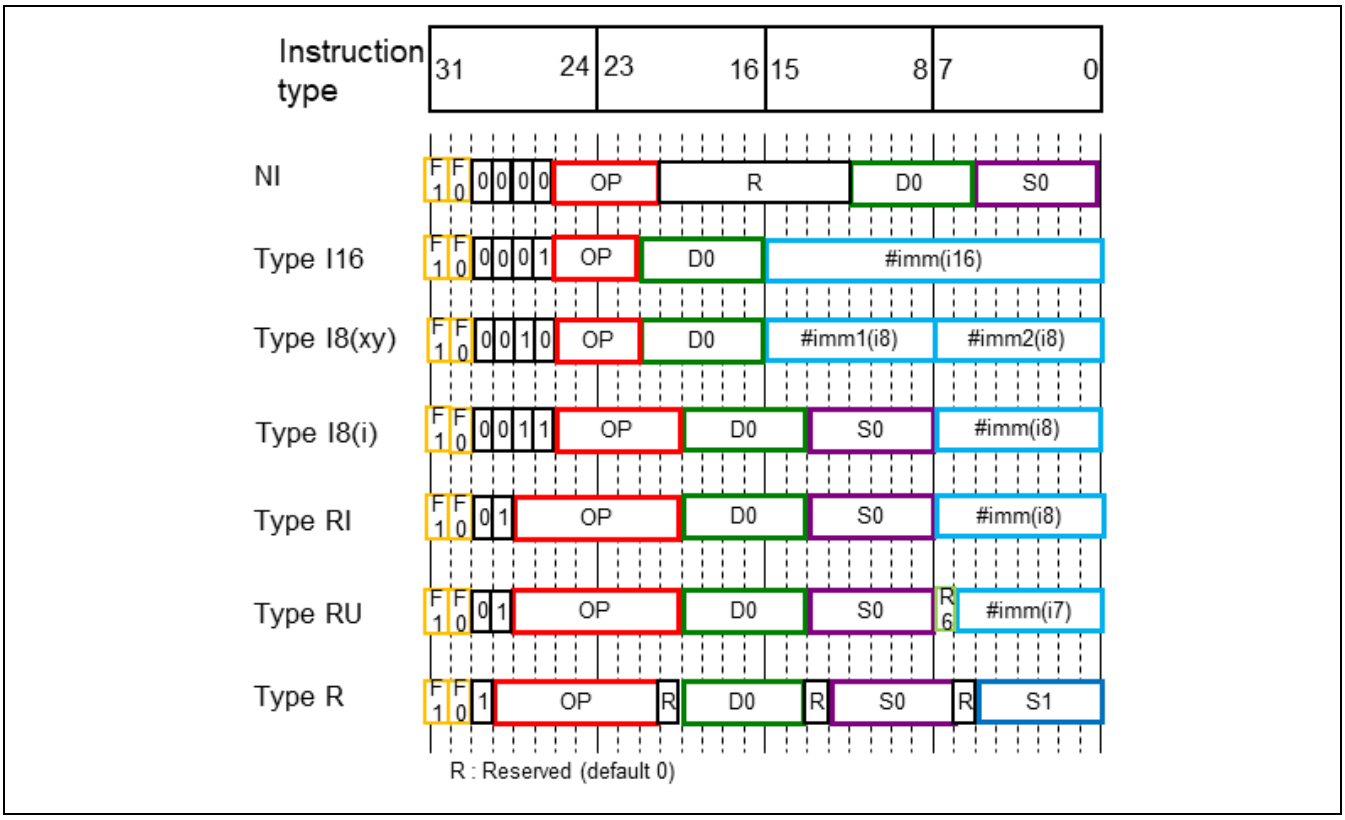

Figure U32.10.1 List of Instruction Formats

All instructions have a fixed length of 32 bits. Each instruction belongs to one of the six types of instructions: TypeNI, TypeI16, TypeI8(xy), TypeI8(i), TypeRI,/TypeRU, and TypeR.

NI	No Immediate. Instruction format with two register operands.
I16	Instruction format with one register operand and one immediate source value of 16-bit signed integer data.
I8(xy)	Instruction format with one register operand and two immediate source values of 8-bit signed integer data.
I8(i)	Instruction format with two register operands and one immediate source value of 8-bit integer data.
RI	Instruction format with two register operands and one immediate source value of 8-bit integer data. Whether an immediate value is signed or unsigned differs with the instruction.
RU	Instruction format with two register operands and one immediate source value of 7-bit integer data. The R6 bit is used to distinguish if R6 is referred to access the uniform storage. When the R6 bit is 1, R6 can be used as a general purpose register. To control this bit, refer to Section U32.9 Note 4.
R	Instruction format with three register operands.

Execution or non-execution of the instruction can be selected depending on the value of the status register (SR) by setting either the F0 bit or F1 bit of the instruction to 1. This enables the instruction to be conditionally executed without using a branch instruction.

The instruction is always executed when the F0 and F1 bits are both set to 0. Setting both the F0 bit and F1 bit to 1 is prohibited.

Table U32.10.1 Execution/Non-Execution Based on the Status Register and F0/F1 Flag State

	{F1, F0} == {0, 0}	{F1, F0} == {0, 1}	{F1, F0} == {1, 0}	{F1, F0} == {1, 1}
SR==0	Always executed*1	Executed*1	Not executed*2	Setting prohibited*2
SR==1		Not executed*2	Executed*1	

*1: Illegal instruction error can take place when the command is corrupted. *2: Operation is not guaranteed. No illegal instruction error takes place even if other bits are corrupted.

*1 For light CVe cluster, SAM2 and SAM4 instructions are implemented as SAM8 instructions. For the information which CVe cluster is implemented as light CVe cluster, refer to Table 58.1 of User's Manual: Hardware, section 58.1.2 Specifications of the IMP-X7 by Products.
*2 For light CVe cluster, the number of execution steps is by 1 decreased. For the information which CVe cluster is implemented as light CVe cluster, refer to Table 58.1 of User's Manual: Hardware, section 58.1.2 Specifications of the IMP-X7 by Products.

U32.10.3 Pipeline Operation of CVengine Thread

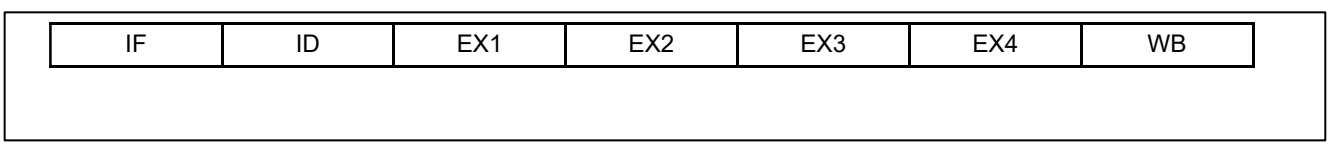

Figure U32.10.2 Pipeline Configuration of CVengine Thread

The CVengine thread is a microprocessor that issues single instructions to be processed in a pipeline. The pipeline is shown in the above picture. The pipeline has seven stages: instruction fetching (IF), decoding and register reading (ID),

1st execution (EX1), 2nd execution (EX2), 3rd execution (EX3), 4th execution (EX4), and write-back (WB). A single instruction is executed as a combination of pipeline stages.

U32.10.3.1 Pipeline operations for each instruction group

The pipeline operations for each instruction group are shown below.

(1) ET1 group

IF	ID	EX1	EX2	EX3	EX4	WB
- Instruction fetch	- Instruction decode - Forwarding - Register read	- Operation				- Write-back

(2) ES2 group

IF	ID	EX1	EX2	EX3	EX4	WB
- Instruction fetch	- Instruction decode - Forwarding - Register read	- Operation	- Operation			- Write-back

(3) ES3 group

IF	ID	EX1	EX2	EX3	EX4	WB
- Instruction fetch	- Instruction decode - Forwarding - Register read	- Operation	- Operation	- Operation		- Write-back

(4) ESF3 group

IF	ID	EX1	EX2	EX3	EX4	WB
- Instruction fetch	- Instruction decode - Forwarding - Register read	- Operation	- Operation	- Operation		- Write-back

(5) ESF4 group

IF	ID	EX1	EX2	EX3	EX4	WB
- Instruction fetch	- Instruction decode - Forwarding - Register read	- Operation	- Operation	- Operation	- Operation	- Write-back

(6) LS group

IF	ID	EX1	EX2	EX3	EX4	WB
- Instruction fetch	- Instruction decode - Forwarding - Register read	- Memory data access	- Memory data access	- Memory data access	- Memory data access	- Write-back

(7) BR group

IF	ID	EX1	EX2	EX3	EX4	WB
- Instruction fetch	- Instruction decode - Forwarding - Register read - Branch determination					

(8) CO group

IF	ID	EX1	EX2	EX3	EX4	WB
- Instruction fetch	- Instruction decode - Forwarding					- Control

For instructions of the ET1 and CO groups, the number of instruction steps and the number of issuance cycles are both 1, and the subsequent instruction is executed consecutively. Even if an instruction immediately following an ET1 or CO group instruction, it is dependent on that ET1 or CO group instruction, forwarding from the EX1 stage to the ID stage is performed and the subsequent instruction can be executed without stalling the pipeline. Also, even if there is an instruction that is dependent on the ET1 or CO group instruction that is multiple instructions before it, forwarding from each stage is performed and the pipeline is not stalled. However, forwarding is not done for registers used for transfer of side information like, e.g., R0 and R1 for LDRXY or R6 for uniform memory access.

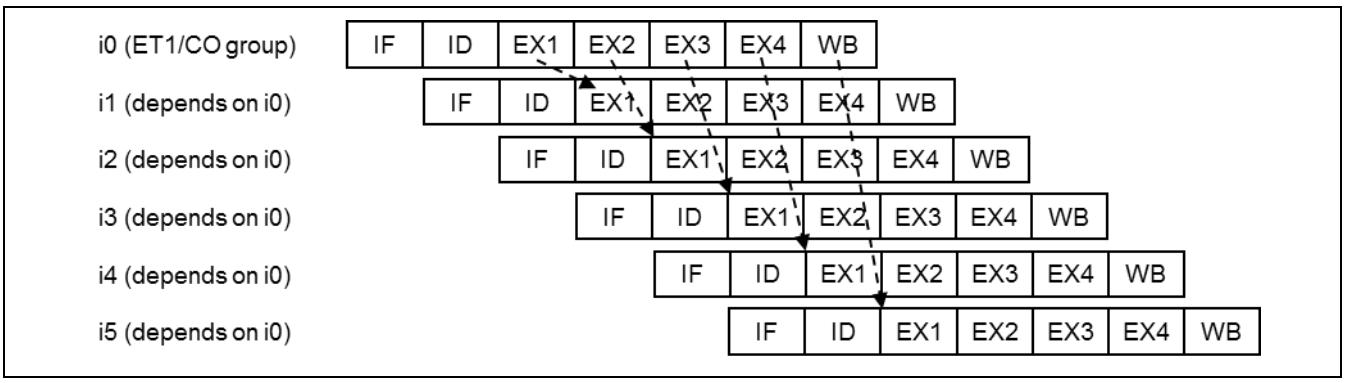

Figure U32.10.3 Execution of an ET1/CO Group Instruction and its Dependent Instructions

For instructions of the ES2 group, the number of instruction steps is 2 and the number of issuance cycles is 1. The subsequent instruction is executed consecutively in case it is not dependent on the ES2 group instruction. If an instruction immediately following an ES2 group instruction is dependent on that ES2 group instruction, the pipeline is stalled by one cycle. If there is an instruction that is dependent on the ES2 group instruction that is at least two instructions before it, forwarding from each stage is performed and the pipeline is not stalled. However, forwarding is not done for registers used for transfer of side information like, e.g., R0 and R1 for LDRXY or R6 for uniform memory access.

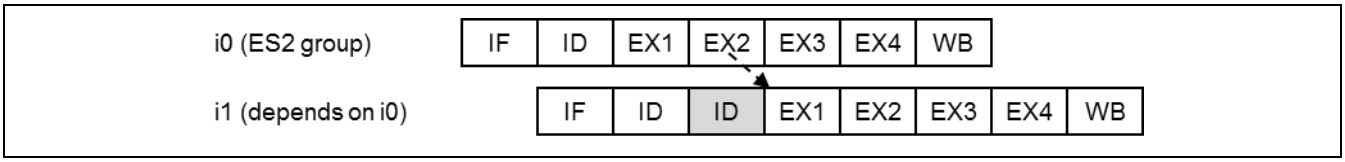

Figure U32.10.4 Execution of an ES2 Group Instruction and its Dependent Instructions

For instructions of the ES3/ESF3 group, the number of instruction steps is 3 and the number of issuance cycles is 1. The subsequent instruction is executed consecutively in case it is not dependent on the ES3/ESF3 group instruction. If there is an instruction that is dependent on the ES3/ESF3 group instruction that is immediately before or two instructions before it, the pipeline is stalled. If there is an instruction that is dependent on the ES3/ESF3 group instruction that is at least three instructions before it, forwarding from each stage is performed and the pipeline is not stalled. However, forwarding is not done for registers used for transfer of side information like, e.g., R0 and R1 for LDRXY or R6 for uniform memory access.

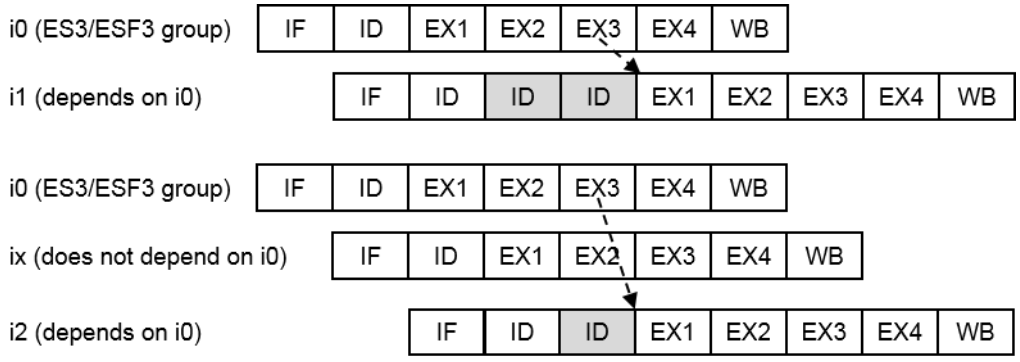

Figure U32.10.5 Execution of an ES3/ESF3 Group Instruction and its Dependent Instructions

For instructions of the ESF4 group, the number of instruction steps is 4 and the number of issuance cycles is 1. The subsequent instruction is executed consecutively in case it is not dependent on the ESF4 group instruction. If there is an instruction that is dependent on the ESF4 group instruction that is immediately before, two instructions before, or three instructions before it, the pipeline is stalled. If there is an instruction that is dependent on the ESF4 group instruction that is at least four instructions before it, forwarding from each stage is performed and the pipeline is not stalled. However, forwarding is not done for registers used for transfer of side information like, e.g., R0 and R1 for LDRXY or R6 for uniform memory access.

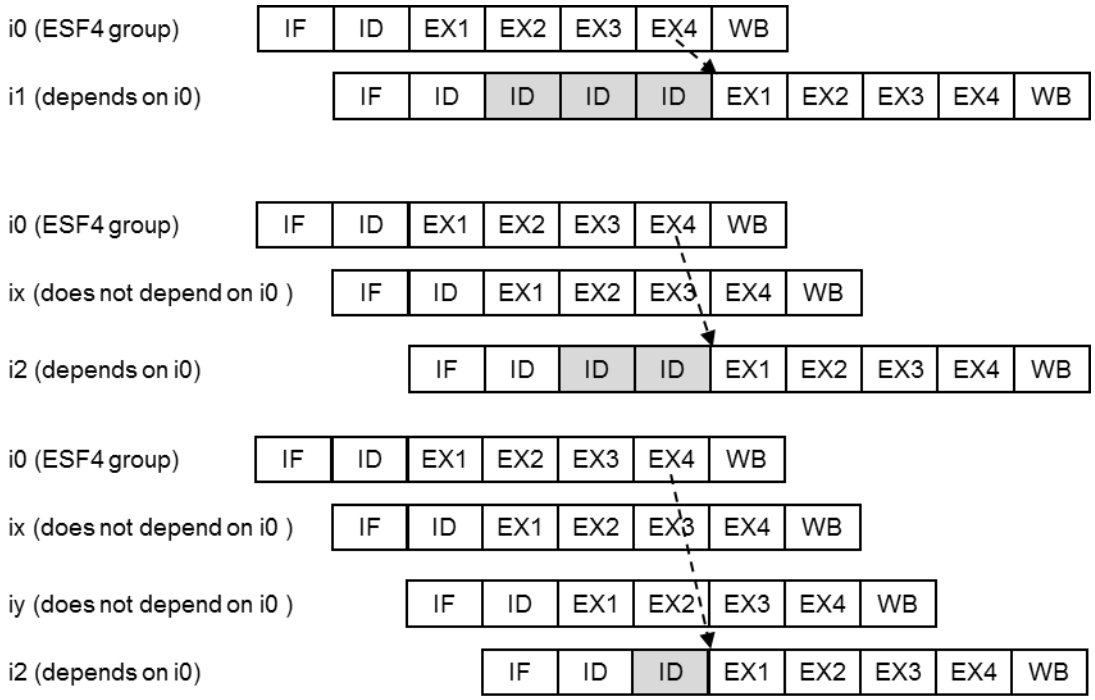

Figure U32.10.6 Execution of an ESF4 Group Instruction and its Dependent Instructions

For instructions of the LS group, the number of instruction steps is 5 and the number of issuance cycles is 1 for loading and the number of instruction steps and the number of issuance cycles are both 1 for storage. For a load instruction, the subsequent instruction is executed consecutively in case it is not dependent on the LS group instruction. If an instruction immediately following a load instruction is dependent on that load instruction, the pipeline is stalled by four cycles. If there is an instruction that is dependent on the LS group instruction that is at least four instructions before it, forwarding is performed, and the pipeline is not stalled. However, forwarding is not done for registers used for transfer of side information like, e.g., R0 and R1 for LDRXY or R6 for uniform memory access.

Since an LS group instruction accesses the data cache, the pipeline is stalled when a cache miss occurs. The number of stall cycles depends on the bus congestion which the CVengine is connected to and the external memory state.

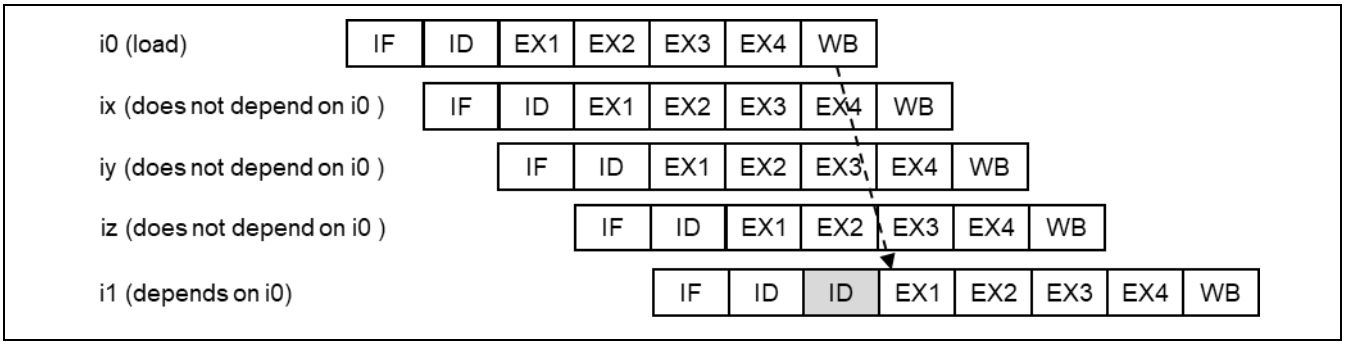

Figure U32.10.7 Execution of a Load Instruction and its Dependent Instructions

For storage, the subsequent instruction is always executed consecutively.

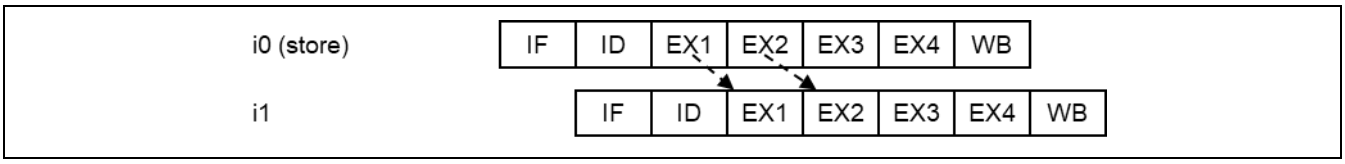

Figure U32.10.8 Execution of a Store Instruction and its Dependent Instructions

A BR group instruction always causes 1-cycle stall when the branch condition is satisfied.

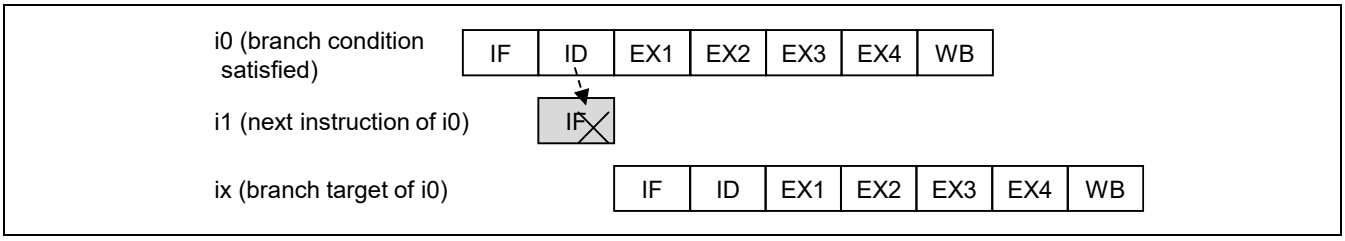

Figure U32.10.9 Execution When the Branch Condition of a BR Group Instruction is Satisfied

If the branch condition is not satisfied, the pipeline is not stalled.

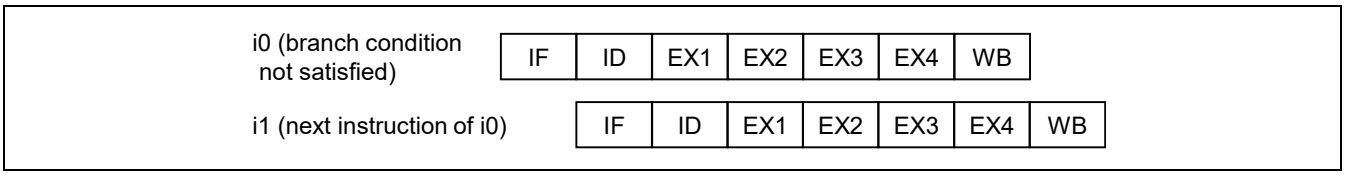

Figure U32.10.10 Execution When the Branch Condition of a BR Group Instruction is Not Satisfied

U32.10.3.2Pipeline stall on arbitration

Multiple threads in the same core share the operation unit used in executing instructions of the ES2, ES3/ESF3 and ESF4 groups. Therefore, when more than one threads is requesting for the same operation unit at the same time, the pipeline may be stalled due to arbitration.

U32.10.3.3Pipeline stall on FMAD/FMADU/FMSU/FMSUU and FADD/FADDU/FSUB/FSUBU

FMAD/FMADU/FMSU/FMSUU followed by an FADD/FADDU/FSUB/FSUBU the following instruction (e.g., FADD) is delayed by 1 clock cycle.

Example:

```
FMSU    R20, R21, R22
FADD    R26, R25, R24
```

U32.10.3.4Forwarding with 32-bit and 64-bit instructions

A 32-bit result can be forwarded to a 64-bit source as shown in the example below:

```
ADD     R25, R17, R19
ADD     R24, R21, R23
ASMU    R24, R24, 14
```

Additionally, also for a 64-bit result and a 32-bit source, forwarding is done as shown in the example below:

```
MULLS   R16, R22, R23
```

```
ADD         R25, R17, R19
```

U32.10.3.5Forwarding with R6 register

R6 register can be used as a general purpose register. Refer to section U32.9 Note 4 for detail. Since R6 is not a regular general purpose register, forwarding is done differently to other general purpose registers.

When LD instruction (only if accessing to Uniform) and RU type instruction are both used, conflict can occur on ID and EX2 stages so pipeline stalls 1 cycle.

```
LD          R16, R17, R3        (Accessing to Uniform)
ADD         R18, R19, R20
ADDU        R21, R22, $2        (Using R6 as offset base)
```

- Forwarding is not possible to RU type instructions when using R6 as offset base.

  ```
  ADD         R6, R16, R17
  ADDU        R18, R6, $4         (RU type)
  ```

  Forwarding is done to non-RU type instructions; no stall happens in the case below.

  ```
  ADD         R6, R16, R17
  ADD         R18, R6, R19        (non-RU type)
  ```

- Forwarding is not supported for branch instructions. The number of execution steps for branch instructions that update the general purpose register set (e.g., CALL and CALLR) is 1 clock cycle for general purpose registers. For register R6, which does not belong to the general purpose register set, no forwarding is supported, so 5 NOP cycles are added.

U32.10.4 Number of Execution Cycles of Special Instructions of CVengine Thread

The CVengine thread has operation units dedicated to special operations, such as square root. A special operation is executed by writing to a specific register number and the result is stored in the same register number.

After these operations are started, the number of cycles shown in the following table is necessary at minimum to be able to read the result. Since these operation units are shared by multiple threads, if the same operation unit is accessed simultaneously, the number of required cycles will increase when the access right cannot be acquired due to arbitration. Also, as RCP0 (R14) and RCP1 (R15) use the same operation unit, contention occurs when operations to write to these registers happen at the same time.

Table U32.10.3 Number of Execution Cycles of Special Instructions

Operation Type (Register)	Number of Execution Cycles
SIN (R8)	5
COS (R9)	5
1/SQRT (R10)	5
EXP2 (R11)	5
LOG2 (R12)	5
SQRT (R13)	5
RCP (R14 and R15)	6

When executing a read instruction that uses these register values before the result has been written, the thread will stall until the results are available.

U32.11 Vertex Issue

The Vertex Issue is a sub module of CVengine. The Vertex Issue manages the CVengine cluster. A typical sequence of Vertex Issue behavior is the following.

1. Vertex Issue is invoked by the host processor.
2. Vertex Issue fetches command from the Command List.
3. Upon WPR commands in the Command List, Vertex Issue sets values to the Configuration Registers.
4. Upon POINT and RECT commands in the Command List, Vertex Issue throws a set of XY coordinates to a thread in idle state. Which XY coordinates are assigned to which thread is determined by Vertex Issue automatically.
5. Upon TRAP command in the Command List, the Vertex Issue returns interrupt to the host processor.

Note: The Vertex Issue has a Command List pre-fetch buffer, the size is 640 bytes.

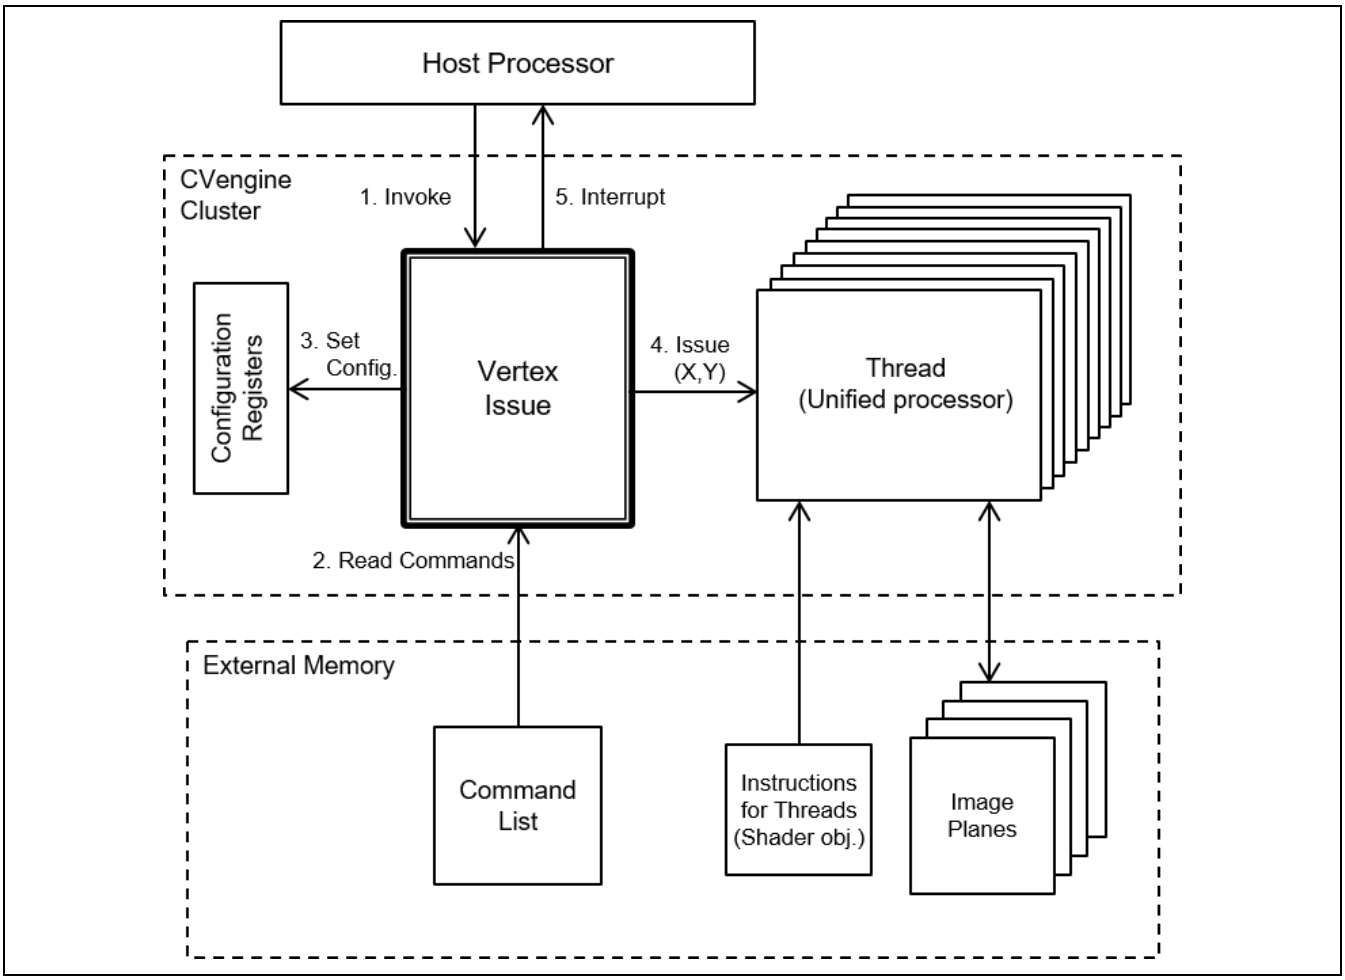

Figure U32.11.1 Vertex Issue behavior

U32.11.1 Synchronization with WUP and SLP commands

To make synchronization among the cores, CNN, PSC, IMP DMAC, IMP core and CVengine core, two commands (WUP and SLP) are provided.

WUP: This command is issued by a core to wake up another core from the sleep (SLP) state.
If the WUP command is issued to a core that is operating and the core later attempts to enter the SLP state, the core will immediately wake up and cannot enter the SLP state. However, note that even if the WUP command is issued to a core two or more times, the requests are not accumulated.
When entering the SLP state, each core specifies which cores should issue the WUP command to wake it up from the SLP state. Each core wakes up only after it has received the WUP signal from all specified cores.

SLP: This command stops command fetch and decoding in the core that has issued the command and makes the core wait for the WUP signal input in the SLP state.
When issuing this command, the cores that should wake up the current core by sending the WUP signal should be specified. Upon receiving the WUP signal from all specified cores, the core wakes up from the SLP state and resumes command fetch and decoding.

The following illustrates synchronization operation.

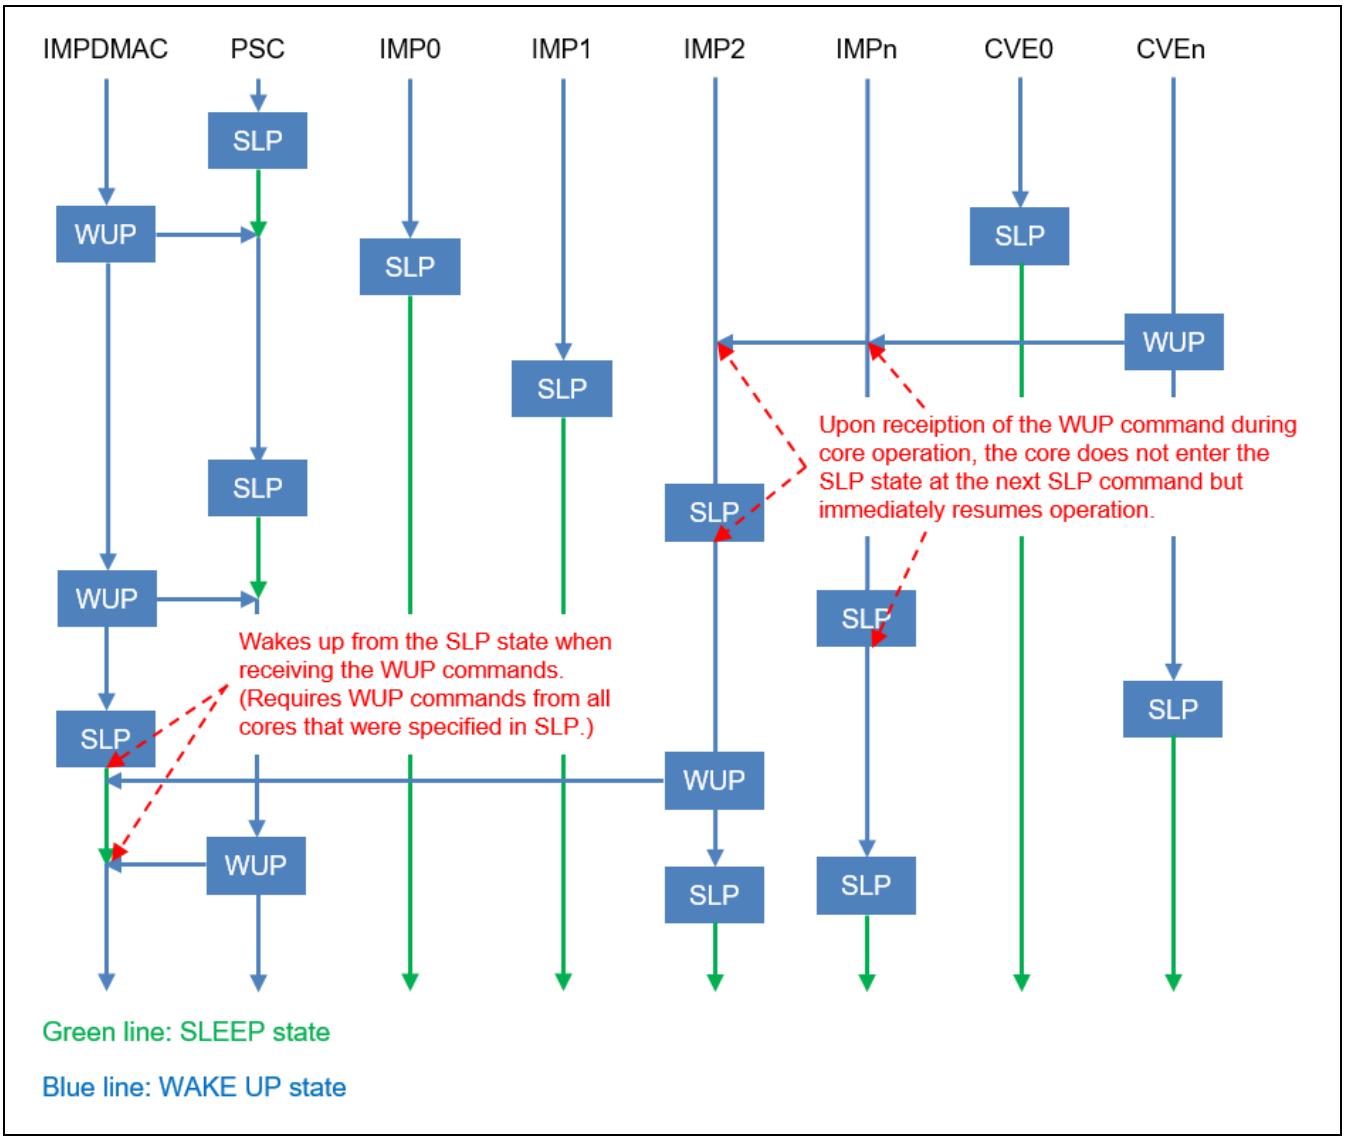

Figure U32.11.2 Vertex Issue behavior

U32.12 Configuration Registers

While executing CVengine, access from Arm is prohibited except for Status Register1(SR1). Also, it is prohibited to change values using WPR command while executing threads. The read values from un-mapped addresses are undefined. Access to addresses other than those in the following lists of registers is prohibited, otherwise operation cannot be guaranteed.

The registers having address from H'780 to H'790 are duplicated to each thread and accessible from the thread program only. Host CPU cannot access them.

Value of the registers with "WPR support" checked can be set using WPR command in the Command List.

Table U32.12.2 Register Configuration - Control Register

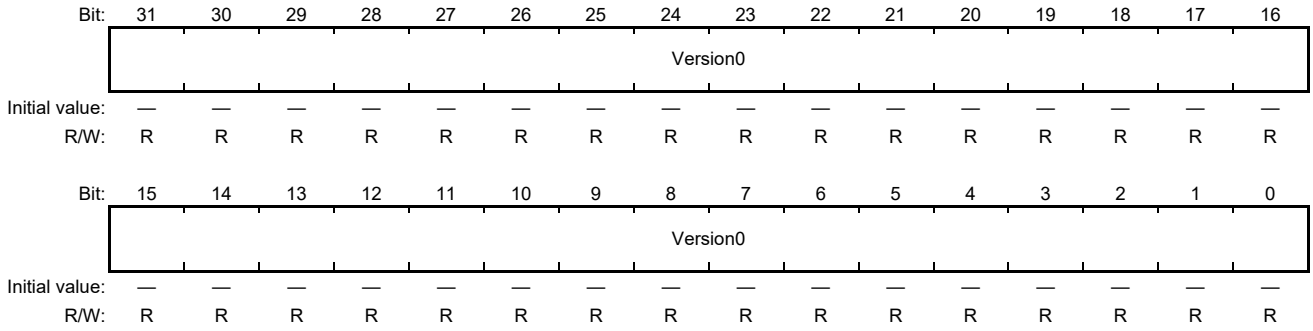
U32.12.1 Register Description

[Legend]

Initial value:	Register value after a reset
—:	Undefined value
R/W:	Readable/writable. The written value can be read.
R:	Read-only. The write value should be the same as the read value. Only modify the target bit (Read Modify Write) because the initial value should not be changed.
-/W:	Write-only. The read value is undefined.

U32.12.1.1 Version Control Register 0 (VCR0)



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	Version0	H'00000007	R	These bits indicate the version of this module for R-Car V4M.

U32.12.1.2ReSeT Register (RSTR)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SWRST
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
0	SWRST	0	R/W	Software Reset Software Reset is supplied to CVengine Core if this bit is "1". It is required to write "0" to this bit to release the software reset before writing other registers. 0: Release the software reset 1: Supply the software reset Setting this bit to 1 is prohibited when the PS bit in the CR register is 1. In that case, operation is not guaranteed. While CL, Thread or TGDMAC is being executed, the PS bit shows “1”. Data cache is invalidated after a software reset. It is prohibited to read or write the CVengine registers (accept reading this register) while software reset is supplied to the CVengine.

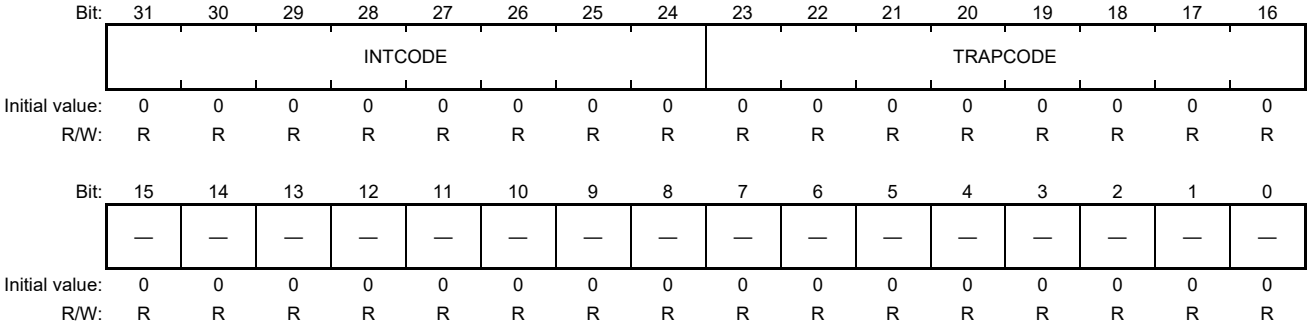
U32.12.1.3Control Register (CR)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PS
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
0	PS	0	R/W	Processing Start If "1" is written to this bit, CVengine Core Issue starts fetching and executing CL from the address specified in DLSAR register. During the execution, "1" is read from this bit. Otherwise, "0" is read. It is prohibited to write "1" and "0" during its execution.

U32.12.1.4Status Register 0 (SR0)



Bit	Bit Name	Initial Value	R/W	Description
31 to 24	INTCODE	H'00	R	INT interrupt code When INT command in the command list is executed, the CODE field of the INT command that can be defined by the user is copied to this field. Refer to Section U32.13.7 . This field is updated regardless of the setting of ICR register.
23 to 16	TRAPCODE	H'00	R	TRAP interrupt code When TRAP command in the command list is executed, the CODE field of the TRAP command that can be defined by the user is copied to this field. Refer to Section U32.13.5 . This field is updated regardless of the setting of ICR register.
15 to 0	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.

U32.12.1.5Status Register 1 (SR1)

Each bit of this register is only set to 1 when the corresponding bit in the interrupt control register (ICR) is 1. When any bit of this register is set to 1 while the corresponding bit in the interrupt mask register (IMR) is 0, an interrupt is generated. Each bit of this register is cleared to 0 when 1 is written to the corresponding bit in the status clearing register (SCR).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	WUPCOVF	USINT	USIER	—	CLBRK	—	—	—	—	—	SBO0ME	PBCOVF	INT	IER	TRAP
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 15	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
14	WUPCOVF	0	R	WUP Receive Counter overflow Refer to U30G. IMP-X7 System, Inter module synchronization for the details when using this bit.
13	USINT	0	R	INT instruction interruption of thread.
12	USIER	0	R	Command error decode This bit shows that an illegal instruction is decoded in the thread program. 0: An illegal instruction has not been decoded. 1: An illegal instruction has been decoded. Additional condition the illegal instruction error takes place is described in Table U32.10.1.
11	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
10	CLBRK	0	R	CL BREAK 0: CL does not break 1: CL break CL break cannot be used if CLBRKENB of ICR1 register is set to 0. Set CLBRKENB of ICR1 register to 1 to use CL break function. Command list continues execution after clearing this bit using CLBRKCLR bit of SCR1 register.
9 to 5	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
4	SBO0ME	0	R	SBO0 memory size error

Bit	Bit Name	Initial Value	R/W	Description
3	PBCOVF	0	R	Performance Busy Counter Overflow 0: A performance counter overflow has not been detected. 1: A performance counter overflow has been detected. Refer to Section U32.8.8 for detail.
2	INT	0	R	INT command decode This bit shows that INT command is decoded. Once this bit gets "1", the CL execution is stopped unless this status becomes "0". 0: An INT command has not been decoded. 1: An INT command has been decoded.
1	IER	0	R	Undefined command decode in CL or GOSUB overflow/underflow This bit shows that undefined command is decoded. Once an undefined command is decoded, the CL execution is stopped. 0: An unknown command has not been decoded. 1: An unknown command has been decoded. Reset IMP CVe by using SWRST bit of RSTR register after the IER error.
0	TRAP	0	R	TRAP command decode This bit shows that TRAP command is decoded, and the CL execution finishes. 0: A TRAP command has not been decoded. 1: A TRAP command has been decoded.

U32.12.1.6Status Clear Register 1 (SCR1)

Writing 1 to each effective bit of this register clears the corresponding bit in status register 1 (SR1) to 0.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	WUPCOVFCLR	USINTCLR	USIERCLR	—	CLBRKCLR	—	—	—	—	—	SBO0MECLR	PBCOVFCLR	INTCLR	IERCLR	TRACLR
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	-/W	-/W	-/W	R	-/W	R	R	R	R	R	-/W	-/W	-/W	-/W	-/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 15	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
14	WUPCOVFCLR	0	-/W	By writing "1" to this bit, the WUPCOVF bit in SR1 register is cleared.
13	USINTCLR	0	-/W	By writing "1" to this bit, the USINT bit in SR1 register is cleared.
12	USIERCLR	0	-/W	By writing "1" to this bit, the USIER bit in SR1 register is cleared.
11	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
10	CLBRKCLR	0	-/W	By writing "1" to this bit, the CLBRK bit in SR1 register is cleared. Command list continues execution after clearing CLBRK bit of SR1 register.
9 to 5	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
4	SBO0MECLR	0	-/W	By writing "1" to this bit, the SBO0ME bit in SR1 register is cleared.
3	PBCOVFCLR	0	-/W	By writing "1" to this bit, the PBCOVF bit in SR1 register is cleared.
2	INTCLR	0	-/W	By writing "1" to this bit, the INT bit in SR1 register is cleared.
1	IERCLR	0	-/W	By writing "1" to this bit, the IER bit in SR1 register is cleared.
0	TRACLR	0	-/W	By writing "1" to this bit, the TRAP bit in SR1 register is cleared.

U32.12.1.7Interrupt Control Register 1 (ICR1)

When each effective bit of this register is 0, the corresponding bit in status register 1 (SR1) is not set to 1. Changing value of this register does not affect current value of SR1 register.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	WUPCOVFENB	USINTENB	USIERENB	—	CLBRKENB	—	—	—	—	—	SBO0MEENB	PBCOVFENB	INTENB	IERENB	TRAENB
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R/W	R/W	R/W	R	R/W	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 15	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
14	WUPCOVFENB	0	R/W	By writing "1" to this bit, the WUPCOVF bit in SR1 register can be set.
13	USINTENB	0	R/W	By writing "1" to this bit, the USINT bit in SR1 register can be set.
12	USIERENB	0	R/W	By writing "1" to this bit, the USIER bit in SR1 register can be set.
11	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
10	CLBRKENB	0	R/W	By writing "1" to this bit, the CLBRK bit in SR1 register can be set. When this bit is 0, CL break operation is not possible.
9 to 5	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
4	SBO0MEENB	0	R/W	By writing "1" to this bit, the SBO0ME bit in SR1 register can be set.
3	PBCOVFENB	0	R/W	By writing "1" to this bit, the PBCOVF bit in SR1 register can be set.
2	INTENB	0	R/W	By writing "1" to this bit, the INT bit in SR1 register can be set.
1	IERENB	0	R/W	By writing "1" to this bit, the IER bit in SR1 register can be set.
0	TRAENB	0	R/W	By writing "1" to this bit, the TRAP bit in SR1 register can be set.

U32.12.1.8Interrupt Mask Register 1 (IMR1)

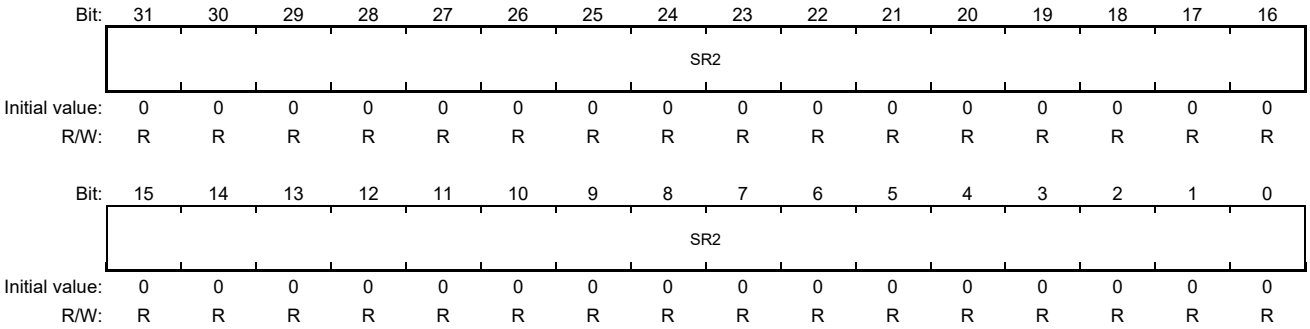
An interrupt is generated when any bit of status register 1 (SR1) is set to 1 while the corresponding bit in this register is 0.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	WUPCOVFMSK	USINTMSK	USIERMSK	—	CLBRKMSK	—	—	—	—	—	SBO0MEMSK	PBCOVFMSK	INTMSK	IERMSK	TRAMSK
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R/W	R/W	R/W	R	-/W	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

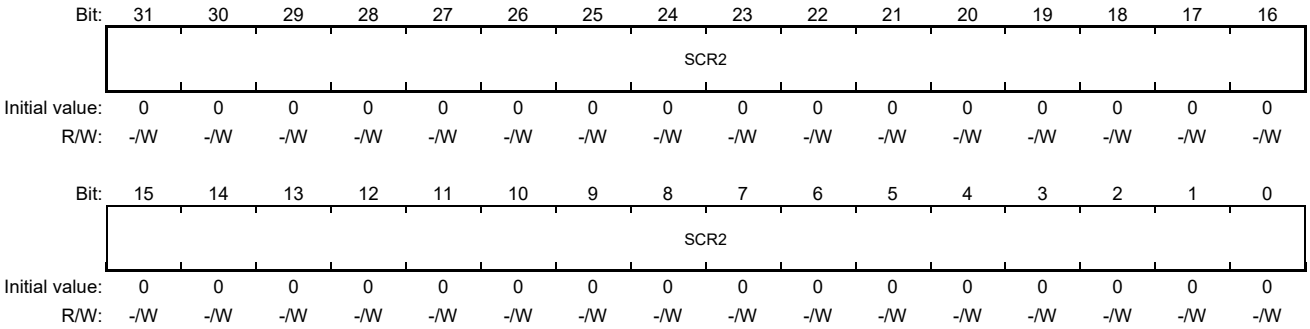
Bit	Bit Name	Initial Value	R/W	Description
31 to 15	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
14	WUPCOVFMSK	0	R/W	By writing "1" to this bit, the interrupt occurred by WUPCOVF bit in SR1 register is masked.
13	USINTMSK	0	R/W	By writing "1" to this bit, the interrupt occurred by USINT bit in SR1 register is masked.
12	USIERMSK	0	R/W	By writing "1" to this bit, the interrupt occurred by USIER bit in SR1 register is masked.
11	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
10	CLBRKMSK	0	-/W	By writing "1" to this bit, the interrupt occurred by CLBRK bit in SR1 register is masked. This bit is always read as 0.
9 to 5	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
4	SBO0MEMSK	0	R/W	By writing "1" to this bit, the interrupt occurred by SBO0ME bit in SR1 register is masked.
3	PBCOVFMSK	0	R/W	By writing "1" to this bit, the interrupt occurred by PBCOVF bit in SR1 register is masked.
2	INTMSK	0	R/W	By writing "1" to this bit, the interrupt occurred by INT bit in SR1 register is masked.
1	IERMSK	0	R/W	By writing "1" to this bit, the interrupt occurred by IER bit in SR1 register is masked.
0	TRAMSK	0	R/W	By writing "1" to this bit, the interrupt occurred by TRAP bit in SR1 register is masked.

U32.12.1.9Status Register 2 (SR2)



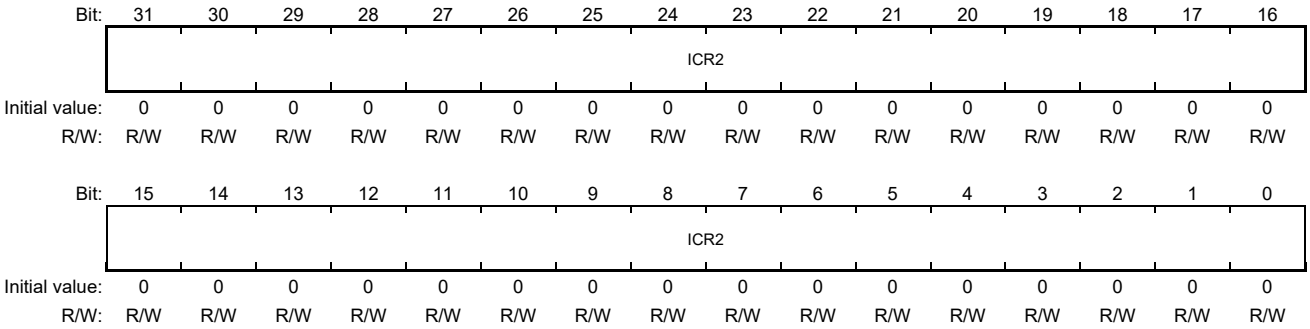
Bit	Bit Name	Initial Value	R/W	Description
31 to 0	SR2	All 0	R	INT command decode for thread These bits show that INT command is decoded by thread. Once each bit gets "1", the CL execution is stopped unless each status becomes "0". 0: An INT command has not been decoded by thread. 1: An INT command has been decoded by thread. bit31: core3.thread7, bit30: core3.thread6, bit29: core3.thread5, bit28: core3.thread4, bit27: core3.thread3, bit26: core3.thread2, bit25: core3.thread1, bit24: core3.thread0 bit23: core2.thread7, bit22: core2.thread6, bit21: core2.thread5, bit20: core2.thread4, bit19: core2.thread3, bit18: core2.thread2, bit17: core2.thread1, bit16: core2.thread0 bit15: core1.thread7, bit14: core1.thread6, bit13: core1.thread5, bit12: core1.thread4, bit11: core1.thread3, bit10: core1.thread2, bit9: core1.thread1, bit8: core1.thread0 bit7: core0.thread7, bit6: core0.thread6, bit5: core0.thread5, bit4: core0.thread4, bit3: core0.thread3, bit2: core0.thread2, bit1: core0.thread1, bit0: core0.thread0

U32.12.1.10Status Clear Register 2 (SCR2)



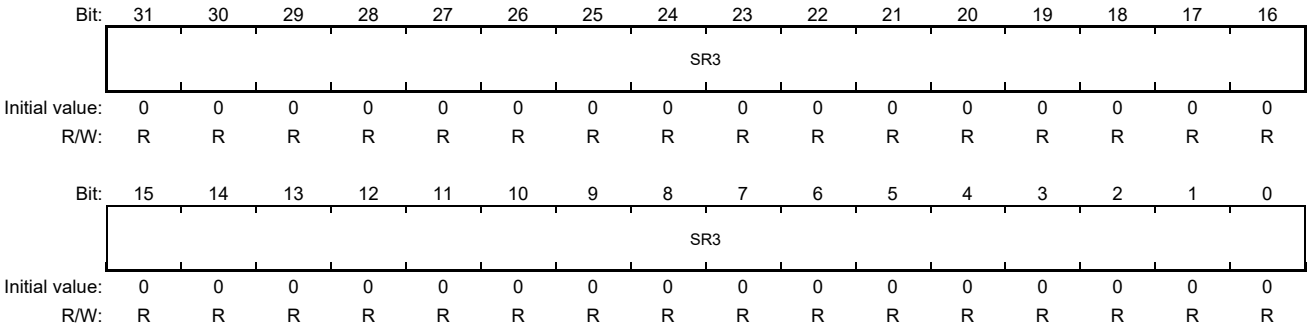
Bit	Bit Name	Initial Value	R/W	Description
31 to 0	SCR2	All 0	-/W	By writing "1" to each bit, each bit in SR2 register is cleared. bit31: core3.thread7, bit30: core3.thread6, bit29: core3.thread5, bit28: core3.thread4, bit27: core3.thread3, bit26: core3.thread2, bit25: core3.thread1, bit24: core3.thread0 bit23: core2.thread7, bit22: core2.thread6, bit21: core2.thread5, bit20: core2.thread4, bit19: core2.thread3, bit18: core2.thread2, bit17: core2.thread1, bit16: core2.thread0 bit15: core1.thread7, bit14: core1.thread6, bit13: core1.thread5, bit12: core1.thread4, bit11: core1.thread3, bit10: core1.thread2, bit9: core1.thread1, bit8: core1.thread0 bit7: core0.thread7, bit6: core0.thread6, bit5: core0.thread5, bit4: core0.thread4, bit3: core0.thread3, bit2: core0.thread2, bit1: core0.thread1, bit0: core0.thread0

U32.12.1.11 Interrupt Control Register 2 (ICR2)



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	ICR2	All 0	R/W	By writing "1" to a bit of ICR2, an interrupt of the corresponding thread is setting the USINT bit of SR1 when USINTENB of ICR1 is set. bit31: core3.thread7, bit30: core3.thread6, bit29: core3.thread5, bit28: core3.thread4, bit27: core3.thread3, bit26: core3.thread2, bit25: core3.thread1, bit24: core3.thread0 bit23: core2.thread7, bit22: core2.thread6, bit21: core2.thread5, bit20: core2.thread4, bit19: core2.thread3, bit18: core2.thread2, bit17: core2.thread1, bit16: core2.thread0 bit15: core1.thread7, bit14: core1.thread6, bit13: core1.thread5, bit12: core1.thread4, bit11: core1.thread3, bit10: core1.thread2, bit9: core1.thread1, bit8: core1.thread0 bit7: core0.thread7, bit6: core0.thread6, bit5: core0.thread5, bit4: core0.thread4, bit3: core0.thread3, bit2: core0.thread2, bit1: core0.thread1, bit0: core0.thread0

U32.12.1.12Status Register 3 (SR3)



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	SR3	All 0	R	Indicates whether any illegal instruction has been decoded. To clear any bit of this register, software reset is needed. 0: No illegal instruction has been decoded in the thread. 1: An illegal instruction has been decoded in the thread. bit31: core3.thread7, bit30: core3.thread6, bit29: core3.thread5, bit28: core3.thread4, bit27: core3.thread3, bit26: core3.thread2, bit25: core3.thread1, bit24: core3.thread0 bit23: core2.thread7, bit22: core2.thread6, bit21: core2.thread5, bit20: core2.thread4, bit19: core2.thread3, bit18: core2.thread2, bit17: core2.thread1, bit16: core2.thread0 bit15: core1.thread7, bit14: core1.thread6, bit13: core1.thread5, bit12: core1.thread4, bit11: core1.thread3, bit10: core1.thread2, bit9: core1.thread1, bit8: core1.thread0 bit7: core0.thread7, bit6: core0.thread6, bit5: core0.thread5, bit4: core0.thread4, bit3: core0.thread3, bit2: core0.thread2, bit1: core0.thread1, bit0: core0.thread0

U32.12.1.13Shader Core MaSK Register (SCMSKR)

When only 1 core is activated, 8 out of 32 threads work. This register is to reduce power consumption. To use debugger, remain this register in default.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
3 to 0	SCMSKR	All 0	R/W	Specify if each core in a cluster is used or not. [Bit3] 0: Core3 is used. 1: Core3 is not used. [Bit2] 0: Core2 is used. 1: Core2 is not used. [Bit1] 0: Core1 is used. 1: Core1 is not used. [Bit0] 0: Core0 is used. 1: Core0 is not used.

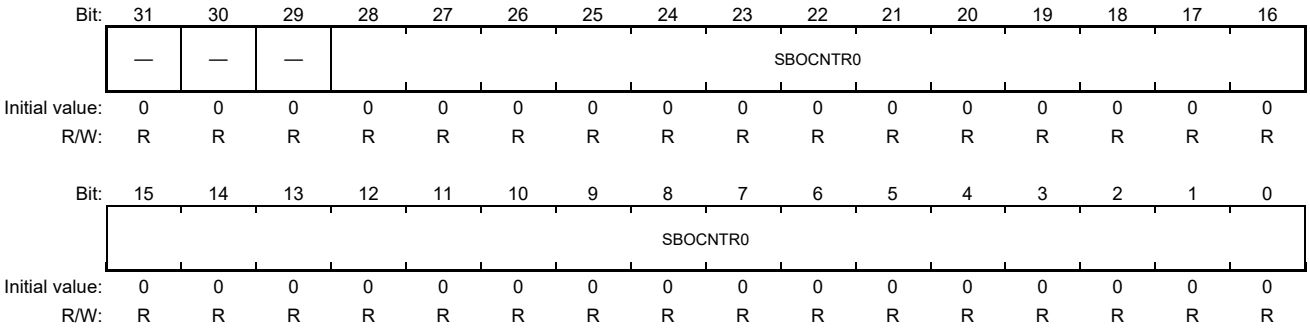
U32.12.1.14Thread Group Control Register 0 (TGCR0)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	TGRSEL		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
2 to 0	TGRSEL	All 0	R/W	To select which core to read the performance counter. 0 : Read PFCTOTALR0 from Core 0 1 : Read PFCTOTALR0 from Core 1 2 : Read PFCTOTALR0 from Core 2 3 : Read PFCTOTALR0 from Core 3 This field works with SELUSPFC. Refer to U32.12.1.50 .

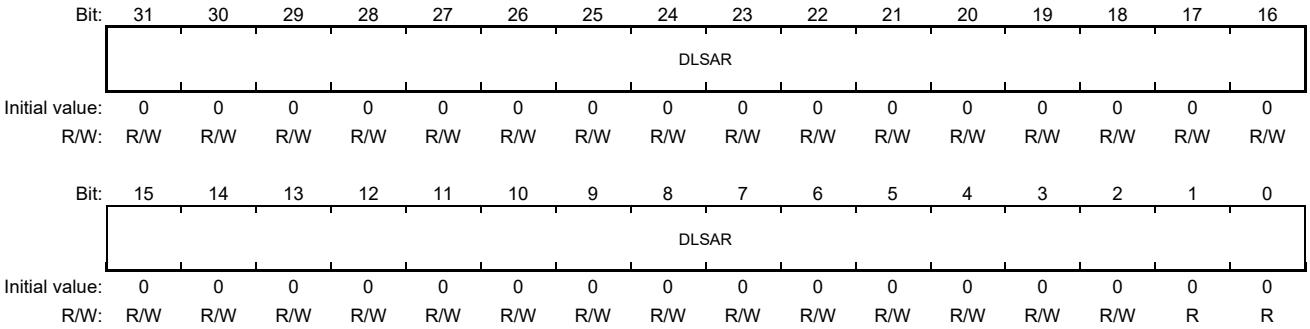
U32.12.1.15SBO CouNT Register0 (SBOCNTR0)



Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
28 to 2 1,0	SBOCNTR0	All 0	R	It expresses "SBO0 Output Number" (4byte unit). These bits are cleared by reset, Processing Start, and writing 1 to the SBOCNTCLR bit in SBOCR0. When SBOBAR0 is written, this register must be cleared. The values of the lowest 2 bits are fixed to 0.

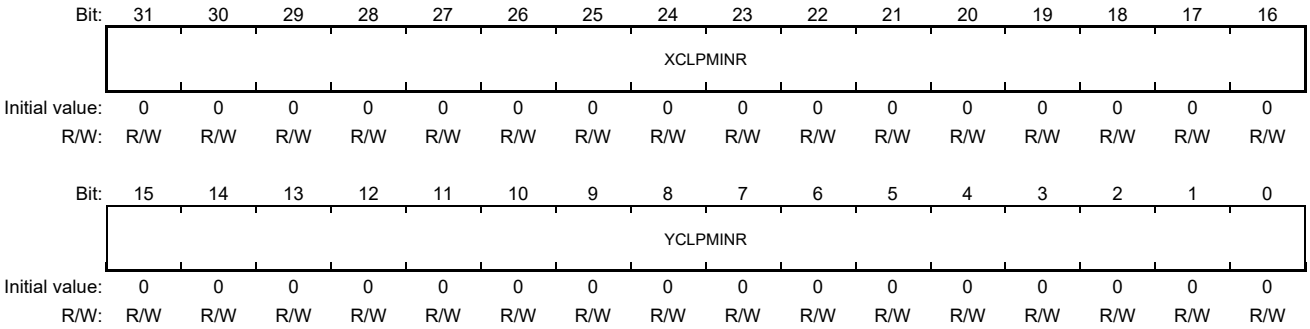
U32.12.1.16Descriptor List Start Address Register (DLSAR)

The “Descriptor List” is an alias of “Command List”.



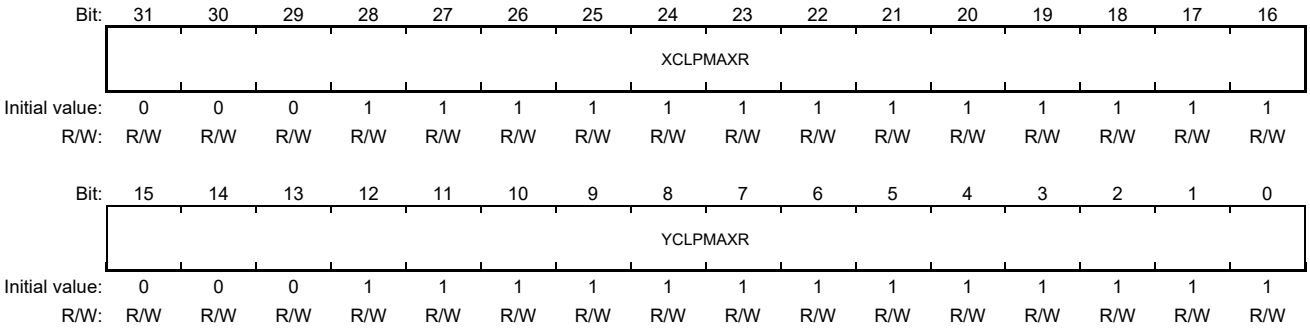
Bit	Bit Name	Initial Value	R/W	Description
31 to 2	DLSAR	All 0	R/W	Descriptor List start address
1,0			R	This register specifies the start address of CL execution. The start address should be specified as 4-byte alignment. The values of the lowest 2 bits are fixed to 0.

U32.12.1.17CLiPping MINimum Register (CLPMINR)



Bit	Bit Name	Initial Value	R/W	Description
31 to 16	XCLPMINR	H'0000	R/W	X's clipping minimum area (-32768 - 32767)
15 to 0	YCLPMINR	H'0000	R/W	Y's clipping minimum area (-32768 - 32767)

U32.12.1.18CLiPping MAXimum Register (CLPMAXR)



Bit	Bit Name	Initial Value	R/W	Description
31 to 16	XCLPMAXR	H'1FFF	R/W	X's clipping maximum area (-32768 - 32767)
15 to 0	YCLPMAXR	H'1FFF	R/W	Y's clipping maximum area (-32768 - 32767)

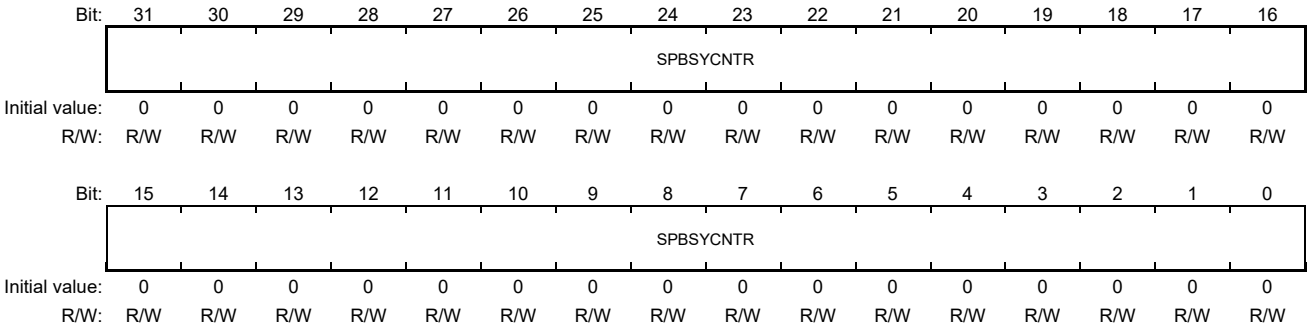
U32.12.1.19Shader Performance Control Register (SPCR)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	BSYCNTENB
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
0	BSYCNTENB	0	R/W	BuSY CouNTer ENaBle Counts cycle numbers of CVengine cluster is busy at cluster clock frequency. Value must be set while CVengine cluster is not working. 0: not counting busy cycles of CVengine cluster. 1: count busy cycles of CVengine cluster.

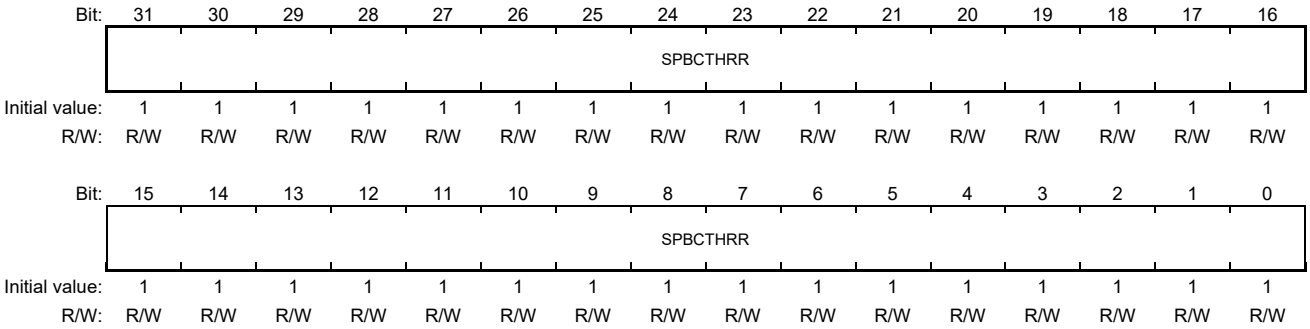
U32.12.1.20Shader Performance BuSY CouNTer Register (SPBSYCNTR)



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	SPBSYCNTR	All 0	R/W	While SPCR.BSYCNTENB is 1, this register counts cycles of CVengine clusters busy. CVengine cluster is busy while the PS bit in the CR register is 1. When accessing from CPU, the value of this register must be written or read while CVengine cluster is not in processing state. Write 0 to this register to clear the counter. Hardware does not take care of any overflow handlings, so software must take care of it.

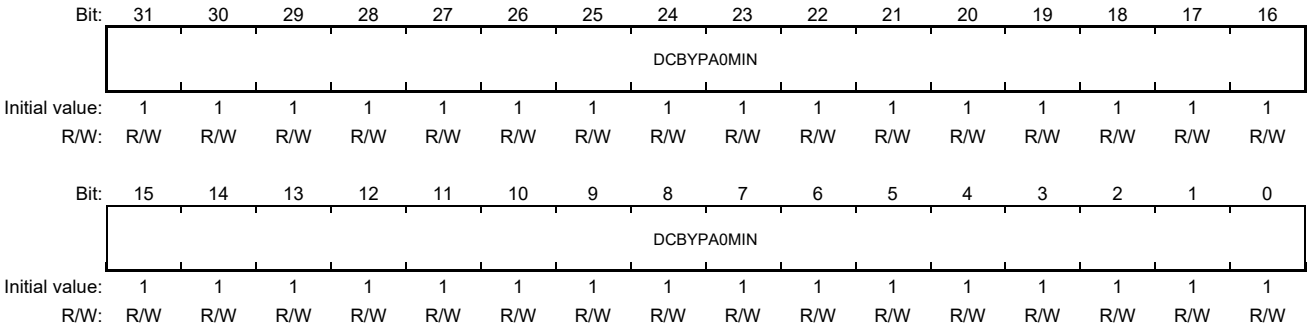
U32.12.1.21 Shader Performance Busy Counter THReshold Register (SPBCTHRR)

This register is used for the Guard Timer. Refer to Section U32.8.8 for detail.



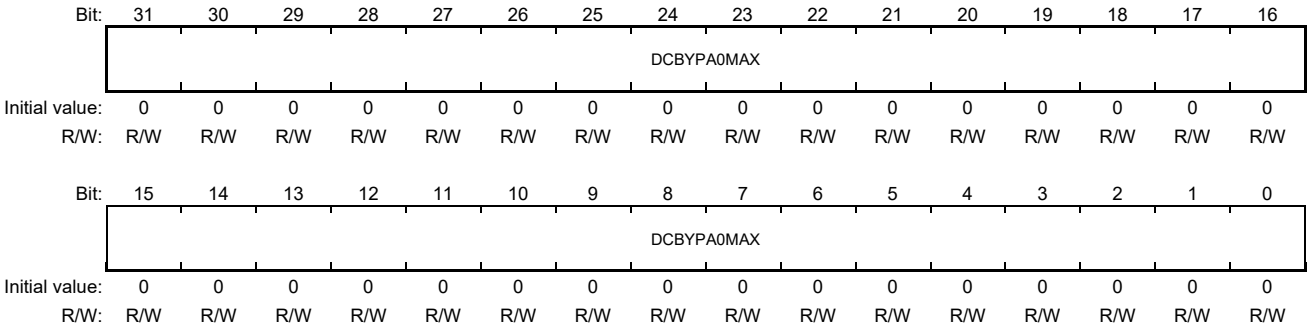
Bit	Bit Name	Initial Value	R/W	Description
31 to 0	SPBCTHRR	All 1	R/W	Shader Performance Busy Counter Threshold value. This register is compared with SPBSYCNTR. When accessing from CPU, the value of this register must be written or read while CVengine cluster is not in processing state.

U32.12.1.22Data Cache BYPass Area 0 MIN (DCBYPA0MIN)



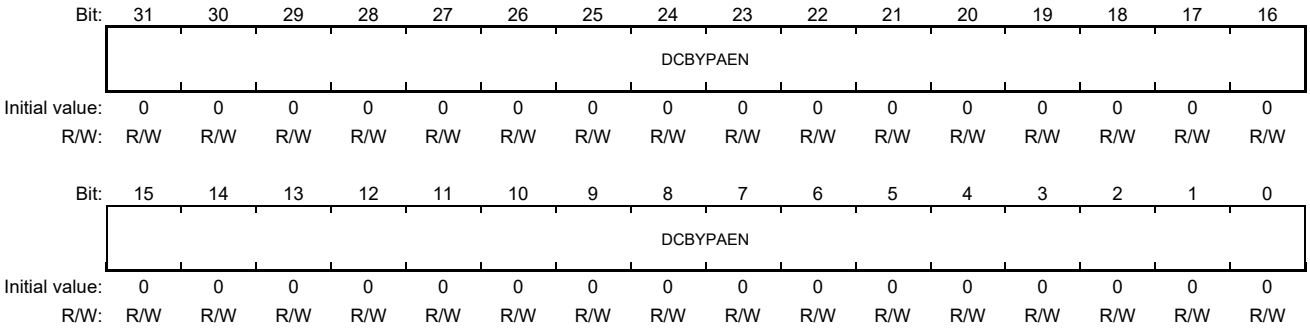
Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DCBYPA0MIN	All 1	R/W	This register holds memory address of the lower border of the D$ bypass memory area.

U32.12.1.23Data Cache BYPass Area 0 MAX (DCBYPA0MAX)



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DCBYPA0MAX	All 0	R/W	This register holds memory address of the higher border of the D$ bypass memory area.

U32.12.1.24Data Cache BYPass Area Enable (DCBYPAEN)



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DCBYPAEN	All 0	R/W	Specify the thread to enable D$ bypassing. Refer to section U32.8.9 . bit31: Core3 Thread7, bit30: Core3 Thread6, bit29: Core3 Thread5, bit28: Core3 Thread4, bit27: Core3 Thread3, bit26: Core3 Thread2 bit25: Core3 Thread1, bit24: Core3 Thread0, bit23: Core2 Thread7, bit22: Core2 Thread6, bit21: Core2 Thread5, bit20: Core2 Thread4, bit19: Core2 Thread3, bit18: Core2 Thread2 bit17: Core2 Thread1, bit16: Core2 Thread0, bit15: Core1 Thread7, bit14: Core1 Thread6, bit13: Core1 Thread5, bit12: Core1 Thread4, bit11: Core1 Thread3, bit10: Core1 Thread2 bit9: Core1 Thread1, bit8: Core1 Thread0, bit7: Core0 Thread7, bit6: Core0 Thread6, bit5: Core0 Thread5, bit4: Core0 Thread4, bit3: Core0 Thread3, bit2: Core0 Thread2 bit1: Core0 Thread1, bit0: Core0 Thread0,

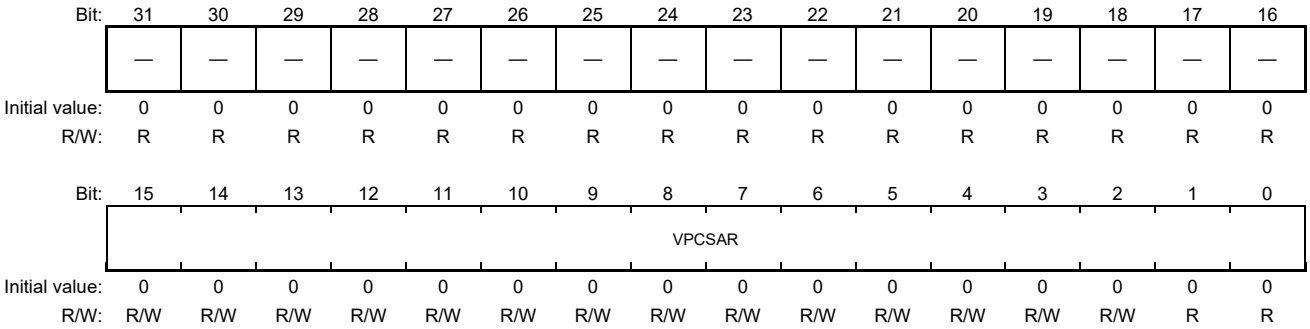
U32.12.1.25Data Cache BYPass Area ConTroL (DCBYPACTL)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DCBYPACTL
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

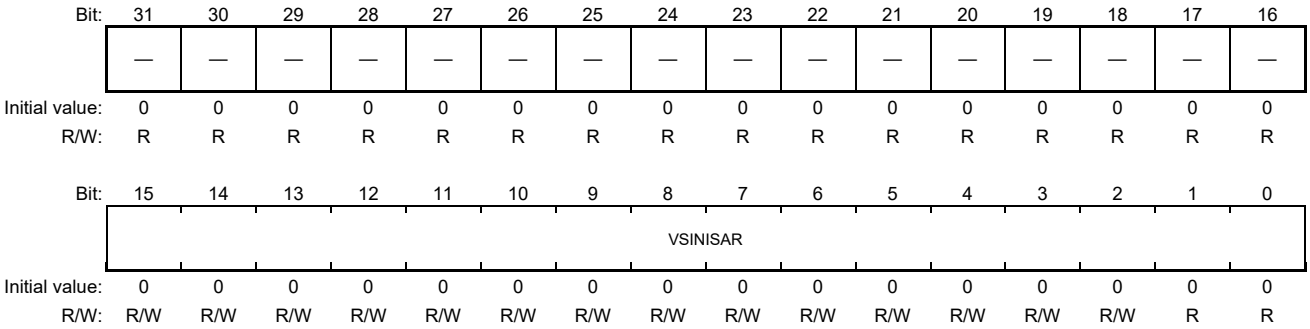
Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
0	DCBYPACTL	0	R/W	1: Enable, 0: Disable Enable Core# and Thread# replacement to the upper 16 bits of writing data for all threads which have the D$ bypassing enabled by respective bits of DCBYPAEN. Refer to section U32.8.9 .

U32.12.1.26Vs PC Start Address Register (VPCSAR)



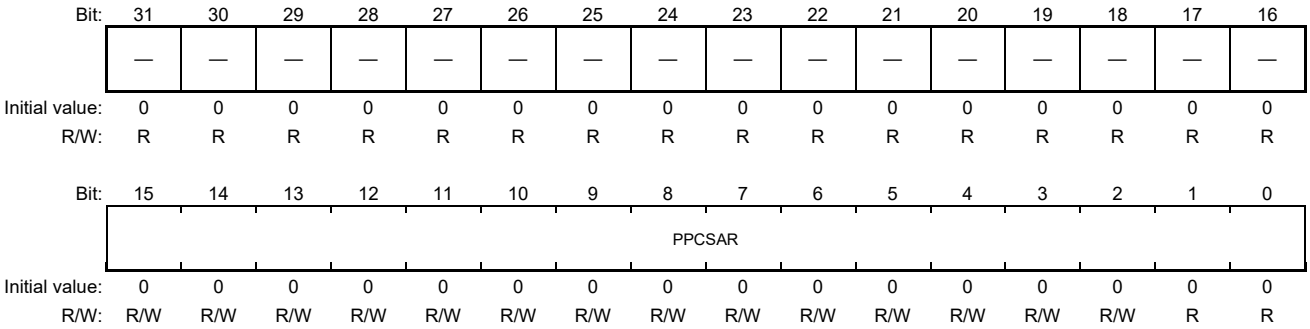
Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
15 to 2	VPCSAR	H'0 0000	R/W	Start address for master thread.
1,0			R	When RECT, POINT or POINTS is executed, thread (master) executes from the address of VPCSAR+VIBAR (VIBAR is the beginning of the instruction area and VPCSAR is the offset in the area). The area of the instructions must be less than 64KB. The values of the lowest 2 bits are fixed to 0.

U32.12.1.27Vs SINI Start Address Register (VSINISAR)



Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
15 to 2	VSINISAR	H'0 0000	R/W	SINI start address for master thread.
1,0			R	When SINI is executed, thread (master) executes from the address of VSINISAR+VIBAR (VIBAR is the beginning of the instruction area and VSINISAR is the offset in the area). The area of the instructions must be less than 64KB. The values of the lowest 2 bits are fixed to 0.

U32.12.1.28Ps PC Start Address Register (PPCSAR)



Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
15 to 2	PPCSAR	H'0 0000	R/W	Start address for slave thread.
1,0			R	When RECT, POINT or POINTS are executed, thread (slave) executes from the address of PPCSAR+PIBAR (PIBAR is the beginning of the instruction area and PPCSAR is the offset in the area). The area of the instructions must be less than 64KB. The values of the lowest 2 bits are fixed to 0.

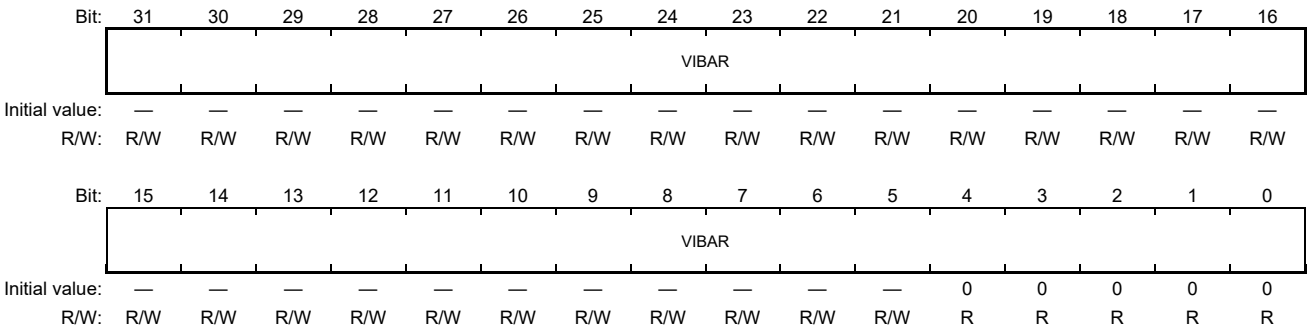
U32.12.1.29Ps SINI Start Address Register (PSINISAR)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PSINISAR															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R

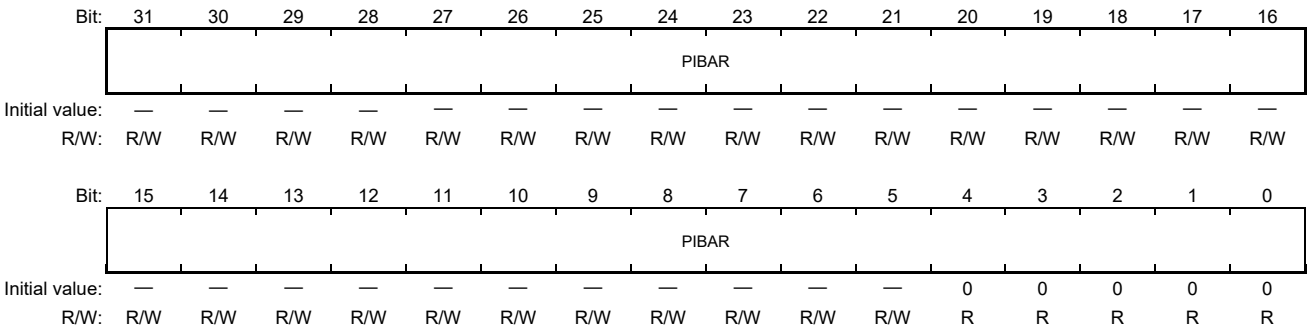
Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
15 to 2	PSINISAR	H'0 0000	R/W	SINI start address for slave thread.
1,0			R	When SINI is executed, thread (slave) executes from the address of PSINISAR+PIBAR (PIBAR is the beginning of the instruction area and PSINISAR is the offset in the area). The area of the instructions must be less than 64KB. The values of the lowest 2 bits are fixed to 0.

U32.12.1.30Vs I$ Base Address Register (VIBAR)



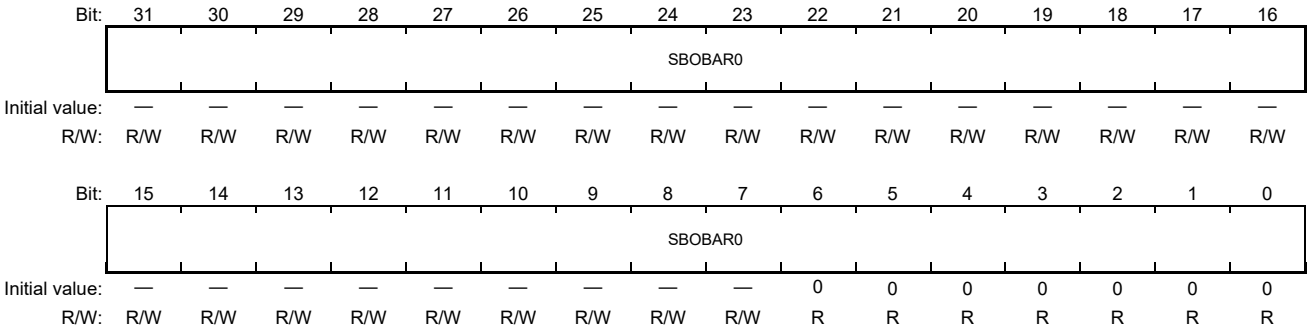
Bit	Bit Name	Initial Value	R/W	Description
31 to 5	VIBAR	Undefined	R/W	These bits set the base address of I$ in the thread (master)
4 to 0		All 0	R	The address is obtained by multiplying the setting by 64. Note that bit 5 must be set to 0. Operation cannot be guaranteed if a value other than 0 is written in bit 5. The values of the lowest 5 bits are fixed to 0.

U32.12.1.31Ps I$ Base Address Register (PIBAR)



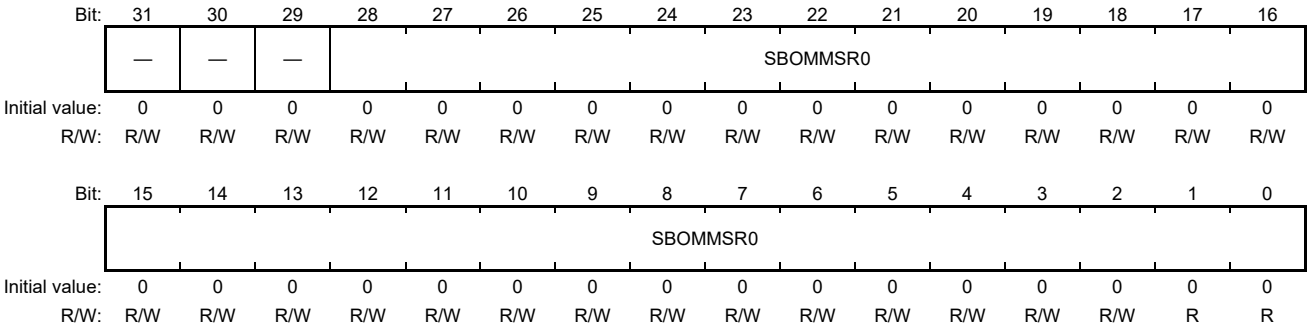
Bit	Bit Name	Initial Value	R/W	Description
31 to 5	PIBAR	Undefined	R/W	These bits set the base address of I$ in thread (slave).
4 to 0		All 0	R	The address is obtained by multiplying the setting by 64. Note that bit 5 must be set to 0. Operation cannot be guaranteed if a value other than 0 is written in bit 5. The values of the lowest 5 bits are fixed to 0. The values must always be set same as VIBAR.

U32.12.1.32SBO Base Address Register 0 (SBOBAR0)



Bit	Bit Name	Initial Value	R/W	Description
31 to 7	SBOBAR0	Undefined	R/W	When this register is written, SBOCNTR0 must be cleared.
6 to 0		All 0	R	Note: Before rewriting this register, SBO0 must be flushed by SYNCM command. The values of the lowest 7 bits are fixed to 0.

U32.12.1.33SBO Max Memory Size Register 0 (SBOMMSR0)



Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	All 0	R/W	Reserved These bits are always read as 0. These bits must be set to 0 when these are written. Operation cannot be guaranteed if a value other than 0 is written here.
28 to 2	SBOMMSR0	All 0	R/W	This register must be set in 4-byte unit.
1,0			R	If it is over this limited value, the SBO0 is issued the transaction with byte-enable 0 and output the interrupt signal by setting SR1. SBO0ME bit. Note: Before rewriting this register, SBO0 must be flushed by SYNCM command. Unless the interrupt status bit is cleared, no further interrupt is issued upon exceeding the limit. The values of the lowest 2 bits are fixed to 0.

U32.12.1.34SBO Control Register 0 (SBOCR0)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SBOCNTCLR	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	SIGNEDEXT	PCKMODE	XYPCK
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	SBOCNTCLR	0	R/W	By writing "1" to this bit, SBOCNTR0 is cleared. The read value is always 0.
30 to 3	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
2	SIGNEDEXT	0	R/W	By writing "1" to this bit, the SBO0 expands X and Y to 32-bit range as signed integer. By writing "0" to this bit, the SBO0 expands X and Y to 32-bit range as unsigned integer.
1	PCKMODE	0	R/W	When XYPCK is “1”, this bit decides the way of concatenation about the coordinates. 0: {x[15:0], y[15:0]} 1: {y[15:0], x[15:0]} When XYPCK is “0”, this bit has no effect.
0	XYPCK	0	R/W	By writing "1" to this bit, the SBO0 handles X(16-bit) and Y(16-bit) as a pair of data.

U32.12.1.35DMac Control Register 0 (DMCR0)

This register is for GWM-DMAC. The host processor cannot access this register during processing state, only Command list can access it.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

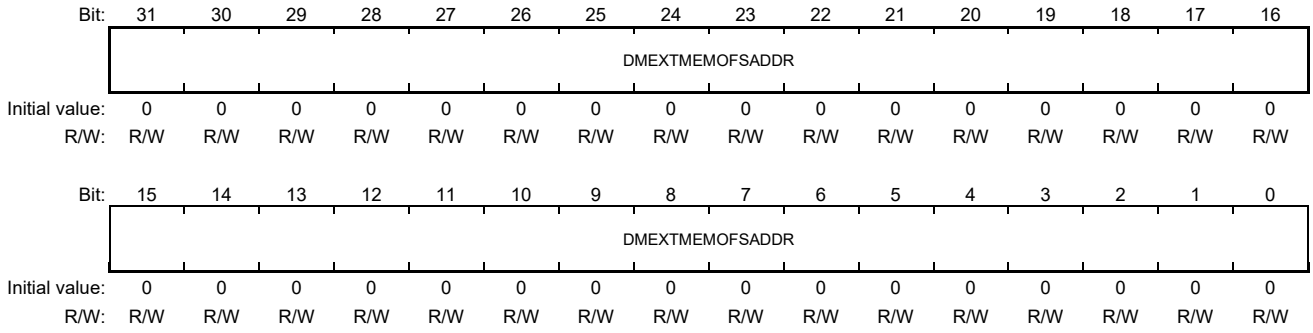
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	SELOFSADR	—	—	DIR	—	SELPLN			SELWAIT	—	DMACST	DMACEX
Initial value:	0	0	1	1	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R	R	R/W	R	R/W	R/W	R/W	R/W	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 14	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
13,12	—	All 1	R/W	Reserved These bits are always read as 1. These bits must be set to 1 when written.
11	SELOFSADR	0	R/W	0: DMEXTMEMOFSADDR is used as X,Y coordinate 1: DMEXTMEMOFSADDR is used as the offset address in 32-bit format.
10,9	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
8	DIR	0	R/W	Specify the direction of DMA transfer. 0: GWM to the external memory 1: The external memory to GWM
7	—	0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
6 to 4	SELPLN	000	R/W	Specify the plane number (0-7) which determines the address and the stride to calculate a base address of the external memory. Addition of IMGBARn, where n is the plane number specified in this field, and DMEXTMEMOFSADDR makes the start address of the DMA transfer of the external memory.
3	SELWAIT	0	R/W	Specify the mode of SYNCS instruction of command list. 0: SYNCS exits when the DMAC transfer completes. 1: SYNCS exits when the DMAC startup completes. DMAC registers can be set for a next DMA transfer after the DMAC startup completes.

Bit	Bit Name	Initial Value	R/W	Description
2	—	0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
1	DMACST	0	R	This bit becomes "1" when DMAC is started and returns to "0" when DMAC transfer is finished.
0	DMACEX	0	R/W	By writing "1" to this bit, DMAC is started. This bit becomes "0" when DMAC has been started. Note: It is prohibited to write DMAC registers before this bit becomes "0".

U32.12.1.36DMac EXTernal MEMory OFfSet ADDress Register (DMEXTMEMOFSADDR)

This register is for GWM-DMAC. The host processor cannot access this register during processing state, only Command list can access it.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DMEXTMEMOFSADDR	All 0	R/W	SELOFSADR=0: bit31-16: X coordinate (signed) in bytes, bit15-0: Y coordinate (signed). SELOFSADR=1: bit31-0: Offset address. Addition of IMGBARn, where n is the plane number specified by DMCR0.SELPLN, and DMEXTMEMOFSADDR makes the start address of the DMA transfer of the external memory in bytes.

U32.12.1.37DMac GWM Base ADDress Register (DMGWMBADDR)

This register is for GWM-DMAC. The host processor cannot access this register during processing state, only Command list can access it.

Bit 31 to 16 of GWM address will be filled automatically with 0 by HW.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

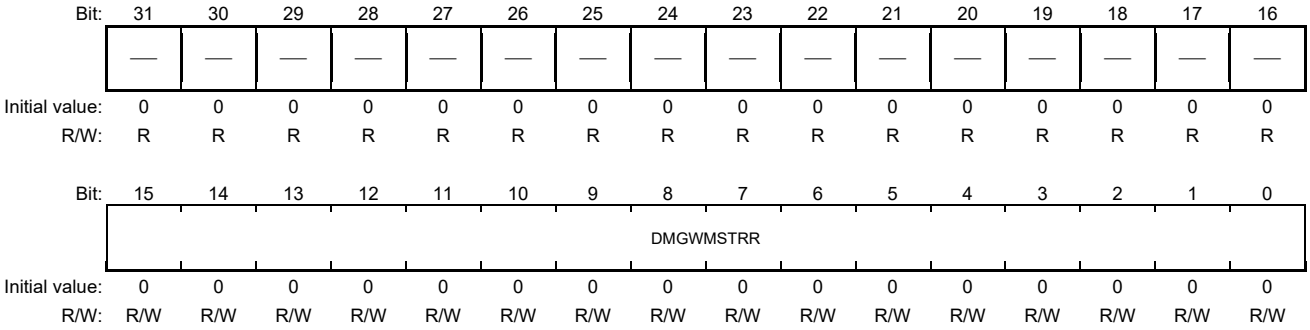
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DMGWMBADDR															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
15 to 0	DMGWMBADDR	All 0	R/W	Specify the start address for DMA transfer within GWM.

U32.12.1.38DMac GWM STRide Register (DMGWMSTRR)

This register is for GWM-DMAC. The host processor cannot access this register during processing state, only Command list can access it.

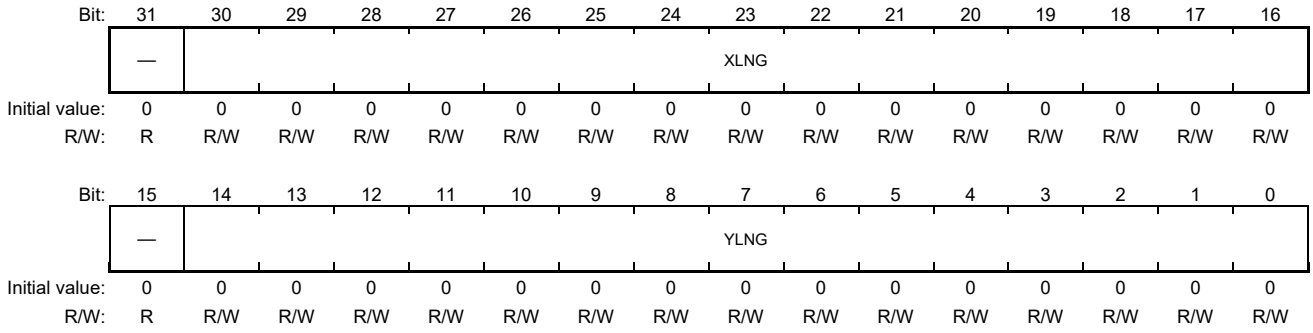
Bit 31 to 16 of GWM stride will be sign-extended automatically by HW.



Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
15 to 0	DMGWMSTRR	All 0	R/W	These bits set the signed stride of GWM by byte unit.

U32.12.1.39DMac LeNGth Register (DMLNGR)

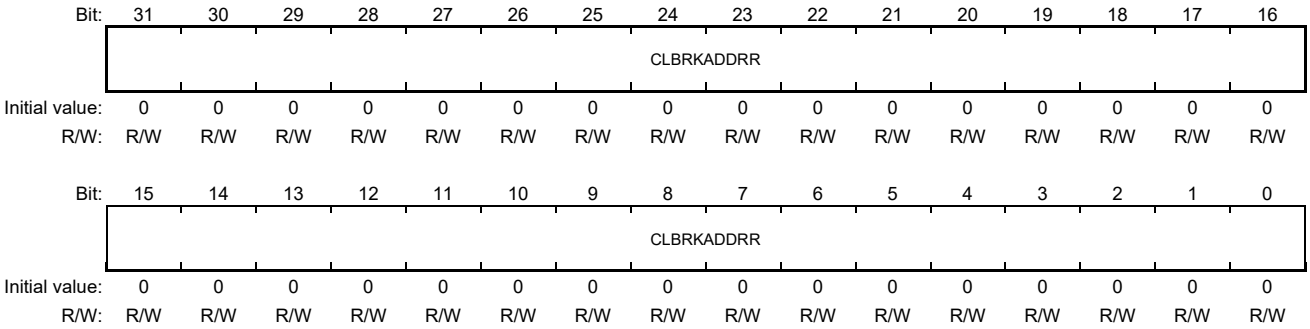
This register is for GWM-DMAC. The host processor cannot access this register during processing state, only Command list can access it.



Bit	Bit Name	Initial Value	R/W	Description
31	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written.
30 to 16	XLNG	H'0000	R/W	A width in the range of 1 to 16384 in byte unit. Value must satisfy the plane format alignment.
15	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written.
14 to 0	YLNG	H'0000	R/W	A pixel height in the range of 1 to 16384.

U32.12.1.40CL BReaK ADDRess Register (CLBRKADDRR)

This register is for specification of the CL break address.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CLBRKADDRR	H'00000000	R/W	CL break address specification. Specify a 32bit command list address (4byte aligned). Data address is prohibited.

U32.12.1.41CL CoNDitional GoSuB Register (CLCNDGSBR)

This register specifies the condition in case of a conditional GOSUB instruction.

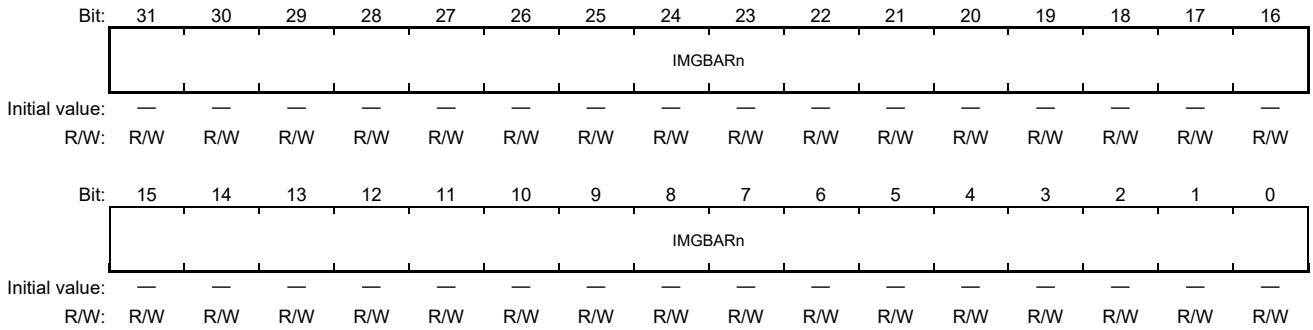
Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CLCND GSBR
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written.
0	CLCNDGSBR	H'0	R/W	Condition for conditional GOSUB instruction: . 1: GOSUB is executed 0: GOSUB is not executed, NOP is instead executed (Bit 22 of the GOSUB command should be 1 for NOP operation)

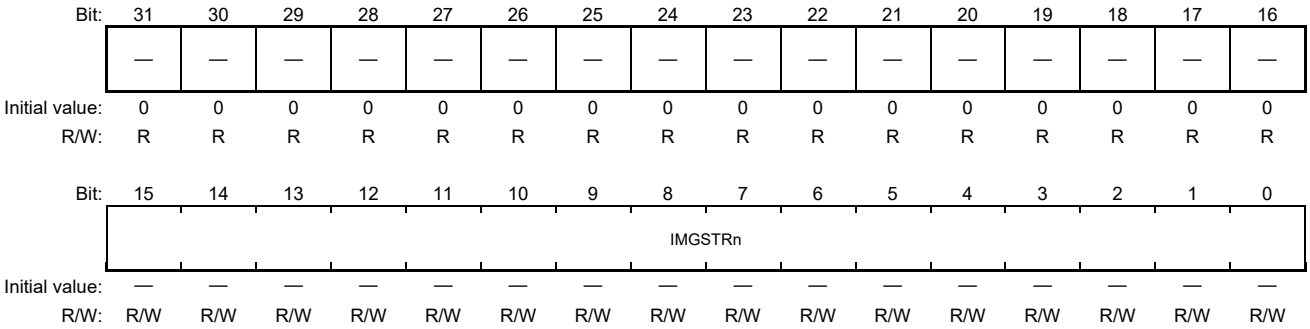
U32.12.1.42IMaGe Base Address Register n (IMGBARn) (n = 0 to 11)

The number n (n = 0 to 11) of this register shall be set to the Control Registers CR8 and CR9 to select which plane to be read or written by a thread. Refer to section U32.6.2 .



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	IMGBARn	Undefined	R/W	Alignment must be done depending on the Pixel Format (IMGC0Rn.PFORMAT). When Pixel Format is unsigned short or short, the lowest 1 bit of this register must be set to 0. When Pixel Format is int or float, the lowest 2 bits of this register must be set to 0.

U32.12.1.43IMaGe STRide Register n (IMGSTRn) (n = 0 to 11)



Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
15 to 0	IMGSTRn	Undefined	R/W	IMGSTRn is a signed 16bit value. When Pixel Format is unsigned char or char, this register must be aligned to 1-byte borders. When Pixel Format is unsigned short or short, this register must be aligned to 2-byte borders. When Pixel Format is int or float, this register must be aligned to 4-byte borders. This register must be specified in 1-byte unit in any case.

U32.12.1.44IMaGe Control0 Register n (IMGC0Rn) (n = 0 to 11)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	CLPMODE			—	—	—	—	—	PFORMAT2		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R/W	R	R	R	R	R	R/W	R/W	R/W

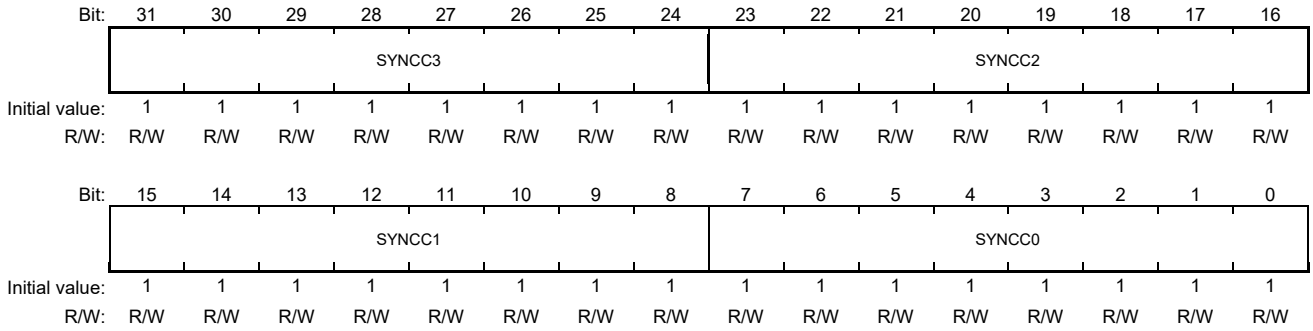
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	RNDMODE_F2I			—	—	—	SATENBO	—	PFORMAT		
Initial value:	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R/W	R	R	R	R/W	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 27	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
26 to 24	CLPMODE	000	R/W	Specify the Clipping Mode (Border Mode of OpenCV to set the extra padding to the image). Refer to section U32.8.7 . 3'b000: NORMAL (no border) 3'b001: REPLICATE 3'b010: REFLECT 3'b011: REFLECT101 3'b100: WRAP 3'b101: CONSTANT 3'b110: It is prohibited to write 3'b111: It is prohibited to write Note: The number of times of the repetition is limited to one for each top/bottom/left/right of image size in the clipping (except for CONSTANT).
23 to 19	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
18 to 16	PFORMAT2	000	R/W	Pixel format for thread (slave). 0: unsigned char 1: char 2: unsigned short 3: short 4: Reserved 5: int 6: Reserved 7: float

Bit	Bit Name	Initial Value	R/W	Description
15 to 11	—	0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
10 to 8	RNDMODE_F2I	001	R/W	Float to Integer Format Conversion Round Mode 0: IEEE 754 round to nearest (Round half to even) 1: IEEE 754 round to zero 2: IEEE 754 round to positive infinity (Not supported) 3: IEEE 754 round to negative infinity (Not supported) 4: round to nearest up (Not supported) 5: round away from zero (Not supported) 6: Reserved 7: Reserved
7 to 5	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
4	SATENBO	0	R/W	Saturation Enable (Output) 0: Disable saturation function. 1: Enable saturation function. If saturation occurs when the thread write some data to external memory, the output data will be treated as maximum value. This function has no effect when PFORMAT is set to7 (float).
3	—	0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
2 to 0	PFORMAT	000	R/W	Pixel Format for thread (master). 0: unsigned char 1: char 2: unsigned short 3: short 4: Reserved 5: int 6: Reserved 7: float

U32.12.1.45SYNChronization Control Register 0 (SYNCCR0)

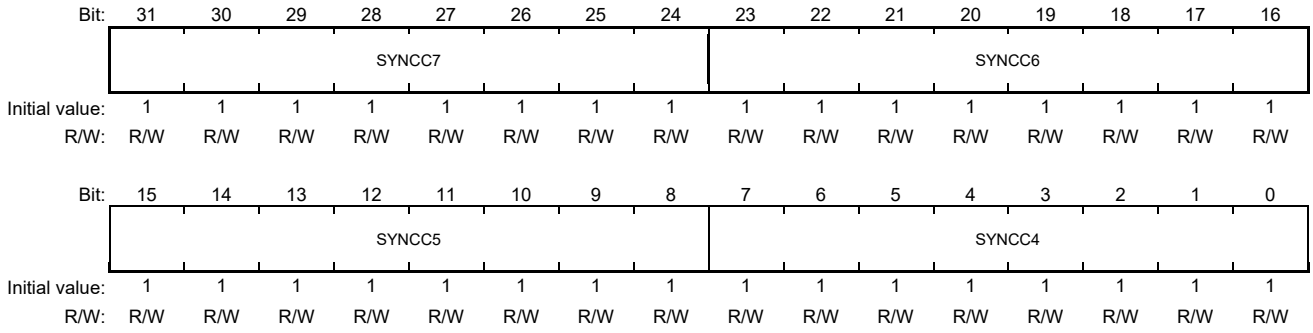
It is recommended to write this register while all the assigned cores are not running. Refer to Section U32.11.1 , Section U32.13.14 and Section U32.13.15 for details.



Bit	Bit Name	Initial Value	R/W	Description
31 to 24	SYNCC3	All 1	R/W	Specify the core corresponding to bit 3 of CORE Number field of WUP and SLP commands. [31:28] : Core Type [27:24] : Core Number
23 to 16	SYNCC2	All 1	R/W	Specify the core corresponding to bit 2 of CORE Number field of WUP and SLP commands. [23:20] : Core Type [19:16] : Core Number
15 to 8	SYNCC1	All 1	R/W	Specify the core corresponding to bit 1 of CORE Number field of WUP and SLP commands. [15:12] : Core Type [11:8] : Core Number
7 to 0	SYNCC0	All 1	R/W	Specify the core corresponding to bit 0 of CORE Number field of WUP and SLP commands. [7:4] : Core Type [3:0] : Core Number

U32.12.1.46SYNChronization Control Register 1 (SYNCCR1)

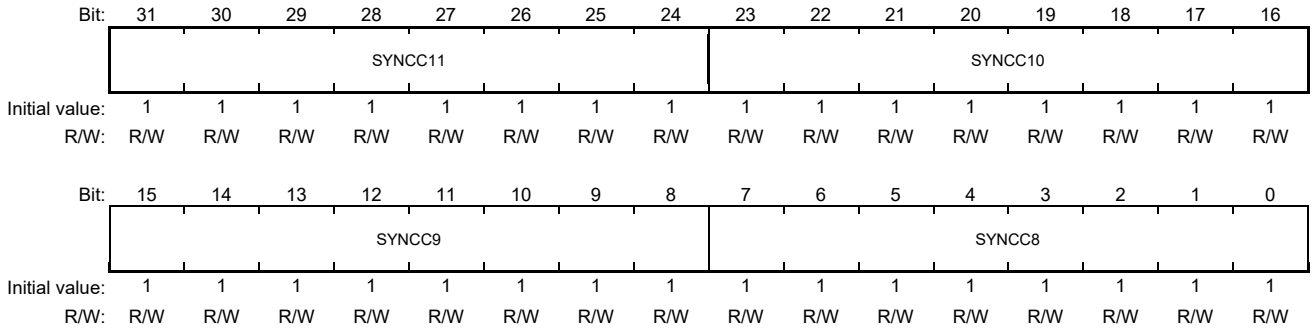
It is recommended to write this register while all the assigned cores are not running. Refer to Section U32.11.1 , Section U32.13.14 and Section U32.13.15 for details.



Bit	Bit Name	Initial Value	R/W	Description
31 to 24	SYNCC7	All 1	R/W	Specify the core corresponding to bit 7 of CORE Number field of WUP and SLP commands. [31:28] : Core Type [27:24] : Core Number
23 to 16	SYNCC6	All 1	R/W	Specify the core corresponding to bit 6 of CORE Number field of WUP and SLP commands. [23:20] : Core Type [19:16] : Core Number
15 to 8	SYNCC5	All 1	R/W	Specify the core corresponding to bit 5 of CORE Number field of WUP and SLP commands. [15:12] : Core Type [11:8] : Core Number
7 to 0	SYNCC4	All 1	R/W	Specify the core corresponding to bit 4 of CORE Number field of WUP and SLP commands. [7:4] : Core Type [3:0] : Core Number

U32.12.1.47SYNChronization Control Register 2 (SYNCCR2)

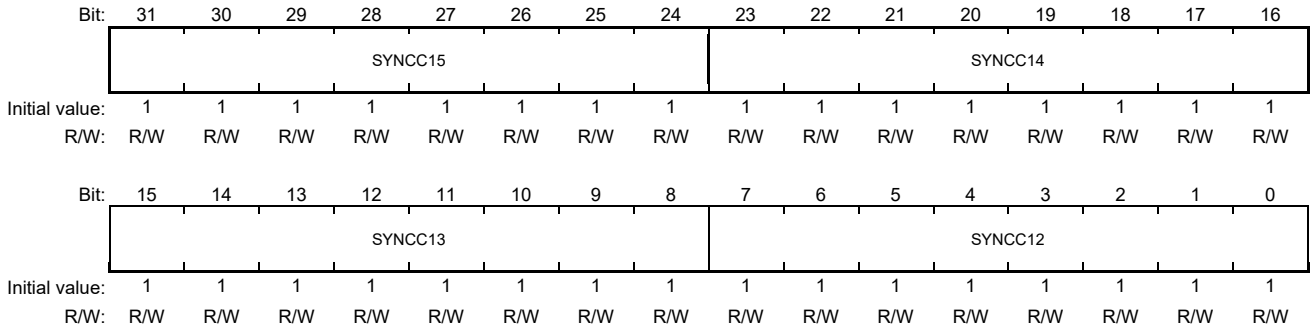
It is recommended to write this register while all the assigned cores are not running. Refer to Section U32.11.1 , Section U32.13.14 and Section U32.13.15 for details.



Bit	Bit Name	Initial Value	R/W	Description
31 to 24	SYNCC11	All 1	R/W	Specify the core corresponding to bit 11 of CORE Number field of WUP and SLP commands. [31:28] : Core Type [27:24] : Core Number
23 to 16	SYNCC10	All 1	R/W	Specify the core corresponding to bit 10 of CORE Number field of WUP and SLP commands. [23:20] : Core Type [19:16] : Core Number
15 to 8	SYNCC9	All 1	R/W	Specify the core corresponding to bit 9 of CORE Number field of WUP and SLP commands. [15:12] : Core Type [11:8] : Core Number
7 to 0	SYNCC8	All 1	R/W	Specify the core corresponding to bit 8 of CORE Number field of WUP and SLP commands. [7:4] : Core Type [3:0] : Core Number

U32.12.1.48SYNChronization Control Register 3 (SYNCCR3)

It is recommended to write this register while all the assigned cores are not running. Refer to Section U32.11.1 , Section U32.13.14 and Section U32.13.15 for details.



Bit	Bit Name	Initial Value	R/W	Description
31 to 24	SYNCC15	All 1	R/W	Specify the core corresponding to bit 15 of CORE Number field of WUP and SLP commands. [31:28] : Core Type [27:24] : Core Number
23 to 16	SYNCC14	All 1	R/W	Specify the core corresponding to bit 14 of CORE Number field of WUP and SLP commands. [23:20] : Core Type [19:16] : Core Number
15 to 8	SYNCC13	All 1	R/W	Specify the core corresponding to bit 13 of CORE Number field of WUP and SLP commands. [15:12] : Core Type [11:8] : Core Number
7 to 0	SYNCC12	All 1	R/W	Specify the core corresponding to bit 12 of CORE Number field of WUP and SLP commands. [7:4] : Core Type [3:0] : Core Number

U32.12.1.49TG Shader Enable Register 1 (TGSEN1)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	SLVEN							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	MSTEN							
Initial value:	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
23 to 16	SLVEN	H'00	R/W	Slave Thread Enable. Specify Slave Thread threads. When the SINI command is used, execution of Slave Thread starts from the PC set in the PSINISAR register. When Slave Thread has been started by Master Thread, execution starts from the PC set in the PPCSAR register. [Bit23] 0: Does not use Thread 7 as Slave Thread. 1: Uses Thread 7 as Slave Thread. [Bit22] 0: Does not use Thread 6 as Slave Thread. 1: Uses Thread 6 as Slave Thread. [Bit21] 0: Does not use Thread 5 as Slave Thread. 1: Uses Thread 5 as Slave Thread. [Bit20] 0: Does not use Thread 4 as Slave Thread. 1: Uses Thread 4 as Slave Thread. [Bit19] 0: Does not use Thread 3 as Slave Thread. 1: Uses Thread 3 as Slave Thread. [Bit18] 0: Does not use Thread 2 as Slave Thread. 1: Uses Thread 2 as Slave Thread. [Bit17] 0: Does not use Thread 1 as Slave Thread. 1: Uses Thread 1 as Slave Thread. [Bit16] 0: Does not use Thread 0 as Slave Thread. 1: Uses Thread 0 as Slave Thread. Note: If both MSTEN and SLVEN are set to 0, the thread is disabled. It is prohibited to set both MSTEN and SLVEN to 1.
15 to 8	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	MSTEN	All 1	R/W	Master Thread Enable. Specify Master Thread. When the SINI command is used, execution of Master Thread starts from the PC set in the VSINISAR register. When Master Thread has been started by Vertex Issue, execution starts from the PC set in the VPCSAR register. [Bit7] 0: Does not use Thread 7 as Master Thread. 1: Uses Thread 7 as Master Thread. [Bit6] 0: Does not use Thread 6 as Master Thread. 1: Uses Thread 6 as Master Thread. [Bit5] 0: Does not use Thread 5 as Master Thread. 1: Uses Thread 5 as Master Thread. [Bit4] 0: Does not use Thread 4 as Master Thread. 1: Uses Thread 4 as Master Thread. [Bit3] 0: Does not use Thread 3 as Master Thread. 1: Uses Thread 3 as Master Thread. [Bit2] 0: Does not use Thread 2 as Master Thread. 1: Uses Thread 2 as Master Thread. [Bit1] 0: Does not use Thread 1 as Master Thread. 1: Uses Thread 1 as Master Thread. [Bit0] 0: Does not use Thread 0 as Master Thread. 1: Uses Thread 0 as Master Thread. Note: If both MSTEN and SLVEN are set to 0, the thread is disabled. It is prohibited to set both MSTEN and SLVEN to 1.

U32.12.1.50 Unified Shader PerFormance Counter ConTrol Register (USPFCCTLR)

This register is for the performance counter which allows user to aquire detailed performance information from each thread in each core.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PFCENB	PFCTOVF	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	RW	RW	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	SELUSPFC			PFCMOD							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

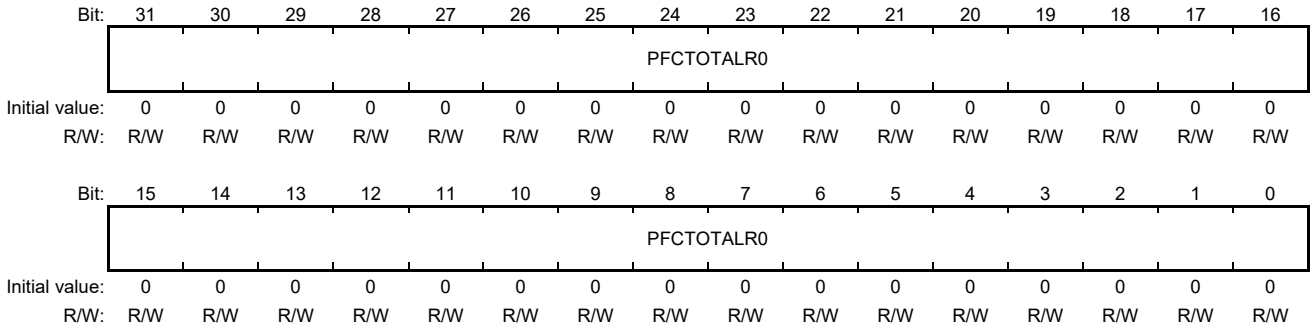
Bit	Bit Name	Initial Value	R/W	Description
31	PFCENB	0	R/W	PerFormance Counter ENaBle 0: Performance counter is disabled. 1: Performance counter is enabled. Even if this bit is 1, performance counter is counted only during thread executing. But performance counter is not counted during SINI executing.
30	PFCTOVF	0	R/W	PerFormance Counter Total register OVerFlow 0: Performance Counter Total register did not overflow. 1: Performance Counter Total register did overflow.
29 to 11	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
10 to 8	SELUSPFC	All 0	R/W	SELecting Unified Shader to use PerFormance Counter. 0: Select thread 0 1: Select thread 1 2: Select thread 2 3: Select thread 3 4: Select thread 4 5: Select thread 5 6: Select thread 6 7: Select thread 7 This field works with TGRSEL. Refer to U32.12.1.14 .

7 to 0	PFCMOD	All 0	R/W	PerFormance Counter MODe 0x00: Number of Thread Starts 0x01: Number of SINI command list instruction calls 0x02: Number of stall cycles due to Thread Starts 0x03: Number of execution cycles until TRAP 0x04: Number of instruction fetch cycles 0x05: Number of stalls during instruction fetches 0x06: Number of branches that were entered 0x07: Number of RCP0 (R14) accesses 0x08: Number of RCP1 (R15) accesses 0x09: Number of SQRT accesses 0x0a: Number of EXP accesses 0x0b: Number of LOG access cycles 0x0c: Number of stall cycles during RCP0 accesses 0x0d: Number of stall cycles during RCP1 accesses 0x0e: Number of stall cycles during SQRT accesses 0x0f: Number of stall cycles during EXP accesses 0x10: Number of stall cycles during LOG2 accesses 0x11: Number of ACTST calls 0x12: Number of stalls due to ACTST calls 0x13: Number of data dependency stall cycles 0x15: Number of LDW instruction execution cycles 0x16: Number of STW instruction execution cycles 0x17: Number of LWM/GWM access stall cycles 0x18: Number of data load cycles 0x19: Number of data store cycles 0x1a: Number of data load or store stall cycles 0x1f: Number of SBO (streaming buffer output) write cycles 0x20: Number of SBO (streaming buffer output) write stall cycles 0x28: Number of stall cycles caused by UDI 0x29: Number of execution cycles of FADD group 0x2a: Number of execution stall cycles of FADD group 0x2b: Number of execution cycles of FMUL group 0x2c: Number of execution stall cycles of FMUL group 0x2d: Number of execution cycles of MUL group 0x2e: Number of execution stall cycles of MUL group 0x2f: Number of execution cycles of ASM group 0x30: Number of execution stall cycles of ASM group 0x32: Number of execution cycles of CSCS group 0x33: Number of execution stall cycles of CSCS group 0x34: Number of execution cycles of CSUS group 0x35: Number of execution stall cycles of CSUS group 0x36: Number of execution cycles of L2F group 0x37: Number of execution stall cycles of L2F group 0x38: Number of execution cycles of MAC group 0x39: Number of execution stall cycles of MAC group 0x3a: Number of execution cycles of PACK group 0x3b: Number of execution stall cycles of PACK group 0x3c: Number of execution cycles of GASS group

Bit	Bit Name	Initial Value	R/W	Description
				0x3d: Number of execution stall cycles of GASS group
				0x3e: Number of execution cycles of GMAD group
				0x3f: Number of execution stall cycles of GMAD group
				0x40: Number of execution cycles of LLROT group
				0x41: Number of execution stall cycles of LLROT group
				0x42: Number of execution cycles of RCPSQRT group
				0x43: Number of execution cycles of SIN group
				0x44: Number of execution cycles of COS group
				0x45: Number of execution stall cycles of RCPSQRT group
				0x46: Number of execution stall cycles of SIN group
				0x47: Number of execution stall cycles of COS group
				0x48: Number of stall cycles caused by LWM DMAC busy
				0x49: Number of execution stall cycles of slave busy
				0x4a: Number of execution cycles of SIMDABS group
				0x4b: Number of execution stall cycles of SIMDABS group
				0x4c: Number of execution cycles of SIMDADDSUB group
				0x4d: Number of execution stall cycles of SIMDADDSUB group
				0x4e: Number of execution cycles of SIMDCMP group
				0x4f: Number of execution stall cycles of SIMDCMP group
				0x50: Number of execution cycles of SIMDIMUL group
				0x51: Number of execution stall cycles of SIMDIMUL group
				0x52: Number of execution cycles of SIMDMAXMIN group
				0x53: Number of execution stall cycles of SIMDMAXMIN group
				0x54: Number of execution cycles of SIMDSHFT group
				0x55: Number of execution stall cycles of SIMDSHFT group
				0x56: Number of execution cycles of FOD group
				0x57: Number of execution stall cycles of FOD group
				0x58: Number of D$ bypass load cycles
				0x59: Number of D$ bypass store cycles
				0x5a: Number of D$ bypass load or store stall cycles
				0x5b: Number of blocking semaphore load cycles
				0x5c: Number of blocking semaphore store cycles
				0x5d: Number of blocking semaphore load or store stall cycles

U32.12.1.51PerFormance Counter TOTAL Register0 (PFCTOTALR0)

This register works with the register USPFCCTLR. Refer to U32.12.1.50 .



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	PFCTOTALR0	All 0	R/W	PerFormance Counter TOTAL Register0 This register shows the total cycles counted in the mode set by PFCMOD. Refer to U32.12.1.50 .

U32.12.1.52Unified Shader ConTRoL Register 0 (USCTRL0)

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
16	PFTCHEN	1	R/W	Pre-FeTCH ENable. 0: Disables pre fetch function of thread instruction buffer. 1: Enables pre fetch function of thread instruction buffer.
15 to 0	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.

U32.12.1.53TGDMac Control Register 0 (TGDMCR0)

This register is for LWM-TGDMAC. The host processor cannot access this register, only threads can access it. Each thread has its own register to control LWM-TGDMAC.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

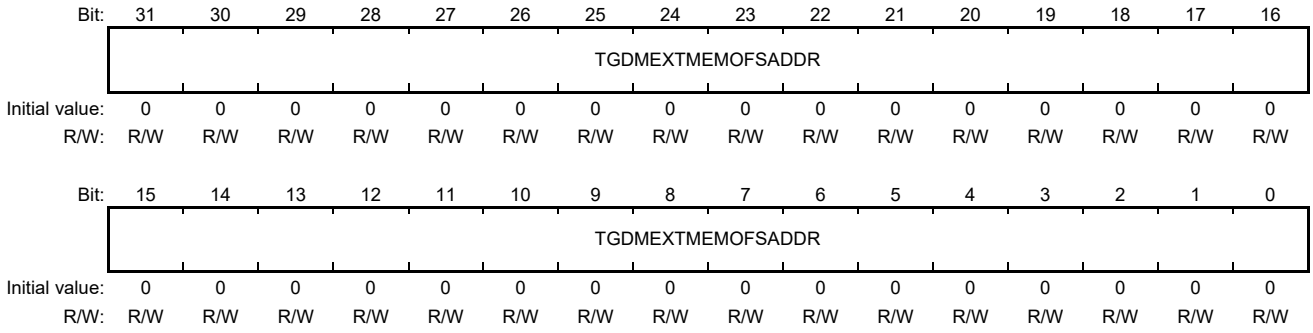
	—	—	EXTSIZE		SELOFSADR	—	—	DIR	—	SELPLN			SELWAIT	—	DMACST	DMACEX
Initial value:	0	0	1	1	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R	R	R/W	R	R/W	R/W	R/W	R/W	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 14	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
13,12	EXTSIZE	11	R/W	Specify the transaction size of external memory. For IMPC: 2'b00: 32 bytes 2'b01: 64 bytes 2'b11: 128 bytes For DDR access, these bits must be set to 2’b11.
11	SELOFSADR	0	R/W	0: TGDMEXTMEMOFSADDR is used as X,Y coordinate. 1: TGDMEXTMEMOFSADDR is used as offset address in 32-bit format.
10,9	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
8	DIR	0	R/W	Specify the direction of DMA transfer. 0: LWM to the external memory 1: The external memory to LWM
7	—	0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
6 to 4	SELPLN	000	R/W	Specify the plane number (0-7) which determines the address and the stride for calculating base address of the external memory. Addition of the base address of the plane number specified in this field and the external offset address makes the base address of the external memory.

Bit	Bit Name	Initial Value	R/W	Description
3	SELWAIT	0	R/W	Specify the mode of WAITDMAC instruction. 0: WAITDMAC exits when the DMAC transfer completes. 1: WAITDMAC exits when the DMAC startup completes. DMAC registers can be set for a next DMA transfer after the DMAC startup completes.
2	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
1	DMACST	0	R	This bit becomes "1" when DMAC is started and becomes "0" when DMAC transfer is finished.
0	DMACEX	0	R/W	By writing "1" to this bit, DMAC is started. This bit becomes "0" when DMAC has been started. Note: It is prohibited to write DMAC registers before this bit becomes "0".

U32.12.1.54TGDMac EXTernal MEMory OFfSet ADDress Register (TGDMEXTMEMOFSADDR)

This register is for LWM-TGDMAC. The host processor cannot access this register, only threads can access it. Each thread has its own register to control LWM-TGDMAC.

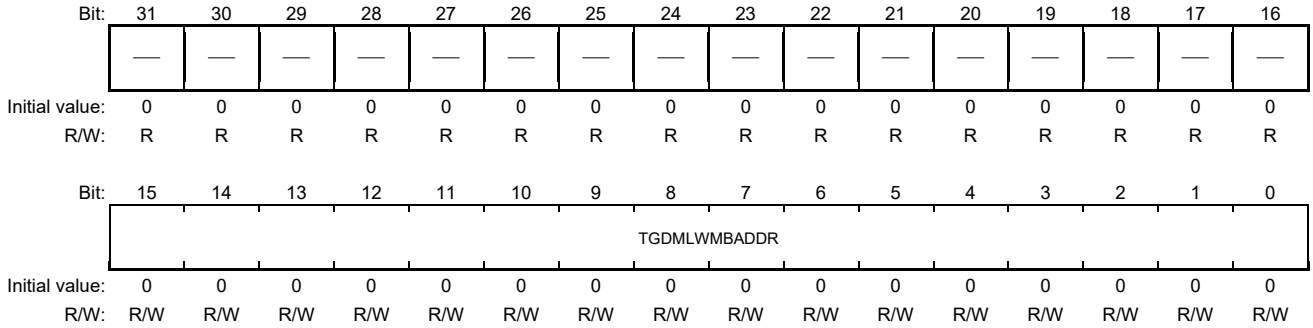


Bit	Bit Name	Initial Value	R/W	Description
31 to 0	TGDMEXTMEMOFSADDR	All 0	R/W	SELOFSADR=0: bit31-16: X coordinate (signed) in bytes, bit15-0: Y coordinate (signed). SELOFSADR=1: bit31-0: Offset address. Addition of IMGBARn, where n is the plane number specified by DMCR0.SELPLN, and TGDMEXTMEMOFSADDR makes the start address of the DMA transfer of the external memory in bytes.

U32.12.1.55TGDMac LWM Base ADDress Register (TGDMLWMBADDR)

This register is for LWM-TGDMAC. The host processor cannot access this register, only threads can access it. Each thread has its own register to control LWM-TGDMAC.

Bit 31 to 16 of LWM address will be filled automatically with 0 by HW.



Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
15 to 0	TGDMLWMBADDR	All 0	R/W	Specify the start address for DMA transfer within LWM.

U32.12.1.56TGDmac LWM STRide Register (TGDMLWMSTRR)

This register is for LWM-TGDMAC. The host processor cannot access this register, only threads can access it. Each thread has its own register to control LWM-TGDMAC.

Bit 31 to 16 of LWM stride will be sign-extended automatically by HW.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TGDMLWMSTRR															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
15 to 0	TGDMLWMSTRR	All 0	R/W	These bits set the signed stride of LWM by byte unit.

U32.12.1.57TGdmac LeNGth Register (TGLNGR)

This register is for LWM-TGDMAC. The host processor cannot access this register, only threads can access it. Each thread has its own register to control LWM-TGDMAC.

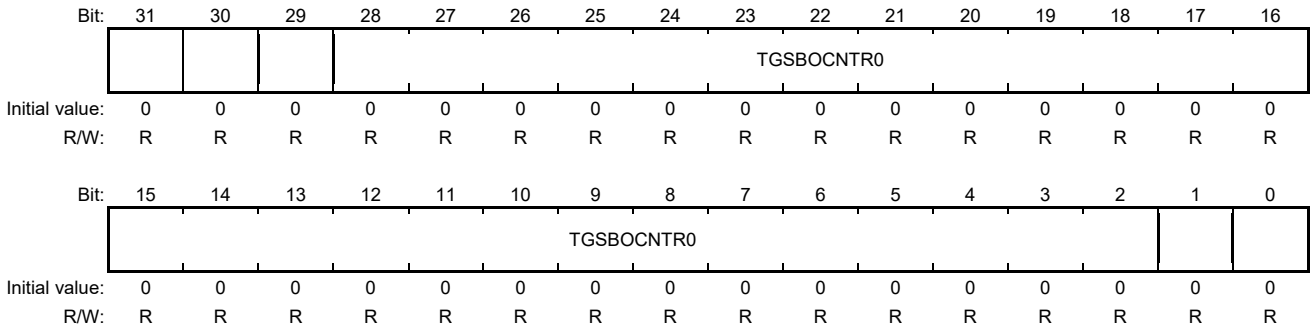
Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	XLNG														
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	YLNG														
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
30 to 16	XLNG	H'0000	R/W	A width in the range of 1 to 16384 in byte unit. Value must satisfy the plane format alignment.
15	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
14 to 0	YLNG	H'0000	R/W	A height in the range of 1 to16384 in byte unit.

U32.12.1.58TGSBO CouNT Register0 (TGSBOCNTR0)

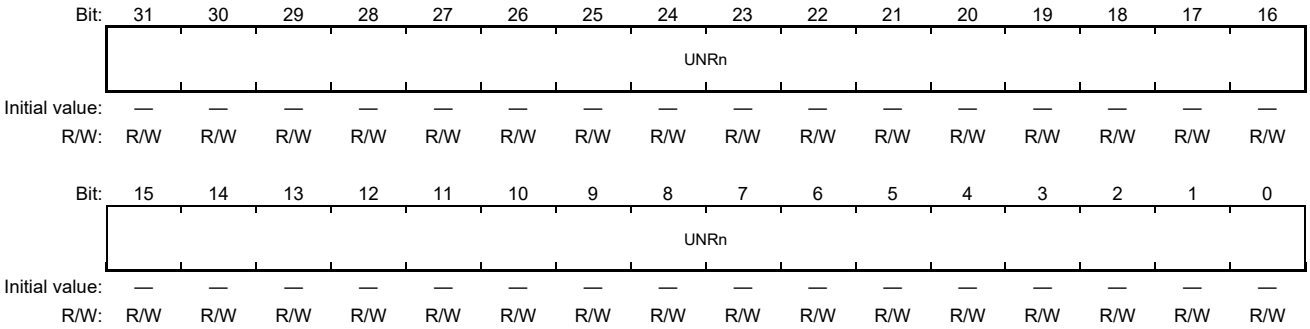
This register indicates the number of write accesses to the SBO port by all 32 threads of a cluster. Even so US thread writes to SBO, it will not be reflected immediately. Also the time point the data is really written out may be later than the update of this register. Wait for the end of US thread on the VI before using it.



Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.
28 to 2	TGSBOCNTR0	H'0000000	R	Number of 4byte write accesses to the SBO port for all 32 threads of a cluster.
1 to 0	—	All 0	R	Reserved These bits are always read as 0. Operation cannot be guaranteed if a value other than 0 is written here.

U32.12.1.59UNiform Register n (UNRn) (n = 0 to 63)

All UNR register are readable and writable from Arm. From CVengine, all UNR register are read only.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	UNRn	Undefined	R/W	Set contents of the n-th Uniform storage

U32.13 Command List (CL)

It is prohibited to use instructions not listed on this section.

U32.13.1 POINT (Point)

(1) Functionality

Issue coordinates specified in CL to master threads. The coordinates are placed along with the command.

The coordinate space is 65,536 × 65,536, in which -32,768 ≤ X ≤ 32,767 and -32,768 ≤ Y ≤ 32,767.

When clip bit is 1, (X, Y) coordinates are clipped according to the clipping area. Refer to section U32.8.7 .

Note: User is required to execute SYNCS instruction with bit[15:13]==b'110 before and after executing this instruction.

(2) Command Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OP CODE=0011_0000(H'30)								Reserved (all 0)							clip	N(1≦N≦65535)															
X0 (signed 16-bit, -32768 - 32767)																Y0 (signed 16-bit, -32768 - 32767)														
X1(signed 16-bit, -32768 - 32767																Y1(signed 16-bit, -32768 - 32767)														

…

X(N-1)(signed 16-bit, -32768 - 32767)	Y(N-1)(signed 16-bit, -32768 - 32767)

U32.13.2 POINTS (Point Separate)

(1) Functionality

Issue coordinates specified in CL to master threads. The coordinates should be placed at the address specified by the “Address” field of this command.

The coordinate space is 65,536 × 65,536, in which -32,768 ≤ X ≤ 32,767 and -32,768 ≤ Y ≤ 32,767.

When clip bit is 1, the corresponding coordinates at the addresses are clipped according to the clipping area. Refer to section U32.8.7 .

Note: User is required to execute SYNCS instruction with bit[15:13]==b'110 before and after executing this instruction.

(2) Command Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OP CODE=0011_0011(H'33)								Reserved (all 0)							clip	N(1≦N≦65535)															
Address																															

U32.13.3 RECT (RECTangle)

(1) Functionality

Generate coordinates automatically and issue the generated coordinates to master threads. The coordinates are generated in Raster-scan order.

Note: User is required to execute SYNCS instructions with bit[15:13]==b'110 before and after executing this instruction.

When clip bit is 1, (X, Y) coordinates are clipped according to the clipping area. Refer to section U32.8.7 .

From (Xs, Ys), it generates coordinates according to the parameters. The (X[i][j], Y[i][j]) coordinate is generated like the following behavior model, then it is clipped according to the clipping area if clip bit is 1.

The dX1, dY1, dX2, and dY2 are specified by signed 16-bit fixed point format. The number of the bits of decimal point is decided by sft.

Xs, Ys are specified by unsigned fixed point format. The number of the bits of decimal point is decided by sftxy. The value of sft must be more than the value of sftxy.

(Of any sftxy value, Xs and Ys work as signed 16-bit)

Note: Uses X[i][j] and Y[i][j] in the following ranges:

-32768<=X[i][j]<=32767, -32768<=Y[i][j]<=32767

< behavior model >

```
(0<= sft <= 11, 0<=sftxy<=3, sft >= sftxy)
X_ls = Xs << (sft - sftxy);
Y_ls = Ys << (sft - sftxy);
for (j=0; j<Ylen; j++) {
    X0[0][j] = X_ls;
    Y0[0][j] = Y_ls;
    X[0][j] = X0[0][j] >> sft;
    Y[0][j] = Y0[0][j] >> sft;
    for(i=1; i<Xlen; i++) {
        X0[i][j] = X0[i-1][j] + dX;
        Y0[i][j] = Y0[i-1][j] + dY2;
        X[i][j] = X0[i][j] >> sft;
        Y[i][j] = Y0[i][j] >> sft;
    }
    X_ls = X_ls + dX2;
    Y_ls = Y_ls + dY;
}
```

U32.13.4 NOP(No OPeration)

(1) Functionality

Wait for N cycle and go to the next command.

(2) Command Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OP CODE=1000_0000(H'80)								Reserved (all 0)																			N(1≦N≦16)				

U32.13.5 TRAP(TRAP)

(1) Functionality

Finishes CL execution and reflects it to the Status Register if permitted by Interrupt Control Register. Also, regardless of Interrupt Control Register, the value of CODE field is reflected to Status Register.

Note: User is required to execute SYNCM instruction with bit11=1, bit2=1 and bit0=1 before executing this instruction.

(2) Command Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OP CODE=1000_1000(H'88)								Reserved (all 0)																CODE							

U32.13.6 WPR(Write PaRameter)

(1) Functionality

From the register address specified from ADD field, the successive N registers are written by DATA0 to DATA N-1 respectively. ADD[23:8] should be specified by 1Byte unit. Registers written by this command must be “WPR support” registers. Otherwise, operation cannot be guaranteed. Refer to “Offset” column on Table U32.12.2 to see the register address for ADD field and refer to “WPR support” column also.

When WPR is used after executing POINT, POINTS or RECT, SYNCS with bit15=1 and bit14=1 must be executed before executing WPR.

(2) Command Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

DATA 0																															
DATA 1																															
DATA 2																															

…

DATA N-1

U32.13.7 INT(INTerrupt)

(1) Functionality

The INT bit of Status Register gets “1” if it is permitted by Interrupt Control Register. Also, regardless of Interrupt Control Register, the value of CODE field is reflected to Status Register. The CL execution is stopped till the INT bit of Status Register becomes “0”.

Before stopping CL execution, the instruction buffer in Vertex Issue and the instruction cache of the thread are cleared, and SBO and data cache of the thread are flushed. Since the pre-fetch instruction buffer is cleared with this command, CL commands can be re-written during interruption.
Note: SBO Base Address Register must be set before next CL execution when SBO is used.

Remarks:

- Renesas uses the INT command internally in software debug solution.
- INT codes 0xe0 to 0xff is reserved for this debug solution or Renesas internal purpose. 0x00 to 0xdf are available for users.

INT_PBCOVF is used for the Guard Timer. Refer to Section U32.8.8 for detail.

(2) Command Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

*1 INT_PBCOVF

U32.13.8 JUMP(JUMP)

(1) Functionality

This is the command to jump to the specified address.

It allows jumping to the address specified in JMPADD field. Setting 1 to RLT field uses JMPADD as relative address to JUMP command address and setting 0 in RLT field uses JMPADD as absolute address of the command list. Specify 4-byte unit command address in the JMPADD field.

(2) Command Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OP CODE=1001_0000(H'90)								RLT	Reserved (all 0)																						
JMPADD																															

U32.13.9 GOSUB(GOSUB)

(1) Functionality

This is the command to save current CL address to the hardware buffer and jump to the specified address.

It allows jumping to the address specified in GSADD field and returning to the address next to the GOSUB command by RET command. Specify 4-byte unit command address in the GSADD field, nesting of up to 4 level is supported. Setting 1 to RLT field uses GSADD as relative address to GOSUB command address and setting 0 in RLT field uses GSADD as absolute address of the command list. Setting 1 in CON field executed GOSUB conditionally and setting 0 in the CON field executed GOSUB unconditionally. Setting 1 in CON field and 0 in CLCNDGSBR bit of CLCNDGSBR register changes GOSUB command into NOP command. After the CLCNDGSBR register is set, a SYNCS command should be added before using the GOSUB command.

(2) Command Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OP CODE=1001_0001(H'91)								RLT	CON	Reserved (all 0)																					
GSADD																															

U32.13.10 RET(RETurn)

(1) Functionality

Jumps to the address saved by a GOSUB command. Initial value of address buffer is not defined, so executing RET command to an address buffer which had not been saved by GOSUB command is prohibited.

(2) Command Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OP CODE=1001_1001(H'99)								Reserved (all 0)																							

U32.13.11 SYNCM(SYNChronize Memory)

(1) Functionality

Flush or clear each cache specified in the command. After all cache operation specified in the command finishes, the next command is fetched and executed. It is prohibited to specify both flush and clear to the same cache at the same time. The command should be used after SYNCS because some threads might still be running.

If I$ CLR bit is 1, Instruction cache of the thread is cleared. If SBO CLR bit is 1, SBO is cleared, and the data left in SBO disappear. If D$ CLR bit is 1, Data cache of the thread is cleared. If SBO FLUSH bit is 1, SBO is flushed. If D$ FLUSH bit is 1, Data cache of the thread is flushed.

Upon SBO output, SBO Base Address Register is incremented to indicate the current SBO output address. And flushing or clearing SBO does not clear SBO Base Address Register. So, if SBO had been flushed or cleared, SBO Base Address Register must be set before next CL execution.

(2) Command Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OP CODE=1000_1010(H'8A)								Reserved (all 0)											0	I$ CLR	SBO CLR	0	D$ CLR	Reserved (all 0)					SBO FLUSH	0	D$ FLUSH

U32.13.12 SYNCS(SYNChronize Shader)

(1) Functionality

Wait for the end of execution of Threads. After all specified CVengine and/or DMAC's Threads get idle, the next command is executed.

(2) Command Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OP CODE=1000_1011(H'8B)								Reserved (all 0)								See Below			Reserved (all 0)												

bit[15:13]==b'111 : Wait until running threads, running LWM TGDMAC and running GWM-DMAC transfers are completed

bit[15:13]==b'110 : Wait until running threads and running LWM TGDMAC transfers are completed

bit[15:13]==b'001 : Wait until running GWM-DMAC transfers are completed

bit[15:13]==else : All other settings are prohibited

U32.13.13 SINI(Shader INItialize)

(1) Functionality

This command starts each enabled thread once and returns processing to the CL. The command does not wait for the threads to finish execution, for details refer to section U32.12.1.27 and U32.12.1.29 .

Note: User is required to execute SYNCS instructions with bit[15:13]==b'110 after executing this instruction.

(2) Command Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OP CODE=0001_0001(H'11)								Reserved (all 0)																							

U32.13.14 SLP(SLeeP)

(1) Functionality

This command stops execution of the succeeding commands in the CL until all specified WUP signals are received.

Specify the necessary WUP signals as the core numbers in the CORE Number field. Multiple bits can be set to 1 at the same time.

The correspondence between core numbers and actual cores can be specified through the SYNCCR0, SYNCCR1, SYNCCR2 and SYNCCR3 registers. Refer to Section U32.12.1.46 , Section U32.12.1.47 , Section U32.12.1.48 and Section U32.12.1.49 .

Each SYNCCRn register contains 4 SYNCCn fields. Each SYNCCn field is 8-bit long. Its upper 4 bits determine CORE Type and lower 4 bits determine CORE Number.

The available CORE Types are:

0: IMP Core
1: CVengine
2: IMP DMAC
3: Pyramid Scaler
4: CNN
5: LSDMAC
6: IMR
7: DTA

And possible CORE Numbers for each CORE Type are:

IMP Core: 0-4
CVengine: 0-7
DMAC: 0-3
Pyramid Scaler: 0-1
CNN: 0-2
LSDMAC: 0

All the cores must have the same CORE Type and CORE Number settings.

Using this command and the WUP command enables synchronization among cores. Refer to Section U32.11.1 .

(2) Command Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OP CODE=1010_0001(H'A1)								Reserved (all 0)								SYNCC enable															

U32.13.15WUP(Wake UP)

(1) Functionality

This command issues the WUP signal to the cores specified in this command. Multiple bits can be set to 1 at the same time.

The WUP signal triggers a wake up event at the target. The WUP command can be issued to a core even when it is not in the SLP state. However, two or more WUP requests are not accumulated. (Issuing the WUP command to a core and issuing it again to the same core before the core wakes up is not supported. i.e., the second WUP does not trigger a wake up for a second SLP at the target core.). Between 2 WUP commands at least 8 other commands must be inserted.

The correspondence between core numbers and actual cores can be specified through the SYNCCR0, SYNCCR1, SYNCCR2 and SYNCCR3 registers. Refer to Section U32.12.1.46 , Section U32.12.1.47 , Section U32.12.1.48 and Section U32.12.1.49 .

For settings of SYNCCRn register, refer to U32.13.14 .

Using this command and the SLP command enables synchronization among cores. Refer to Section U32.11.1 .

(2) Command Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OP CODE=1010_0000(H'A0)								Reserved (all 0)								SYNCC enable															

U32.14 Appendix

This section describes the four methods for improving performance of the CVengine thread.

U32.14.1 Effective Use of 0th Level Cache

Each thread implements the 0th level cache for accessing the D$.

The size of the 0th level cache is 256 bits. When reading data from the D$ in a single access operation, each thread reads the surrounding data that includes the accessed data within its 256-bit aligned boundary.

Data to be written from each thread is directly written to the D$. If a hit occurs in the 0th level cache, the 0th level cache is overwritten. If a miss occurs in the 0th level cache, data is written to only the D$ and 0th level cache is not changed.

As a result of monitoring programs, access to the D$ has been observed in multiple cases to be a bottleneck in good performance.

Accordingly, each thread being able to effectively use the 256-bit data in the 0th level cache is expected to improve performance.

Be noticed that the 0th level cache is only connected to D$ thus it does not work for accessing to any other memory (e.g., LWM).

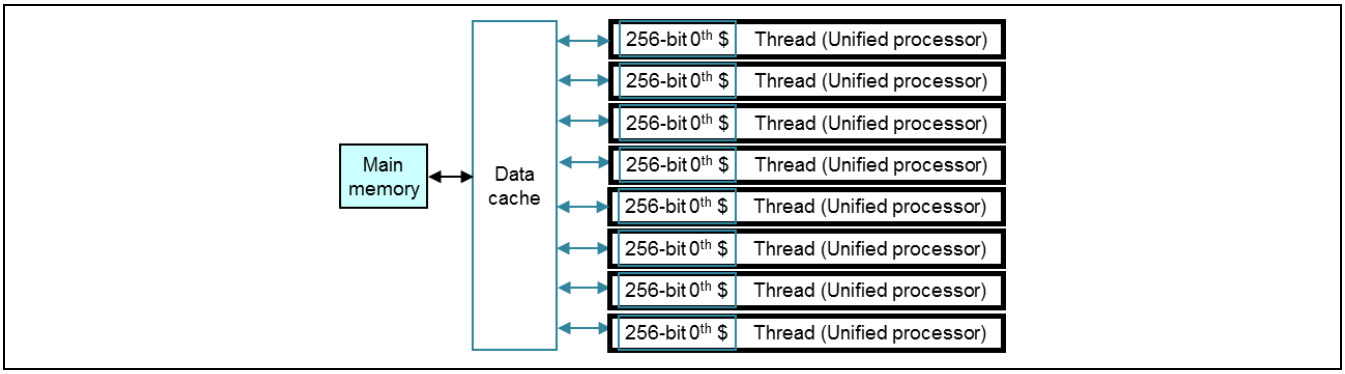

Figure U32.14.1 Arrangement and Configuration of 0th Level Cache

Those are two examples use cases for 256 bit alignment. In case of processing an 8-bit/pixel image, programming so that 32 (256 bits/8 bits = 32) consecutive pixels are processed by a single thread enables all of the necessary data to be accessed by a single access to the D$ and also prevents multiple threads from reading the same 256 bits of data. In case of 32-bit/pixel data, programming so that 8 (256 bits/32 bits = 8) consecutive pixels are processed by a single thread similarly enables all of the necessary data to be accessed by a single access to the D$ and also prevents multiple threads from reading the same 256 bits of data.

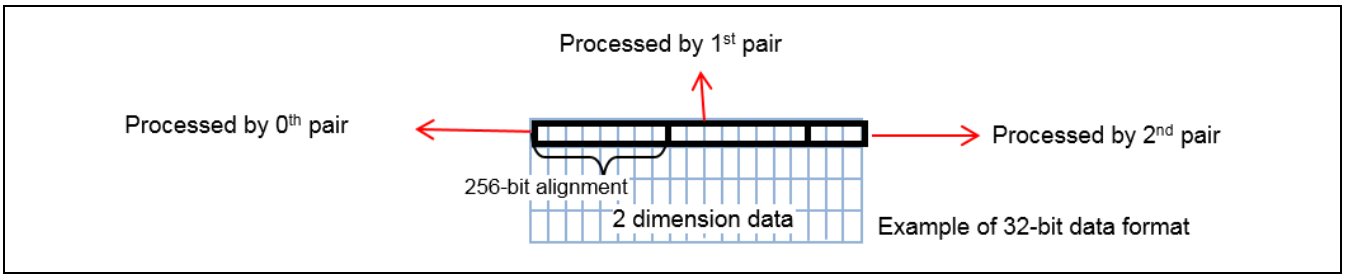

Figure U32.14.2 Example of Efficiently Using 0th Level Cache

U32.14.2 Kernel Processing for Each Area

One thread needs to read multiple surrounding pixels of the center pixel in kernel processing that is specific and frequently used in image recognition. In kernel processing, a surrounding pixel that has been read once becomes the center pixel in the next kernel or can be used as a surrounding pixel. Therefore, in kernel processing, if a certain thread has processed a kernel, the same thread processing the neighboring kernels can reduce the overhead in data loading.

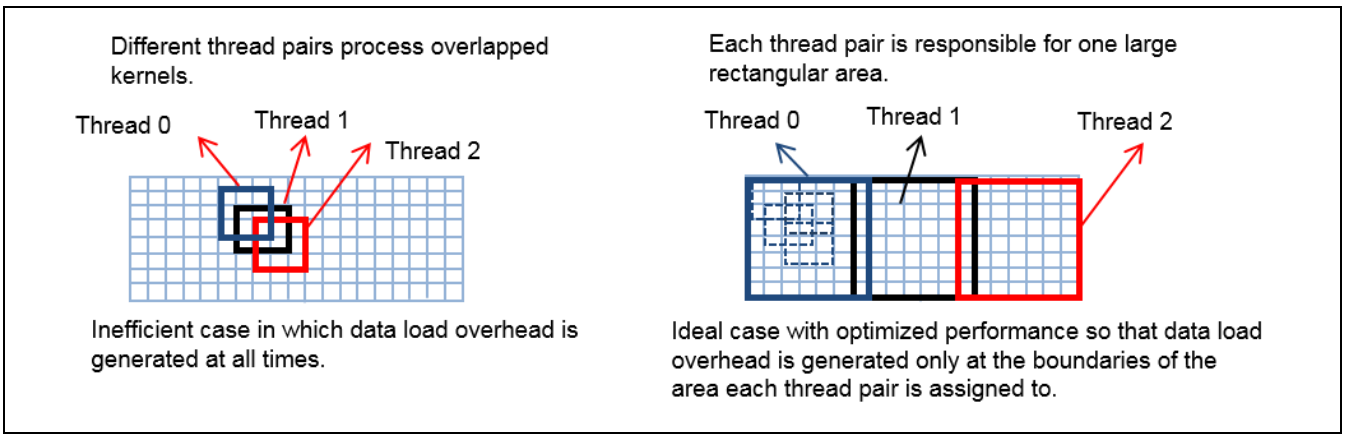

Figure U32.14.3 Example of Efficiently Assigning Processing Areas

U32.14.3 Loop Unrolling

Instructions of the BR group always cause 1-cycle stall when the branch condition is satisfied. Therefore, when there is a loop in a program to generate a branch, stall cycles for the number of loops will occur. Cycles to calculate the number of loops and execute the compare instructions for determining the loop are also required.

Therefore, when there is sufficient program capacity and the number of loops is unique, optimization by loop unrolling is effective to improve the thread performance.

U32.14.4 Effective Use of Instruction Buffers

Each thread implements buffers to hold the instructions fetched from the I$.

This level-0 instruction cache is implemented as a set of 8 buffers, with 256 bits for each of the 8 buffers. When fetching an instruction from the L1 I$ in a single access operation, each thread reads the surrounding data that includes the instruction to be fetched within its 256-bit aligned boundary.

If the instruction to be fetched is not in any of the buffers, the surrounding data that includes the instruction to be fetched is aligned at the 256-bit boundary and is stored in one buffer. The subsequent 256-bit data is stored in another buffer.

When the last instruction in a buffer X gets executed, then buffer (X + 2)%8 gets pre-loaded with 8 instructions (256 bits).

If inner loop is larger than 55 instructions but less than or equal 64 instructions, disabling pre-fetch function of the instruction buffer can improve performance. The preloading which is taken place at instruction 56 can be prevented and 64 instructions of inner loop can be hold inside instruction buffer. Refer to section U32.12.1.52 .

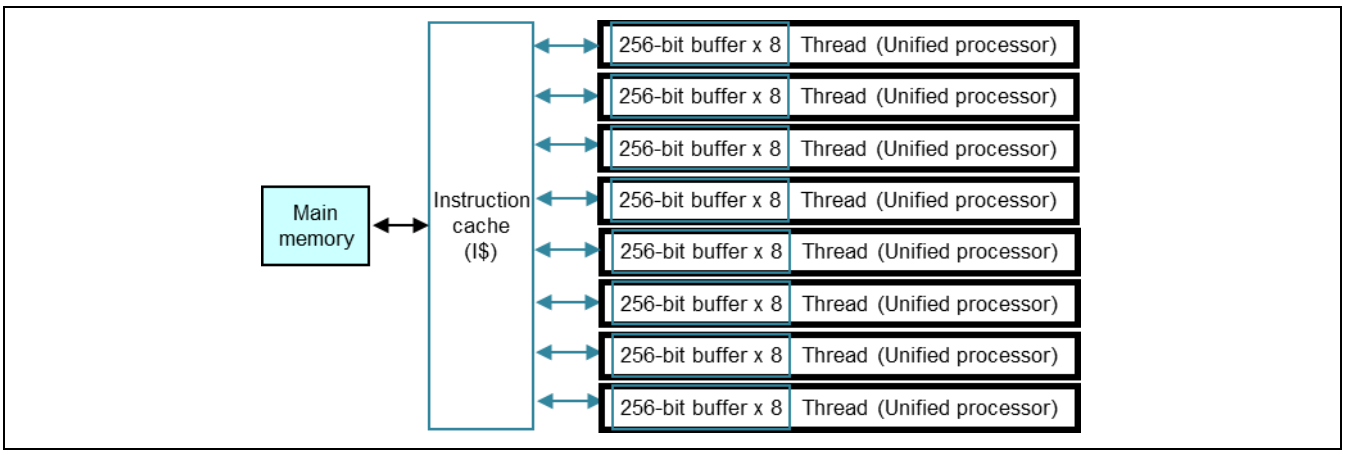

Figure U32.14.4 Arrangement and Configuration of Instruction Buffers

For example, if there is a loop in the program, storing the first instruction of a loop in the start address of the 256-bit aligned memory may improve the efficiency of instruction fetch. The effect is greater especially if the number of iterations of the loop is large.

U32.14.5 Tiling Approach

Size the D$ is reduced from former R-Car SoCs, refer to U32.1.2 , it is recommended to use DMA for data loading from DDR to Scratchpad memory or LWM, for details, refer to section U32.8.3 .

U32.15 Usage Notes

U32.15.1 Synchronized system between modules

For synchronized system between modules, refer to the Section U34.IMP-X7_system, U34.10.5 Inter Module Synchronization of IMP-X7_System manual.

U32.15.2 Power shutdown

For power shutdown, refer to User's Manual: Hardware, section 58.7.1, Shutting Down the Power Supply.

U32.15.3 Module Standby Mode

For module standby mode, refer to User's Manual: Hardware, section 58.7.2, Module Standby Mode.

U32.15.4 CPG Software Reset

For software reset of CPG, refer to User's Manual: Hardware, section 58.7.3, Software Reset by the Clock Pulse Generator (CPG).

U32.15.5 SOU register limitation

SOU registers (R8 to R15) cannot be used as destination register of the following load instructions:

LDRCI, FLDRCI

LDRCIU, FLDRCIU

LDBUI, LDBSI, LDHUI, LDHSI, LDI

LDBU, LDBS, LDHU, LDHS, LD

LDRXY, FLDRXY

LDRXYU, FLDRXYU

If the register R8 to R15 are not used as SOU registers but as general-purpose registers, they can be used as destination register of the load instructions.

U32.16 Safety Mechanism

U32.16.1 EDC for CVe

U32.16.1.1Overview

EDC is applied to the following internal RAMs of CVe. All RAMs in CVe are protected by EDC.

- SRAM for Global Work Memory
- SRAM for Local Work Memory
- SRAM for Level 1 Instruction Cache (Data Array)
- SRAM for Level 2 Instruction Cache (Data Array)
- SRAM for Data Cache (Data Array)
- SRAM for Data Cache (Byte Enable Array)
- SRAM for Stream Buffer Output

EDC is also applied to AXI Master Bus I/F and AXI Slave Bus I/F.

U32.16.1.2Hardware Description

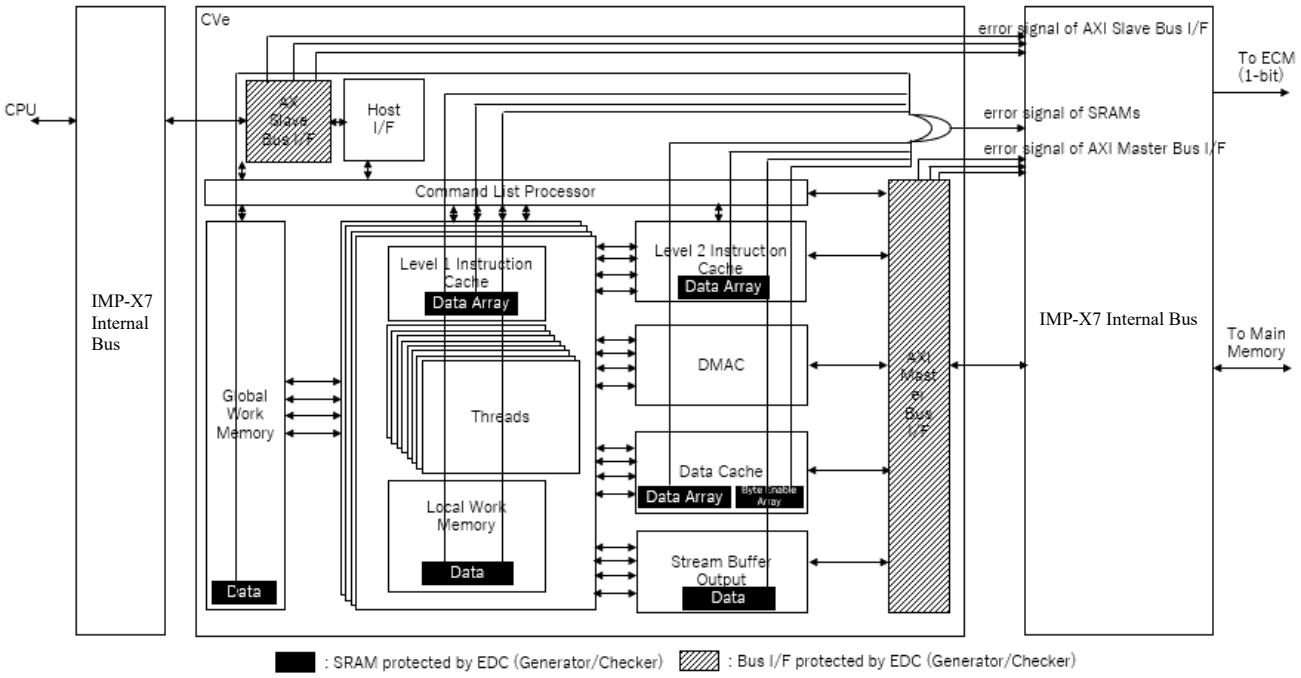

Figure U32.16.1 Block diagram of EDC protection of CVe

(1) RAM

When using the EDC function of memory (after every power on reset or software reset by CPG or Runtime Test or POST), it is necessary to initialize the memories.

The EDC code is generated and written to SRMs described in Section U32.16.1.1 when data is written to each SRAM. And the data and the corresponding code are compared when it is read out.

Since initial values in SRAM are undefined, it is required to initialize the contents of SRAM of Local Work Memory, Global Work Memory, Data Cache Data Array, and Data Cache Byte Enable Array since unwritten area of the SRAMs can be read out. The initialization can be done automatically by using MEMINITR register for Global Work Memory and Local Work Memory initialization. The initialization status for each SRAM can be checked by reading the status bits of MEMINITR register.

< Procedure to initialize Global Work Memory >

Execute following steps from (1) to (3) to initialize the Global Work Memory.

(1)Check gwm_state bit in MEMINITR register equal 0 (MEMINITR [16] = 1'b0). If this bit is 1, clear this bit by CPG software reset.

(2)Set gwm_init bit in MEMINITR register to 1

(3)Check gwm_state bit in MEMINITR register equal 1 (MEMINITR [16] = 1'b1)

< Procedure to initialize Local Work Memory >

Execute following steps from (1) to (3) to initialize the Local Work Memory.

(1)Check lwm3_state, lwm2_state, lwm1_state, lwm0_state, bits in MEMINITR register equal 0 (MEMINITR [23:20] = 4'b0000). If these bits are 1, clear these bits by CPG software reset.

(2)Set lwm3_init, lwm2_init, lwm1_init, lwm0_init, bits in MEMINITR register to 1

(3)Check lwm3_state, lwm2_state, lwm1_state, lwm0_state bits in MEMINITR register equal 1 (MEMINITR [23:20] = 4'b1111)

For Data Cache Data Array and Data Cache Enable Array, the memories have to be set into testmode by writing H'8006 4100 to the Memory Control Register 0 (MCR0) register to set the testmode bit and areasel bits before writing by CPU H'0000 0000 from address H'C000 to address H'DFE0 every 32byte and finally switching back to normal mode by writing H'0100 0000 to the MCR0 register.

< CPU initialization procedure for D$ Memory >

Execute following steps from (1) to (3) to initialize the D$ Memory.

(1)Write H'8006 4100 to the Memory Control Register 0 (MCR0) register to set the testmode bit and areasel bits.

(2)The CPU writes H'0000 0000 from address H'C000 to address H'DFE0 every 32byte.

(3)Write H'0100 0000 to the MCR0 register.

(2) Bus I/F

An EDC protection is implemented in bus interface of CVe.

(3) . Register Description

Register Name	Abbreviation	R/W	Address	Initial value	Access Size
Memory Initialization Register	MEMINITR	R/W	(Base Address) + H'0F8	H'0000 0000	32
Memory Control Register 0	MCR0	R/W	(Base Address) + H'040	H'0100 0000	32

Note : Refer to the Manual of IMP-X7 about the Base Address of each channel of CVe

(a) MEMory INITialization Register (MEMINITR)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

U33. Convolutional Neural Network (IMP CNN)

U33.1 Overview

The Convolutional Neural Network of image processing unit is abbreviated as IMP CNN. It performs a fast execution of a Convolutional Neural Network with optional enabling additional CNN layers like RELU (Rectified Linear Units) or pooling for up to k input and m output layers with a simple instruction set. The CNNs can be used for applications like semantic segmentation for detection of lanes, pedestrians, cars, or any other object; object detection and classification to identify the vehicles, traffic signs, pedestrians, etc. Current state of the art networks reaches results which exceed human accuracy. The most important layer for a CNN is the Convolutional layer which consumes around 90% of the processing power. Other important layers are RELU, Pooling, Deconvolution, etc.

This CNN-IP can not only perform many convolutions in parallel, but also can merge additional layers into a single run. This CNN-IP provides an advanced solution for special recognition tasks within the R-Car family. In the following, first some basics about the CNN-IP are described

Compared with other designs, this setup has two major advantages:

a) Less memory consumption, because of the combined logic eliminates the need for temporal storage significantly.

b) High accuracy since the quantization-error (downshift normalization) is applied to the sum of up to k convolution results. This stands in contrast to other designs, which apply normalization on a smaller scope and have overall a bigger quantization error.

This CNN-IP is a configurable – not programmable IP. Its function is controlled by registers. These registers can be set by a command list (CL), which is processed by the command issue hardware unit. The actual data processing is done in a pipelined way as shown in Figure U33.4. That means, in each cycle a pixel is processed for each channel.

Figure U33.1 shows the result of semantic segmentation, which is a sample application of CNN. The different stages of the processing have produced a combined image showing the detection of the different items in the scene such as cars, road, and sky. This produces classification of the objects detected in the image.

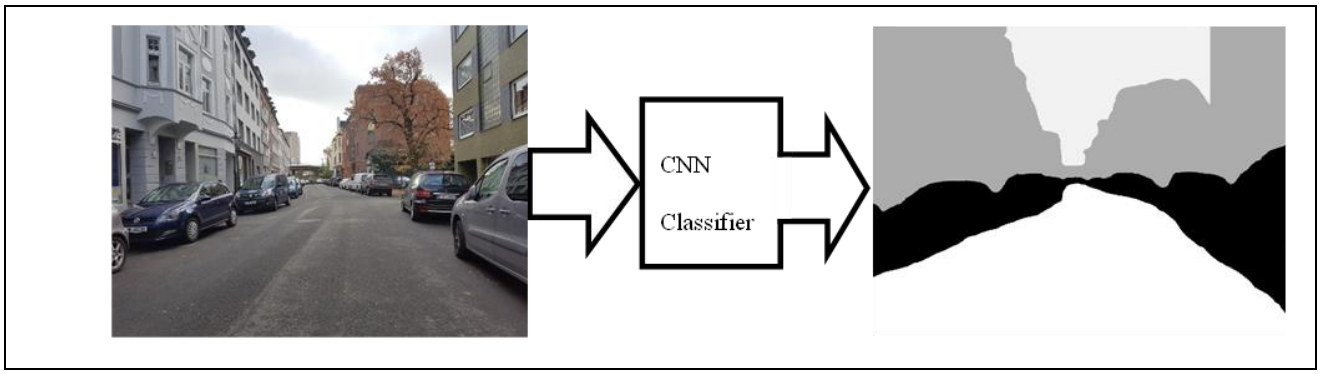

Figure U33.1 Use case example for sematic segmentation

Figure U33.2 shows the different layers of processing of which the convolution, (Bounded) RELU, Pooling, Deconvolution and Pixel Labelling take place. The output after processing gives the segmentation result.

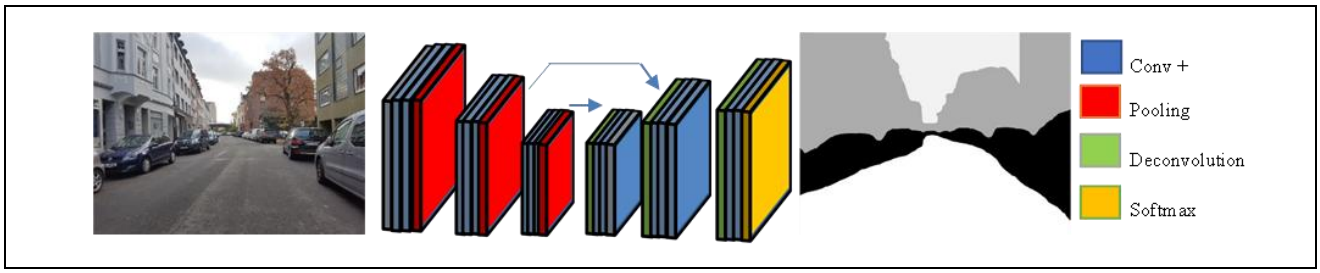

Figure U33.2 Example network for Semantic Segmentation

This module is treated as safety related function in case of functional safety supported product. For the details, refer to functional safety documents.

The CNN-IP module supports processing of complex CNNs basically by taking small portions, also called tiles, of an image and run the filtering process on each of them. Once the processing has been carried out on the data a result is passed to the next layer. The images are filtered with known feature patterns stored in a database to produce as output the likelihood of a successful match as shown in Figure U33.3

A dedicated CNN-IP hardware accelerator is the most efficient hardware implementation (computation vs. cost / power). The solution is pipeline based, meaning the overhead is very small compared to a software equivalent system. Furthermore, additional functions are available without the cost of delays.

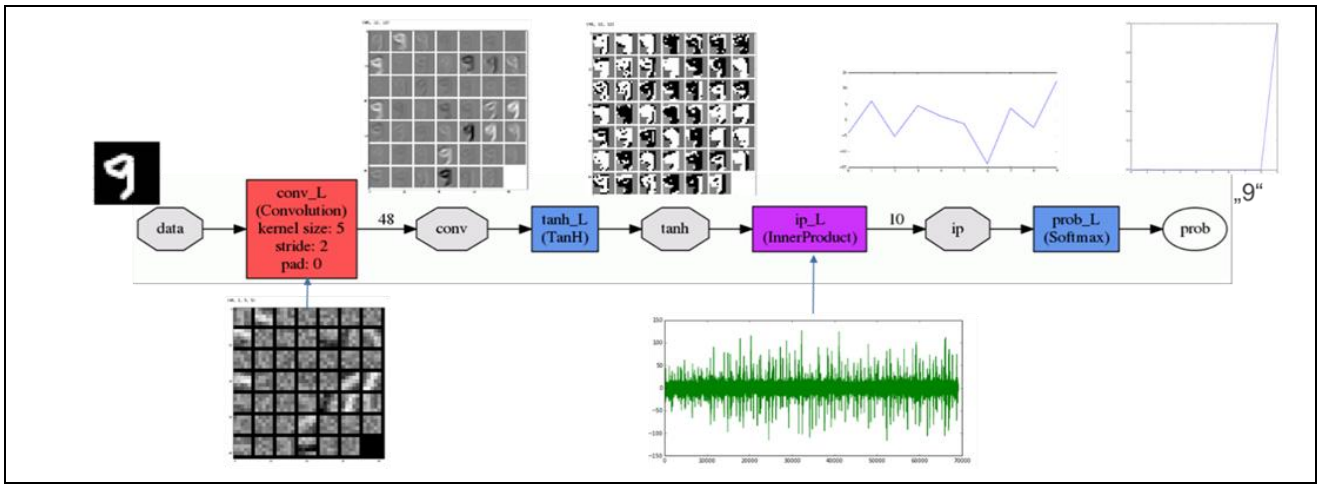

Figure U33.3 Processing flow of image processing and likelihood weighting of a match

U33.1.1 Features

The following terms and symbols are used throughout the CNN specification:

Table U33.1 The Description of terms

Terms	Description
CNN	Convolutional Neural Network
CL	Command list to control the registers in CNN-IP
SPMC	The dedicated memory for IMP CNN (refer U34.IMP-X7_system), including of SPMC0 and SPMC1.
DMAI	To load FM from SPMC0 memory
DMAW	To load weights from SPMC0 memory
CNV	The main function of the CNN-IP, doing convolution with FM and weights
DMA3DC	To carry the previous convolution results to ARI module, adding up to current convolution results when the channels of FM greater than number of input channels in CNN-IP
ARI	The sub processes Activation, Channel pool, XY Pool are abbreviated as ARI
DMAO	A module to store the output data to the SPMC0/SPMC1
DMAx	Each DMA (DMAI/DMAW/DMA3DC/DMAO)
DMAxS	DMAIS/DMAWS/DMA3DC/DMAOS
FM	Feature Map
HW	Hardware
WT	weight
Pix	pixel
CH/ch	channel
ich/och	Input channel/output channel
s8/u8, s16/m16,	Signed 8bit/unsigned 8bit, signed 16bit/mixed 16bit
m32	Mixed 32bit
Block channel	The set of 32 channels or 16 channels to be read or written at the same time when DMAI or DMAO is accessed by packed or planar fast type In case of 32 channels set Block channel 0 (blk-ch0): Channel 0 to 31 Block channel 1 (blk-ch1): Channel 32 to 63 Block channel 2 (blk-ch2): Channel 64 to 95 Block channel 3 (blk-ch3): Channel 96 to 127 Block channel 4 (blk-ch4): Channel 128 to 159 Block channel 5 (blk-ch5): Channel 160 to 191 Block channel 6 (blk-ch6): Channel 192 to 223 Block channel 7 (blk-ch7): Channel 224 to 255 In case of 16 channels set Block channel 0 (blk-ch0): Channel 0 to 15 Block channel 1 (blk-ch1): Channel 16 to 31 Block channel 2 (blk-ch2): Channel 32 to 47 Block channel 3 (blk-ch3): Channel 48 to 63 Block channel 4 (blk-ch4): Channel 64 to 79 Block channel 5 (blk-ch5): Channel 80 to 95 Block channel 6 (blk-ch6): Channel 96 to 111 Block channel 7 (blk-ch7): Channel 112 to 127

The CNN-IP has N (16 (8bpp) / 8 (16bpp)) DMAI HW input channels. In case of 1*5x5 CNV mode, half of the DMAI HW input channels can be utilized, and each DMAI HW input channel holds 1 FM input channel, so 8 (8bpp) / 4 (16bpp) FM input channel can be processed in parallel.

In case of 2*3x3 CNV mode, 1 DMAI HW input channel holds a group of 2 FM input channels, so 32 (8bpp) / 16 (16bpp) FM input channels can be processed in parallel.

In case of 4*1x1 CNV mode, 1 DMAI HW input channel holds a group of 4 FM input channels, so 64 (8bpp) / 32 (16bpp) FM input channels can be processed in parallel.

In case of 8*1x1 CNV mode, 1 DMAI HW input channel holds a group of 8 FM input channels, so 128 (8bpp) / 64 (16bpp) FM input channels can be processed in parallel.

In case of 16*1x1 CNV mode, 1 DMAI HW input channel holds a group of 16 FM input channels, so 256 (8bpp) / 128 (16bpp) FM input channels can be processed in parallel.

The reachable performance for each mode is shown in Table U33.2.

Table U33.2 CNN Performance

Performance = DMAI channel * FM channel per group * OUTPUT channel * Kernel size * Frequency * Parallel pixels

Pixel format	DMAI channel	FM channel per group	OUTPUT channel	Kernel size	Frequency	Parallel pixels	Performance
8bpp	8	1	32	5x5	800MHz	1	5.1TMACs
16bpp	4	1	16	5x5	800MHz	1	1.3 TMACs
8bpp	16	2	32	3x3	800MHz	1	7.4 TMACs
16bpp	8	2	16	3x3	800MHz	1	1.8 TMACs
8bpp	16	4	32	1x1	800MHz	1	1.6 TMACs
16bpp	8	4	16	1x1	800MHz	1	0.4 TMACs
8bpp	16	8	32	1x1	800MHz	1	3.2 TMACs
16bpp	8	8	16	1x1	800MHz	1	0.8 TMACs
8bpp	16	16	32	1x1	800MHz	1	6.5 TMACs
16bpp	8	16	16	1x1	800MHz	1	1.6 TMACs

The following features are supported with the CNN-IP, for details and some limitations of features, please refer U33.3 Operation/ U33.4 Command list

- General feature:
  - Command list support: a list of supported instructions to control the CNN module is available
  - CL debugging support: Help users debug their programs by setting the break point address of CL
  - GOSUB/JUMP support: Absolute and relative address handing
  - 1 pixel processing per clock cycle
  - Double Buffering of DMAI, DMA3DC and DMAO parameters is supported.
- DMAI feature:
  - DMAI enable: enable/disable
  - Magnification mode of pixel repeat/skip (up/downscale): 0 to 4 for x, y direction
  - Magnification mode of pixel repeat (upscale) filling: repeat constant or repeat identity
  - DMAI data type: u8, s8, s16
  - DMAI transfer mode: planar or planar fast or packed
  - DMAI x length: 1 to 128 pixels
  - DMAI y length: 1 to 2048 rows
  - DMAI convolutional mode : 1*5x5, 2*3x3, 4*1x1, 8*1x1，16*1x1
  - Padding mode: Constant, identity (North/South: 0 to 7, West/East: 0 to 16)
  - Convolution stride (x-dir/y-dir): 1 to 3
  - Dilated convolution (x-dir): 0 to 3
  - Start position on FM(x-dir/y-dir): x-dir: 0 to 15, y-dir: 0 to 7
  - Start address: DMAI SPMC0 start address
- DMAW feature:
  - Start address: DMAW SPMC0 start address
  - Weight mode: depthwise mode,1*5x5, 2*3x3, 4*1x1, 8*1x1，16*1x1
  - Weight data type: s8, s16
  - DMAW transfer mode: packed
  - Weight preset mode: Setting N, VAL bits of CLW command via CL to select which mode to be used
- CNV feature:
  - Input channel processing: N (16bpp: 8, 8bpp: 16)
    - 2*3x3: 2*N (16bpp: 16, 8bpp: 32)
    - 4*1x1: 4*N (16bpp: 32, 8bpp: 64)
    - 8*1x1: 8*N (16bpp: 64, 8bpp: 128)

  - 16*1x1: 16*N (16bpp: 128, 8bpp: 256)
  - 1*5x5: (16pp: 4, 8bpp: 8)
- Output channel processing: (16bpp: 16, 8bpp: 32)
- Deconvolution is also supported (in case of semantic segmentation): Magnification + Convolution

- ARI feature:
  - ARI enable: enable/disable
  - ARI data type: s8, s16
  - ARI x length: 1 to 128 pixels
  - ARI y length: 1 to 2048 rows
  - DMA3DC value addition
  - Bias addition 16bit and 32bit: enable/disable
  - 16bit upscaler
  - Downshift of fractional position for MAC(ARI/DMAO) output channels: -47 to 0 (“-” means downshift)
  - Activation functions: RELU, BRELU, Leaky ReLU, Sigmoid, ELU, Tanh, H-Swish, Swish, Mish, Exp
  - Channel Pooling: Max, Rank, Label
  - X/Y pooling: XY MAX, XY average, Upper left XY

- DMA3DC feature:
  - Start address: DMA3DC SPMC1 start address
  - DMA3DC enable: enable/disable
  - DMA3DC data type: s8, s16, m16, m32
  - DMA3DC transfer mode: packed
  - Upshift of fractional position for all DMA3DC channel: 0 to 31
  - DMA3DC x length: 1 to 128 pixels
  - DMA3DC y length: 1 to 1024 rows
- DMAO feature :
  - Start address: DMAO SPMC0/SPMC1 start address
  - DMAO data type: s8, s16, m16, m32
  - DMAO x length: 1 to 128 pixels
  - DMAO y length: 1 to 2048 rows
  - DMAO transfer mode: planar fast/packed
  - DMAO enable: enable/disable
- Statistics generation:
  - Global SUM: sum of DMAO channel x (x: 0 to 31)
  - MAX: holding the maximal value of channel x (x: 0 to 31)
  - MIN: holding the minimum value of channel x (x: 0 to 31)
- The CNN-IP performs the following tasks in parallel:
  - DMAI for loading FM
  - Convolutional layer
    - 1*5x5 or 2*3x3 or 4*1x1 or 8*1x1 or 16*1x1convolution on the fly
  - Addition using DMA3DC:
    - Many channels should be processed (greater than number of input channels in CNN-IP)
    - Element-wise sum up: sum up the same pixel position over all channels.
  - Activation layer
  - Channel Pooling layer
  - XY Pooling layer
  - DMAO for storing the new FM for next layer

U33.1.2 CNN Block Diagram

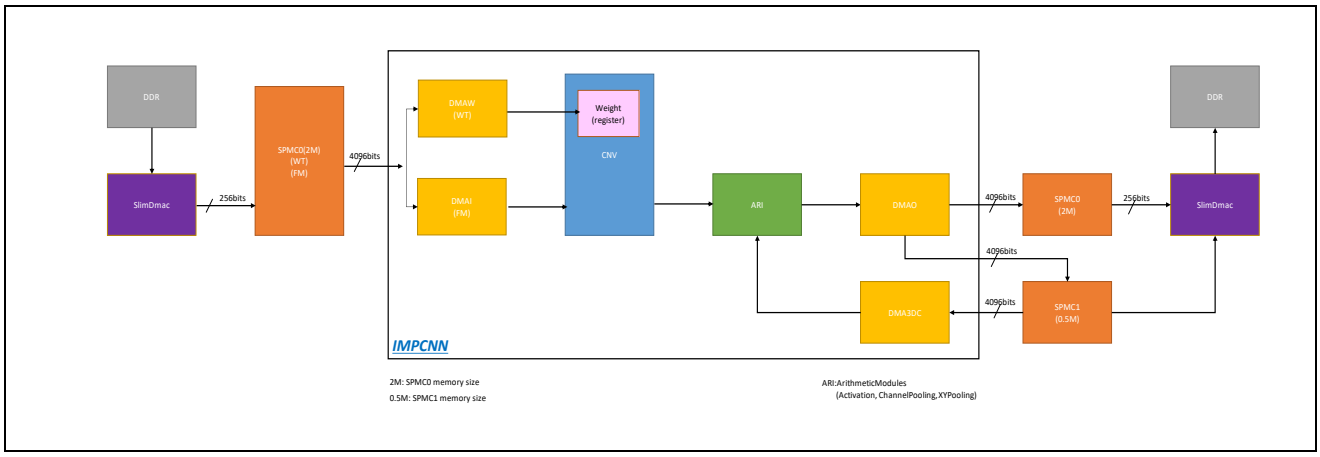

Figure U33.4 CNN Block Diagram

CNN IP includes the following main functional modules: DMAW is used to load weights. DMAI is responsible for loading FM from SPMC0 memory in planar type or planar fast type or packed format by setting the DMAIS_MODE bit of DMAIS register. CNV is responsible to do convolution based on kernel mode by setting DMAIS_TYPE bit of DMAIS register. Activation, Channel Pool, XY Pool are done in ARI by setting ARICSR register. DMAO is used to output the convolution results into SPMC0 memory in planar fast type or packed format (planar type is not supported in DMAO) by setting DMAOS_PLANAR bit of DMAOS register. Further, it is also used to output the temporary convolution results into SPMC1 memory. DMA3DC returns the previous run results to the current ARI module to add them, and the loop iterates through the execution until the last run.

U33.1.3 CNN Register Configuration

Accessing to addresses not listed in this register list is prohibited. Operation cannot be guaranteed when accessing to an address, which is not listed. Access size is 32-bit. Operation cannot be guaranteed when accessing by other than 32-bit. Operation cannot be guaranteed when writing to a register from CPU during IMP CNN execution.

Table U33.3 CNN Register Configuration Table for 4th Generation R-Car Series Products R-Car V4H/V4M

Register Name	Symbol	Access Possible From CP-R/ CP-W/ CL-R/ CL-W*1	Value after Reset	Trigger	Offset Address*4	RESET *2

Notes:

1. CP = central processor, CL = command list, R = read, W = write
2. H: Power on reset, S: Software reset by the SWRST bit of the SWRST register
3. Undefined value.
4. In the CNN register address area, offset addresses larger than 0x7000 are forbidden to access for read and write direction by WPR instruction and other IP.

U33.1.4 CNN Connected Module

The modules connected to CNN and their function descriptions are shown in Table U33.4.

Table U33.4 Connected Modules

Connected Modules	Function of the Connected Modules
CPG	Reset and Clock Stop Signal Supplier
INTTOP	Interrupt Controller
ECM	FUSA error Interrupt Controller

Note: FUSA (Road Vehicle Functional Safety)

U33.2 Register Description

Initial value: Register value after a reset
—: Undefined value
R/W: Readable/writable. The written value can be read.
R: Read-only. The write value should be the same as the read value.
-/W: Write-only. The read value is undefined.

U33.3 Operation

U33.3.1 SPMC storage format

This section describes data format stored in SPMC (Scratchpad memory).

Table U33.5 Data format stored in SPMC0/1

Format in SPMC0/1		DMAI/DMAW	DMA3DC	DMAO
Planar format (FM)	Planar type (s8, u8, s16)	√		
	Planar fast type (s8, u8, s16)	√		√
Packed format (FM)	Packed s8/u8 type	√	√	√
	Packed s16 type	√	√	√
	Packed m16 type		√	√
	Packed m32 type		√	√
Packed format (Weight)	8*1x1 s8	√		
	8*1x1 s16	√		
	4*1x1 s8	√		
	4*1x1 s16	√		
	2*3x3 s8	√		
	2*3x3 s16	√		
	1*5x5 s8	√		
	1*5x5 s16	√		
	16*1x1 s8	√		
	16*1x1 s16	√		
	Depthwise s8	√		
	Depthwise s16	√		

The WT output is defined as ich{n}-och{m}-w{p}h{q} (WT) and the FM output as ich{n} (FM), and each symbol has the meaning shown in Table U33.6.

Table U33.6 Symbol in Block Diagram

Data Type	Symbol	Descriptions
WT	ich{n}	WT for input channel{n} (n = 0 to 255)
	och{m}	WT for output channel{m} (m = 0 to 31)
	w{p}	WT for kernel width{p} (p = 0 to 4)
	h{q}	WT for kernel height{q} (q = 0 to 4)
FM	ich{n}	FM for input channel{n} (n = 0 to 255) (*1)

The ranges of {n}, {m}, {p}, and {q} above depend on the Kernel mode. The ranges of ich, och, and wh for each kernel are listed in Table U33.7. For details of each Kernel, refer to section (2).

(*1) The index of ich is converted by the part function in Figure U33.20.

Table U33.7 Value range of ich, och, wh per kernel

Kernel	n (Ich{n})	m (och{m})	p (w{p}}	q(h{q})
16*1x1	0 to 255	0 to 31	0	0
8*1x1	0 to 127		0	0
4*1x1	0 to 63		0	0
2*3x3	0 to 31		0 to 2	0 to 2

1*5x5	0 to 7		0 to 4	0 to 4

(1) Planar Format

(a) Planar type

In planar type, one channel's data is stored continuously in SPMC0. An example of ChN (channel N) data stored in SPMC0 is illustrated in Figure U33.5. Data in planar type is 2D, it is possible to set the line stride separately from the 1-line size setting (x-size). The storage of 8bpp/16bpp data in SPMC0 is little-endian, 16bpp data must be stored in 2byte alignment.

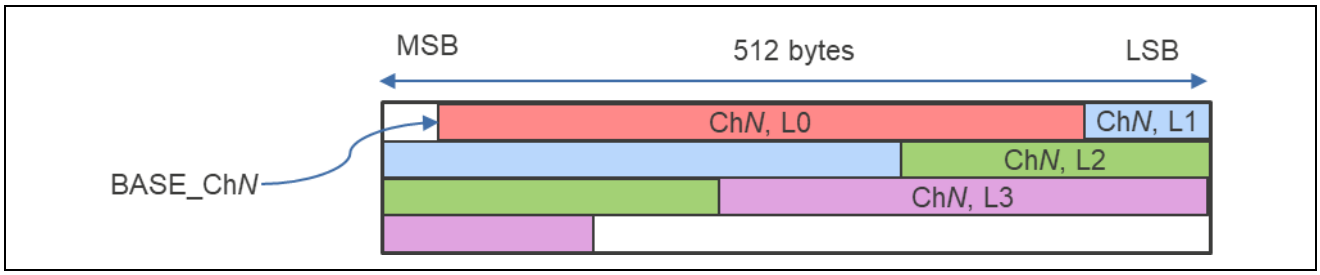

Figure U33.5 Planar type

Planar type for DMAI is selected by specifying the DMAIS_MODE bit of DMAIS register as 0. Note that planar type cannot be selected for DMAO.

(b) Planar fast type

When FM is transferred by planar fast type, multiple channels (32ch *16pix) can be read from SPMC0 simultaneously, so that the data to be provided to the CNV module is transmitted earlier than by planar type. Planar fast type can be selected for the input data by specifying the DMAIS_MODE bit of DMAIS register as 1 and the DMAOS_PLANAR bit of DMAOS register as 1 for the output data, respectively.

To enable planar fast type, the BASE_ChN (the start address of channel N) must be 1 pixel aligned (no magnification) or 16byte aligned (magnification used). The line stride must be 16 pixels aligned. Assuming that one channel's size is M byte, BASE_ChN, is calculated as follows.

8bit: BASE_ChN = BASE_Ch0 + (16 * Skip_factor + FLOOR(M,512)) * ChN
Skip_factor is an odd number from 1 to 33. If the channel size is M byte,
Skip_factor = 2 * (FLOOR ((M - FLOOR(M,512) + 15) / 32,1)) + 1,
If all channels's size is M byte, the channel stride is a constant value.

16bit: BASE_ChN = BASE_Ch0 + (32 * Skip_factor + FLOOR(M,512)) * ChN
Skip_factor is an odd number from 1 to 17. If the channel size is M byte,
Skip_factor = 2 * (FLOOR ((M - FLOOR(M,512) + 31) / 64,1)) + 1,
If all channels' size is M byte, the channel stride is a constant value.

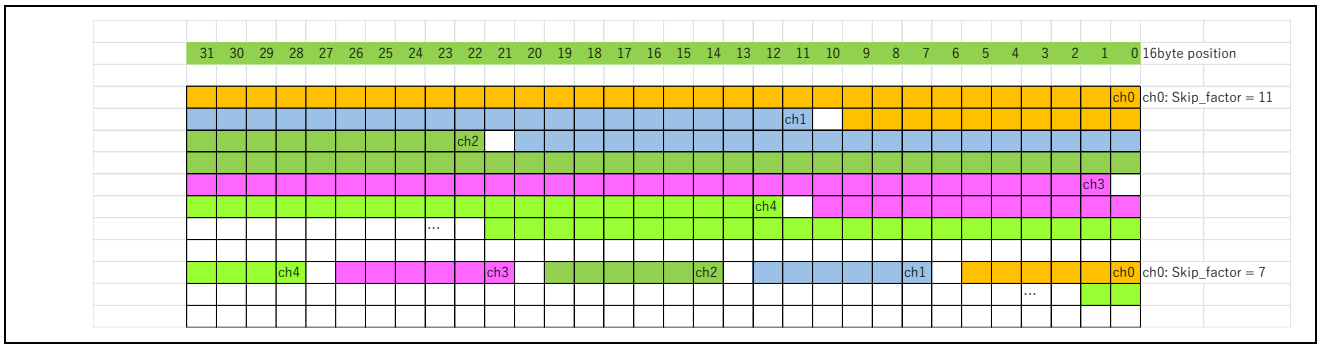

Figure U33.6 Placement of each channel of planar fast type in SPMC0

(2) Packed format (FM)

In packed format, 32 channels' data with 32 channels/1pixels (8bpp) or 16 channels' data with 16 channels/1 pixel (16bpp) is packed and stored in SPMC0. Since multiple channels (32 channels or 16 channels) can be read from SPMC0 at the same time, data can be supplied to the CNV module at an earlier time point than in the planar type. There are four types of packed formats (a) to (d).

(a) Packed s8/u8 type

32 channels/1 pixel data is stored in raster scan order. 32 channels*16 pixels*8bpp of 512byte alignment is the element unit. The horizontal stride is DMAxST(stride) and the vertical size is DMAxLY. The horizontal stride DMAxST must be specified as multiple of 16 pixels. If the channel number to be accessed is C (C up to 32 channels. In case of larger number of channels, channels get divided in different groups of up to 32 channel and are separately stored.), the horizontal position is X, and the vertical position is Y, then the Offset from the base address in SPMC0 is
Offset =(Y* DMAxST + X) *32+C
The above is independent of kernel size, and all have the same offset. Figure U33.7 shows an example with DMAxST=48.

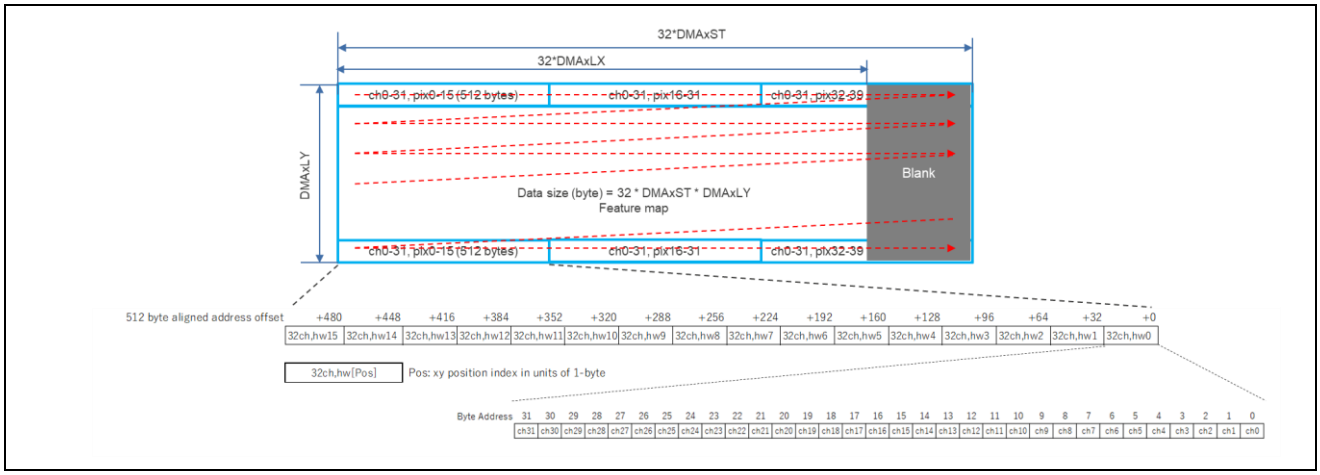

Figure U33.7 Packed s8/u8 type

(b) Packed s16 type

16 channels/1 pixels data is stored in raster scan order. 16 channels*16 pixels*16bpp of 512byte alignment is the element unit. The horizontal stride is DMAxST(stride) and the vertical size is DMAxLY. The horizontal stride DMAxST must be specified as multiple of 16 pixels. If the channel number to be accessed is C (C up to 16 channels. In case of larger number of channels, channels get divided in different groups of up to 16 channel and are separately stored.), the horizontal position is X and the vertical position is Y, the Offset from the base address in SPMC0 is
Offset = (Y * DMAxST + X) * 16 * 2 + C * 2
The above is independent of kernel size, and all have the same offset.
Figure U33.8 shows an example with DMAxST=48.

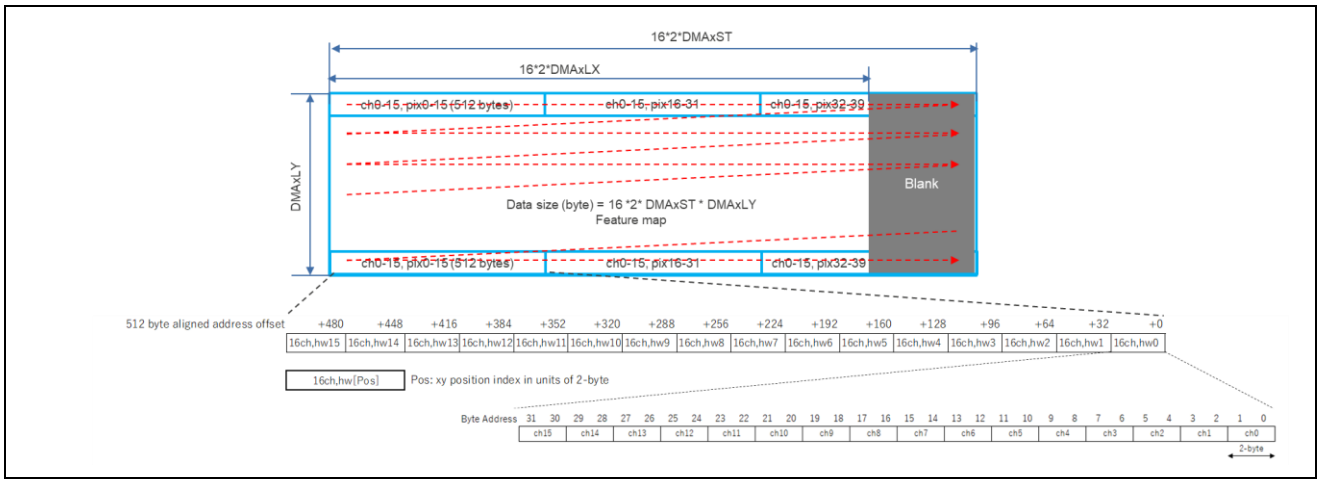

Figure U33.8 Packed s16 type

(c) Packed m16 type

Data for 32 channels is stored in raster scan order. 32 channels*8 pixels*16bpp of 512byte align is the element unit. The horizontal stride is DMAxST(stride) and the vertical size is DMAxLY. The horizontal stride DMAxST must be specified as multiple of 8 pixels If the channel number to be accessed is C(C up to 32 channels. In case of larger number of channels, channels get divided in different groups of up to 32 channel and are separately stored.), the horizontal position is X and the vertical position is Y, the Offset from the base address in SPMC1 memory is
Offset = (Y * DMAxST + X) * 32 * 2 +C*2
The above is independent of kernel size, and all have the same offset. Figure U33.9 shows an example with DMAxST=24.

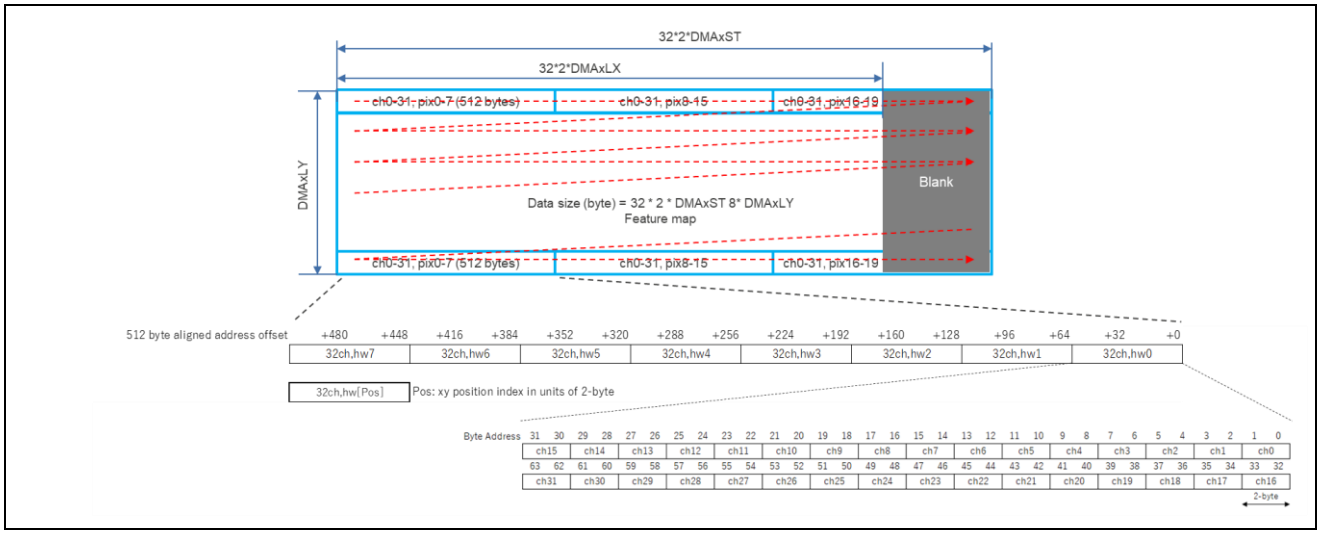

Figure U33.9 Packed m16 type

(d) Packed m32 type

Data for 32 channels is stored in raster scan order. 32 channels*4 pixels*32bpp of 512byte align is the element unit. The horizontal stride is DMAxST(stride) and the vertical size is DMAxLY. The horizontal stride DMAxST must be specified as multiple of 4 pixels. If the channel number to be accessed is C (C up to 32 channels. In case of larger number of channels, channels get divided in different groups of up to 32 channel and are separately stored.), the horizontal position is X and the vertical position is Y, the Offset from the base address in SPMC1 is

Offset = (Y * DMAxST + X) * 32 * 4 + C * 4

The above is independent of kernel size, and all have the same offset. Figure U33.10 shows an example with DMAxST=12.

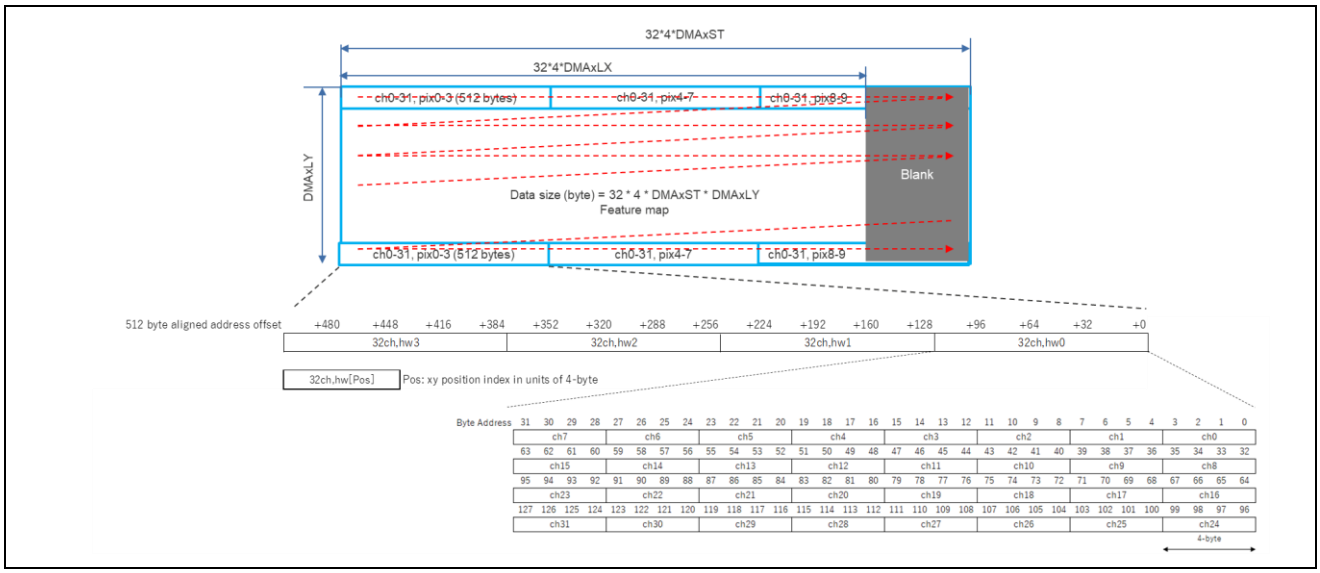

Figure U33.10 Packed m32 type

(3) Packed format (weight)

DMAI uploads weights from SPMC0 and transfers them to the CNV module. The weight formats corresponding to each kernel mode and data formats are shown in (a) to (f). Please note, weight area size must be set in multiple of 512byte.

(a) 16*1x1

Weight area size is 8KB (s8) or 4KB (s16) in 16*1x1 kernel mode. The data order of input channels within 32byte is LSB first (Little Endian).Weight coefficients of unused channels must be filled with 0 data.

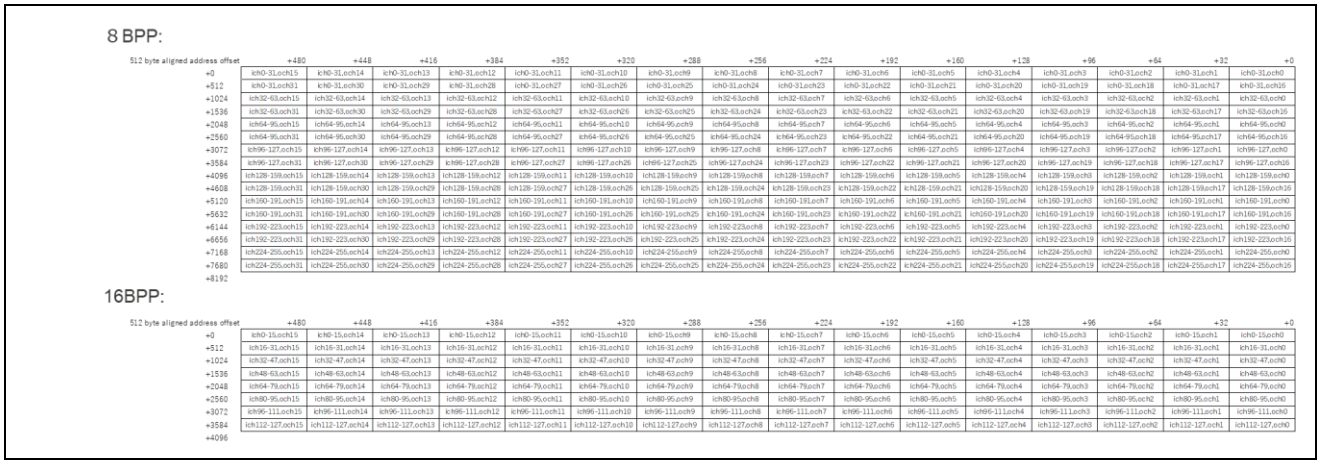

Figure U33.11 Weight 16*1x1

(b) 8*1x1

Weight area size is 4KB (s8) or 2KB (s16) in 8*1x1 kernel mode. The data order of input channels within 32byte is LSB first (Little Endian).Weight coefficients of unused channels must be filled with 0 data.

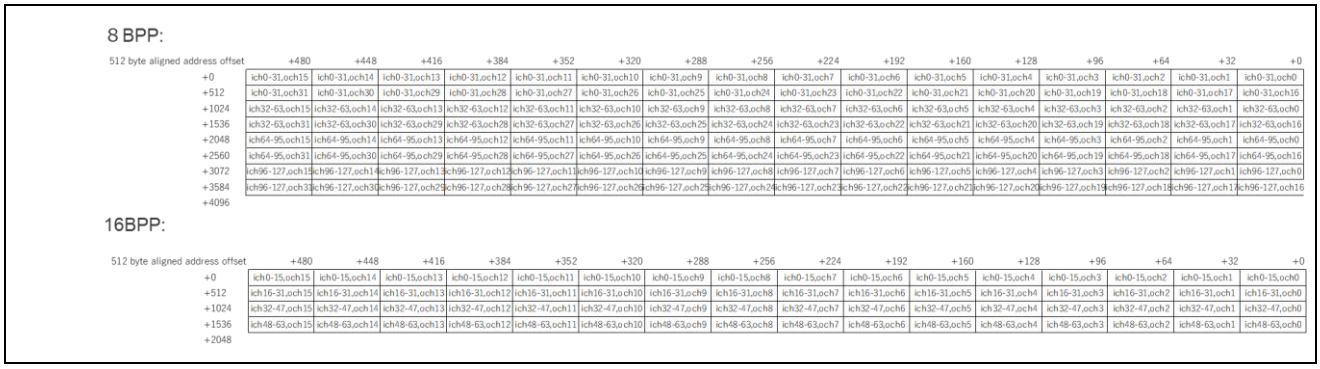

Figure U33.12 Weight 8*1x1

(c) 4*1x1

Weight area size is 2KB (s8) or 1KB (s16) in 4*1x1 kernel mode. The data order of input channels within 32byte is LSB first. Weight coefficients of unused channels must be filled with 0 data.

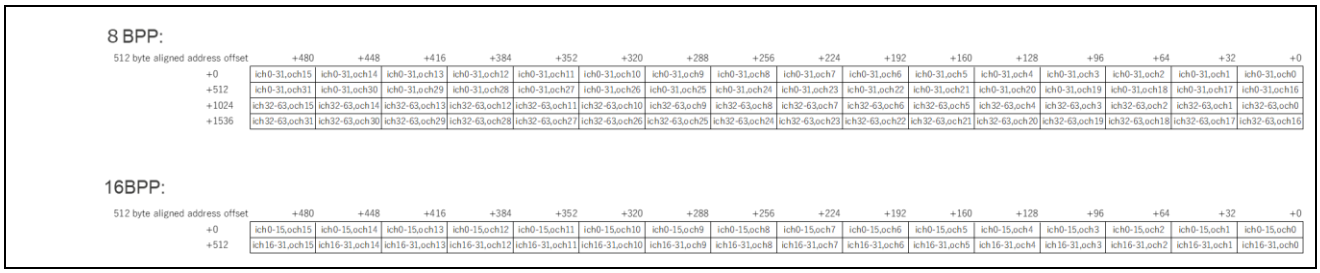

Figure U33.13 Weight 4*1x1

(d) 2*3x3

Weight area size is 9KB (s8) or 4.5KB (s16) in 2*3x3 kernel mode, weights are stored in raster order. The data order of input channels within 32byte is LSB first. Weight coefficients of unused channels must be filled with 0 data.

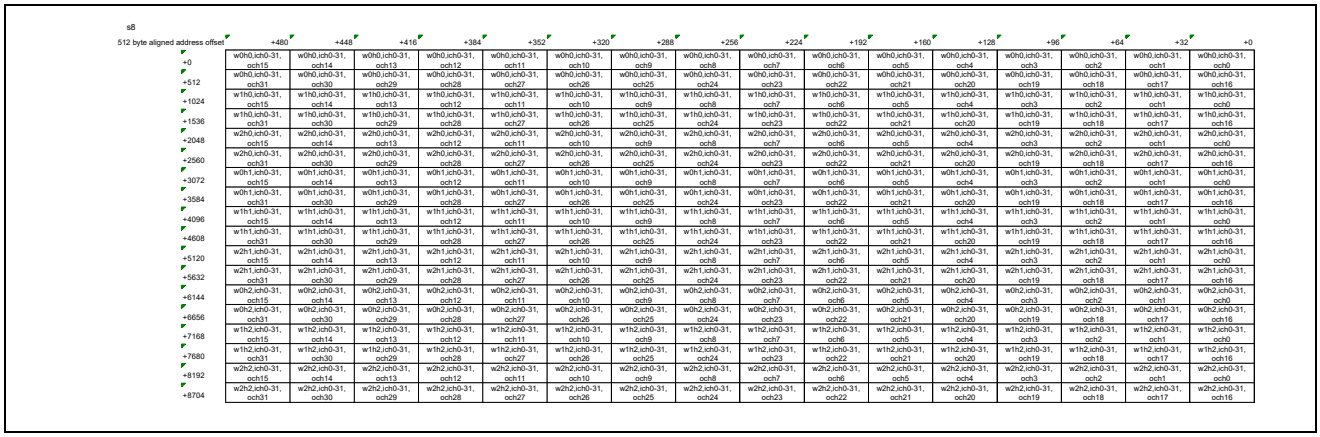

Figure U33.14 Weight 2*3x3 (s8)

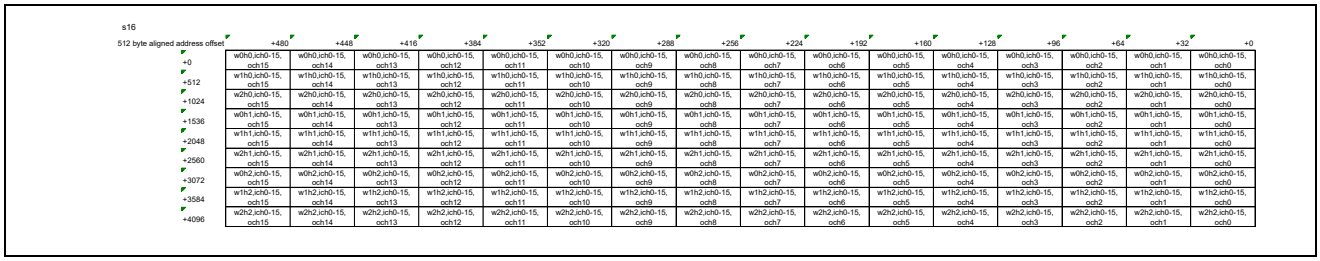

Figure U33.15 Weight 2*3x3 (s16)

(e) 1*5x5

Weight area size is 6.5KB (s8) or 3.5KB (s16) in 1*5x5 kernel mode, weights are stored in raster order. The loop structure within 32byte is like other Kernel modes, with input channels using inner loop followed by output channels and kernel elements. The data order of och within 32byte and ich within 8byte are both LSB first. Weight coefficients of unused channels must be filled with 0 data.

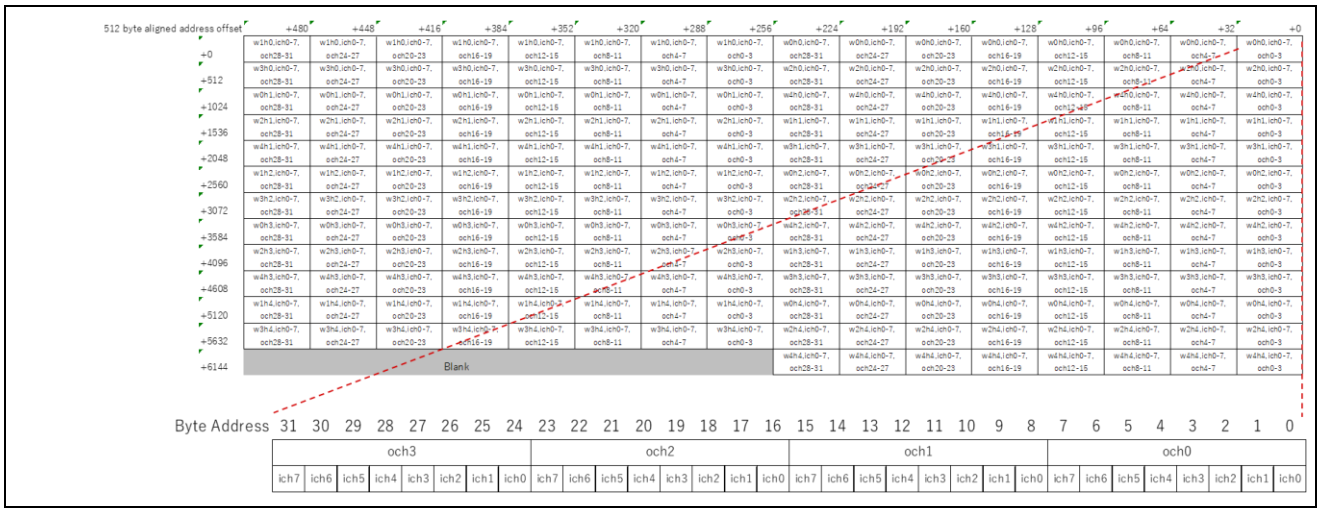

Figure U33.16 Weight 1*5x5 (s16)

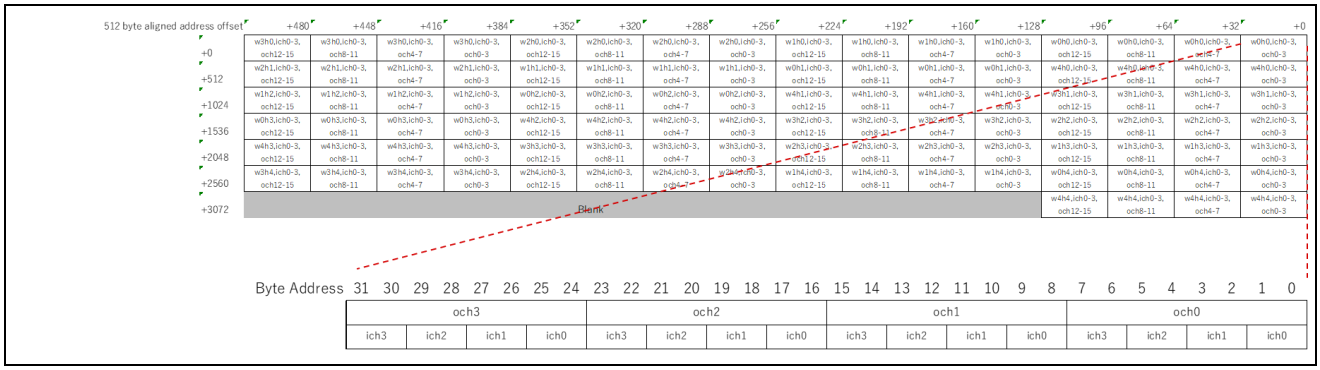

Figure U33.17 Weight 1*5x5 (s8)

(f) Depthwise

Weight area size is 0.5KB (s8 or s16) in 2*3x3 kernel depthwise mode, weights are stored in raster order. The data order of ich within 32byte is LSB first (Little Endian). Weight coefficients of unused channels must be filled with 0 data.

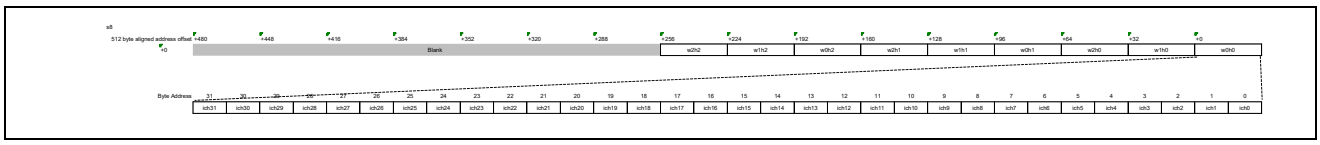

Figure U33.18 Weight depthwise (s8)

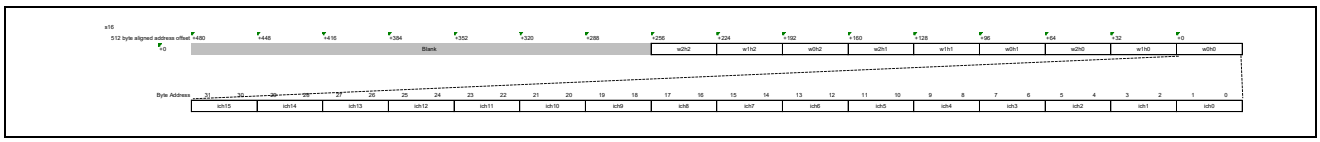

Figure U33.19 Weight depthwise (s16)

U33.3.2 DMAI module

(1) DMAI module block diagram

DMAI module loads weights from SPMC0 to transfer them into WT buffer, and loads FM from SPMC0 after finishing weight transmission to transfer them into each line memory.
While loading FM from SPMC0, each required FM element is read from Line Memory and sent to CNV module.

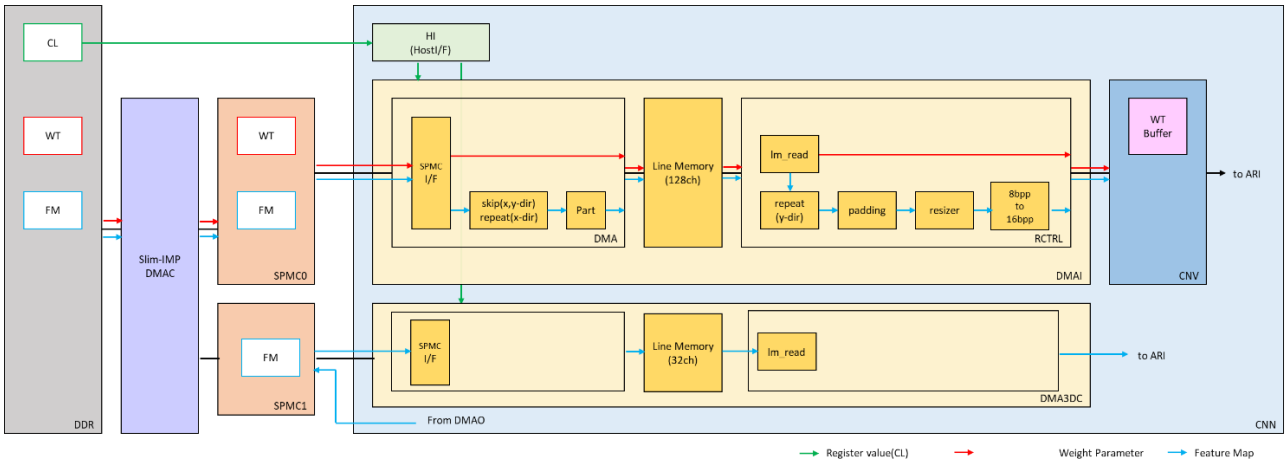

Figure U33.20 DMAI/DMA3DC block diagram

Table U33.8 Block name in DMAI block diagram

Block name	Input	Output	Function
DDR	-	CL/FM/WT	Main memory stored CL, FM and WT.
Silm-IMP DMAC	FM/WT	FM/WT	DMAC for transfer data between DDR and SPMC0/1.
SPMC0	-	FM/WT	SRAM for FM and WT 2MB. These data are transferred from DDR by Slim-IMP DMAC.
SPMC1	Temp data	Temp data	SRAM to store temp processed data for 3DC 0.5MB.
HI	CL	reg. value	Host I/F. Reads CL and decodes register values.
DMAI.DMA	FM/WT	FM/WT	Direct Memory Access to SPMC0 for input FM and WT
SPMC I/F	FM/WT	FM/WT	SPMC Interface
Skip(x,y-dir)/Repeat(x-dir)	FM	FM	Skip and Repeat function
Part	FM	FM	Partially selects channels and converts the channel id
LineMemory	FM/WT	FM/WT	LineMemory. 128ch. Internal Memory for FM and WT. It is switched for each application.
DMAI.RCTRL	FM/WT	FM/WT	Read data controller. Adjusts output image size and controls sub-modules within DMAI.
lm_read	FM/WT	FM/WT	LineMemory Reader.
Repeat(y-dir)	FM	FM	Repeat FM in Y direction.
Padding	FM	FM	Padding the specified value to the area where FM is not available at the edge of the picture.
Resizer	FM	FM	Transforms an input FM to the size specified by ARI_LEN register.
DMA3DC	FM	FM	DMAC for 3DC data. Transfers 3DC data from SPMC1 to ARI.
CNV	FM	-	Convolution engine.
WT Buffer	WT	-	Internal buffer for WT in CNV.
ARI	-	-	Arithmetic engine.

(2) DMAI kernel mode

DMAI has 1*5x5, 2*3x3, 4*1x1, 8*1x1 and 16*1x1 kernel modes. The functions that can be realized for each kernel mode are different (shown in Table U33.9). Also, the combination of each function is restricted as shown in Table U33.10. Each kernel mode is explained in section (a) to (d).

Table U33.9 DMAI supported function per each kernel mode

Function	Direction	1x1	3x3	5x5
Convolution Striding	X		✓ (1-3)	✓ (1-3)
	Y		✓ (1-3)	✓ (1-3)
Dilated Convolution	X			✓ (0-3)

Padding	✓	✓	✓	✓	✓	

✓ Supported

(a) Mode 1*5x5

The 1*5x5 mode is the base mode of this architecture. It is selected when not setting any of the special modes in the DMAIS register. In 1*5x5 kernel mode, DMAI transfers up to 8 channels of FM for 8bpp and 4 channels of FM for 16bpp to the CNV module. It is supported in common and individual setup for start address and padding. The method of setup is shown under point (6) of this sub chapter. The 1*5x5 kernel mode is performing one 5 pixels times 5 pixels

convolution per active channel. Smaller convolutions, like 2*3x3 or 4*1x1 also 8*1x1 can be mapped onto the 1*5x5 convolution by setting the weights for the not used convolution elements to zero.
In 1*5x5 kernel mode, DMAI reads WT parameter in the format shown in section U33.3.1(3)(e)(8-ich x 32-och for a total of 256 sets of 5x5 WT parameters for 8bpp, 4-ich x 16-och for a total of 64 sets of 5x5 WT parameters for 16bpp). The correspondence between the 5x5 WT parameters and pixel positions for each ich/och combination is shown in Figure U33.21. Figure U33.21 shows the correspondence between Pixel and WT for output pixel positions of x4-y4, but the same relationship applies to other output pixel positions. 1*5x5 kernel mode supports convolutional striding and dilated Convolution, where the output pixel position and the pixel position of kernel are skipped, respectively. For convolutional striding and dilated convolution, refer to point (15) and (16) of this sub chapter. To use 1*5x5, set B'0000 to DMAIS_TYPE bit.

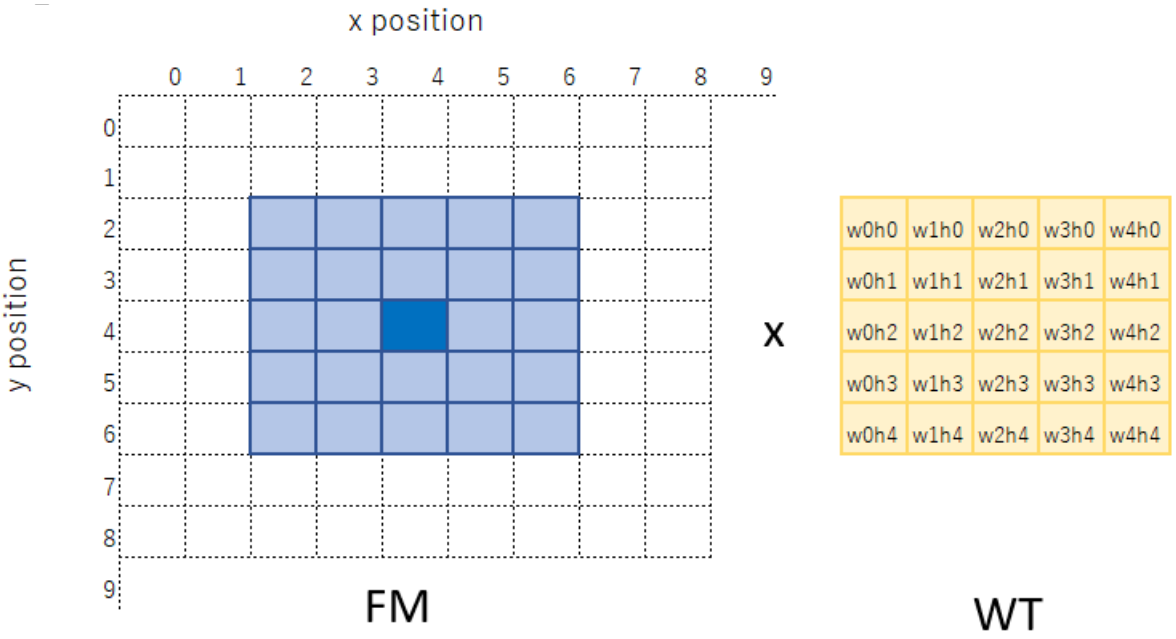

Figure U33.21 Correspondence between WT and FM for 1*5x5 kernel mode

(b) Mode 2*3x3

To speed up the convolution process when performing smaller sized convolutions, like e.g., 3x3 convolution, a 2*3x3 mode has been added. It is selected by setting the DMAIS_TYPE bit of the DMAIS register. In 2*3x3 kernel mode, DMAI transfers up to 32 channels of FM for 8bpp and 16 channels of FM for 16bpp to the CNV module. In 2*3x3 kernel mode, DMAI reads WT parameter in the format shown in section U33.3.1(3)(d) (32-ich x 32-och for a total of 1024 sets of 3x3 WT parameters for 8bpp, 16-ich x 16-och for a total of 256 sets of 3x3 WT parameters for 16bpp). The correspondence between the 3x3 WT parameters and pixel positions for each ich/och combination is shown in Figure U33.22. Figure U33.22 shows the correspondence between Pixel and WT for output pixel positions of x4-y4, but the same relationship applies to other output pixel positions. 2*3x3 kernel mode supports convolutional striding, where the output pixel positions are skipped. For convolutional striding, refer to point (15) of this sub chapter. To use 2*3x3, set B'0100 to DMAIS_TYPE bit.

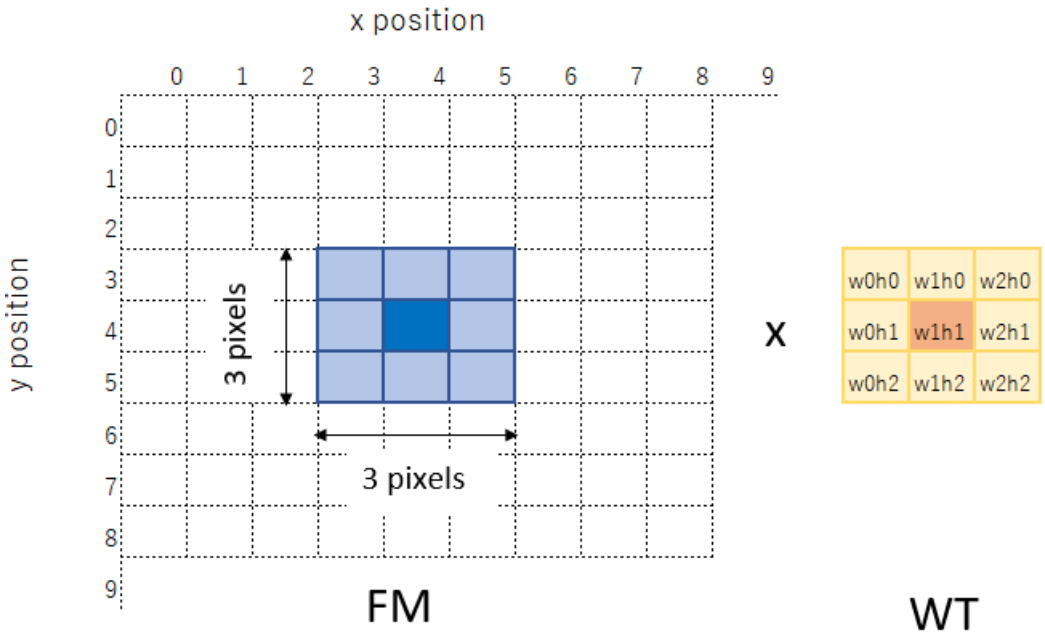

Figure U33.22 Correspondence between WT and FM for 2*3x3 kernel mode

(c) Mode 4*1x1

To speed up the convolution process for the convolution with very small 1x1 convolution matrix, a 4*1x1 mode has been added. It is selected by setting the DMAIS_TYPE bit of the DMAIS register. In 4*1x1 kernel mode, DMAI transfers up to 64 channels of FM for 8bpp and 32 channels of FM for 16bpp to the CNV module. DMAI also has 8*1x1 kernel mode, but 4*1x1 kernel mode has higher line memory tolerance. Therefore, it is better to use 4*1x1 kernel mode when the number of input channels is 64ch or less.
However, as shown under point (d) of this sub chapter, 8*1x1 kernel mode supports up to 128 input channels. Therefore, if the number of input channels is larger than 64, it is better to select 8*1x1 to reduce the number of CNN activation, and the processing performance per input channel will be higher.
In 4*1x1 kernel mode, DMAI reads WT parameter in the format shown in section U33.3.1(3)(c)(64-ich x 32-och for a total of 2048 sets of 1x1 WT parameters for 8bpp, 32-ich x 16-och for a total of 512 sets of 1x1 WT parameters for 16bpp). To use 4*1x1, set B'0010 to DMAIS_TYPE bit.

(d) Mode 8*1x1

To speed up the convolution process for the convolution with very small 1x1 convolution matrix, a 8*1x1 mode has been added. It is selected by setting the DMAIS_TYPE bit of the DMAIS register. In 8*1x1 kernel mode, DMAI transfers up to 128 channels of FM for 8bpp and 64 channels of FM for 16bpp to the CNV module.
In 8*1x1 kernel mode, DMAI reads WT parameter in the format shown in section U33.3.1(3)(b)(128-ich x 32-och for a total of 4096 sets of 1x1 WT parameters for 8bpp, 64-ich x 16-och for a total of 1024 sets of 1x1 WT parameters for 16bpp). To use 8*1x1, set B'1000 to DMAIS_TYPE bit.

(e) Mode 16*1x1

To speed up the convolution process for the convolution with very small 1x1 convolution matrix, a 16*1x1 mode has been added. It is selected by setting the DMAIS_TYPE bit of the DMAIS register. In 16*1x1 kernel mode, DMAI transfers up to 256 channels of FM for 8bpp and 128 channels of FM for 16bpp to the CNV module. As shown in Table U33.12, the horizontal size supported by 16*1x1 is half that of other kernel modes. However, MAC activation rate for 16*1x1 is twice that of 8*1x1 and four times that of 4*1x1. Therefore, when the number of input channels is larger than 128, it is more advantageous to use 16*1x1 instead of 8*1x1 in performance.
In 16*1x1 kernel mode, DMAI reads WT parameter in the format shown in section U33.3.1(3)(a) (256-ich x 32-och for a total of 8192 sets of 1x1 WT parameters for 8bpp, 128-ich x 16-och for a total of 2048 sets of 1x1 WT parameters for 16bpp). To use 16*1x1, set B'1100 to DMAIS_TYPE bit. 16*1x1 kernel supports only packed format, set 2'B10 to DMAIS_MODE to use 16*1x1 kernel.

(3) DMAI Format

DMAI can read three formats as FM. The register settings for selecting each format are as follows.

- Planar type
  - ✧ Set 0 to DMAIS_MODE
- Planar fast type
  - ✧ Set 1 to DMAIS_MODE
- Packed
  - ✧ Set 2 to DMAIS_MODE

As section U33.3.1(2)(a) and U33.3.1(2)(b) show, 1 block channel in packed format consists of 32 channels in 8bpp and 16 channels in 16bpp. Maximum number of input channels for 4*1x1 kernel mode is 64 channels (8bpp) or 32 channels (16bpp), so DMAI reads 2 block channels for 4*1x1 kernel mode. Maximum number of input channels for 8*1x1 kernel mode is 128 channels (8bpp) or 64 channels (16bpp), so DMAI reads 4 block channels for 8*1x1 kernel mode. Maximum number of input channels for 16*1x1 kernel mode is 256 channels (8bpp) or 128 channels (16bpp), so DMAI reads 8 block channels for 16*1x1 kernel mode. Refer to section (5) for how to set start address of each block channel.
Table U33.11 shows the format that each kernel supports.

Table U33.11 Supported format per kernel

Kernel	Supported format		
	Planar type	Planar fast type	Packed
1*5x5	✓	✓	✓
2*3x3	✓	✓	✓
4*1x1	✓	✓	✓
8*1x1	✓	✓	✓
16*1x1			✓

(4) Picture start address, width, height, and stride

The tile dimension is specified in pixel and rows. The size in x-direction is specified in pixel, set the pixel size in DMAILX. The size in y-direction is specified in rows, set row size in DMAILY. The allowed value for the supported tile dimension depends on the utilized magnification parameters. As result, after magnification operation has been performed, the width must not be larger than 128 pixels while the height must not be larger than 2048 rows. This results for the tile dimension depending on the used magnification parameters shown in Table U33.9 to the allowed value ranges for x and y as shown in Table U33.12 and Table U33.13.

Table U33.12 Allowed tile dimensions depending on magnification parameter setting (x direction)

(1) 8*1x1, 4*1x1, 2*3x3 and 1*5x5 case

DMAIMM	DMAIPMV	Allowed dimension x
00	any	0 < DMAILX <= 128
01	4	0 < DMAILX <= 640
01	3	0 < DMAILX <= 512
01	2	0 < DMAILX <= 384
01	1	0 < DMAILX <= 256
01	0	0 < DMAILX <= 128
10, 11	0	0 < DMAILX <= 128

10, 11	1	0 < DMAILX <= 64
10, 11	2	0 < DMAILX <= 42
10, 11	3	0 < DMAILX <= 32
10, 11	4	0 < DMAILX <= 25

(2) 16*1x1 case

DMAIMM	DMAIPMV	Allowed dimension x
00	any	0 < DMAILX <= 64
01	1	0 < DMAILX <= 128
01	0	0 < DMAILX <= 64
10, 11	0	0 < DMAILX <= 64

Table U33.13 Allowed tile dimensions depending on magnification parameter setting (y direction)

DMAIMM	DMAIRMV	Allowed dimension y
00	any	0 < DMAILY <= 2048
01	4	0 < DMAILY <= 10240
01	3	0 < DMAILY <= 8192
01	2	0 < DMAILY <= 6144
01	1	0 < DMAILY <= 4096
01	0	0 < DMAILY <= 2048
10, 11	0	0 < DMAILY <= 2048
10, 11	1	0 < DMAILY <= 1024
10, 11	2	0 < DMAILY <= 682
10, 11	3	0 < DMAILY <= 512
10, 11	4	0 < DMAILY <= 409

Start address and line stride of the FM in SPMC0 are set by DMAISA and DMAIST, respectively; DMAISA is set in byte unit and DMAIST is set in pixel unit. Packed format and Planar format are shown in section U33.3.1; DMAI can cut out any rectangle of FM stored in SPMC0. The blue rectangles in Figure U33.23 and Figure U33.24 show the FM cutout from SPMC0 in the planar case and the Packed case, respectively. The blue rectangles are the cutout image: 32byte/pix for packed (32-ch pack * 8bpp, 16-ch pack * 16bpp), 1byte/pix for planar-8bpp, and 2byte/pix for planar-16bpp, for line stride and horizontal size x32, x1, and x2, respectively, for the settings. SPMC0 is 2MB of scratchpad memory shared by FM and WT. The value set in line stride register (DMAIST) must be greater than or equal to the value in horizontal size register (DMAILX).

Figure U33.23 Partial FM read out from SPMC0 (planar)

Figure U33.24 Partial FM read out from SPMC0 (packed)

When planar type or packed is selected, DMAI can cut out FM at any pixel position. When planar fast type is selected, DMAI can cut out FM at any pixel position when Magnification is not used, but when Magnification is used, the cut-out position is restricted to 16byte align. Restriction of DMAISA is shown in Table U33.14.

Table U33.14 Restriction of DMAI start address

Combination of register value			Restriction of DMAI start address	Note
Format (DMAIS [10:9])	Magnification (*1) 0: No magnification 1: Magnification	bpp (DMAIPARAM [17:16])	DMAISA	
0 (planar type)	In any case	8bpp (0, 1)	None	1 pixel aligned (8bpp is 1byte/pixel)
	In any case	16bpp (2)	DMAISA [0] = 0	1 pixel aligned (16bpp is 2byte/pixel)
1 (planar fast type)	0	8bpp (0, 1)	None	1 pixel aligned (8bpp is 1byte/pixel)
		16bpp (2)	DMAISA [0] = 0	1 pixel aligned (16bpp is 2byte/pixel)
	1	In any case	DMAISA [3:0] = 0	16byte aligned in case that magnification is used.
2 (packed)	In any case	In any case	DMAISA [4:0] = 0	1 pixel aligned (1 pixel is corresponding to 32byte)

(*1) Magnification
0 for DMAIMM = 0 or (DMAIPMV=0 and DMAIRMV=0)
1 for DMAIMM != 0 and (DMAIPMV!=0 or DMAIRMV!=0)

Restriction of line stride (DMAIST) is shown in Table U33.15.
When planar fast type is selected, DMAIST is restricted to 16 pixels units to satisfy the condition of memory allocation described in section U33.3.1(1)(b). When packed format is selected, as explained in section U33.3.1(2), the format is 16 pixels units in the horizontal direction, and invalid data is stored in such a way that if it is not 16 pixels units, it is rounded up to 16 pixels. Therefore, line stride is restricted to 16 pixels units.

Table U33.15 Restriction of DMAI line stride

Classification of registers value	Restriction of line stride	Note
DMAIS_MODE (DMAIS [10:9])	DMAIPARAM [15:0] (DMAIST [15:0])	
0 (planar type)	None	1 pixel aligned
1 (planar fast type)	DMAIST [3:0] = 0	16 pixels aligned
2 (packed)	DMAIST [3:0] = 0	16 pixels aligned

(5) Channel offset

Channel offset specifies the difference between the start addresses of 2 neighbored input channels. It is set to the DMAICO register. DMAICO is set by pixel unit. DMAICO is effective except in the 1*5x5 DMAISA individual setup (part (6) of this sub chapter) and in Wrap-direct (part (8) of this sub chapter). DMAICO must be set to 0 when using DMAISA individual setup.

By using this channel offset, it can be made sure that each channel can work on its own data set. Since only 1 offset is used, there exists less flexibility for the start address specification of each single channel than in the individual channel setup case. Further to mention is that inactive channels are still counting for the distance calculation, so, e.g., if byte pixels are processed and channel 0 has as start address H'1_0000 and the offset is specified as H'2_0000, then channel 2 is starting at address H'5_0000, independent of whether channel 1 is active or not.
Restriction of channel offset (DMAICO) is shown in Table U33.16.

Table U33.16 Restriction of DMAI channel offset

Format (DMAIS [10:9])	Method of DMAISA setup	Restriction of DMAICO	Note
0 (planar type)	Individual setup	Set 0 to DMAICO	-
	Common setup	None	1 pixel unit
1 (planar fast type)	Common setup	Set 5H'10 to DMAICO [4:0]	16 pixels unit and bit 4 is 1
2 (packed)	Common setup	Set 4H'0 to DMAICO [3:0]	16 pixels unit

Table U33.17 shows the Start address of each channel using channel offset. The addresses in Table U33.17 are for common DMAISA setup; refer to part (6) of this sub chapter for the start addresses of each channel in individual DMAISA setup.

Table U33.17 Start address of each channel for common DMAISA setup

Format (DMAIS [10:9])	bpp (DMAFM [1])	Start Address of each channel (byte unit)
0, 1 (planar)	0 (8bpp)	DMAISA + DMAICO x ch-idx (n=0 to 127)
	1 (16bpp)	DMAISA + 2 * DMAICO x ch-idx (n=0 to 63)
2 (packed)	Any	DMAISA + 32 * DMAICO x blkch-idx (n=0 to 7)

ch-idx: Channel index for planar indicating channel index before channel conversion by part function (see part (11) of this sub chapter)
blkch-idx: Block channel index for packed

(6) Common and individual channel setup

The architecture is supporting an individual and common setup. For the common setup, always same parameter is used for all channels, and register setting can be realized at high speed. For the individual setup, each parameter which supports individual setup can be specified for each channel individually, which offers the largest flexibility, but comes with the longest setup time. This individual setup is only supported for the 1*5x5 kernel mode and planar type format. Individual setup is possible only when 1*5x5 planar type is used, and the target registers are DMAISA and PADD registers. The common DMAISA setup register is DMAISA and the individual DMAISA setup registers are DMAISA00, DMAISA01, DMAISA04, DMAISA05, DMAISA08, DMAISA09, DMAISA12 and DMAISA13. Refer to Table U33.25 for the common PADD setup register and individual PADD setup registers. If write-access occurs to the common DMAISA setup register, the same value is overwritten in all individual DMAISA registers; the same applies to the PADD register.
Since the common setup register and the individual setup registers are supposed to be used by exclusive write access, do not write both the common and individual registers during the same frame's register setup period. Also, always use the common setup register except for 1*5x5 and planar type format. If violated, operation is not ensured. The relationship between the start address and register for each channel when using the individual DMAISA setup is shown in Table U33.18. Set 0 to DMAICO in case of individual DMAISA setup.
Individual DMAISA setup registers (DMAISA00,01,04,05,08,09,12,13) have same restriction as common DMAISA setup register (planar type restriction in Table U33.14)

Table U33.18 Start address of each channel for individual DMAISA setup

Format (DMAIS [10:9])	**bpp (DMAFM [1])**	**Start Address of each channel (byte unit)**

0 (planar type)	0 (8bpp)	DMAISA00 (Ch0) DMAISA01 (Ch1) DMAISA04 (Ch2) DMAISA05 (Ch3) DMAISA08 (Ch4) DMAISA09 (Ch5) DMAISA12 (Ch6) DMAISA13 (Ch7)
	1 (16bpp)	DMAISA00 (Ch0) DMAISA04 (Ch1) DMAISA08 (Ch2) DMAISA12 (Ch3)

Ch id inside (): Indicates channel index before channel conversion by part function (see part (11) of this sub chapter)

(7) Weight loading

The register settings for the WT format in section U33.3.1(3) is shown in Table U33.19. Start address should be set to DMAWSA; start address is restricted to 512byte align, so the lower 9bit of DMAWSA should be set to 0. When loading weight in depthwise mode (DMAWS.DMAWS_TYPE=B'0001), the CLW command with N field=B'00000 must be executed before starting the transfer by setting DMAWS.DMAWS_START to 1.

Table U33.19 Format register settings (DMAWS) and WT size

Packed format (weight)		DMAWS [5:1]		Area Size (Kbyte)
Kernel mode	s8/s16	DMAWS_FM	DMAWS_TYPE[3:0]	
16*1x1	s8	0	B'1100	8
	s16	1	B'1100	4
8*1x1	s8	0	B'1000	4
	s16	1	B'1000	2
4*1x1	s8	0	B'0010	2
	s16	1	B'0010	1
2*3x3	s8	0	B'0100	9
	s16	1	B'0100	4.5
1*5x5	s8	0	B'0000	6.5
	s16	1	B'0000	3.5
Depthwise	s8	0	B'0001	0.5
	s16	1	B'0001	0.5

(8) Wrap around area

DMAI supports Wrap-around. Wrap-around is supported only for the packed type format (DMAIS_MODE=B'10). Wrap-around start and end addresses shall be 512byte aligned.
Wrap-around has two options; Wrap-ico (set by DMAIS_WRAP=1, DMAIS_WRAP_MODE=0) and Wrap-direct (set by DMAIS_WRAP=1, DMAIS_WRAP_MODE=1).
Figure U33.25 shows a conceptual diagram when Wrap-ico is selected, using 8*1x1 mode as an example. Set the start address in DMAISA, Wrap-around start address in DMAIWA_START, and Wrap-around end address in DMAIWA_END for block channel0 (ch0-31 plane). Each address of block channel 1 to 7 is calculated by adding DMAICO to each address of block channel 0. Wrap-around start address and Wrap-around end address are set in 512byte units.
Figure U33.26 shows a conceptual diagram when Wrap-direct is selected, using 8*1x1 mode as an example. When Wrap-direct is selected, the start address, Wrap-around start address, and Wrap-around end address of block channels 0 to 7 can be set individually and directly.
Table U33.20 shows the relationship between the start address, Wrap-around start address, Wrap-around end address and registers settings for each block channel for Wrap-ico and Wrap-direct, respectively.
The relationship between the offset address of FM and the access address of SPMC0 is shown below; for offset, refer to section U33.3.1(2).

- Access Address has not wrap-arounded yet (DMAISA + offset < DMAIWA_END*512)
  - SPMC0 access address: DMAISA + offset
- Access Address has already wrap-arounded (DMAISA + offset >= DMAIWA_END*512)
  - SPMC0 access address: DMAISA + offset - (DMAIWA_END - DMAIWA_START) * 512

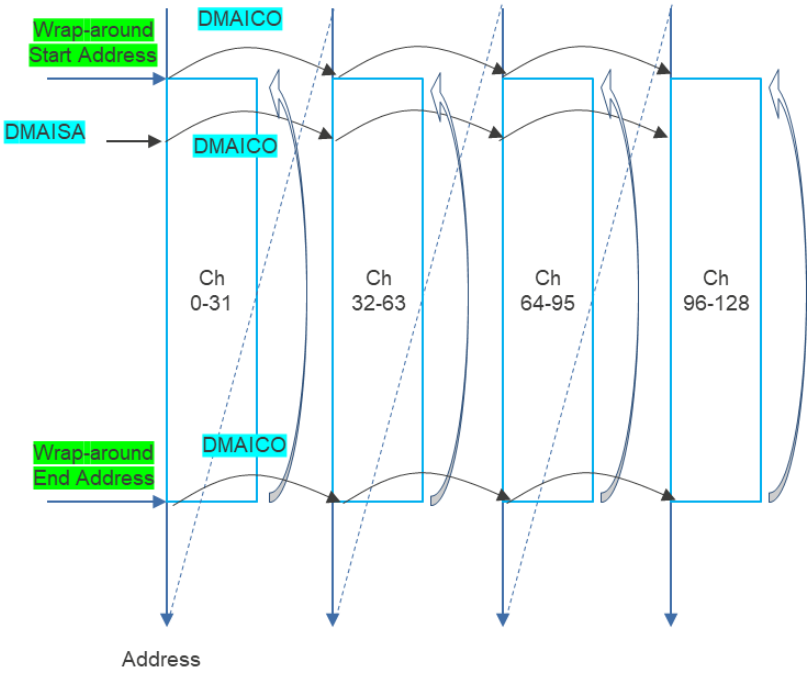

Figure U33.25 FM wrap around ico (Wrap-ico)

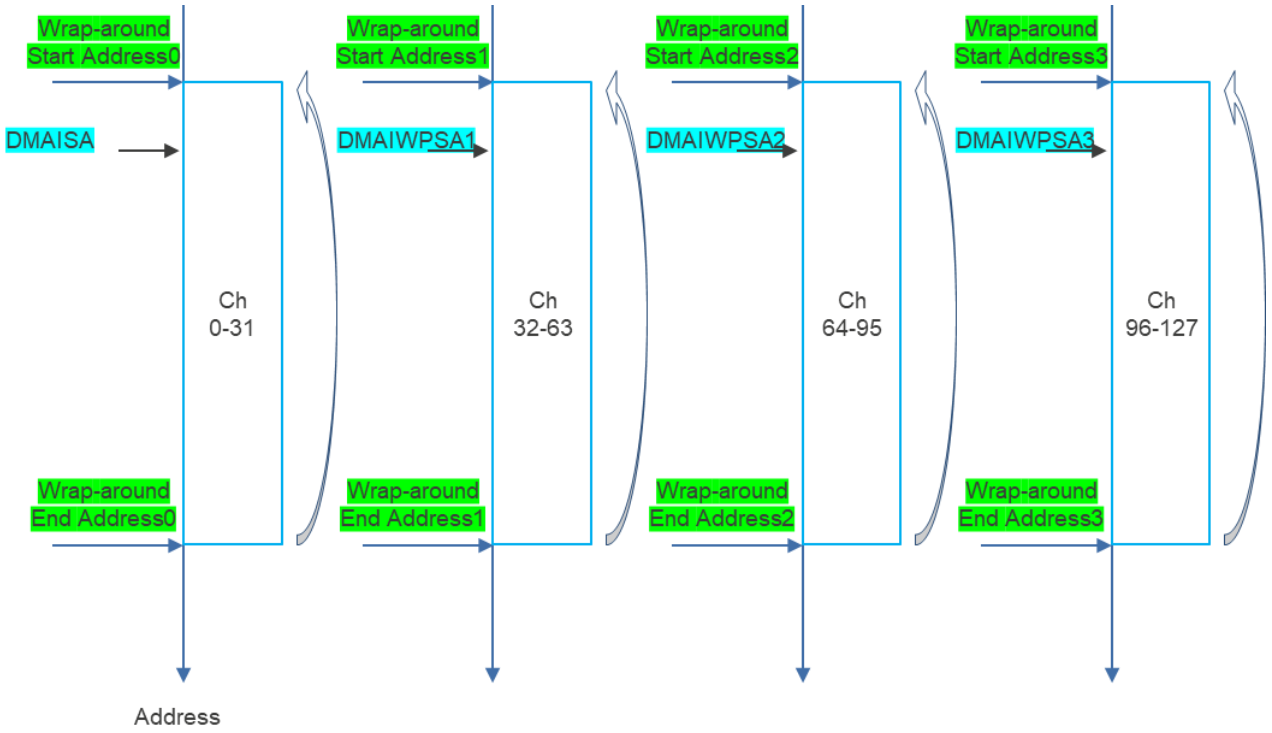

Figure U33.26 FM wrap around direct (Wrap-direct)

Table U33.20 FM Wrap-around address

Wrap mode	Block channel ID	Start address	Wrap start address	Wrap end address
Wrap-ico	0 (ch0-31)	DMAISA	DMAIWA_START * 512	DMAIWA_END * 512
	1 (ch32-63)	DMAISA + 32 * 1 * DMAICO	DMAIWA_START * 512 + 32 * 1 * DMAICO	DMAIWA_END * 512 + 32 * 1 * DMAICO
	2 (ch64-95)	DMAISA + 32 * 2 * DMAICO	DMAIWA_START * 512 + 32 * 2 * DMAICO	DMAIWA_END * 512 + 32 * 2 * DMAICO
	3 (ch96-127)	DMAISA + 32 * 3 * DMAICO	DMAIWA_START * 512 + 32 * 3 * DMAICO	DMAIWA_END * 512 + 32 * 3 * DMAICO
	4 (ch128-159)	DMAISA + 32 * 4 * DMAICO	DMAIWA_START * 512 + 32 * 4 * DMAICO	DMAIWA_END * 512 + 32 * 4 * DMAICO
	5 (ch160-191)	DMAISA + 32 * 5 * DMAICO	DMAIWA_START * 512 + 32 * 5 * DMAICO	DMAIWA_END * 512 + 32 * 5 * DMAICO
	6 (ch192-223)	DMAISA + 32 * 6 * DMAICO	DMAIWA_START * 512 + 32 * 6 * DMAICO	DMAIWA_END * 512 + 32 * 6 * DMAICO
	7 (ch224-255)	DMAISA + 32 * 7 * DMAICO	DMAWA_START * 512 + 32 * 7 * DMAICO	DMAIWA_END * 512 + 32 * 7 * DMAICO
Wrap-direct	0 (ch0-31)	DMAISA	DMAIWA_START * 512	DMAIWA_END * 512
	1 (ch32-63)	DMAIWPSA1	DMAIWPA1_START * 512	DMAIWPA1_END * 512
	2 (ch64-95)	DMAIWPSA2	DMAIWPA2_START * 512	DMAIWPA2_END * 512
	3 (ch96-127)	DMAIWPSA3	DMAIWPA3_START * 512	DMAIWPA3_END * 512
	4 (ch128-159)	DMAIWPSA4	DMAIWPA4_START * 512	DMAIWPA4_END * 512
	5 (ch160-191)	DMAIWPSA5	DMAIWPA5_START * 512	DMAIWPA5_END * 512
	6 (ch192-223)	DMAIWPSA6	DMAIWPA6_START * 512	DMAIWPA6_END * 512
	7 (ch224-255)	DMAIWPSA7	DMAIWPA7_START * 512	DMAIWPA7_END * 512

The following is a list of restrictions when using Wrap-around.

1. Start address must be set within the Wrap-around range.
   DMAWA_START * 512 <= DMAISA < DMAWA_END * 512 (for Wrap-ico and Wrap-direct)
   DMAIWPA1_START * 512 <= DMAIWPSA1 < DMAIWPA1_END * 512 (for Wrap-direct)
   DMAIWPA2_START * 512 <= DMAIWPSA2 < DMAIWPA2_END * 512 (for Wrap-direct)
   DMAIWPA3_START * 512 <= DMAIWPSA3 < DMAIWPA3_END * 512 (for Wrap-direct)
   DMAIWPA4_START * 512 <= DMAIWPSA4 < DMAIWPA4_END * 512 (for Wrap-direct)
   DMAIWPA5_START * 512 <= DMAIWPSA5 < DMAIWPA5_END * 512 (for Wrap-direct)
   DMAIWPA6_START * 512 <= DMAIWPSA6 < DMAIWPA6_END * 512 (for Wrap-direct)
   DMAIWPA7_START * 512 <= DMAIWPSA7 < DMAIWPA7_END * 512 (for Wrap-direct)

2. The Wrap around area must be same size with FM size or larger
   (DMAIWA_END – DMAIWA_START) * 512 >= 32 * DMAIST * DMALY (for Wrap-ico and Wrap-direct)
   (DMAIWPA1_END – DMAIWPA1_START) * 512 >= 32 * DMAIST * DMAILY (for Wrap-direct)
   (DMAIWPA2_END – DMAIWPA2_START) * 512 >= 32 * DMAIST * DMAILY (for Wrap-direct)
   (DMAIWPA3_END – DMAIWPA3_START) * 512 >= 32 * DMAIST * DMAILY (for Wrap-direct)
   (DMAIWPA4_END – DMAIWPA4_START) * 512 >= 32 * DMAIST * DMAILY (for Wrap-direct)
   (DMAIWPA5_END – DMAIWPA5_START) * 512 >= 32 * DMAIST * DMAILY (for Wrap-direct)
   (DMAIWPA6_END – DMAIWPA6_START) * 512 >= 32 * DMAIST * DMAILY (for Wrap-direct)
   (DMAIWPA7_END – DMAIWPA7_START) * 512 >= 32 * DMAIST * DMAILY (for Wrap-direct)

3. Wrap-direct start address registers (DMAIWPSA1 to DMAIWPSA7) have same restriction as DMAISA register (packed restriction in Table U33.14)

(9) Magnification (repeat and skip)

The magnification operation is responsible for resizing the picture dimension, allowing a resizing from 1/5 to 5 of the FM width and height. It is set over the DMAIPARAM register.
For the repeat mode, 2 filling options exist as shown in Figure U33.27, the constant filling (DMAIMM=B'10) and identity filling (DMAIMM=B'11) option. The constant filling option adds the constant value specified by the PADD_CONST_VAL register to the newly added pixel. 0-filling is also possible by setting 0 to the PADD_CONST_VAL register.
The identity filling option is repeating the last pixel value. The magnification operation is supported in x and y direction.
For skip mode, rounding up is implemented.

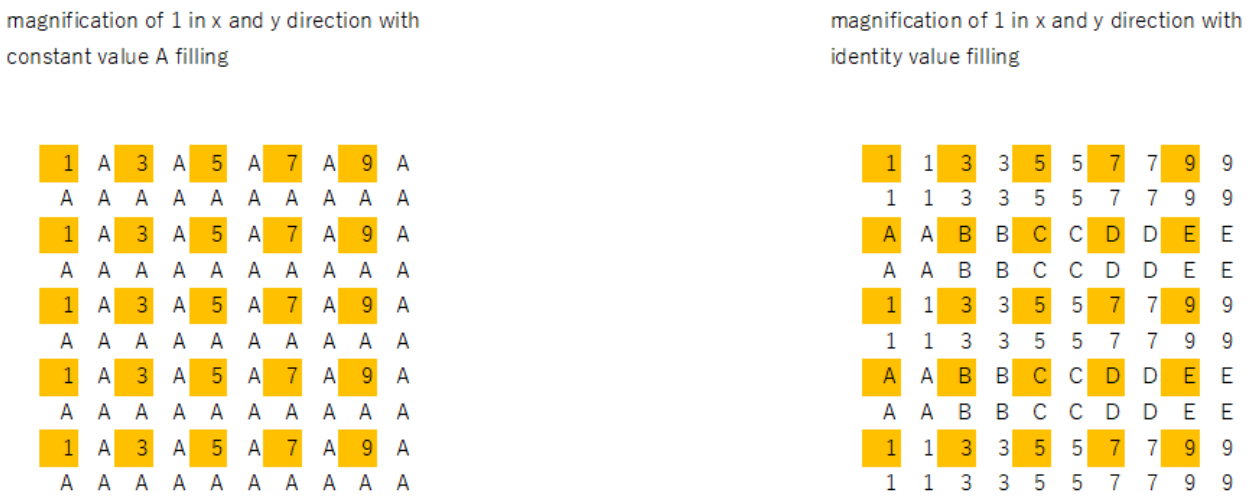

Figure U33.27 Supported magnification mode examples

(10) Channel enable

DMAI channels can be enabled/disabled by the DMAIE register in units of the number of FM channels determined for each kernel mode, and power consumption can be reduced by disabling them.
The relationship between the number of FM input channels and the bits in the DMAIE register is shown in Table U33.21.
The FM input channel shown in the Table U33.21 is corresponding to FM(ich') in Section (11) of this chapter, so it is the channel number after part function conversion.

Table U33.21 Relation between FM input channel and DMAIE register bits

DMAIS Register	ARICSR Register	The FM input channel assigned to the DMAIE register bit															
		bit 15	bit 14	bit 13	bit 12	bit 11	bit 10	bit 9	bit 8	bit 7	bit 6	bit 5	bit 4	bit 3	bit 2	bit 1	bit 0
DMAIS_TYPE[3:0]	DMAIFM bit setting																
B'0000 (1*5x5) (*1)	s8/u8	7	6	7	6	5	4	5	4	3	2	3	2	1	0	1	0
	s16	-	3	-	3	-	2	-	2	-	1	-	1	-	0	-	0

	s16	-	14~15	-	12~13	-	10~11	-	8~9	-	6~7	-	4~5	-	2~3	-	0~1
B'1000 (8*1x1)	s8/u8	120~127	112~119	104~111	96~103	88~95	80~87	72~79	64~71	56~63	48~55	40~47	32~39	24~31	16~23	8~15	0~7
	s16	-	56~63	-	48~55	-	40~47	-	32~39	-	24~31	-	16~23	-	8~15	-	0~7
B'1100 (16*1x1)	s8/u8	240~255	224~239	208~223	192~207	176~191	160~175	144~159	128~143	112~127	96~111	80~95	64~79	48~63	32~47	16~31	0~15
	s16	-	112~127	-	96~111	-	80~95	-	64~79	-	48~63	-	32~47	-	16~31	-	0~15

(*1) When DMAI is executed in 1*5x5 kernel mode, bit 0 and bit 2, bit 1 and bit 3, bit 4 and bit 6, bit 5 and bit 7, bit 8 and bit 10, bit 9 and bit 11, bit 12 and bit 14, bit 13 and bit 15 of the DMAIE register must be set to enabled/disabled as a set.

Notes:
1.It is prohibited to run CNN with the DMAIE register set to 16'h0000. At least one channel must be enabled by setting DMAIE register.
2.When the DMAI format conversion function is enabled and FM is converted from u8/s8 to s16, DMAIE should be specified according to the converted format (s16). Therefore, only even bits of DMAIE are available, and odd bits should be set to 0. For details on the DMAI format conversion function, see (12).

(11) Channel Part

The Part function converts ch-id of FM input channel in the SPMC. Ch-id of the FM input channel (indicated by FM(ich) in Figure U33.28) in the SPMC0 is converted for CNV module by the Part function. (FM input channel after Part function is indicated by FM(ich') in Figure U33.28). The conversion formula is shown in Table U33.22. The coefficients with each ich index number in WT-Format (shown in section U33.3.1(3)) correspond to FM input channels with the same ich index after ch-id conversion by Part function (indicated by FM(ich') in Figure U33.28). In the case of enabling 8bpp to 16bpp conversion, FM format is in 8bpp format and the WT format is in 16bpp format.
For packed format, channel index of FM(ich) corresponds to index number with symbol ch in the FM format in section U33.3.1(2). In case of 4*1x1, 8*1x1, 16*1x1 kernel, there are multiple block channels and the relationship between ch-id and each block channel is as follows.

- 8bpp
  - FM(ich0)-FM(ich31) : ch0-31 in blk-ch0
  - FM(ich32)- FM(ich63) : ch0-31 in blk-ch1
  - FM(ich64)- FM(ich95) : ch0-31 in blk-ch2
  - FM(ich96)- FM(ich127) : ch0-31 in blk-ch3
  - FM(ich128)- FM(ich155) : ch0-31 in blk-ch4
  - FM(ich160)- FM(ich191) : ch0-31 in blk-ch5
  - FM(ich192)- FM(ich223) : ch0-31 in blk-ch6
  - FM(ich224)- FM(ich255) : ch0-31 in blk-ch7
- 16bpp
  - FM(ich0)- FM(ich15) : ch0-15 in blk-ch0
  - FM(ich16)- FM(ich31) : ch0-15 in blk-ch1
  - FM(ich32)- FM(ich47) : ch0-15 in blk-ch2
  - FM(ich48)- FM(ich63) : ch0-15 in blk-ch3

- FM(ich64)- FM(ich79) : ch0-15 in blk-ch4
- FM(ich80)- FM(ich95) : ch0-15 in blk-ch5
- FM(ich96)- FM(ich111) : ch0-15 in blk-ch6
- FM(ich112)- FM(ich127) : ch0-15 in blk-ch7

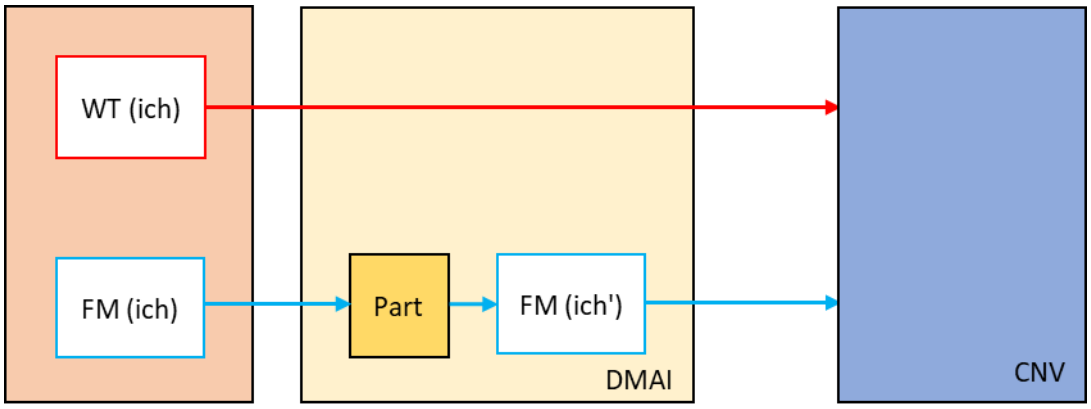

Figure U33.28 Part function

Table U33.22 Part function ch-id conversion formula

Kernel mode	Input bpp (DMAIFM [1])	DMAIS_ 8TO16BIT_ CONV	Output bpp	DMAIS_ PART	Pack	Planar (*2)	Conversion from ch to ich' by Part function

2*3x3	16bpp (1)	0	16bpp	5	✓		ich'{n} = ich{n+4} (n= 0 to 3)
2*3x3	8bpp (0)	0	8bpp	6	✓		ich'{n} = ich{n+16} (n= 0 to 7)
2*3x3	16bpp (1)	0	16bpp	6	✓		ich'{n} = ich{n+8} (n= 0 to 3)
2*3x3	8bpp (0)	0	8bpp	7	✓		ich'{n} = ich{n+24} (n= 0 to 7)
2*3x3	16bpp (1)	0	16bpp	7	✓		ich'{n} = ich{n+12} (n= 0 to 3)
4*1x1	8bpp (0)	0	8bpp	0	✓	✓	ich'{n} = ich{n} (n= 0 to 63)
4*1x1	16bpp (1)	0	16bpp	0	✓	✓	ich'{n} = ich{n} (n= 0 to 31)
4*1x1	8bpp (0)	1	16bpp	2	✓	✓	ich'{n} = ich{n} (n= 0 to 31)
8*1x1	8bpp (0)	0	8bpp	0	✓	✓	ich'{n} = ich{n} (n= 0 to 127)
8*1x1	16bpp (1)	0	16bpp	0	✓	✓	ich'{n} = ich{n} (n= 0 to 63)
8*1x1	8bpp (0)	1	16bpp	2	✓	✓	ich'{n} = ich{n} (n= 0 to 63)
16*1x1	8bpp (0)	0	8bpp	0	✓		ich'{n} = ich{n} (n= 0 to 255)
16*1x1	16bpp (1)	0	16bpp	0	✓		ich'{n} = ich{n} (n= 0 to 127)

(*1) Set 0 in WT coefficient of missing ich.
Ex: In case of 2x3x3 && DMIAS_PART=2 && DMAIFM [1] && DMAIS_8TO16BIT_CONV=0, odd ich (ich1, ich3, ich5, ich7, ... ich31) is unused, therefore, set 0 in the WT coefficient of those ich
(*2) Planar here indicates planar type or planar fast type

(12) DMAI Format conversion

CNV 16bit convolution can be performed by converting the u8/s8 FM to s16 FM. If user want to do this operation, please set DMAIS. DMAIS_8TO16BIT_CONV as shown in Table U33.23.

Table U33.23 Register setting for DMAI format conversion

Format conversion (FM format to ARI format)	DMAIPARAM.DMAIFM	DMAIS. DMAIS_8TO16BIT_CONV	ARICSR.DMAIFM
s8 to s16	B00	B1	B10
u8 to s16	B01	B1	B10
s16 to s16(NOT convert)	B10	B0	B10

Setting DMAIS.DMAIS_8TO16BIT_CONV to 1'b1 changes the format of PADD_CONST_VAL by changing DMAIPARAM.DMAIFM as follows.

In case of DMAIPARAM.DMAIFM=2'b00, PADD_CONST_VAL is treated as signed 8bit, and the sign is extended to treat it as 16bit data. On the other hand, DMAIPARAM.DMAIFM=2'b01, PADD_CONST_VAL is treated as unsigned 8bit and zero is extended to treat it as 16bit data.

(13) Offset address

Offset addresses to FM and weight parameter start addresses can be set using the DMAIOA and DMAWOA registers.

To quickly change between input data sets of consecutively processed input channels of the same layer with the same dimensions, by specifying an offset address, the next start address is calculated automatically by adding this offset address to the current start address, which is afterwards replaced by the newly calculated start address.
When writing to the DMAIOA register, both DMAISA and DMAISAxx are updated. When writing to the DMAWOA register, DMAWSA is updated. The DMAIOA and DMAWOA registers are write-only registers, and updates by these registers can be obtained by reading the corresponding starting address registers.

For example, if 0x80000 is set to DMAISA and then 0x1000 is written to DMAIOA, DMAISA becomes 0x81000.

(14) Padding

The padding parameters define an extra area around the loaded tile. Supported padding function is shown in Table U33.24.

If choosing common setup, the same value is used for all input channels defined by the PADDN, PADDS, PADDW and PADDE bits of the PADD_STRIDE_STARTPOS register, while if choosing individual setup, each channel can be setup with a different value using the PADDxxN, PADDxxS, PADDxxW and PADDxxE bits of the PADDxx_yy registers.

There exist 2 different padding modes, called the constant padding and identity padding as shown in Figure U33.29.

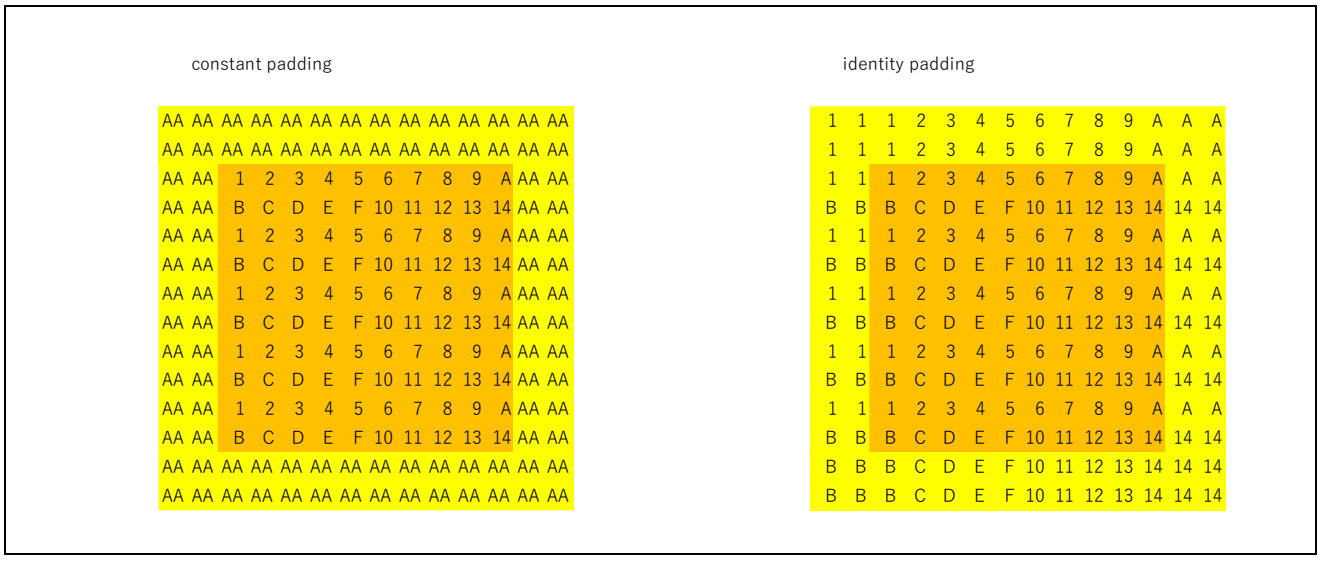

Figure U33.29 Supported padding mode examples

Figure U33.29 is showing an example padding of 2 pixels in each direction. On left side, the constant padding is shown, which is adding constant value set in the PADD_CONST_VAL register for the padded pixels. 0-padding is possible by setting PADD_CONST_VAL register to 0. On the right side, the identity padding is shown, which is duplicating the nearest corner pixel for each padded pixel.

The padding on the left is called west padding, the right is east padding, the top is named north padding, and the below is south padding. The number of Padding pixels for each padding is set by the registers shown in Table U33.25.

Table U33.24 Supported padding function

Padding Mode	Direction		The number of pixels		
			Kernel size		
			1x1	3x3	5x5
Constant	X(Hrizontal)	West	Not supported	0 to 2	0to 16

		East	Not supported	0 to 2	0to 16
	Y(Vertical)	North	Not supported	0 to 2	0 to 7
		South	Not supported	0 to 2	0 to 7
Identity	X(Hrizontal)	West	Not supported	0 to 2	0to 16
		East	Not supported	0 to 2	0to 16
	Y(Vertical)	North	Not supported	0 to 2	0 to 7
		South	Not supported	0 to 2	0 to 7

Table U33.25 Register for padding setting

Common setup	North	PADD_STRIDE_STARTPOS.PADDN
	South	PADD_STRIDE_STARTPOS.PADDS
	West	PADD_STRIDE_STARTPOS.PADDW
	East	PADD_STRIDE_STARTPOS.PADDE
Individual setup (Only usable for planar type and 1*5x5 kernel mode)	North	PADD00_01.PADD00N PADD00_01.PADD01N PADD04_05.PADD04N PADD04_05.PADD05N PADD08_09.PADD08N PADD08_09.PADD09N PADD12_13.PADD12N PADD12_13.PADD13N
	South	PADD00_01.PADD00S PADD00_01.PADD01S PADD04_05.PADD04S PADD04_05.PADD05S PADD08_09.PADD08S PADD08_09.PADD09S PADD12_13.PADD12S PADD12_13.PADD13S
	West	PADD00_01.PADD00W PADD00_01.PADD01W PADD04_05.PADD04W PADD04_05.PADD05W PADD08_09.PADD08W PADD08_09.PADD09W PADD12_13.PADD12W PADD12_13.PADD13W
	East	PADD00_01.PADD00E PADD00_01.PADD01E PADD04_05.PADD04E PADD04_05.PADD05E PADD08_09.PADD08E PADD08_09.PADD09E PADD12_13.PADD12E PADD12_13.PADD13E

(15) Convolutional striding

The convolutional striding defines the pixel movement steps in x and y direction of the convolution operation. If the convolutional striding parameter is set in x and y direction to 1, e.g., which is the default value, for every pixel a convolution operation is calculated.

By increasing the parameter in x/y direction, convolution operations for pixels can be skipped. If the convolutional striding parameter is set in x and y direction to 2, e.g., every other column/row is processed. Allowed values for the convolutional striding parameter are 1 till 3 for x and y direction. Convolutional striding is not supported at the same time with dilated convolution or magnification.Supported convolutional striding function is shown in Table U33.26.

The same value is used for all input channels defined by STRX bits for x-direction and STRY bits for y-direction of the PADD_STRIDE_STARTPOS register. The register setting is shown in Table U33.27.

Table U33.26 Convolutional striding function

Direction	Convolutional striding parameter		
	Kernel size		
	1x1	3x3	5x5
X (Horizontal)	1	1 to 3	1 to 3
Y (Vertical)	1	1 to 3	1 to 3

Table U33.27 Register for convolutional stride setting

Direction	Register Name
X	PADD_STRIDE_STARTPOS.STRX
Y	PADD_STRIDE_STARTPOS.STRY

(16) Dilated convolution

The dilated convolution parameter DIL_CONV is defining the number of skipped pixels in x direction between 2 taken pixels for the calculation of a convolution matrix.

If the dilated convolution setting in x direction is 1, e.g., then for a 5x5 matrix which needs 5 pixels in x direction, instead of the pixels 2,3,4,5,6 (Figure U33.30 (1)) the pixels 0,2,4,6,8 are taken when the center of convolution matrix is 4. (Figure U33.30 (2))

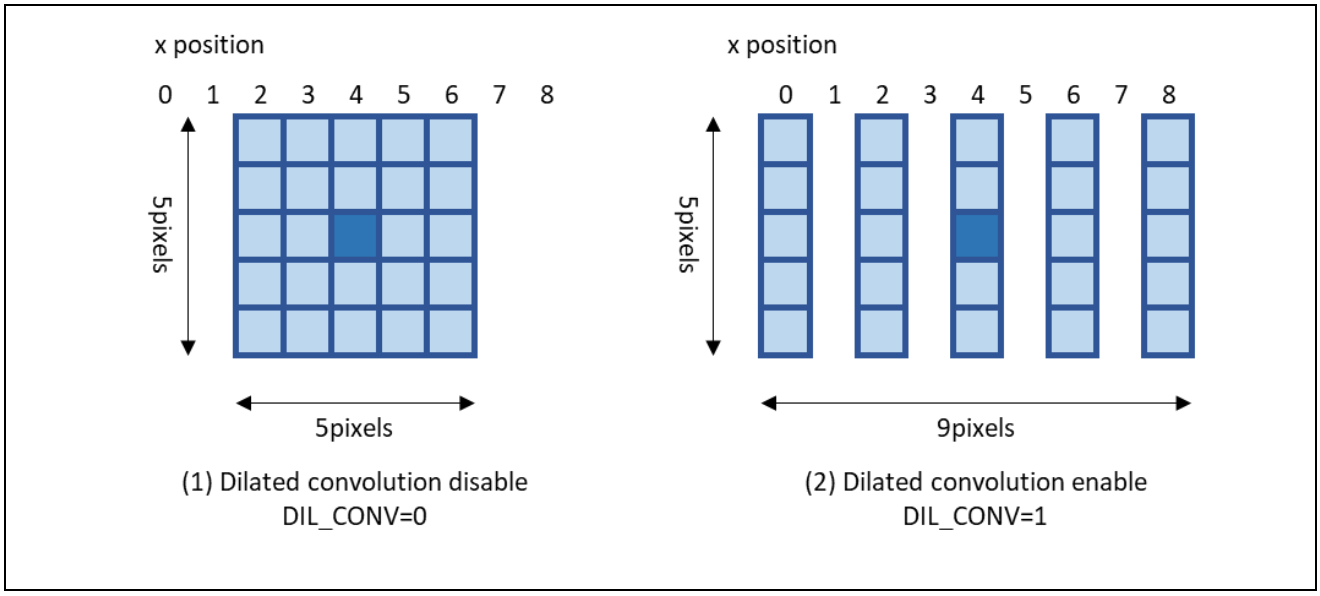

Figure U33.30 Dilated convolution setting examples

Allowed values for the dilated convolution parameter are 0 to 3 for x direction. A dilated convolution setting for y direction is not supported. Dilated convolution is not supported at the same time with convolutional striding or magnification. The supported dilated convolution function is shown in Table U33.28.

The same value is always used for all input channels defined by DIL_CONV bits of PADD_STRIDE_STARTPOS register.

Table U33.28 Supported dilated convolution

Direction	Dilated convolution parameter		
	Kernel size		
	1x1	3x3	5x5
X(Horizontal)	Not supported	Not supported	0 to 3
Y(Vertical)	Not supported	Not supported	Not supported

Table U33.29 Register for dilated convolution setting

Direction	Register Name
X	PADD_STRIDE_STARTPOS.DIL_CONV

(17) Start position

The start position defined by START_POS_X and START_POS_Y defines the setting of the start position in x and y direction, from where values are read out and given to the convolution unit.
The supported start position function values are shown in Table U33.30.
The same value defined by START_POS_X bits for x-direction and START_POS_Y bits for y-direction of the PADD_STRIDE_STARTPOS register is used for all input channels.

Please note the following restriction:
CEILING(DMAIL.DMAILY * Magnification(1, 2, 3, 4, 5, 1/2, 1/3, 1/4, 1/5)) >=
PADD_STRIDE_STARTPOS.START_POS_Y+1

Table U33.30 Supported start address

Direction	Start position		
	Kernel size		
	1x1	3x3	5x5
X(Horizontal)	Not supported	0 to 15	0 to 15
Y(Vertical)	Not supported	0 to 7	0 to 7

Table U33.31 Register for start position setting

Direction	Register Name
X	PADD_STRIDE_STARTPOS. START_POS_X
Y	PADD_STRIDE_STARTPOS. START_POS_Y

U33.3.3 DMA3DC module

(1) DMA3DC module block diagram

DMA3DC reads the intermediate convolution result data (up to 32 channels) of convolution by the CNV module and supplies it to the ARI module. Intermediate data is stored in SPMC1 (0.5Mbyte). DMA3DC block diagram is shown in Figure U33.20. The data formats of intermediate result data are the four types shown in section U33.3.1(2).

(2) Picture start address, width, height, and stride

The tile dimension is specified in pixel and rows. Pixel is the size in x-direction, set the pixel size in DMA3DCLX (up to 128 pixels). Row is the size in y-direction, set row size in DMA3DCLY (up to 1024 lines).
Start address and line stride of the FM in SPMC1 are set by DMA3DCSA and DMA3DCST, respectively; DMA3DCSA is set in byte unit and DMA3DCST is set in pixel unit. SPMC1 is 0.5MB of scratchpad memory. DMA3DCSA must be set 512byte aligned. DMA3DCST must be set in 16 pixels units for s8 and s16 format, 8 pixels units for m16 format, and 4 pixels units for m32 format. As can be understood in the light of chapter U33.3.1(2), the stride setting is aligned to 512 byte. The value set in line stride register (DMA3DCST) must be 0 or greater than or equal to the value in horizontal size register (DMA3DCLX).

(3) Offset address

Offset address to 3DC data start address can be set using the DMA3DCOA register.

To quickly change between input data sets of consecutively processed 3DC channels of the same layer with the same dimensions, by specifying an offset address, the next start address is calculated automatically by adding this offset address to the current start address, which is afterwards replaced by the newly calculated start address.
When writing to the DMA3DCOA register, DMA3DCSA is updated.

The DMA3DCOA register is write-only registers, and updates by this register can be obtained by reading the DMA3DCSA register.

For example, if 0x80000 is set to DMA3DCSA and then 0x1000 is written to DMA3DCOA, DMA3DCSA becomes 0x81000.

(4) Channel enable

DMA3DC channels can be enabled/disabled by the DMA3DCE register, and power consumption can be reduced by disabling it.

The relationship between the number of 3DC data channels and the bits in the DMA3DCE register is shown in Table U33.32.

Table U33.32 Relationship of DMA3DC channel to DMA3DCE register bit depending on selected data type

DMA3DCPA RAM Register DMA3DCFM bit setting	The FM input channel assigned to the DMA3DCE register bit															
	bit 15	bit 14	bit 13	bit 12	bit 11	bit 10	bit 9	bit 8	bit 7	bit 6	bit 5	bit 4	bit 3	bit 2	bit 1	bit 0
s8	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
s16	-	7	-	6	-	5	-	4	-	3	-	2	-	1	-	0
m16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
m32	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

DMA3DCPA RAM Register DMA3DCFM bit setting	The FM input channel assigned to the DMA3DCE register bit															
	bit 31	bit 30	bit 29	bit 28	bit 27	bit 26	bit 25	bit 24	bit 23	bit 22	bit 21	bit 20	bit 19	bit 18	bit 17	bit 16
s8	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
s16	-	15	-	14	-	13	-	12	-	11	-	10	-	9	-	8
m16	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
m32	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

When DMA3DC is not used (DMA3DCS is not set), the DMA3DCE register must be set to 32'h0000_0000.
When DMA3DC is used, at least one bit from bit0 to bit7 of the DMA3DCE register must be set.
If a bit in the ARIE register is set to 0, the corresponding bit in the DMA3DCE register must also be set to 0 (exception: ELTWISE MULT 16bit).

(5) Value shift

A further operation on the 3DC data is the data value shifter which is supporting a shift of values [0..31], support of 32bit (8bpp, m16, m32) and 41bit (16bpp) for shifted output value.

Either each SFTCxx register can be defined with a different value or, when all values are same, the SFTC address can be used to write the same value to all SFTCxx registers.

Here is to mention that an overflow check is not performed by hardware, so the user is responsible for any data loss occurring during 3DC data shift.

(6) 3DC input usage

The 3DC data for 3DC addition and Eltwise Mult processing can be specified by the register ARICSR.3DC_INPUT_USAGE. The setting for ARICSR.3DC_INPUT_USAGE depends on the value of register ARICSR. MIXED_MODE and ARICSR. MIXED_MODE2.

When the value of ARICSR. MIXED_MODE is 0 and ARICSR. MIXED_MODE2 is 0, for 32 channels addition, user can specify 32 channels input with 3DC format 8bpp (s8), 16bpp (m16), 32bpp (m32). While for 16 channels even addition, user can specify 16 channels input with 3DC format 16bpp (s16) or specify the first/last 16 channels input with 3DC format 16bpp (m16), 32bpp (m32).

When the value of ARICSR. MIXED_MODE is 0 and ARICSR. MIXED_MODE2 is 1, user can specify 32 channels input with 3DC format 16bpp (m16) for 32 channels Eltwise Mult processing. While for 16 channels even Eltwise Mult processing, user can specify the first/last 16 channels input with 3DC format 16bpp(m16).

For other combinations of ARICSR. MIXED_MODE and ARICSR. MIXED_MODE2, user should use the default value ARICSR.3DC_INPUT_USAGE is 0 to specify 32 channels input with 3DC format 8bpp (s8), 16bpp (m16), 32bpp (m32) for 32 channels addition.

U33.3.4 CNV module

(1) 8bit mode

For 8bit FM modes, signed convolution is supported. The input data for the convolution is either interpreted as 8bit signed values with a range from -128 to 127 or as 8bit unsigned values with the range from 0 to 255, while the weight data is always interpreted as 8bit signed values with a range from -128 to 127.

If you set 0x0 or 0x1 to DMAIPARAM.DMAIFM register, 8bit modes are enabled. In the same way, DMA3DC and ARI formats can be set in DMA3DCPARAM.DMA3DCFM, ARICSR.ARIFM and ARICSR.DMA3DCFM registers. (Please refer to register list for each value setting)

While always 32 output channels can be processed at the same time, the number of simultaneously processable FM input channels has the limitation as follows:
- -1*5x5 kernel => up to 8 FM input channels.
- -2*3x3 kernel => up to 32 FM input channels.
- -4*1x1 kernel => up to 64 FM input channels.
- -8*1x1 kernel => up to 128 FM input channels.
- -16*1x1 kernel => up to 256 FM input channels.

When processing 1x5x5 kernel, set 1 to the ARICSR.CONV_MODE register.

(2) 16bit mode

16bit mode can be set using the same registers as 8bit mode.

In 16bit mode, 16bit signed convolution is supported. For 16bit signed convolution, the input data for the convolution as well as the weight data is interpreted as 16bit signed values with a range from -32768 to 32767.

While always 16 output channels can be processed at the same time, the number of simultaneously processable FM input channels has the limitation as follows:
- -1*5x5 kernel => up to 4 FM input channels.
- -2*3x3 kernel => up to 16 FM input channels.
- -4*1x1 kernel => up to 32 FM input channels. s
- -8*1x1 kernel => up to 64 FM input channels.
- -16*1x1 kernel => up to 128 FM input channels.

When processing 1x5x5 kernel, set 1 to the ARICSR.CONV_MODE register.

(3) Supported FM and weight data type combination

The combinations of FM and weight data type supported by CNV are listed in Table U33.33.

Table U33.33 Supported combinations of FM and WT data type

		Data type of weight data (DMAWS.DMAWS_FM and ARICSR, ARIFM register setting (*2))	
		s8	s16
Data type of FM (DMAIPARAM, DMAIFM register setting)	u8	✓	✓ (*1)
	s8	✓	✓ (*1)
	s16	-	✓

When performing convolution with s8/u8 FM and s16 WT, set 0x1 in the DMAIS.DMAIS_8TO16BIT_CONV register to enable 8bpp to 16bpp conversion for FM. If DMAIS.DMAIS_8TO16BIT_CONV is 1, DMAIE can be set only for even bits; odd bits must be set to 0. ARICSR.DMAIFM register must be set to 0x2 (s16).

(*1) 8bpp => 16bpp format conversion is required in FM settings
(*2) When using DMAI to load weight data, the DMAWS. DMAWS_FM register must be set to the same value as the ARICSR. ARIFM register.

U33.3.5 ARI module

(1) SUMC

(a) 3DC value and BIAS addition

After all convolution results have been added up for an output channel, optionally a 3DC value and a BIAS value can be added. The 3DC value is individual channel value sent from the DMA3DC input channel. The 3DC value is usually used to input the convolution result of the previous run of the same layer when the convolution result of more than the maximum FM input channels that can be processed in one run must be added to get the result of one output channel. The BIAS value can be a common offset value specified by the BIAS register and used for all output channels, or it can be an individual offset value specified by the BIASxx_yy and BIASxx_yy_H register and used for only the specified output channel. The addition of BIAS values is enabled when the ARICSR.BIAS register is set to 1.

When ARICSR.BIAS_32bit is set to 1, a signed 32bit BIAS value can be specified with the BIASxx_yy and BIASxx_yy_H registers. When ARICSR.BIAS_32bit is set to 0, a signed 16bit BIAS value can be specified by the BIASxx_yy register.

(b) Scaler multiplier, zero-point adder and downshifter

To increase accuracy of recognition, 16bits scaler multiplier is prepared for each ARI channel before SFTM shifter. The SCALER value can be a common value specified by the SCALER_MULT_VAL register and used for all output channels, or it can be an individual value specified by the SCALER_MULTxx bits of the SCALER_MULT xx_yy register and used for only the specified output channel.

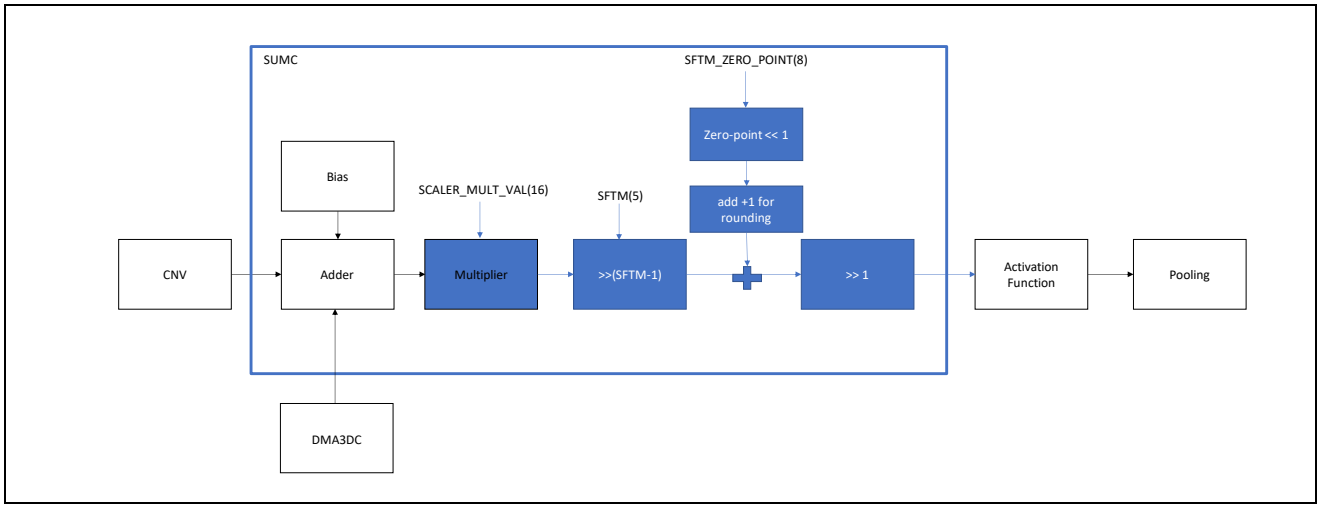

Figure U33.31 The flow of Scaler multiplier, zero-point adder and downshifter

After convolution, 3DC and BIAS addition and optional scaler multiplication, a zero-point adder defined over SFTM_ZERO_POINT register and a downshifter defined over SFTM value can be performed to transfer the intermediate value into the chosen output range.
For this downshifter, the rounding function “round to nearest, half towards +infinity” is available.

The SFTM value can be a common value specified by the SFTM register and used for all output channels, or it can be an individual value specified by the SFTMxx bits of the SFTM xx_yy register and used for only the specified output channel.

(2) Activation

Table U33.34 is showing the supported activation functions and their implementation. They can be selected by using the ACT_FUNC bits in the ARICSR register. The activation function is only available for 8bit and 16bit format setting and for m16 format setting in case, the register bit ARICSR.M16_VAL_AFTER_ACT is set to 1, in case of m32 format setting, the activation function cannot be used.

Table U33.34 Activation functions

Mode	Activation function	16bit output channels	8bit output channels
		Post processing	Post processing
0x0	No activation	-	-
0x1	RELU	-	-
0x2	BRELU	-	-
0x3	Leakage RELU	Support	Support
0x4	Sigmoid	Support	Support
0x5	ELU	Support	Support
0x6	Tanh	Support	Support
0x7	H-Swish	Support	Support
0x8	Swish	Support	Support
0x9	Mish	Support	Support
0xa	Exp	Support	Support

In the following sub chapters, each activation function is described in more detail.

(a) RELU

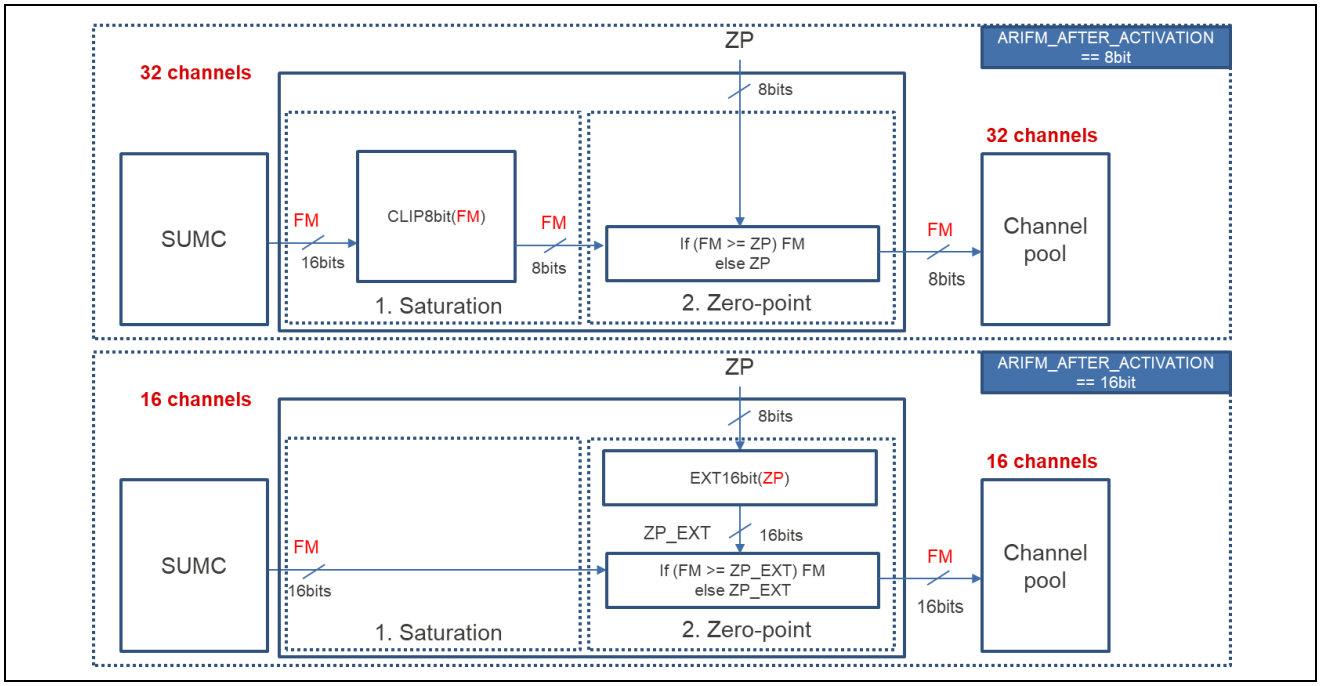

Figure U33.32 RELU activation function flow

Table U33.35 RELU activation function symbols

Symbol	Register bit	Description
FM	-	Feature Map
ARIFM_AFTER_ACTIVATION	ARICSR.ARIFM_AFTER_ACTIVATION	Output data format of Activation function.
ZP	SFTM_ZERO_POINT	Zero-point used for 8bit after SFTM function User must set zero-point to 8'h0 when ARIFM_AFTER_ACTIVATION is 16bit.
ZP_EXT	-	Zero-point after signed extension from 8bits to 16bits

CLIP8bit(FM)	-	Clipping 8bits signed for input value FM:
		CLIP8bit(FM) {
		If (FM < -128)
		{y = -128}
		else if (FM >127)
		{y = 127}
		else {y = FM}
		return y
		}

EXT16bit(ZP)	-	Signed extension from 8bit signed to 16bit signed for ZP.
		EXT16bit(ZP){
		y= (int16) ZP
		return y
		}

The rectified linear unit (RELU) activation function is suppressing all values smaller than zero-point value specified by the SFTM_ZERO_POINT register and replacing them with zero-point value while passing values greater than the zero-point value unchanged. When using 16bit mode, user must set the SFTM_ZERO_POINT register to zero.

For 8bit mode, the rectified linear unit (RELU) activation function is suppressing all values smaller than zero-point value specified by the SFTM_ZERO_POINT register and replacing them with zero-point value while the values greater than zero-point value get passed through unchanged. The input data and zero-point will be clipped to 8bit signed range by function CLIP8bit().

For 16bit mode, the rectified linear unit (RELU) activation function is suppressing all negative values and replacing them with 0 while positive values get passed through unchanged.

(b) BRELU

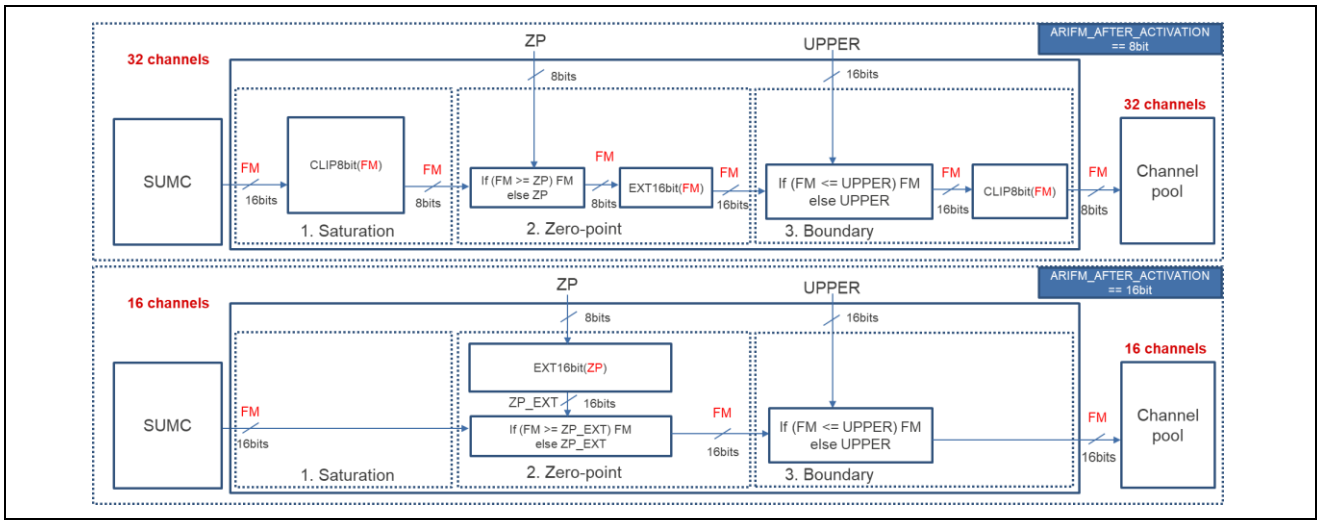

Figure U33.33 BRELU activation function flow

Table U33.36 BRELU activation function symbols

Symbol	Register bit	Description
FM	-	Feature Map
ARIFM_AFTER_ACTIVATION	ARICSR.ARIFM_AFTER_ACTIVATION	Output data format of Activation function.
ZP	SFTM_ZERO_POINT	Zero-point used for 8bit after SFTM function User must set zero-point to 8'h0 when ARIFM_AFTER_ACTIVATION is 16bit.
ZP_EXT	-	Zero-point after signed extension from 8bits to 16bits
UPPER	ARI_BND. ARI_UPPER_BND	ARI upper boundary

CLIP8bit(FM)	-	Clipping 8bits signed for input value FM:
		CLIP8bit(FM) {
		If (FM < -128)
		{y = -128}
		else if (FM >127)
		{y = 127}
		else {y = FM}
		return y
		}

EXT16bit(ZP)	-	Signed extension from 8bit signed to 16bit signed for ZP.
		EXT16bit(ZP){
		y= (int16) ZP
		return y
		}

EXT16bit(FM)	-	Signed extension from 8bit signed to 16bit signed for FM.
		EXT16bit(FM){
		y= (int16) FM
		return y
		}

For 8bit mode, the bounded rectified linear unit (BRELU) activation function is suppressing all values smaller than zero-point value specified by the SFTM_ZERO_POINT register and replacing them with zero-point value.
The values greater than zero-point value are compared with an upper boundary specified by the ARI_UPPER_BND bits of the ARI_BND register. In case the value is larger than the specified upper boundary, the value gets replaced by the upper boundary, otherwise, the value gets passed through unchanged. When using 16bit mode, user must set SFTM_ZERO_POINT register to zero. The input data and zero-point will be clipped to 8bit signed range by function CLIP8bit().

For 16bit mode, the bounded rectified linear unit (BRELU) activation function is suppressing all negative values and replacing them with 0. Positive values are compared with an upper boundary specified by the ARI_UPPER_BND bits of

the ARI_BND register. In case a positive value is larger than the specified upper boundary, the value gets replaced by the upper boundary, otherwise, the positive value gets passed through unchanged.

(c) Leakage RELU

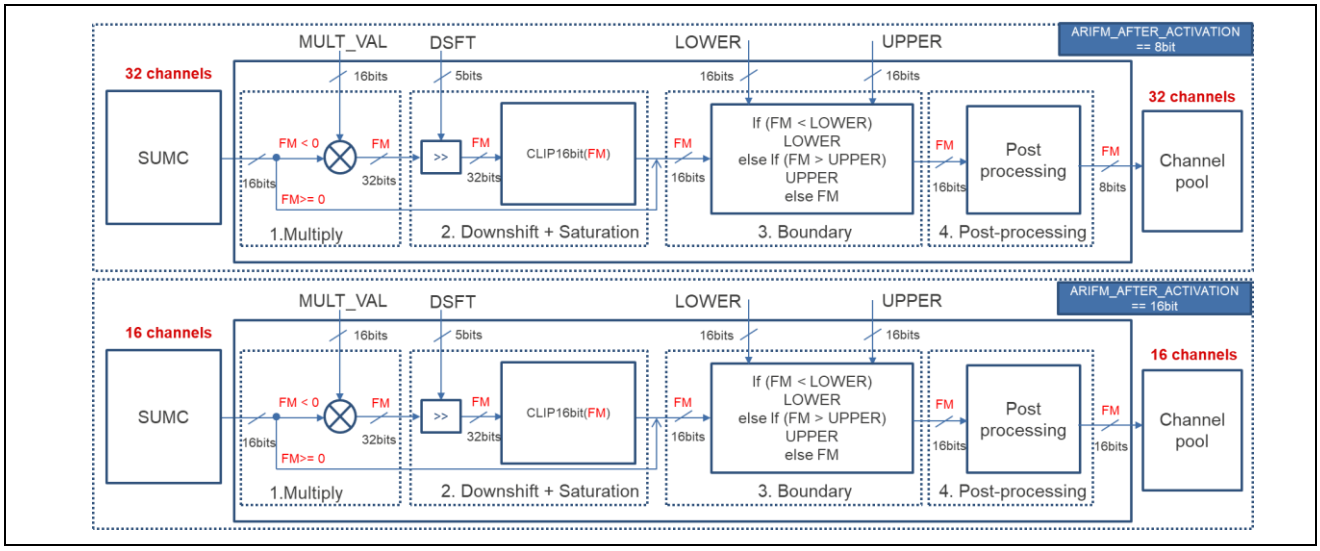

Figure U33.34 LEAKY RELU activation function flow

Table U33.37 Leakage RELU activation function symbols

Symbol	Register bit	Description
FM	-	Feature Map
ARIFM_AFTER_ACTIVATION	ARICSR.ARIFM_AFTER_ACTIVATION	Output data format of Activation function.
MULT_VAL	ACTIVATION_MULT_VAL	Factor for MULT operation
DSFT	ACTIVATION_MULT_POST_SFT	Downshift after MULT operation
UPPER	ARI_BND.ARI_UPPER_BND	ARI upper boundary
LOWER	ARI_BND.ARI_LOWER_BND	ARI lower boundary

CLIP16bit(FM)	-	Clipping 16bits signed for input value FM:
		CLIP16bit(FM) {
		If (FM < -32768)
		{y = -32768}
		else if (FM >32767)
		{y = 32767}
		else {y = FM}
		return y
		}

For positive values, the value is defined between the ARI_LOWER_BND and ARI_UPPER_BND bits of the ARI_BND register. If the value is larger than the upper boundary specified by the ARI_UPPER_BND bits of the ARI_BND register, the value gets replaced by the upper boundary. If the value is smaller than the lower boundary specified by the ARI_LOWER_BND bits of the ARI_BND register, the value gets replaced by the lower boundary.

For negative values, a multiplication with a positive number defined over the ACTIVATION_MULT_VAL register is performed, followed by an arithmetic down shift defined over the ACTIVATION_MULT_POST_SFT register. The result after downshift is saturated to signed 16bit range by function CLIP16bit(). After that, the value is defined between the ARI_LOWER_BND and ARI_UPPER_BND bits of the ARI_BND register like positives value.

(d) Sigmoid

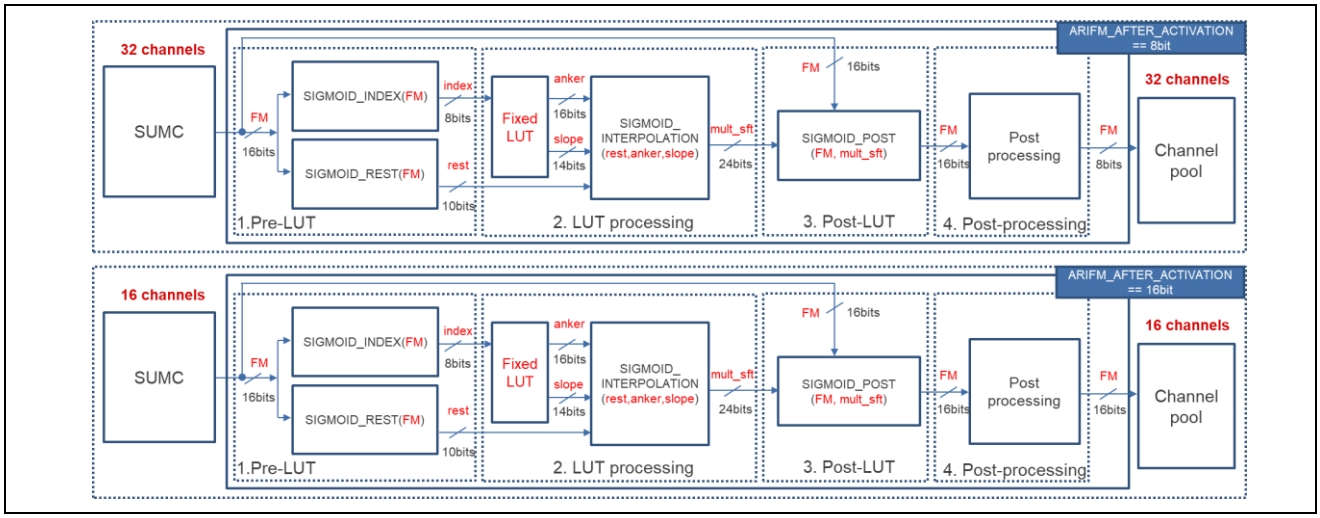

Figure U33.35 SIGMOID activation function flow

Table U33.38 SIGMOID activation function symbols

Symbol	Register bit	Description
FM	-	Feature Map
ARIFM_AFTER_ACTIVATION	ARICSR.ARIFM_AFTER_ACTIVATION	Output data format of Activation function.

SIGMOID_INDEX(FM)	-	Calculate Index value for input value FM:
		SIGMOID_INDEX(FM) {
		abs_x = (FM < 0) ? -FM : FM;
		y = (abs_x / 256)
		return y
		}

SIGMOID_REST(FM)	-	Calculate Rest value for input value FM:
		SIGMOID_REST(FM) {
		abs_x = (FM < 0) ? -FM : FM;
		y = mod(abs_x ,256)
		return y
		}

SIGMOID_INTERPOLATION (rest, anker, slope)	-	Calculate LUT processing value for Sigmoid:
		SIGMOID_INTERPOLATION(rest, anker, slope){
		mult_val = rest * slope;
		y = (mult_val / 512) + anker;
		return y
		}

SIGMOID_POST (FM, intercept)	-	Calculate post-LUT processing value for input value FM:
		SIGMOID_POST (FM, intercept) {
		y= (FM < 0) ? (32768 - intercept) : intercept;
		return y
		}

Sigmoid functions are implemented for positive and negative values by using the LUT, while for 16bit input data the input ranges from -8 to 8 is covered by the LUT with size 128 elements. The input data to LUT is calculated by function SIGMOID_INDEX() and SIGMOID_REST() and the output data after LUT is calculated by function SIGMOID_POST().
After LUT, the value is continuously calculated at “Post processing” logic.

(e) ELU

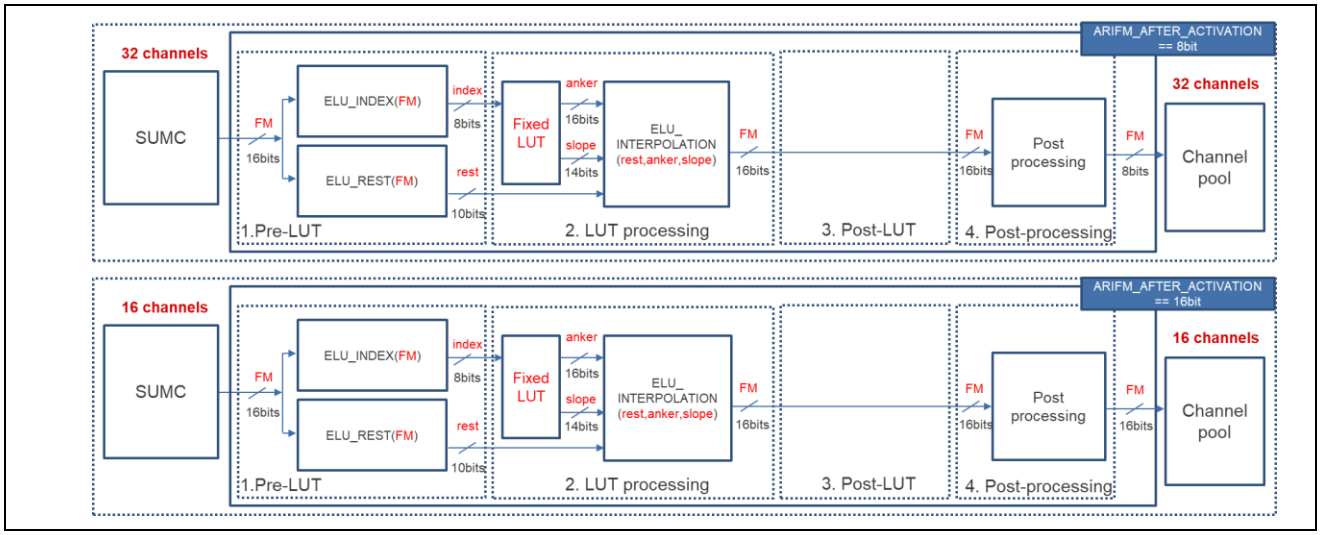

Figure U33.36 ELU activation function flow

Table U33.39 ELU activation function symbols

Symbol	Register bit	Description
FM	-	Feature Map
ARIFM_AFTER_ACTIVATION	ARICSR.ARIFM_AFTER_ACTIVATION	Output data format of Activation function.

ELU_INDEX(FM)	-	Calculate Index value for input value FM:
		ELU_INDEX(FM) {
		y = ((FM + 32768) / 256)
		return y
		}

ELU_REST(FM)	-	Calculate Rest value for input value FM:
		ELU_REST(FM) {
		tmp = mod(FM,256)
		y = mod(tmp + 256,256)
		return y
		}

ELU_INTERPOLATION
(rest, anker, slope)
	-	Calculate LUT processing value for ELU:
		ELU_INTERPOLATION(rest, anker, slope){
		mult_val = rest * slope;
		y = (mult_val / 4096) + anker;
		return y
		}

For the exponential linear unit (ELU) activation function, the positive values get passed through unchanged.
For negative values, an exponential function implemented using an LUT is used to produce small negative values which allows them to push mean unit activations closer to zero. While for 16bit input data the input ranges from -8 to 0 is covered by the LUT with size 256 elements. The input data to LUT is calculated by function ELU_INDEX() and ELU_REST().
After LUT, the value is continuously calculated at “Post processing” logic.

(f) Tanh

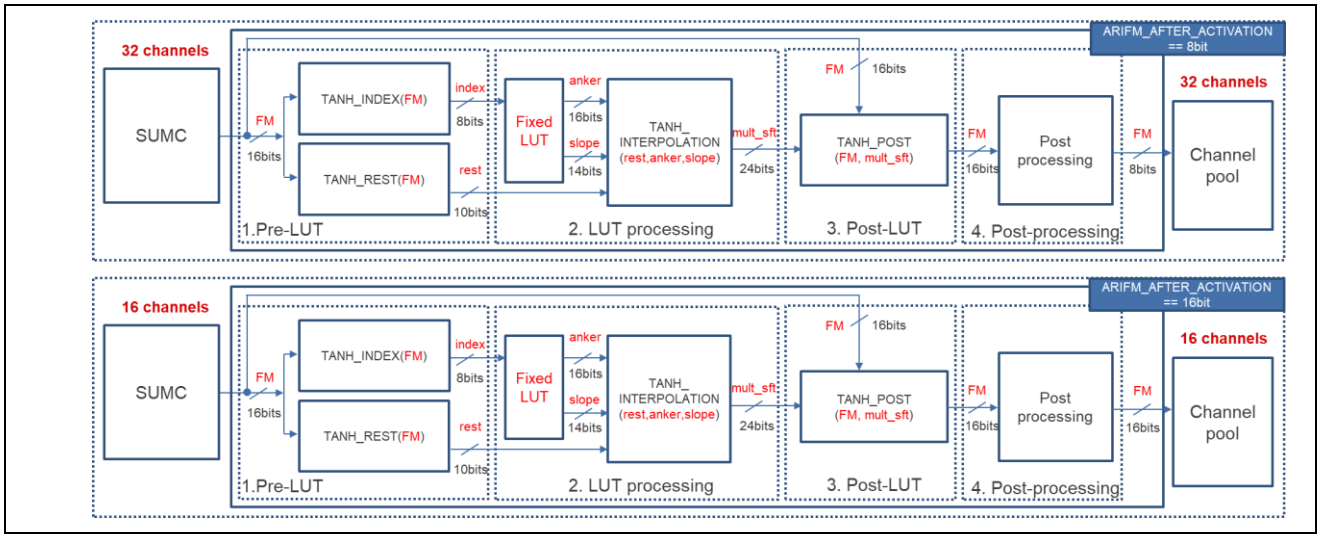

Figure U33.37 TANH activation function flow

Table U33.40 TANH activation function symbols

Symbol	Register bit	Description
FM	-	Feature Map
ARIFM_AFTER_ACTIVATION	ARICSR.ARIFM_AFTER_ACTIVATION	Output data format of Activation function.

TANH_INDEX(FM)	-	Calculate Index value for input value FM:
		TANH_INDEX(FM) {
		abs_x = (FM < 0) ? -FM : FM;
		y = (abs_x / 512)
		return y
		}

TANH_REST(FM)	-	Calculate Rest value for input value FM:
		TANH_REST(FM) {
		abs_x = (FM < 0) ? -FM : FM;
		y = mod(abs_x ,512)
		return y
		}

TANH_INTERPOLATION (rest, anker, slope)	-	Calculate LUT processing value for TANH:
		TANH_INTERPOLATION(rest, anker, slope){
		mult_val = rest * slope;
		y = (mult_val / 1024) + anker;
		return y
		}

TANH_POST(FM, intercept)	-	Calculate post-LUT processing value for input value FM:
		TANH_POST (FM, intercept) {
		y= (FM < 0) ? -intercept : intercept;
		return y
		}

Tanh function is implemented for positive and negative values by using the LUT as done for the ELU activation function, while for 16bit input data the input ranges from -4 to 4 is covered by the LUT with size 64 elements. The input data to LUT is calculated by function TANH_INDEX() and TANH_REST() and the output data after LUT is calculated by function TANH_POST().
After LUT, the value is continuously calculated at “Post processing” logic.

(g) H-Swish

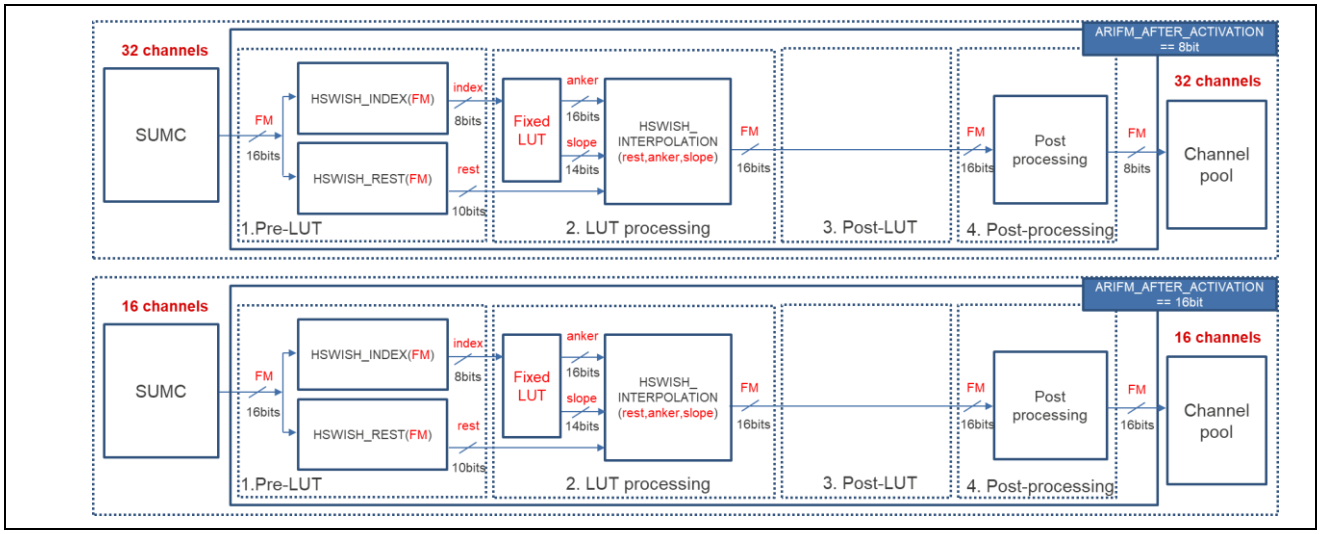

Figure U33.38 H-SWISH activation function flow

Table U33.41 H-SWISH activation function symbols

Symbol	Register bit	Description
FM	-	Feature Map
ARIFM_AFTER_ACTIVATION	ARICSR.ARIFM_AFTER_ACTIVATION	Output data format of Activation function.

HSWISH_INDEX(FM)	-	Calculate Index value for input value FM:
		HSWISH_INDEX(FM) {
		y = ((FM + 32768) / 512)
		return y
		}

HSWISH_REST(FM)	-	Calculate Rest value for input value FM:
		HSWISH_REST(FM) {
		tmp = mod(FM,512)
		y = mod(tmp + 512, 512)
		return y
		}

HSWISH_INTERPOLATION (rest, anker, slope)	-	Calculate LUT processing value for HSWISH:
		HSWISH_INTERPOLATION(rest, anker, slope){
		mult_val = rest * slope;
		y = (mult_val / 4096) + anker;
		return y
		}

H-Swish function is implemented for 16bit input data the input ranges from -8 to 8, if the input value greater than 4, the value gets passed through unchanged. The input data to LUT is calculated by function HSWISH_INDEX() and HSWISH_REST().

The values smaller than 4 are covered by the LUT with size 128 elements and the value after LUT is continuously calculated at “Post processing” logic.

(h) Swish

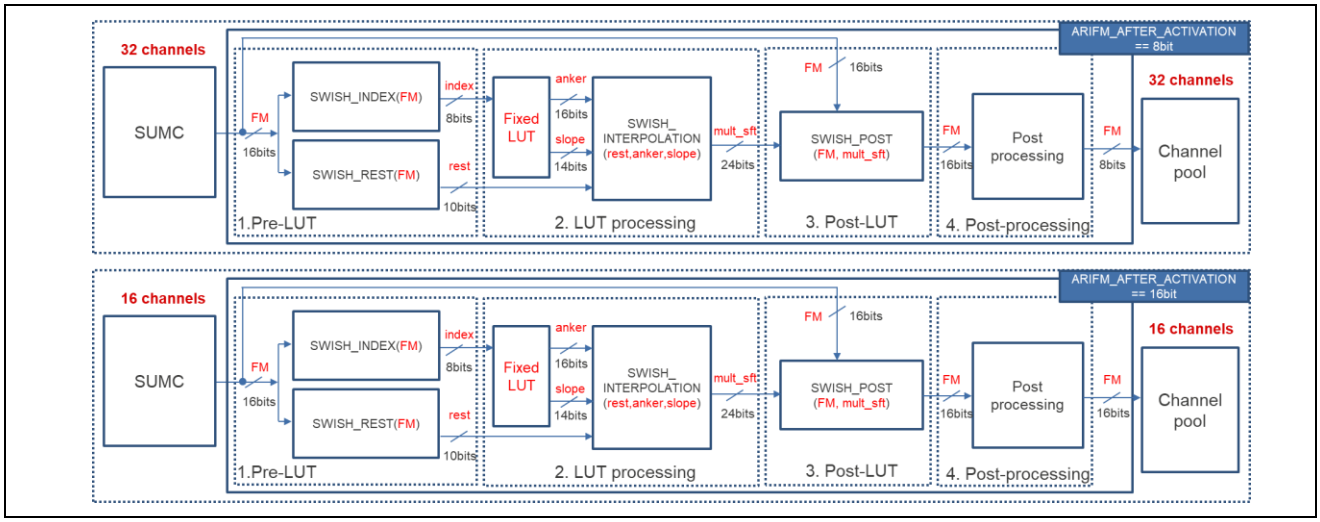

Figure U33.39 SWISH activation function flow

Table U33.42 SWISH activation function symbols

Symbol	Register bit	Description
FM	-	Feature Map
ARIFM_AFTER_ACTIVATION	ARICSR.ARIFM_AFTER_ACTIVATION	Output data format of Activation function.

SWISH_INDEX(FM)	-	Calculate Index value for input value FM:
		SWISH_INDEX(FM) {
		abs_x = (FM < 0) ? -FM : FM;
		y = (abs_x / 256)
		return y
		}

SWISH_REST(FM)	-	Calculate Rest value for input value FM:
		SWISH_REST(FM) {
		abs_x = (FM < 0) ? -FM : FM;
		y = mod(abs_x ,256)
		return y
		}

SWISH_INTERPOLATION (rest, anker, slope)	-	Calculate LUT processing value for SWISH:
		SWISH_INTERPOLATION(rest, anker, slope){
		mult_val = rest * slope;
		y = (mult_val / 512) + anker;
		return y
		}

SWISH_POST(FM, intercept)	-	Calculate post-LUT processing value for input value FM:
		SWISH_POST (FM, intercept) {
		temp_y= (FM < 0) ? (32768 - intercept) : intercept;
		y= temp_y * FM>>15;
		return y
		}

Swish function is implemented for positive and negative values by using the LUT as done for the Sigmoid activation function, while for 16bit input data the input ranges from -8 to 8 is covered by the LUT with size 128 elements. The input data to LUT is calculated by function SWISH_INDEX() and SWISH_REST() and the output data after LUT is calculated by function SWISH_POST().
After LUT, the value is continuously calculated at “Post processing” logic.

(i) Mish

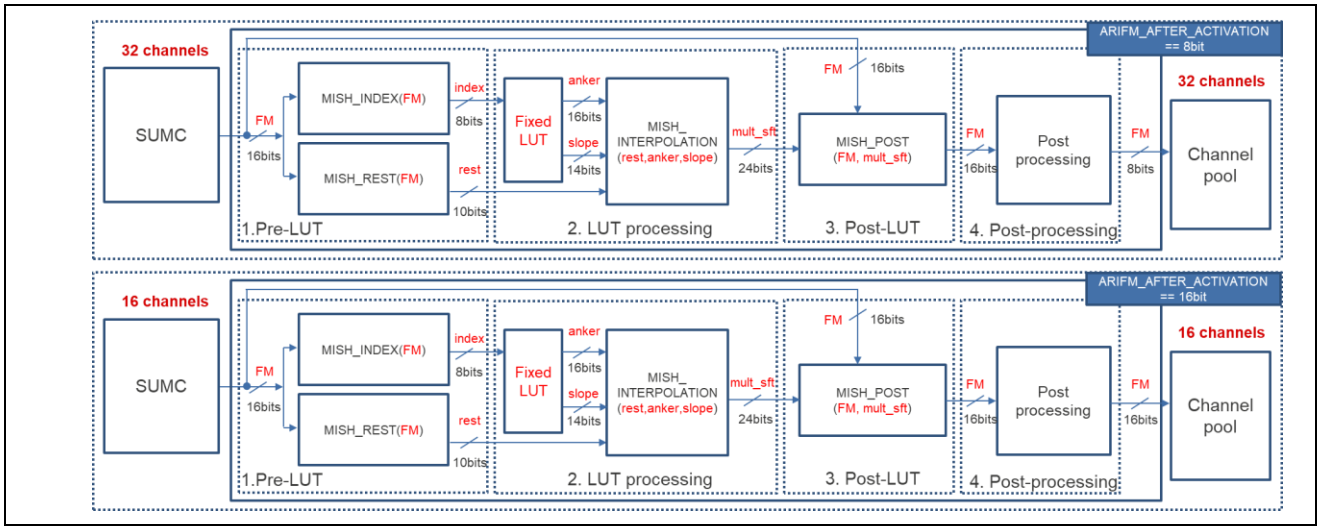

Figure U33.40 MISH activation function flow

Table U33.43 MISH activation function symbols

Symbol	Register bit	Description
FM	-	Feature Map
ARIFM_AFTER_ACTIVATION	ARICSR.ARIFM_AFTER_ACTIVATION	Output data format of Activation function.

MISH_INDEX(FM)	-	Calculate Index value for input value FM:
		MISH_INDEX(FM) {
		y = ((FM + 32768) / 512)
		return y
		}

MISH_REST(FM)	-	Calculate Rest value for input value FM:
		MISH_REST(FM) {
		tmp = mod(FM,512)
		y = mod(tmp + 512, 512)
		return y
		}

MISH_INTERPOLATION (rest, anker, slope)	-	Calculate LUT processing value for MISH:
		MISH_INTERPOLATION(rest, anker, slope){
		mult_val = rest * slope;
		y = (mult_val / 512) + anker;
		return y
		}

MISH_POST(FM, intercept)	-	Calculate post-LUT processing value for input value FM:
		MISH_POST (FM, intercept) {
		y= intercept * FM>>15;
		return y
		}

Mish function is implemented for positive and negative values by using the LUT as done for the Sigmoid activation function, while for 16bit input data the input ranges from -8 to 8 is covered by the LUT with size 128 elements. The input data to LUT is calculated by function MISH_INDEX() and MISH_REST() and the output data after LUT is calculated by function MISH_POST().
After LUT, the value is continuously calculated at “Post processing” logic.

(j) Exp

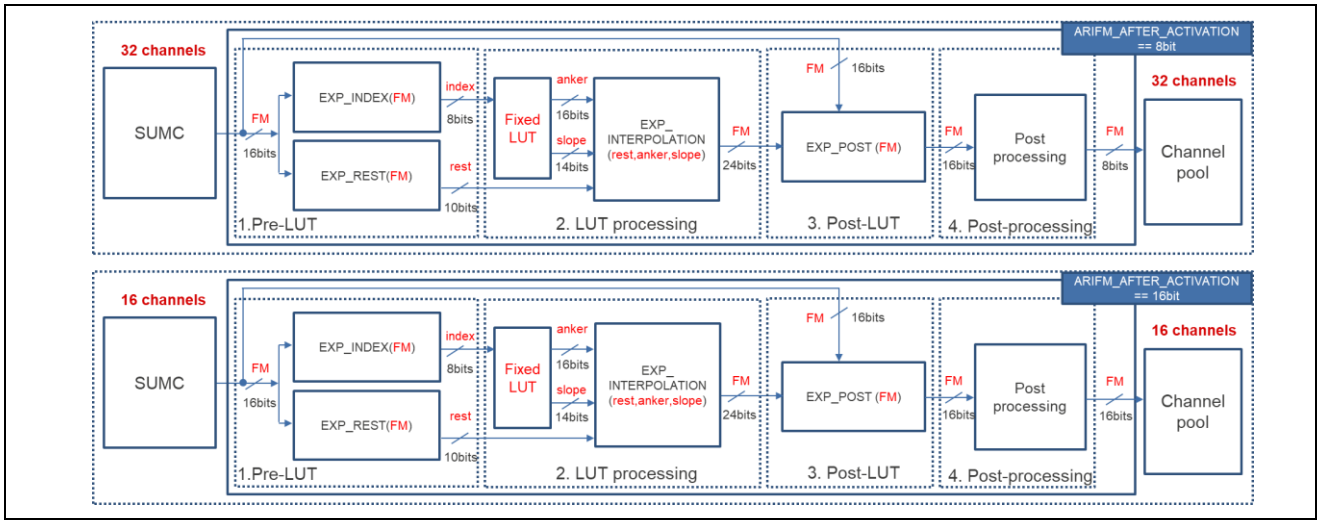

Figure U33.41 EXP activation function flow

Table U33.44 EXP activation function symbols

Symbol	Register bit	Description
FM	-	Feature Map
ARIFM_AFTER_ACTIVATION	ARICSR.ARIFM_AFTER_ACTIVATION	Output data format of Activation function.

EXP_INDEX(FM)	-	Calculate Index value for input value FM:
		EXP_INDEX(FM) {
		y = ((FM + 32768) / 512)
		return y
		}

EXP_REST(FM)	-	Calculate Rest value for input value FM:
		EXP_REST(FM) {
		y = mod(FM,512)
		return y
		}

EXP_INTERPOLATION
(rest, anker, slope)
	-	Calculate LUT processing value for EXP:
		EXP_INTERPOLATION(rest, anker, slope){
		mult_val = rest * slope;
		y = (mult_val / 4096) + anker;
		return y
		}

EXP_POST(FM)	-	Calculate post-LUT processing value for input value FM:
		EXP_POST (FM) {
		y= FM + 4095;
		return y
		}

Exp function is implemented for negative values by using the LUT as done for the ELU activation function, user needs guarantee the input value is always below 0. The input data to LUT is calculated by function EXP_INDEX() and EXP_REST() and the output data after LUT is calculated by function EXP_POST().
After LUT, the value is continuously calculated at “Post processing” logic.

(k) Post processing

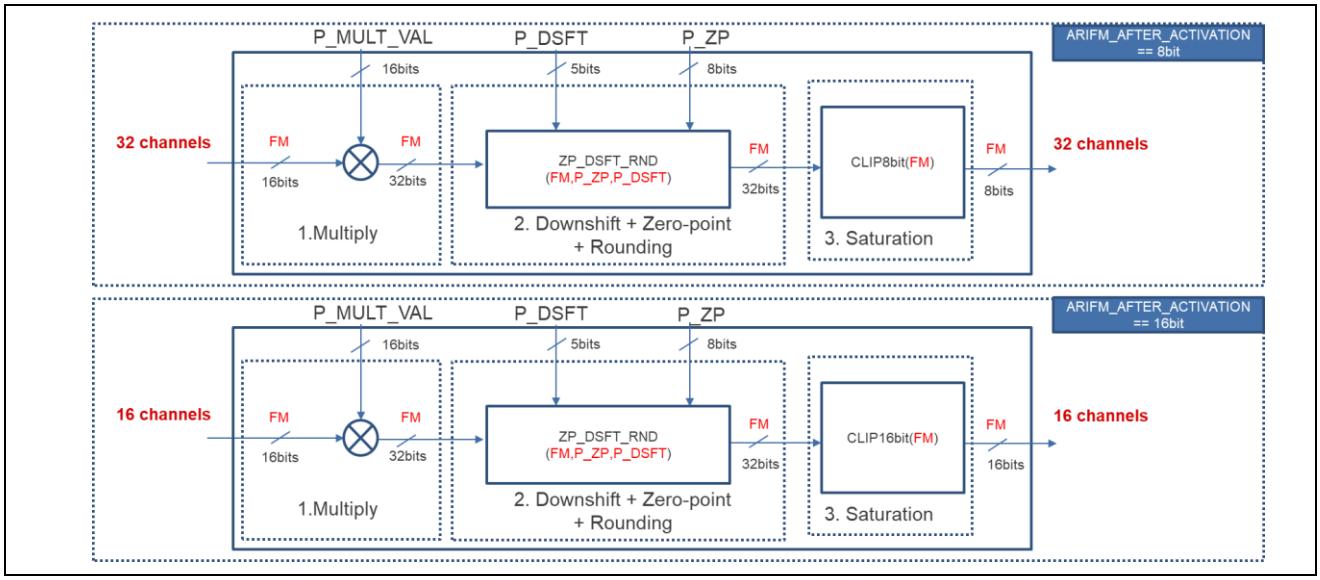

Figure U33.42 Post processing flow

Table U33.45 Post processing function symbols

Symbol	Register bit	Description
FM	-	Feature Map
ARIFM_AFTER_ACTIVATION	ARICSR.ARIFM_AFTER_ACTIVATION	Output data format of Activation function.
P_ZP	ACTIVATION_ZERO_POINT	Zero Point used for 8bit activation functions at post processing User must set zero-point to 8'h0 when ARIFM_AFTER_ACTIVATION is 16bit.
P_MULT_VAL	ACTIVATION_OUTPUT_PARAM. ACTIVATION_OUTPUT_MULT	Factor for MULT operation of post processing
P_DSFT	ACTIVATION_OUTPUT_PARAM. ACTIVATION_OUTPUT_SFT	Downshift after MULT operation of post processing

ZP_DSFT_RND
(FM,P_ZP,P_DSFT)
	-	Downshift + Zero-point + Rounding function
		ZP_DSFT_RND(FM,P_ZP,P_DSFT) {
		y = (((FM >> (P_DSFT-1)) + P_ZP + 1) >> 1
		return y
		}

CLIP8bit(FM)	-	Clipping 8bits signed for input value FM:
		CLIP8bit(FM) {
		If (FM < -128)
		{y = -128}
		else if (FM >127)
		{y = 127}
		else {y = FM}
		return y
		}

CLIP16bit(FM)	-	Clipping 16bits signed for input value FM:
		CLIP16bit(FM) {
		If (FM < -32768)
		{y = -32768}
		else if (FM >32767)
		{y = 32767}
		else {y = FM}
		return y
		}

Post processing implemented a multiplication with a positive number defined over ACTIVATION_OUTPUT_MULT bits of the ACTIVATION_OUTPUT_PARAM register, followed by zero-point adder defined over ACTIVATION_ZERO_POINT register and an arithmetic down shift defined over the ACTIVATION_OUTPUT_SFT bits of the ACTIVATION_OUTPUT_PARAM register.

For this downshifter, the rounding function "round to nearest, half towards +infinity" is available. The value itself is handled on output side with the ARIFM_AFTER_ACITIVATION.

(l) Format dependent data flow

Post processing is supported on output side of activation functions. When user set no activation or RELU or BRELU functions, post processing is not supported.

For other activation modes above, post processing is supported. While for ARIFM_AFTER_ACITIVATION equal to 8bit mode, user can define zero-point over ACTIVATION_ZERO_POINT register, for ARIFM_AFTER_ACITIVATION equal to 16bit mode, ACTIVATION_ZERO_POINT register must be set to zero.

(3) Channel Pool

The channel pooling function is only available for 8bit and 16bit format setting, in case of m16 or m32 format setting, the channel pooling function cannot be used. As channel pooling functions, the channel MAX, channel RANK and channel LABEL functions are supported which are described in the following in more detail.

(a) Channel MAX

The channel MAX function is selected by setting the CPOOL_MODE info bits inside the ARICSR register to 0x1. It searches for each x/y position the maximum value of all channels inside a group and using for the lowest group channel output this value. All other channels of the group get disabled and do not hold valid data afterwards. Supported are the group settings defined in Table U33.46.

Table U33.46 Channel MAX group division

CPOOL_INFO	Group division
0x0	1 group of 32 channels
0x1	2 groups of each 16 channels
0x2	4 groups of each 8 channels
0x3	8 groups of each 4 channels
0x4	16 groups of each 2 channels
0x5	32 groups of each 1 channel
other	Not supported

(b) Channel RANK

The Channel RANK function is selected by setting the CPOOL_MODE info bits inside the ARICSR register to 0x2. The function is sorting all 32 channels (8bit) or 16 channels (16bit) starting with largest value in the channel with lowest channel number. Inactivated channels are sorted to the end in the channels with highest channel number.

The user can additionally define how many lower data bits should be used for the information of the original channel number by specifying the number of bits over CPOOL_INFO bits of ARICSR register. Values from 0 till 5 are here supported. If specifying 0, e.g., then all data bits are used for the data information and the original channel information before sorting is getting lost. If using 32 channels in ARI 8bit mode and all channel information is needed, the user must specify 5 for CPOOL_INFO. In that case, all original channel information is stored out over DMAO replacing the lower 5 bits of the data information.

For the special case of sorting 32 channels and operating in 16bit mode, 2 runs with 16 channels become necessary. To distinguish later between the 2 runs, the user must specify the user information CPOOL_UI in the ARICSR register, which is replacing bit number 5 of the output data.

(c) Channel LABEL

The Channel LABEL function is similar working as the Channel RANK function, however, it is storing only the channel information out over the DMAO channels, the data information is getting lost after the sorting process.

The Channel LABEL function is selected by setting the CPOOL_MODE bits inside the ARICSR register to 0x3. The function is sorting all 32 channels (8bit) or 16 channels (16bit) starting with largest value in the channel with lowest channel number. Inactivated channels are sorted to the end in the channels with highest number.

The user can additional define how many lower bits should be used for the information of the original channel number by specifying the number of bits over CPOOL_INFO bits of ARICSR register. Values from 0 till 5 are here supported. If specifying e.g. 0, then the original channel information before sorting is getting lost. If using 32 channels in ARI 8bit mode and all channel information is needed, the user must specify 5 for the CPOOL_INFO bits. In that case, all original channel information is stored out over DMAO using the lower 5 bits.

For the special case of sorting 32 channels and operating in 16bit mode, 2 runs with 16 channels become necessary. To distinguish later between the 2 runs, the user must specify the user information in the CPOOL_UI bit of the ARICSR register, which is sent out over bit number 5 of the DMAO channel data.

(4) XY Pool

The XY pooling function is only available for 8bit and 16bit format setting, in case of m16 or m32 format setting, the XY pooling function cannot be used. With the XYPOOL_MODE bit of the ARICSR register the XYPOOL mode can be selected, which enables the user to perform a pooling over a defined x/y area of a channel. The output of the selected XY POOL function is replacing the selected area inside the DMAO channel, so that when using an area larger 1x1, a down shrinking of the input size is performed. The supported pooling size is defined by the XPOOL bits of the ARICSR register for x direction and by the YPOOL bits of the ARICSR register for y direction. XPOOL and YPOOL can take values from 0 till 3 causing values for the pooling size in x and y direction from 1 till 4.

(a) XY MAX

In case of a XY MAX pooling function selected by setting the XYPOOL_MODE bits of the ARICSR register to 2b01, the maximal value is searched inside the defined pooling area and replacing the pooling area inside the DMAO output channel.

(b) XY Average

In case of a XY Average pooling function selected by setting the XYPOOL_MODE bits of the ARICSR register to 1b10, the average of all values inside the defined pooling area is calculated and replacing the pooling area inside the DMAO output channel. After the XY Average operation, an ARI format dependent saturation function is supported.
When using XY average pooling, XPOOL and YPOOL bits of the ARICSR register must be the same.

(c) XY upper left

In case of a XY upper left pooling function selected by setting the XYPOOL_MODE bits of the ARICSR register to 2b11, the first value inside the defined pooling area is kept and replacing the pooling area inside the DMAO output channel.

U33.3.6 DMAO module

The DMAO_OUT module, also called as DMAO module, is responsible to store the output data from the 16 (for 16bit) or 32 (for 8bit, mixed mode 16bit/32bit) DMA output buffers to the SPMC. Figure U33.43 is showing a block diagram of this module.

(1) DMAO module block diagram

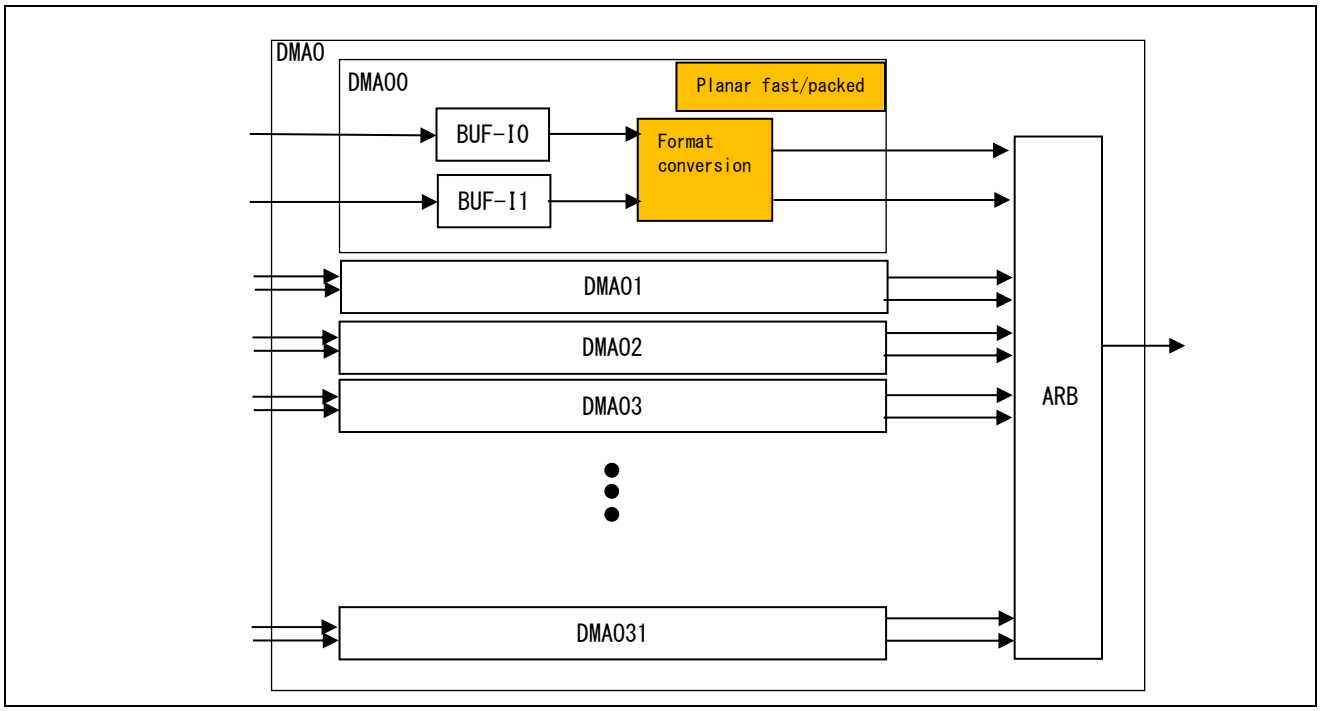

Figure U33.43 DMAO BLOCK

The DMAO module consists of 32 sub modules DMAO0 till DMAO31 and an arbiter.
The arbiter is responsible for the data arbitration between single external channel and 32 internal channels selecting the data from the 32 submodules DMAO0 till DMAO31. Each DMAO sub module has the same structure. It consists of the 2 data buffers and on output side the format conversion unit and the planar fast/packed decision unit.
The format conversion unit on output size is responsible for converting the data from 16bit signed ARI format to 8bit signed DMAO format only.

The planar fast/packed decision unit is specifying the data destination and arrangement of the outgoing data. In planar fast type, every 16 pixels for all channels are transferred at the same time. The pixels for each channel are stored here separately inside the IMPC memory.

In packed mode, first for each channel 1 pixel is sent, before the next pixel for each channel is sent. In this channel interleaved transfer mode, it is required to enable all output channels, so that the data for 1 channel is always received with the same distance. For the case of 16 16bit channels as well as for the case of 32 8bit channels, the distance is 32byte. For the case of 32 channels mixed mode, the distance is 64byte (mixed mode 16bit) and 128byte (mixed mode 32bit). For the Format conversion function in Figure U33.43, please refer to Table U33.48.

(2) Picture start address, width, height, and stride settings

As external start addresses, an address of the SPMC0/SPMC1 address range must be specified. For packed mode, the start address of the channels is defined by using the DMAOSA register, while for planar fast type, the start addresses are defined by using the DMAOSA register and the DMAOCO register. The address must be aligned 16 pixels (s8/s16) for planar fast type. For packed format, the address must be aligned dependent 1 pixel (s8/s16) when output to SPMC0 and dependent on the pixel width to 16 pixels (s8, s16), 8 pixels (m16), 4 pixels (m32) when output to SPMC1.
The tile dimension is specified in pixels and rows. Here, the width defined by the DMAOLX bits of the DMAOL register must not be larger than 128 pixels while the height defined by the DMAOLY bits of the DMAOL register must be smaller than 2048 rows.

The stride defined by the DMAOST register defines the distance in pixel between 2 rows and the stride is specified in pixel. For planar type, the stride is specified multiple of 16 pixels when output to SPMC0. The value set in line stride register (DMAOST) must be greater than or equal to the value in horizontal size register (DMAOLX).

For packed mode, the stride is set as multiple of 16 pixels (8bi/16bit), multiple of 8 pixels (mixed mode 16bit), multiple of 4 pixels (mixed mode 32bit).

If the specified output size is not enough to output the ARI channel data size defined by the ARI_XLEN bits and ARI_YLEN bits of the ARI_LEN register, the rest is thrown away.

Table U33.47 DMAO parameter support

Format in SPMC0/1	SPMC memory	Data type	Start address	Channel offset	Offset address	Stride	Length	Channel part	Wrap-around address
Planar fast type of planar format	SPMC0	s8	16pix aligned	All channels	Support	Multiple of 16pix	0 < x <= 128 0 < y <= 2048	Support	-
		s16	16pix aligned	Only even channels	Support	Multiple of 16pix	0 < x <= 128 0 < y <= 2048	Support	-
Packed	SPMC0	s8	1pix aligned	-	Support	Multiple of 16pix	0 < x <= 128 0 < y <= 2048	Support	Multiple of 512byte
		s16	1pix aligned	-	Support	Multiple of 16pix	0 < x <= 128 0 < y <= 2048	Support	Multiple of 512byte
	SPMC1	s8	16pix aligned	-	Support	Multiple of 16pix	0 < x <= 128 0 < y <= 1024	Support	-
		s16	16pix aligned	-	Support	Multiple of 16pix	0 < x <= 128 0 < y <= 1024	Support	-
		m16	8pix aligned	-	Support	Multiple of 8pix	0 < x <= 128 0 < y <= 1024	-	-
		m32	4pix aligned	-	Support	Multiple of 4pix	0 < x <= 128 0 < y <= 1024	-	-

(3) DMAO Format conversion

The ARI format defined by the ARIFM/ ARIFM_AFTER_ACTIVATION bits of the ARICSR register can be set differently from ARIFM_AFTER_ACTIVATION bit of the DMAOPARAM and the DMAO format defined by the DMAOFM bits of the DMAOPARAM, only the combinations shown in Table U33.48 between ARI format and DMAO format are supported format conversion.

Table U33.48 ARI to DMAO format conversion implementation

ARIFM of ARICSR	ARIFM_AFTER_ACTIVATION of ARICSR	ARIFM_AFTER_ACTIVATION of DMAOPARAM	DMAOFM Of DMAOPARAM	Used formula
s8	s8	s8	s8	DMAO_val = ARI_val[7:0]
s8	s16	s8	s8	DMAO_val = ARI_val[7:0]
s8	s16	s16	s8	DMAO_val = (ARI_val[15:7] + 1) >>1
s8	s16	s16	s16	DMAO_val = ARI_val[15:0]
s16	s16	s8	s8	DMAO_val = ARI_val[7:0]
s16	s16	s16	s8	DMAO_val = (ARI_val[15:7] + 1) >>1
s16	s16	s16	s16	DMAO_val = ARI_val[15:0]

(4) Wrap around area

Wrap-around function for address supports packed format only and can be enabled/disabled by setting the bit DMAOS_WRAP of DMAOS register. The start and end addresses of output areas can be set by DMAOWA_START and DMAOWA_END of DMAOWA register. The start and end addresses shall be 512byte aligned. Initial address defined by DMAOSA register must be set within the range.

(5) Offset address

To fastly change between output data sets of consecutively processed DMAO channels of the same layer with the same dimensions, by specifying an offset address, the next start address is calculated automatically by adding this offset address to the current start address, which is afterwards replaced by the newly calculated start address.

(6) Channel offset

The channel offset is only used for the planar fast type. Here it is specifying the difference between the start addresses of 2 neighbored output channels. It is set over the DMAOCO register. By using this channel offset, it can be made sure that each channel can work on its own data set.

Further to mention is that inactive channels are still counting for the distance calculation, so, e.g., if byte pixels are processed and channel 0 has as start address 0x0000 0000 and the offset is specified as 0x2010, then channel 2 is starting at address 0x0000 4020, independent of whether channel 1 is active or not.

(7) Channel enable

In planar fast type and packed mode, each channel can be individually enabled or disabled by using the bits of the DMAOE register, by disabling them, energy can be saved. However, bit 0 of DMAOE register is mandatory enabled. The disabled channels are counting when e.g., calculating a channel start address for planar fast type.

When the function read-modify-write (specified by bit DMAO_RMW of DMAOS register) is disabled, if the channel is disabled (DMAOE is 0), 0 is written out.

In planar fast and packed mode, if DMAO is not used (DMAOS is not set), DMAOE bits must be set all to zero.

The relationship between the number of DMAO data channels and the bits in the DMAOE register is shown in Table U33.49

There are some limitations, please refer to U33.5.1.

Table U33.49 Relationship of DMAO channel to DMAO register bit depending on selected data type

DMAOPARAM Register DMAOFM bit setting	The output channel assigned to the DMAOE register bit															
	bit 15	bit 14	bit 13	bit 12	bit 11	bit 10	bit 9	bit 8	bit 7	bit 6	bit 5	bit 4	bit 3	bit 2	bit 1	bit 0
s8	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
s16	-	7	-	6	-	5	-	4	-	3	-	2	-	1	-	0
m16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
m32	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

DMAOPARAM Register DMAOFM bit setting	The output channel assigned to the DMAOE register bit															
	bit 31	bit 30	bit 29	bit 28	bit 27	bit 26	bit 25	bit 24	bit 23	bit 22	bit 21	bit 20	bit 19	bit 18	bit 17	bit 16
s8	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
s16	-	15	-	14	-	13	-	12	-	11	-	10	-	9	-	8
m16	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
m32	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Note:
It is prohibited to run CNN with the DMAOE register set to 32'h0000. At least channel 0 must be enabled by setting DMAOE register.

U33.3.7 Statistics

(1) Channel statistics

In case of 8bit and 16bit processing, there exist 3 statistic data which can be generated on request for each channel, the channel max, channel min and channel sum, it is not available for mixed mode (m16 and m32) format settings.
For the channel max and channel min statistics, the maximal and minimal processed value of the channel are stored inside the upper half and lower half of the registers MAX_MIN_x. When the generation of this statistic is enabled by the bit CHANNEL_MAX_MIN of the register ARICSR, the value is each time replaced when a larger/smaller value is processed inside the channel. The register value can be reset or initialized to a special value by writing from CPU a new value inside. Additionally, in the MPRST register there is the MAX_MIN_16S bit for resetting MAX and MIN values for the s16-bit ARI format and the MAX_MIN_8S bit for resetting MAX and MIN values for the s8-bit ARI format. In case of 16bit ARI processing, MAX_MIN_x is holding the maximal and minimal value of channel x, in case of 8bit ARI processing, MAX_MIN_x is holding the maximal and minimal values of channel 2*x and channel 2*x+1.
The channel sum statistic is storing the sum of the processed values of a channel inside the register GLOB_SUM_x. When the generation of this statistic is enabled by the GLOB_SUM_MODE bit of the register ARICSR, the currently processed value of a channel is each time added to the already stored value for the channel. The register value can be reset by using the GLOB_SUM_RESET bit of the register MPRST.

(2) Performance Counter

As performance counter, the architecture supports 4 performance counter registers PERFCNT0 till PERFCNT3 including their control registers PERFCNT0CTRL till PERFCNT3CTRL. The number of cycles provided by these counters are not proven to be working correctly and are not accurate. Renesas does not offer any guarantee for the validity of the cycle counts provided by these counters. The users shall use these counters at their own risk.

The structure of the 4 performance counter control registers is same and is explained in the following for the register PERFCNT0CTRL. The PERFCNTNO bits of the register PERFCNT0CTRL are defining the entity for which the counter is working. For DMAI, 0 till 15 (8bit) or 0 till 7 (16bit) can be defined, while for DMA3DC and DMAO 0 till 31 (8bit, mixed 16bit, mixed 32bit) or 0 till 15 (16bit) can be defined. Alternatively, to count for all HW channels, the value 32 can be set. If CL or ARI is selected, only 0 can be specified. If PERFCNTNO is set to 64, all channels of all units (DMAI, DMA3DC, DMAO, ARI, CL) are selected.
Over the PERFCNTFUNC bits of the register PERFCNT0CTRL the function of the performance counter can be selected as shown inside Table U33.50.

Table U33.50 Supported performance counter functions

PERFCNTFUNC value	PERFCNTFUNC function
H'0	DMAI busy cycles
H'1	DMAI stall cycles
H'2	DMAO busy cycles
H'3	DMAO stall cycles
H'4	DMA3DC busy cycles
H'5	DMA3DC stall cycles
H'6	ARI busy cycles
H'7	ARI stall cycles
H'8	CL busy cycles
H'9	CL stall cycles

If bit 0 of PERFCNTFUNC is set to 1, the stall reason must be set in the PERFCNTSTRSN bits.
Table U33.51 lists the possible stall reasons to select.

Table U33.51 Supported Measured Stall Reasons

Stall reason for DMAI, DMA3DC (when PERFCNT0FUNC is 1 or 5)	
H'2	Stalls caused by wait as data source for data from DMAI/DMA3DC buffer.
Stall reason for DMAO (when PERFCNT0FUNC is 3)	
H'1	Stalls caused by wait as data sink for data from output buffer.
H'2	Stalls caused by wait as data source for data to memory.
Stall reason for ARI (when PERFCNT0FUNC is 7)	
H'0	All stalls
H'1	Stalls caused by wait as data sink for data from input buffer.
H'2	Stalls caused by wait as data source for data to output buffer.
H'3	Stalls caused by wait as data sink for data from 3DC buffer.
Stall reason for CL (when PERFCNT0FUNC is 9)	
H'1	Stalls caused by the cache miss.
H'2	Stalls caused by SYNCS.
H'3	Stalls caused by the bus not being able to receive data requests to memory.

Further, each performance counter can be enabled individually, and an overflow bit is available which is set if the counter overflows.

(3) Register dump

To store statistics from CNN-IP (global sum, max and min) as well as performance counter values quickly to SPMC memory (only SPMC1 is available), additional to the transfer by CPU a DMA Register Dump unit is available, the DMARD unit. For storing the register values, only the start addresses in external memory (aligned to 512byte) must be specified and it must be guaranteed that at least 1 DMAO channel is enabled. Additionally, before setting the start bit, user must guarantee the register values are available. Table U33.52 shows the registers for which the register dump function is implemented, while Figure U33.44 is showing the structure of the dumped 512 bytes.

Table U33.52 Supported registers for dump using DMARD

Offset address	Register name	Description
0x0800 - 0x087C	GLOB_SUM_00 - 31	Global sum of DMAO channel 0 - 31
0x0880 - 0x08BC	MAX_MIN_00 - 15	MAX and MIN of DMAO channel 0-1
0x08D0 - 0x08DC	PERFCNT0 - 3	Performance counter 0-3

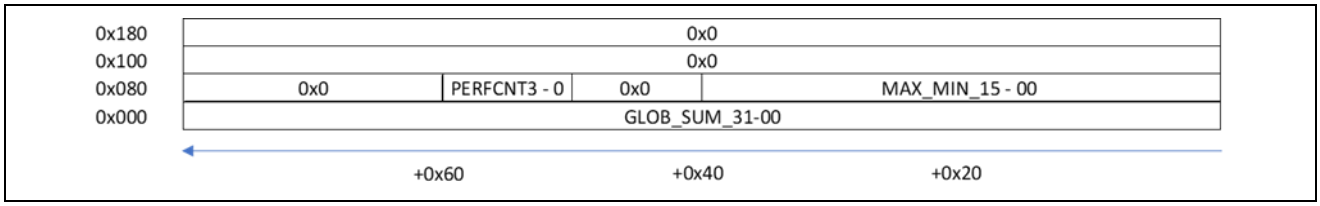

Figure U33.44 Structure of the dumped 512 bytes

The design shares the two busy bits SYNCS.DMAO and SYNCS.BUS between DMAO and DMARD. If the user wants to wait only till DMARD finishes the output of the data before starting the next layer, the user only has to wait until the busy bit SYNCS.DMAO becomes 0. If the user wants to confirm also that the write transaction has finished, the user also has to wait until the busy bit SYNCS.BUS becomes 0.

In the special case, where DMAO and DMARD are writing data out to different SPMC memories, e.g., first DMAO outputs to SPMC0 and then DMARD outputs to SPMC1, the user has to wait until the busy bit SYNCS.BUS becomes 0.

U33.3.8 Other Information

(1) Status register

Status registers are available to store some CNN states to easily make them accessible from CPU. Some of them are only readable, some of them may have additional a possibility to trigger an interrupt to CPU. For the signals which can trigger an interrupt, an enable, mask, and clear bit are additionally provided. This is done to have the chance to disable the update inside the status register SR, to mask the interrupt triggering and to clear the signal status inside SR.

(2) WUP/SLP

The CNN unit supports the WUP/SLP functionality to wake-up other modules or to get woken-up by other modules after entering the sleep state. Over the SYNCC registers, the WUP/SLP connection network is configured. The WUP command wake-ups modules which are specified by the given parameter, while the SLP command defines by the given parameter the modules by which it wants to be woken-up after the transfer into the sleep state. Between 2 wake-up signals to the same module a SLP command must be scheduled for handshaking to the same one. Further, be sure to insert 8 or more non-WUP instructions between two WUP instructions in the CL.

(3) CL debugging

To use the CL break function, following setting is required.
1. Specify the break point address of command list. Make sure that break point is command address of command list.
2. Set CLBE bit in SRE register to 1 and if interrupt is required CLBM bit in SRM register to 0 to use CL break function.

3. Check the CLB status in SR register.
4. To continue execution after CL break, set the CLBC bit of SRC register to 1.

(4) CL index addressing

CL index addressing is supported by adding an address offset provided by CL to a selectable index address from a set of internal registers (index registers, e.g., INDEX[0...7]). The index registers are write-able by CPU.

When using CL index addressing, only 13bits of internal register address is supported. The user also can use compatible mode 16bits of internal register address by setting V3U_COMP_MODE bit of V3U_COMP_MODE register to 1'b1 to disable CL index addressing. The INDEX[0] is fixed set to 0 and cannot be changed.

(5) Double Buffering

To support overlapping execution for multiple layers, double buffering of DMAI, DMA3DC and DMAO and ARI parameters are supported for all registers except DMA start registers and all virtual registers (refer Table U33.3). So, the next layer can be setup before the previous layer has finished.

(6) Bandwidth usage

All DMAs support a bandwidth of 512byte/cycle when accessing SPMC0/1. DMAI/DMAW can access SPMC0 only. DMA3DC can access SPMC1 only. DMAO can access both SPMC0/1. If 2 DMA want to access at the same time to the same SPMC, 1 DMA has to wait while the other DMA can access, so the access is done interleaved in time.

(7) Automatic weight loading

Next to using the DMAW for loading the weights, the CLW instruction can be used when operating with 2x3x3 kernel or 1x5x5 kernel to load predefined values for special purposes. Therefore, the parameter N of the CLW instruction must be set accordingly. Possible values of N with their weight loading purpose are shown in Table U33.54. In the following sub chapters, it will be shown how the non-zero weight elements are set for each selection of N, zero values are blank. It is to mention, that the shown channels in the figures (in-ch and out-ch) present 8bit/16bit HW channels.

(a) Identity matrix

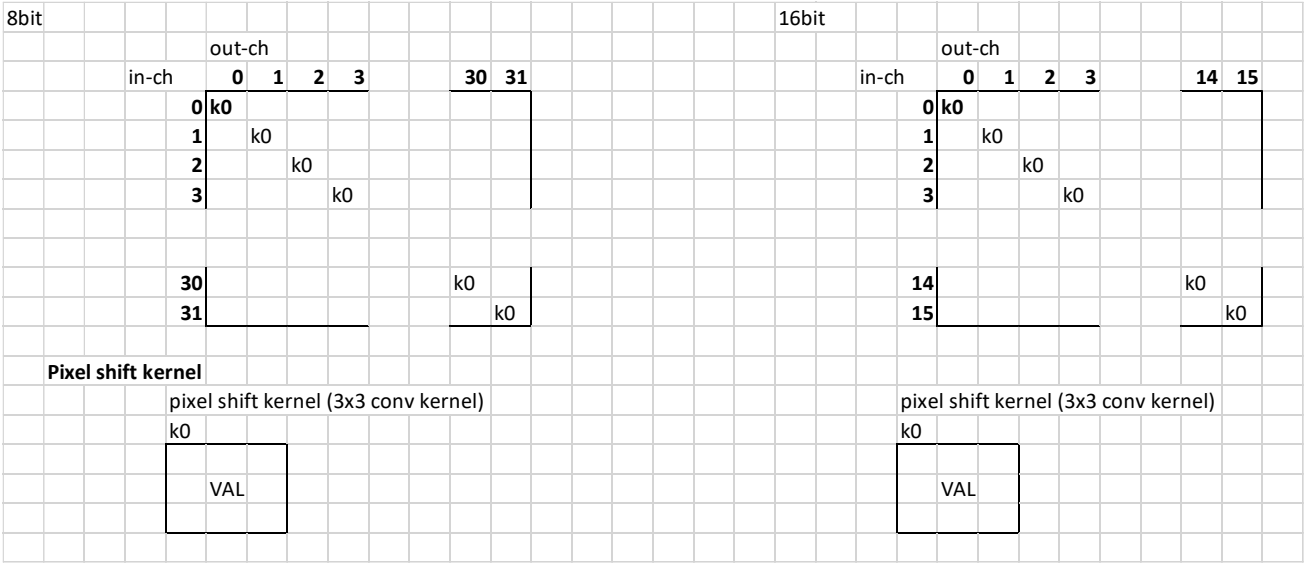

Figure U33.45 Weight loading for identity matrix

Figure U33.45 shows the setting of the non-zero weight elements in case of setting N to 23 (8bit) or 24 (16bit). For the case of the identity matrix, the value specified in the VAL field of the CLW instruction is used as weight.

(b) ELTWISE MAX reorder

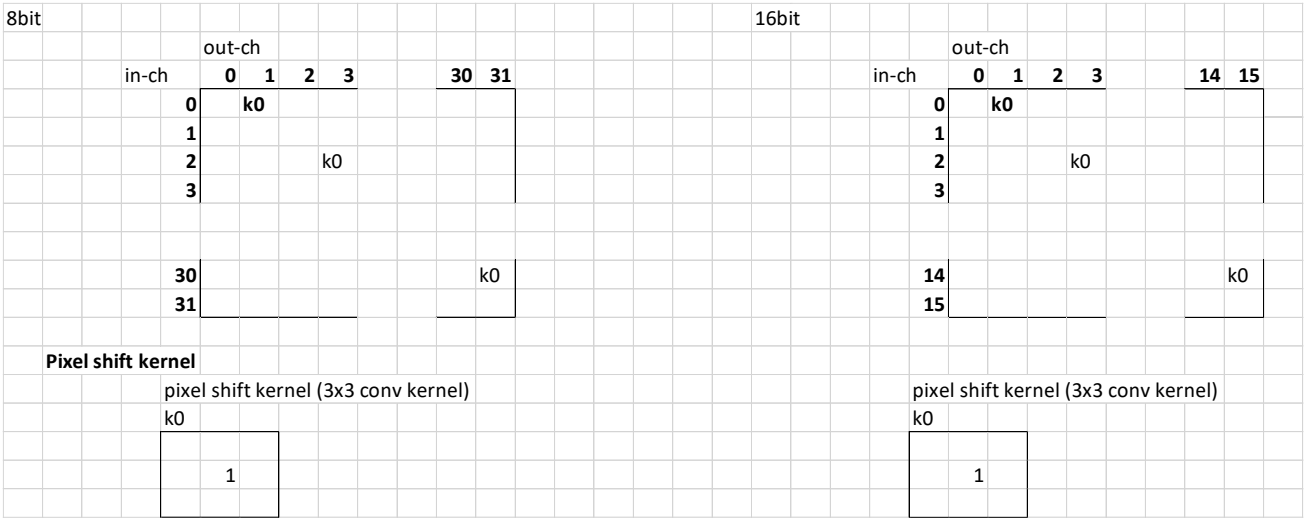

Figure U33.46 Weight loading for ELTWISE MAX reorder

Figure U33.46 shows the setting of the non-zero weight elements in case of setting N to 1 (8bit) or 2 (16bit). For the case of ELTWISE MAX reorder, the fixed value 1 is used as weight.

(c) ELTWISE MAX through

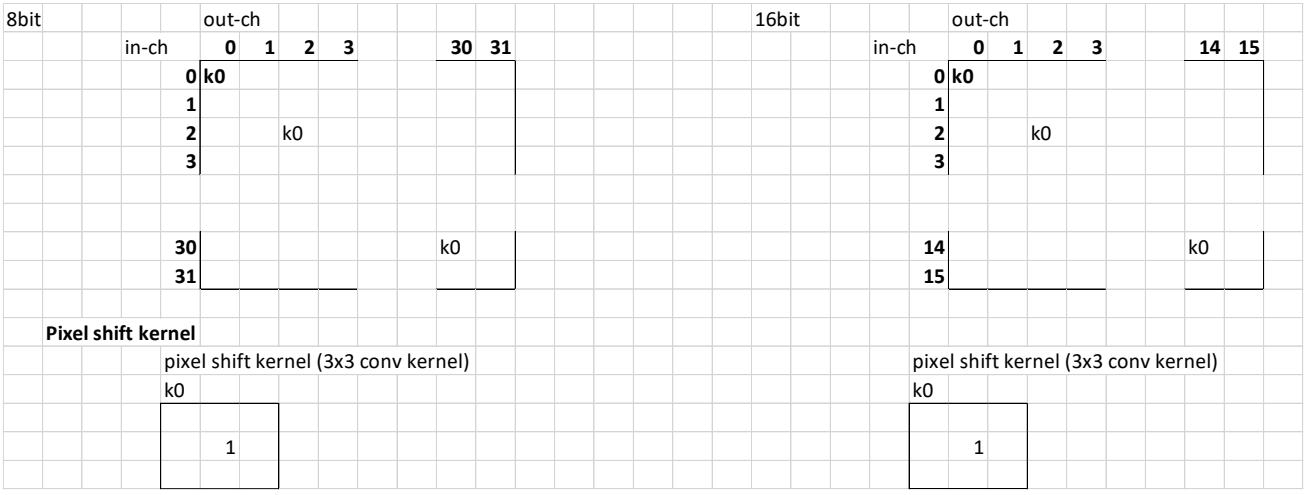

Figure U33.47 Weight loading for ELTWISE MAX through

Figure U33.47 shows the setting of the non-zero weight elements in case of setting N to 3 (8bit) or 4 (16bit). For the case of ELTWISE MAX through, the fixed value 1 is used as weight.

(d) Pool 3x3 stride2 and pool 2x2 stride 1

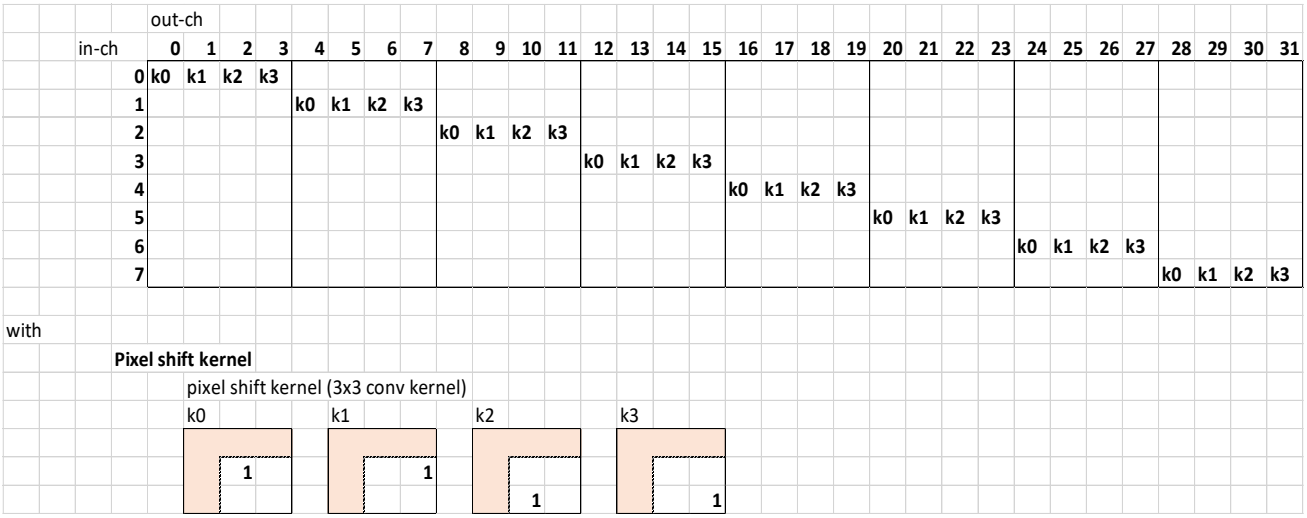

Figure U33.48 Weight setting for 8bit pool 3x3 stride2 and pool 2x2 stride 1

Figure U33.48 shows the setting of the non-zero weight elements in case of setting N to 5. In this case, the weights are set for emulating 8bit overlapped pooling with 3x3 pooling kernel and stride 2 or 2x2 pooling kernel and stride 1. For this case, the fixed value 1 is used as weight.

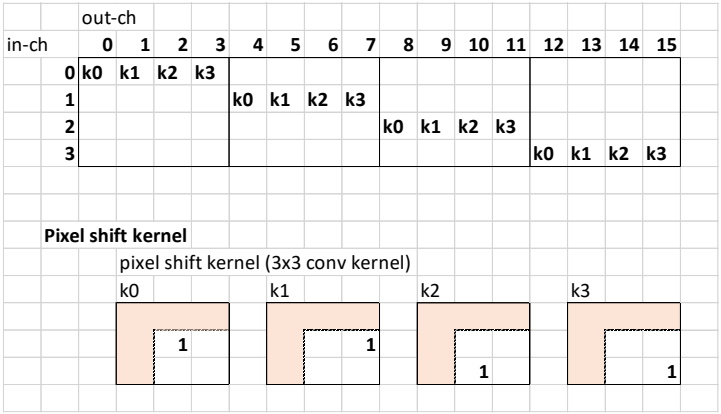

Figure U33.49 Weight setting for 16bit pool 3x3 stride2 and pool 2x2 stride 1

Figure U33.49 shows the setting of the non-zero weight elements in case of setting N to 6. In this case, the weights are set for emulating 16bit overlapped pooling with 3x3 pooling kernel and stride 2 or 2x2 pooling kernel and stride 1. For this case, the fixed value 1 is used as weight.

(e) Pool 3x1 stride 1

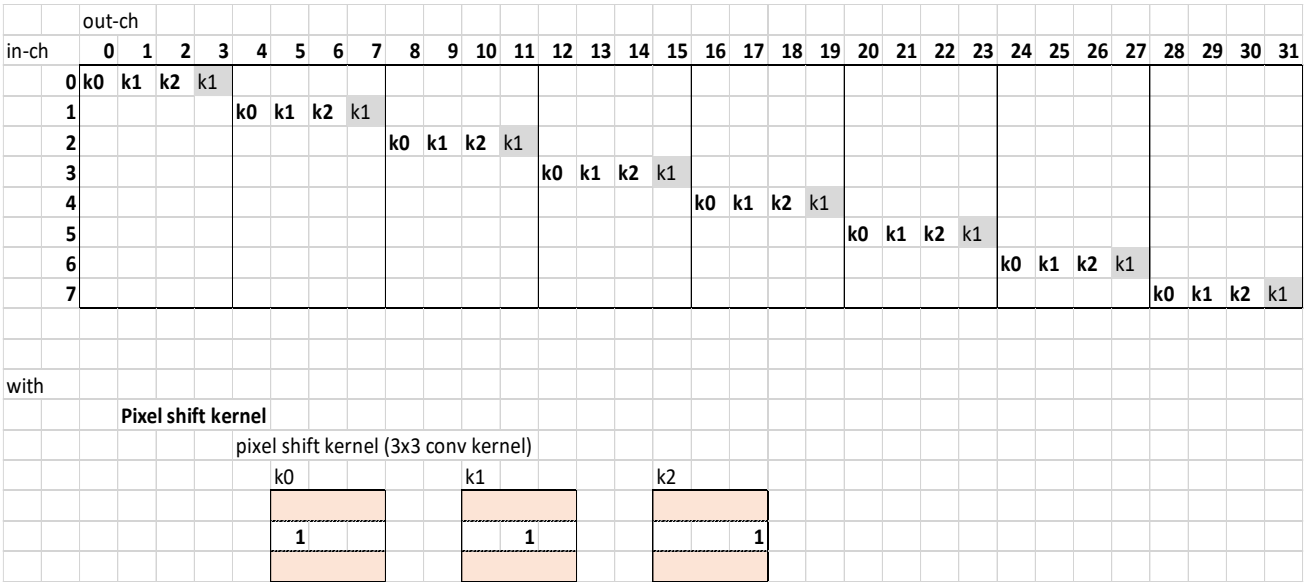

Figure U33.50 Weight setting for 8bit pool 3x1 stride 1

Figure U33.50 shows the setting of the non-zero weight elements in case of setting N to 7. In this case, the weights are set for emulating 8bit overlapped pooling with 3x1 pooling kernel and stride 1. For this case, the fixed value 1 is used as weight.

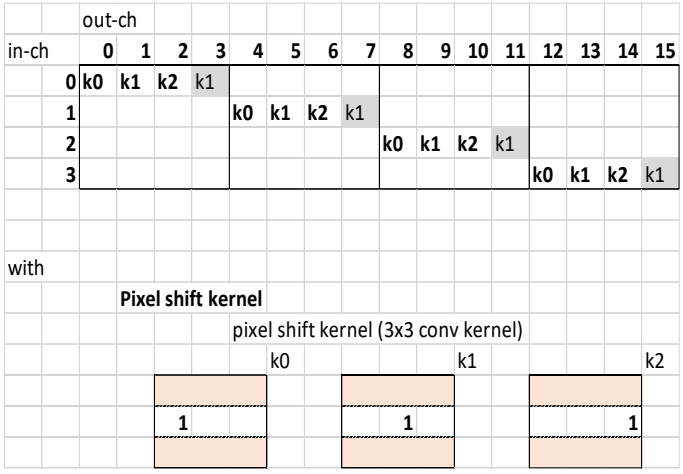

Figure U33.51 Weight setting for 16bit pool 3x1 stride 1

Figure U33.51 shows the setting of the non-zero weight elements in case of setting N to 8. In this case, the weights are set for emulating 16bit overlapped pooling with 3x1 pooling kernel and stride 1. For this case, the fixed value 1 is used as weight.

(f) Pool 1x3 stride 1

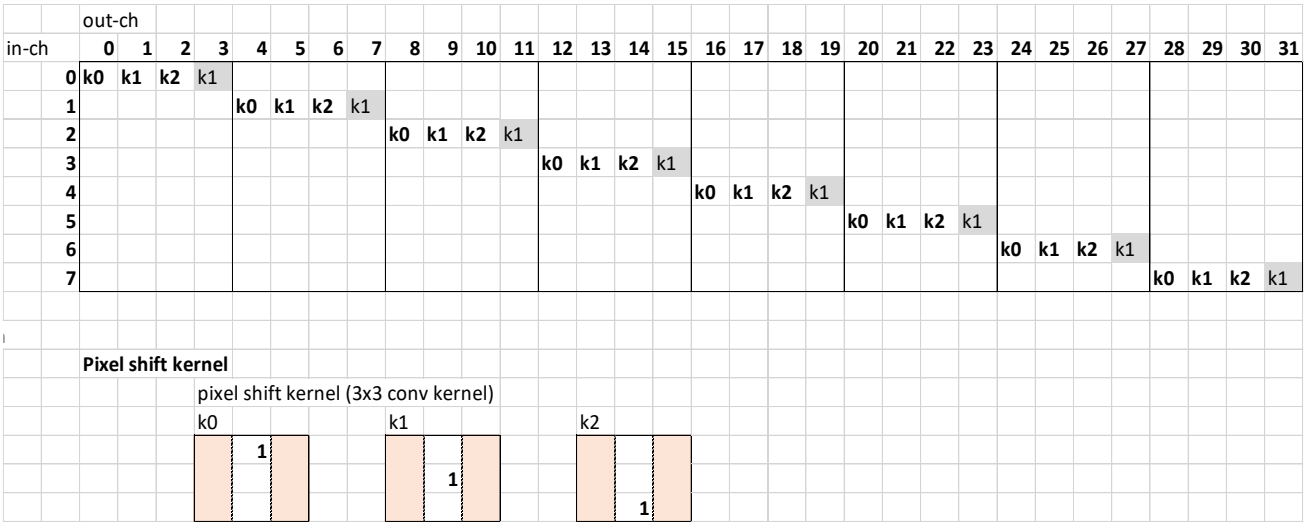

Figure U33.52 Weight setting for 8bit pool 1x3 stride 1

Figure U33.52 shows the setting of the non-zero weight elements in case of setting N to 9. In this case, the weights are set for emulating 8bit overlapped pooling with 1x3 pooling kernel and stride 1. For this case, the fixed value 1 is used as weight.

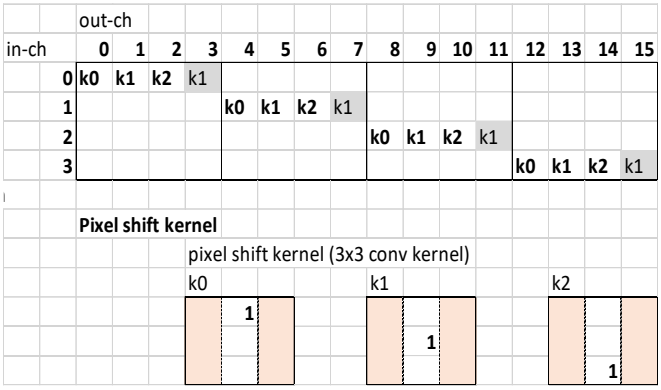

Figure U33.53 Weight setting for 16bit pool 1x3 stride 1

Figure U33.53 shows the setting of the non-zero weight elements in case of setting N to 10. In this case, the weights are set for emulating 16bit overlapped pooling with 1x3 pooling kernel and stride 1. For this case, the fixed value 1 is used as weight.

(g) Pool 2x1 stride 1

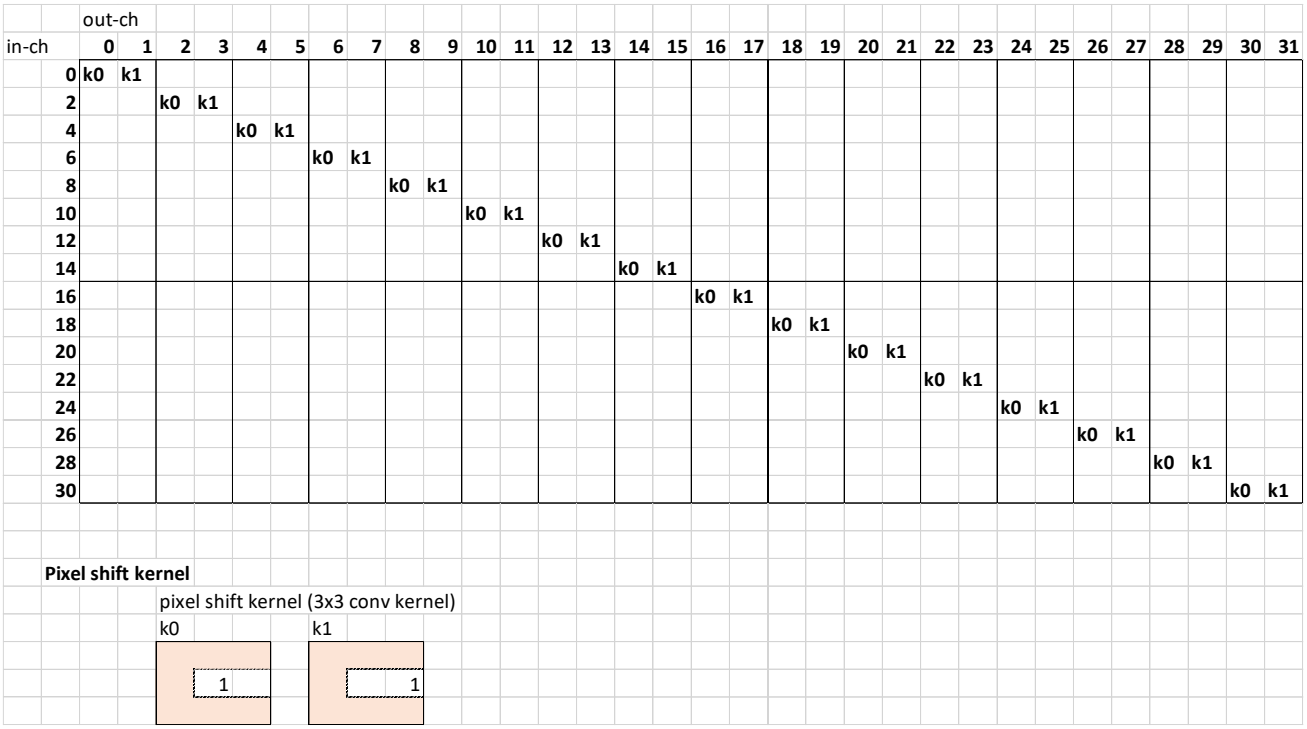

Figure U33.54 Weight setting for 8bit pool 2x1 stride 1

Figure U33.54 shows the setting of the non-zero weight elements in case of setting N to 11. In this case, the weights are set for emulating 8bit overlapped pooling with 2x1 pooling kernel and stride 1. For this case, the fixed value 1 is used as weight.

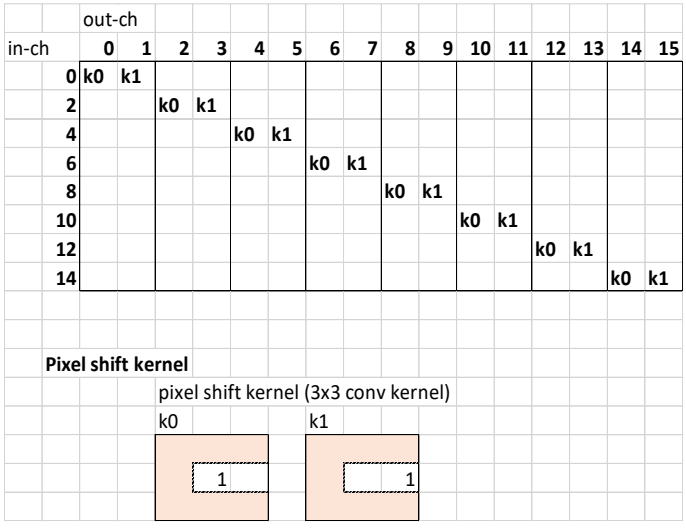

Figure U33.55 Weight setting for 16bit pool 2x1 stride 1

Figure U33.55 shows the setting of the non-zero weight elements in case of setting N to 12. In this case, the weights are set for emulating 16bit overlapped pooling with 2x1 pooling kernel and stride 1. For this case, the fixed value 1 is used as weight.

(h) Pool 1x2 stride 1

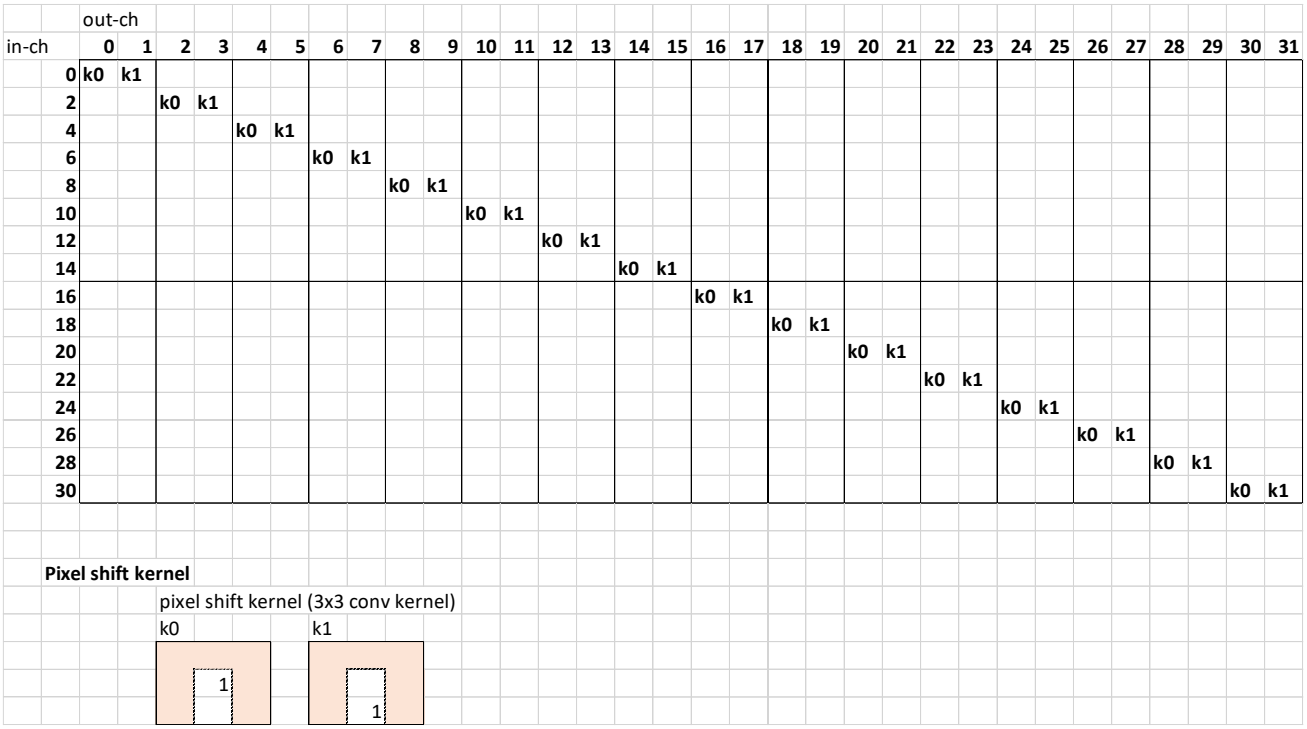

Figure U33.56 Weight setting for 8bit pool 1x2 stride 1

Figure U33.56 shows the setting of the non-zero weight elements in case of setting N to 13. In this case, the weights are set for emulating 8bit overlapped pooling with 1x2 pooling kernel and stride 1. For this case, the fixed value 1 is used as weight.

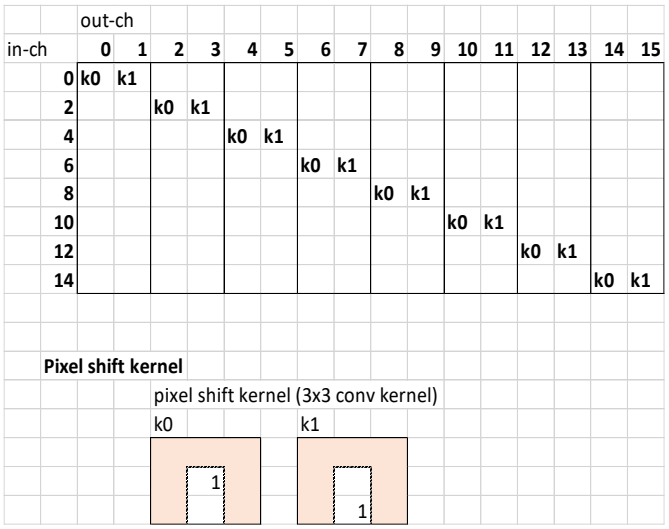

Figure U33.57 Weight setting for 16bit pool 1x2 stride 1

Figure U33.57 shows the setting of the non-zero weight elements in case of setting N to 14. In this case, the weights are set for emulating 16bit overlapped pooling with 1x2 pooling kernel and stride 1. For this case, the fixed value 1 is used as weight.

(i) Bilinear filter 2x2

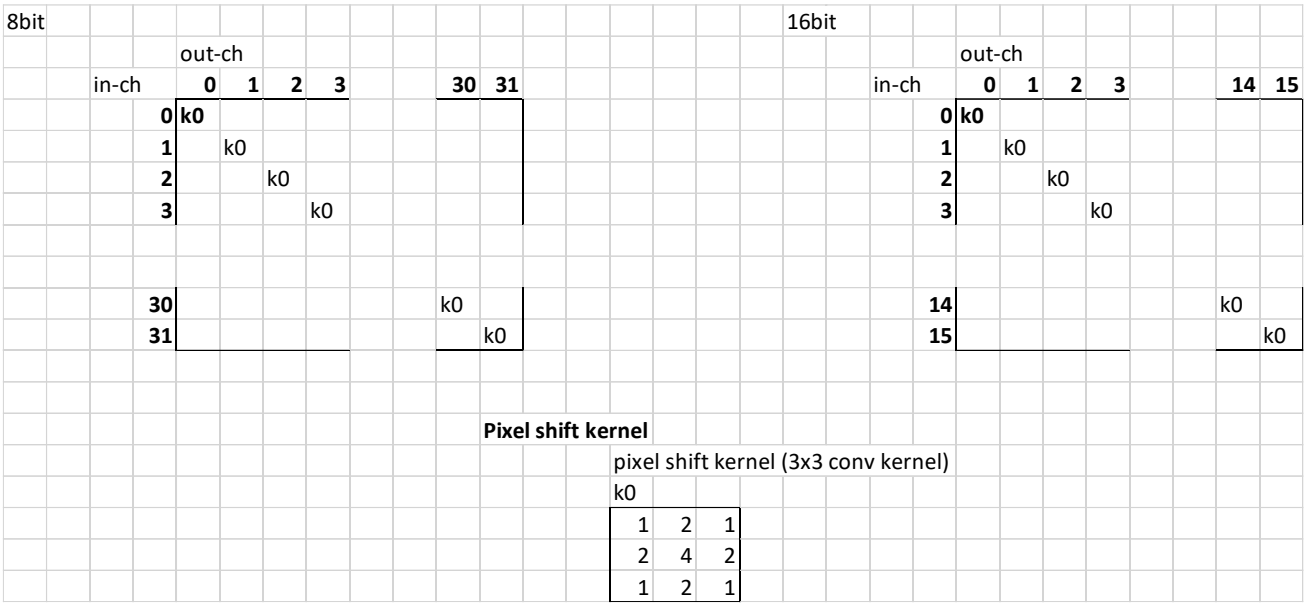

Figure U33.58 Weight setting for bilinear filter 2x2

Figure U33.58 shows the setting of the non-zero weight elements in case of setting N to 15 (8bit) or 16 (16bit). In this case, the weights are set for processing the bilinear filter 2x2.

(j) Bilinear filter 3x3

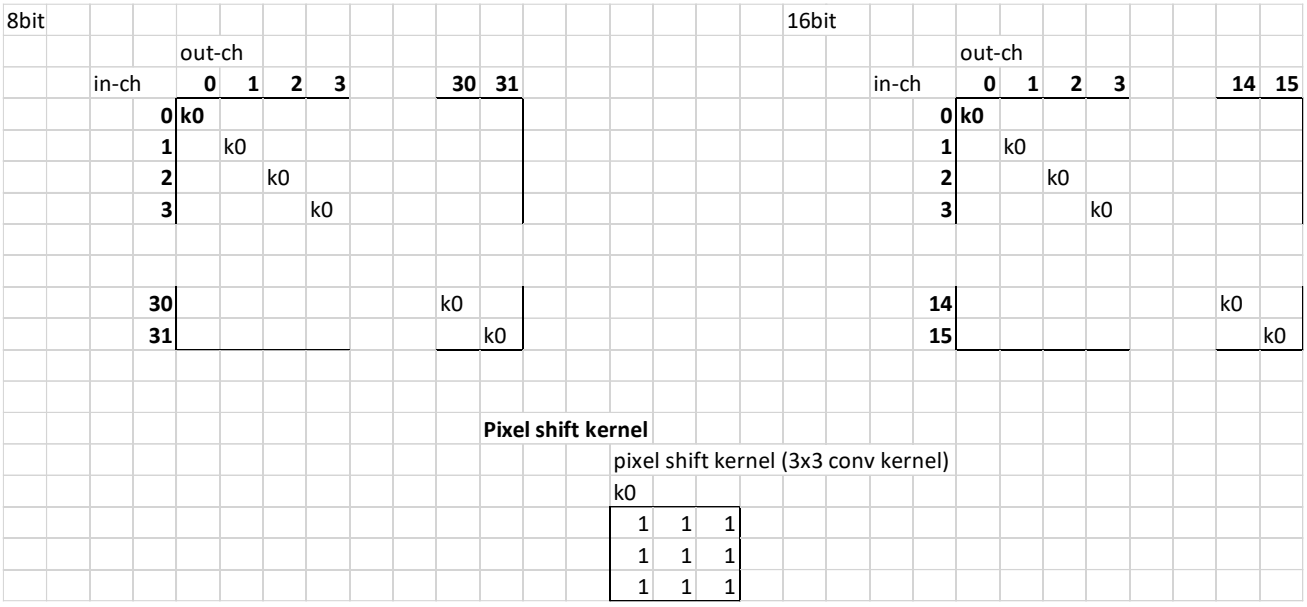

Figure U33.59 Weight setting for bilinear filter 3x3

Figure U33.59 shows the setting of the non-zero weight elements in case of setting N to 17 (8bit) or 18 (16bit). In this case, the weights are set for processing the bilinear filter 3x3.

Figure U33.61 Weight setting for bilinear filter 5x5

Figure U33.61 shows the setting of the non-zero weight elements in case of setting N to 21 (8bit) or 22 (16bit). In this case, the weights are set for processing the bilinear filter 5x5.

U33.3.9 CNN-IP processing flow

1. Complete the necessary settings for all DMAs and ARI for the next tile, execute SLP command, and only execute the start commands after WUP.
2. To start the next tile, if there is a weight transfer, please execute the SYNCS command with CNV bit cleared before starting DMAW and after executing SYNCS command with DMAW bit cleared before starting DMAI. If there is no weight transfer, please execute the SYNCS command with DMAI bit cleared before starting DMAI.
3. "WPR" command must be used for DMAWS/DMAIS/SLSP[*1], while “WPRNBSY” command should be used for other registers. The register setting cycles for each DMA transfer can be masked by setting the registers for each DMA after SLSP start and writing only to each DMA start registers after SYNCS. (Restrictions 4,5,6 must be observed.)"
4. When DMA3DC is not used, set DMA3DCE to 0 before writing to DMAIS register.
5. Except for ELTWISE MULT processing, if for a channel DMA3DC enable is set, ARI enable must be also set.
6. Comply with this restriction: ARI_LEN after XY pooling >=DMAOL.
7. When changing the setting for a DMAO channel from 1 to 0, be sure to set the BUS bit (bit 6) of the SYNCS command to 0 (not masked). If BUS busy is masked and DMAOE is switched for a channel from 1 to 0, the channel clock may be switched off while still bus accesses happen. Other setting, please refer to U33.4.7(b) Note .
8. All register settings (accept register settings described in code sequences in U33.4.1(b) and U33.5.5(8)) must be done between SLSP start and SYNCS DMAI or if at the beginning no SYNCS DMAI is available, before DMAW/DMAI start, whichever is earlier, after, only write to the register to start DMAx processings; no register setting is allowed between DMAI start and SLSP.
   a. If there is a weight transfer with DMAW, the preferred setup flow is:
   (Register setting)→SYNCS(DMAI/CNV)→WPR(DMAWS)→SYNCS(DMAW/DMA3DC/DMAO/ ARI/BUS)→WPR(DMAIS)→WPRNBSY(DMA3DCS) → WPRNBSY(DMAOS)→ WPR(SLSP).

b. If there is a weight setting by CLW, the preferred setup flow is:
(Register setting)→SYNCS(DMAI/CNV)→CLW→WPR(DMAIS)→
SYNCS(DMA3DC/DMAO/ARI/BUS)→WPRNBSY(DMA3DCS) →WPRNBSY(DMAOS)→ WPR(SLSP).
c. If there is no weight transfer, the preferred setup flow is:
(Register setting) → SYNCS(DMAI) → WPR(DMAIS) → SYNCS(DMA3DC/DMAO/ARI/BUS) →
WPRNBSY(DMA3DCS) →WPRNBSY(DMAOS) → WPR(SLSP)."

9. In planar transfer mode, if only some DMAI channels must be enabled, set them continuously, not intermittently (to enable 6 of the 16 channels, e.g., set DMAIE to 0x003F).
10. In case a CLW is needed before weight loading by DMAWS (case a), please put it directly before writing to DMAWS.

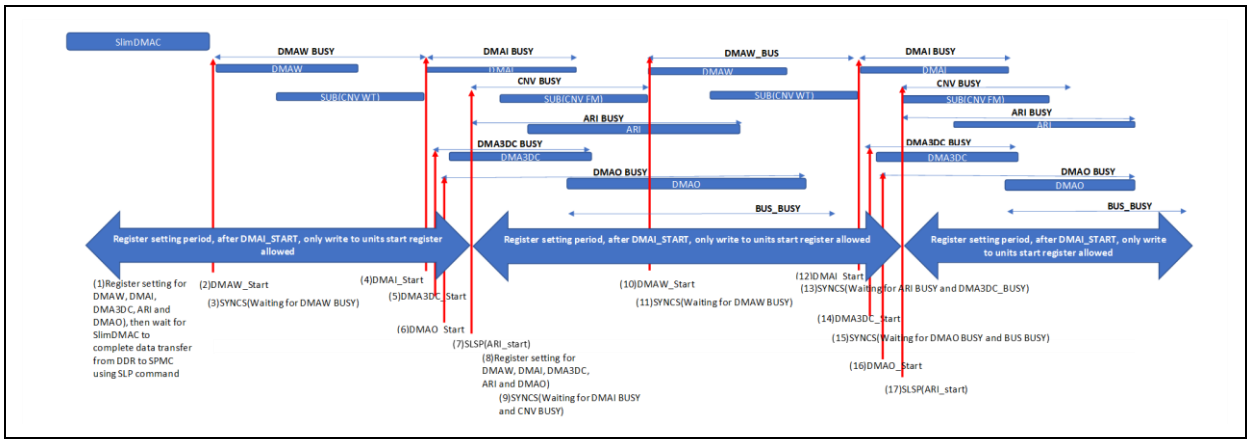

Figure U33.62 Example CL when weight loading over DMAW

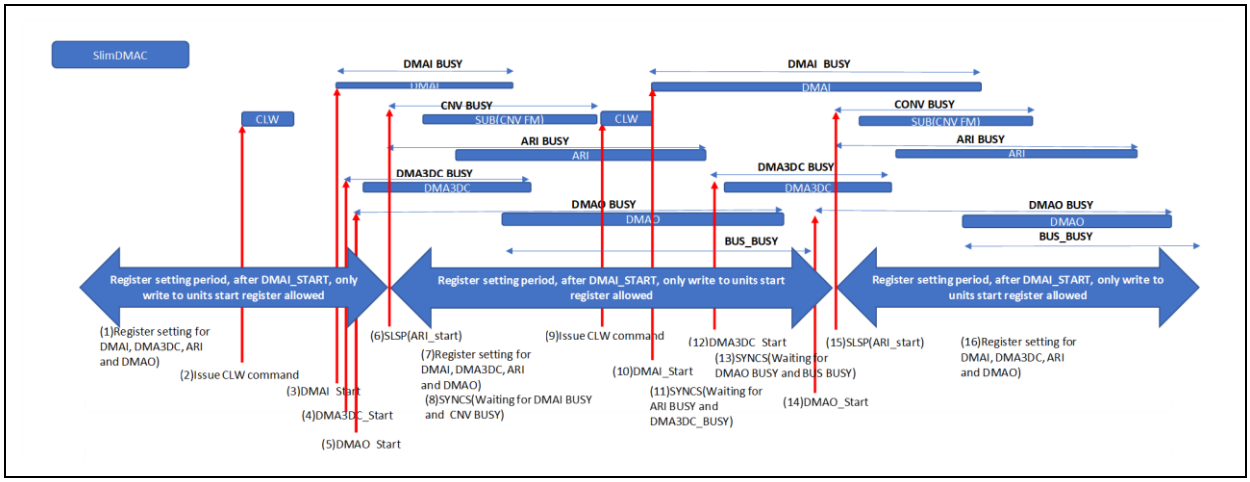

Figure U33.63 Example CL when weight loading over CLW

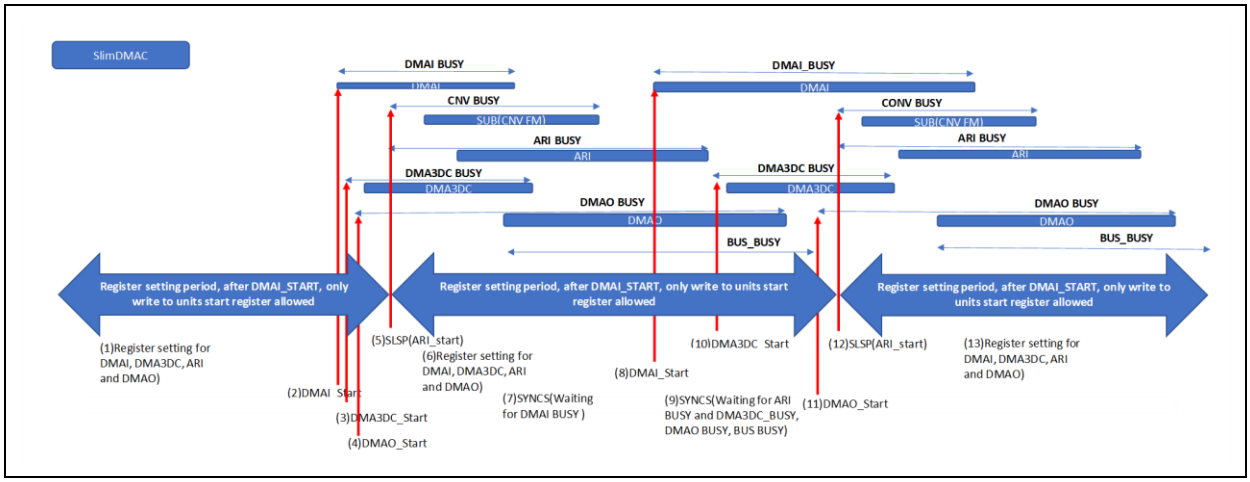

Figure U33.64 Example CL when no weight loading

Note 1: In case of SLSP register, if the following special command sequence (with or without writing to DMA3DCS register) is used, SLSP can be also written by using “WPRNBSY”:

```
0x8b0000xx      // SYNCS
0x55140501      // WPRNBSY DMA3DCS,1 (optional)
0x00000001      // data word (optional)
0x56180701      // WPRNBSY DMAOS,1
0xxxxxxxxx      // data word
0x56004401      // WPRNBSY SLSP,1
0x00000003      // data word
```

U33.4 Command List

It is prohibited to use instructions not listed in this section.

Table U33.53 Instruction list

Instruction	OP CODE	Description
CLW	H'4C	Clear weight buffers
WPR	H'55	Writes a long value to the register
WPRNBSY	H'56	Writes a long value to the register, does not wait till register value has been written
NOP	H'80	No Operation
INT	H'81	Generates an interrupt and waits for the release of the interrupt bit.
TRAP	H'88	End of CL execution
SYNCS	H'8B	Waits for completion of all sub tasks of CNN unit.
JUMP	H'90	Jumps to an address.
GOSUB	H'91	Jumps to a sub routine.
RET	H'99	Returns from a sub routine.
WUP	H'A0	Activates an external unit.
SLP	H'A1	Waits for an activation request from an external unit.

U33.4.1 CLW

(a) Usage

CLW

(b) Function

The CLW instruction clears all weight entries of weight buffer. Please refer to the Table U33.54 for the details of N setting. Regarding the field VAL used if N defined as 23(B'10111) or 24(B'11000), signed 16bit is used for 16bit processing, lower 8bit is used as signed 8bit for 8bit processing. For more details, refer to U33.3.8(7) .
The CLW instruction must be used always surrounded by 2 WPR instructions, which are enabling and disabling the usage of the CLW instruction. For enabling the usage of the CLW instruction, WPR should be used, while for disabling the usage of the CLW instruction, WPRNBSY can also be used. A correct usage sequence looks as follows:

```
0x55009401      ; enabling CLW instruction
0x00000001
0x4C000000      ; example CLW instruction with reset to all zero
0x56009401      ; disabling CLW instruction
0x00000000
```

	Description
Setting in N field	Clear all weight entries of weight buffer 00000: Reset all with 0 00001: Reset for ELTWISE MAX 8bit reorder processing 00010: Reset for ELTWISE MAX 16bit reorder processing 00011: Reset for ELTWISE MAX 8bit through processing 00100: Reset for ELTWISE MAX 16bit through processing 00101: Reset for OverlapPool 4to1 3x3_2 2x2_1 8bit processing 00110: Reset for OverlapPool 4to1 3x3_2 2x2_1 16bit processing 00111: Reset for OverlapPool 4to1 3x1_1 8bit processing 01000: Reset for- OverlapPool 4to1 3x1_1 16bit processing 01001: Reset for OverlapPool 4to1 1x3_1 8bit processing 01010: Reset for OverlapPool 4to1 1x3_1 16bit processing 01011: Reset for OverlapPool 2to1 2x1_1 8bit processing 01100: Reset for OverlapPool 2to1 2x1_1 16bit processing 01101: Reset for OverlapPool 2to1 1x2_1 8bit processing 01110: Reset for OverlapPool 2to1 1x2_1 16bit processing 01111: Reset for Bilinear 2x2 8bit processing 10000: Reset for Bilinear 2x2 16bit processing 10001: Reset for Bilinear 3x3 8bit processing 10010: Reset for Bilinear 3x3 16bit processing 10011: Reset for Bilinear 4x4 8bit processing 10100: Reset for Bilinear 4x4 16bit processing

	10101: Reset for Bilinear 5x5 8bit processing 10110: Reset for Bilinear 5x5 8bit processing 10111: Reset for Identity matrix with signed 8bit const value VAL for 8bit processing 11000: Reset for Identity matrix with signed 16bit const value VAL for 16bit processing

U33.4.2 WPR

(a) Usage

V3U_COMP_MODE == 0: WPR INDEX,ADD,N
V3U_COMP_MODE == 1: WPR ADD,N

(b) Function

The WPR instruction writes the number of values specified in the N field to N consecutive addresses starting from the address specified in the ADD field (data is in order from DATA 0 to DATA N - 1). The ADD field is set in 4byte units. Setting 0 in the N field is prohibited.
If V3U_COMP_MODE bit of V3U_COMP_MODE register is set to 0, the INDEX field is replacing the upper 3 address bits. The INDEX field specifies the number of the index register INDEXN. The value from the index register will be added to the offset specified in the DATA fields of this command. The range of INDEX is (0 to 7). It is advised to use INDEX0 in case of writing values to non-address registers while using INDEX1 till INDEX7 for address registers.

(c) Instruction Format

V3U_COMP_MODE == 0:

U33.4.3 WPRNBSY

(a) Usage

V3U_COMP_MODE == 0: WPRNBSY INDEX,ADD,N
V3U_COMP_MODE == 1: WPRNBSY ADD,N

(b) Function

The WPRNBSY instruction writes the number of values specified in the N field to N consecutive addresses starting from the address specified in the ADD field (data is in order from DATA 0 to DATA N - 1). The ADD field is set in 4byte units.
Setting 0 in the N field is prohibited. In contrast to the WPR instruction, the WPRNBSY instruction does not wait till the previous instruction is finished. Therefore, in case dependencies exist to previously executed commands, WPRNBSY should not be used. Such dependency could be e.g., writing to the SLSP register to start layer processing which should only start after all parameter registers received their parameter values, here normal WPR instruction would be required.
If V3U_COMP_MODE bit of V3U_COMP_MODE register is set to 0, the INDEX field is replacing the upper 3 address bits. The INDEX field specifies the number of the index register INDEXN. The value from the index register will be added to the offset specified in the DATA fields of this command. The range of INDEX is (0 to 7). It is advised to use INDEX0 in case of writing values to non-address registers while using INDEX1 till INDEX7 for address registers.

U33.4.4 NOP

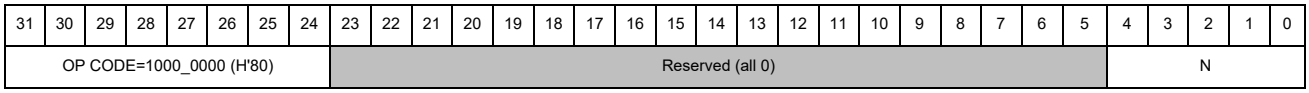
(a) Usage

NOP N

(b) Function

The NOP instruction causes the CNN unit to do nothing for the number of clock cycles specified in the N field before execution of the next instruction. Values up to 16 are supported.

(c) Instruction Format



U33.4.5 INT

(a) Usage

INT CODE

(b) Function

Only when the INTE bit of the SRE register is 1, it is reflected in the INT bit of the SR register.
Regardless of the value of the INTE bit in the SRE register, the value specified in the CODE field is reflected in the INTCODE bits of the SR register.
While the INT bit in the SR register is 1, subsequent instructions are not started.

(c) Instruction Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OP CODE=1000_0001 (H'81)								Reserved (all 0)																CODE							

U33.4.6 TRAP

(a) Usage

TRAP CODE

(b) Function

TRAP terminates execution of the command list. Only when the TRAE bit of the SRE register is 1, it is reflected in the TRA bit of the SR register.
However, regardless of the value of the TRAE bit in the SRE register, the value specified in the CODE field is reflected in TRAPCODE bits of the SR register.

(c) Instruction Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OP CODE=1000_1000 (H'88)								Reserved (all 0)																CODE							

U33.4.7 SYNCS

(a) Usage

SYNCS N

(b) Function

If there is a CNN operation currently being executed, this instruction waits for completion of the execution of that CNN operation. After the CNN operation has been finished, the subsequent instruction is started.
If there is no CNN operation being executed, it is the same as NOP (the following instruction is started).
With the command, parameters can be specified. With the DMAW, DMAI, DMA3DC, ARI, DMAO and BUS bits, the module for which not to wait can be masked, multiple masks are supported. By default, all bits are set to 0, so no module is masked.
With the DMAW bit, the check whether DMAW processing has finished, can be masked.
With the DMAI bit, the check whether DMAI processing has finished, can be masked.
With the DMA3DC bit, the check whether DMA3DC processing has finished, can be masked.
With the DMAO bit, the check whether DMAO processing has finished, can be masked.

With the ARI bit, the check whether convolution and ARI processing has finished, can be masked.
With the CNV bit, the check whether convolution has finished, can be masked. After confirming the completion of CNV, the weight setting by DMAW or CLW command for the next FM process can be started without waiting for the completion of ARI.

With the BUS bit, the check whether the data transfer on the bus has finished, can be masked.
If DMA3DC/DMAI is reading in the next run the data the DMAO is in the current run writing out, the user must take care that preloading DMA3DC/DMAI data is not overtaking the data write out from DMAO by e.g., not masking the check whether the data transfer on the bus has finished.
If in the next run the data is not written to the same SPMC memory, so a change from SPMC0 to SPMC1 or from SPMC1 to SPMC0 happens, the bus bit must be checked additionally before starting the write out to the changed SPMC memory.
Note:
(1) If DMAI on the next layer reads the data that DMAO has written to SPMC0, wait for DMAO completion with both BUS (bit6) and DMAO (bit4) of the SYNCS instruction enabled.
(2) If DMA3DC on the next layer reads the data that DMAO has written to SPMC1, wait for DMAO completion with both BUS (bit6) and DMAO (bit4) of the SYNCS instruction enabled.
(3) If DMAO writes to SPMC0 in this layer and DMAO writes to SPMC1 in the next layer, or if DMAO writes to SPMC1 in this layer and DMAO writes to SPMC0 in the next layer, wait for DMAO completion with both BUS (bit6) and DMAO (bit4) of the SYNCS instruction enabled.
(4) When changing the setting for a DMAO channel from 1 to 0, be sure to set the BUS bit (bit 6) of the SYNCS command to 0 (not masked). If BUS busy is masked and DMAOE is switched for a channel from 1 to 0, the channel clock may be switched off while still bus accesses happen.
(5) If using in this layer DMAO in packed mode and in the next layer in planar fast mode and if not enabling channel 0,8,16 or 24 in the next layer, make sure to wait also for BUS busy before starting DMAO processing of next layer.

(c) Instruction Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

U33.4.8 JUMP

(a) Usage

JUMP RLT

(b) Function

This is the command to jump to the specified address.

It allows jumping to the address specified in JMPADD field. Setting 1 to RLT field uses JMPADD as relative address to JUMP command address and setting 0 in RLT field uses JMPADD as absolute address of the command list. Specify 4byte unit command address in the JMPADD field.

(c) Instruction Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OP CODE=1001_0000 (H'90)								RLT	Reserved (all 0)																						
JMPADD																															

U33.4.9 GOSUB

(a) Usage

GOSUB RLT, CON

(b) Function

This is the command to save current CL address to the hardware buffer and jump to the specified address.
It allows jumping to the address specified in GSADD field and returning to the address next to the GOSUB command by RET command. Specify 4byte unit command address in the GSADD field, nesting of up to 4 level is supported. Setting 1 to RLT field uses GSADD as relative address to GOSUB command address and setting 0 in RLT field uses GSADD as absolute address of the command list. Setting 1 in CON field executed GOSUB conditionally and setting 0 in the CON field executed GOSUB unconditionally. Setting 1 in CON field and 0 in CLCNDGSBR bit of CLCNDGSBR register changes GOSUB command into NOP command. After the CLCNDGSBR register and used index register are set, a SYNCS command should be added before using the GOSUB command.

(c) Instruction Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OP CODE=1001_0001 (H'91)								RLT	CON	Reserved (all 0)																					
GSADD																															

U33.4.10 RET

(a) Usage

RET

(b) Function

The RET instruction returns to the address stored by the GOSUB instruction.

(c) Instruction Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OP CODE=1001_1001 (H'99)								Reserved (all 0)																							

U33.4.11 WUP

(a) Usage

WUP CN

(b) Function

With this instruction, a WUP signal is sent to other modules. A WUP signal is issued to the modules defined by SYNCCm (m = 0 to 15) signals by setting bit 'm' of CN enable field to 1.
Be sure to insert 8 or more instructions other than the WUP instruction between two WUP instructions in the CL.

(c) Instruction Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OP CODE=1010_0000 (H'A0)								Reserved (all 0)								CN															

U33.4.12 SLP

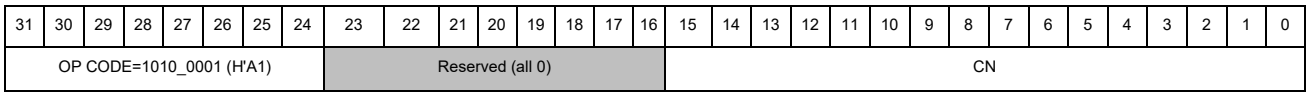
(a) Usage

SLP CN

(b) Function

With this instruction, a WUP signal is received from other modules. By executing the SLP instruction, the module does not start subsequent instructions until it receives the WUP signal from the module to be synchronized. Upon receipt of the WUP signal, execution of the subsequent instruction on the CL is continued.
By setting bit 'm' of the CN enable field to 1, the WUP signal from the module set to SYNCCm (m = 0 to 15) signal is awaited, selection of multiple bits is supported.

(c) Instruction Format



U33.5 Usage Notes

U33.5.1 Synchronized system between modules

For synchronized system between modules, refer to the **Section U34.IMP-X7_system, U34.10.5 Inter Module Synchronization of IMP-X7_System manual.**

U33.5.2 Power shutdown

For power shutdown, refer to User's Manual: Hardware, section 58.7.1, Shutting Down the Power Supply.

U33.5.3 Module Standby Mode

For module standby mode, refer to User's Manual: Hardware, section 58.7.2, Module Standby Mode.

U33.5.4 CPG Software Reset

For software reset of CPG, refer to User's Manual: Hardware, section 58.7.3, Software Reset by the Clock Pulse Generator (CPG).

U33.5.5 Limitation

(1) FM size limitation

The vertical size after magnification function (skip/repeat), that can be supported in one HW activation, is limited to 2048(SPMC0) or 1024(SPMC1), while the horizontal size is limited to 128.

(2) DMAISA setting limitation for planar fast type

The start address in the DMAISA register is limited to 16byte aligned settings when reading the data from multiple channels simultaneously by planar fast type (DMAIS_MODE bit = 1) and selecting a magnification function (skip/repeat) in horizontal direction. If no magnification is used, this limitation is not available.

(3) DMAIE setting limitation for 1*5x5 mode

The processing power of the architecture is not sufficient to support 1*5x5 mode for all input channels, therefore, the number of usable input channels is halved here, so that channel m and channel m+2 together are operating on channel m. The enable signals of channel m and m+2 must be set same.
8bit:
DMAIE[0]=DMAIE[2], DMAIE[1]=DMAIE[3], DMAIE[4]=DMAIE[6], DMAIE[5]=DMAIE[7]
DMAIE[8]=DMAIE[10], DMAIE[9]=DMAIE[11], DMAIE[12]=DMAIE[14], DMAIE[13]=DMAIE[15]
16bit:
DMAIE[0]=DMAIE[2], DMAIE[4]=DMAIE[6], DMAIE[8]=DMAIE[10],DMAIE[12]=DMAIE[14]

(4) Weights setting limitation for 2*3x3 mode

When the DMAIS_PART bits are set to 2 or 3 in 2*3x3 convolution mode, the weights for the odd FM channels must be set to 0, because only the even FM channels hold valid data. In that way, invalid data can be prevented from getting summed up during the convolution sum-up phase.

(5) Magnification and padding mode combination limitation

The combination of repeat constant (magnification mode) and padding identity (padding mode) in Y direction cannot be supported.

(6) PADD_STRIDE_STARTPOS and ARI_LEN setting limitation

If PADD_STRIDE_STARTPOS.START_POS_X is set to a larger value than 0, ARI_LEN.ARI_XLEN must be set to larger value than 2.
If PADD_STRIDE_STARTPOS.STRY is set to a value larger than 1, ARI_LEN.ARI_XLEN must be set to a value larger than 4.

(7) DMAO setting limitation for m16 and m32

DMAOS.DMAOS_RMW should be set to 0 when m16 (DMAOPARAM. DMAOFM=2) or m32 (DMAOPARAM. DMAOFM=3) is selected. Also, don't access SPMC1 with Slim-IMP DMAC or other non-CNN IP at the same time of the DMAO transfer with m16 and m32.

(8) Required settings for special DMAIE values

If DMAIE[15:0] meets condition (a) to (d) below, additional settings are required for DMAI_CONFIG and DMAW_CONFIG. If multiple conditions (a) to (d) apply, set DMAI_CONFIG to the ORed value.

(a) When DMAIE[3:0] is 0x4, 0x8, or 0xC, set DMAI_CONFIG and DMAW_CONFIG as follows before and after setting SLSP.SLSP_START bit to 1.

```
0x56009001    // Write 0x0001 to DMAI_CONFIG[15:0] with WPRNBSY command
0x00000001
0x56009401    // Write 0x1 to DMAW_CONFIG with WPRNBSY command
0x00000001

(Setting SLSP.SLSP_START to 1)

0x55009001    // Write 0x0000 to DMAI_CONFIG[15:0] with WPR command
0x00000000
0x56009401    // Write 0x0 to DMAW_CONFIG with WPRNBSY command
0x00000000
```

(b) When DMAIE[7:4] is 0x4, 0x8, or 0xC, set DMAI_CONFIG and DMAW_CONFIG as follows before and after setting SLSP.SLSP_START bit to 1.

```
0x56009001    // Write 0x0010 to DMAI_CONFIG[15:0] with WPRNBSY command
0x00000010
0x56009401    // Write 0x1 to DMAW_CONFIG with WPRNBSY command
```

0x00000001

(Setting SLSP.SLSP_START to 1)

0x55009001 // Write 0x0000 to DMAI_CONFIG[15:0] with WPR command
0x00000000
0x56009401 // Write 0x0 to DMAW_CONFIG with WPRNBSY command
0x00000000

(c) When DMAIE[11:8] is 0x4, 0x8, or 0xC, set DMAI_CONFIG and DMAW_CONFIG as follows before and after setting SLSP.SLSP_START bit to 1.

0x56009001 // Write 0x0100 to DMAI_CONFIG[15:0] with WPRNBSY command
0x00000100
0x56009401 // Write 0x1 to DMAW_CONFIG with WPRNBSY command
0x00000001

(Setting SLSP.SLSP_START to 1)

0x55009001 // Write 0x0000 to DMAI_CONFIG[15:0] with WPR command
0x00000000
0x56009401 // Write 0x0 to DMAW_CONFIG with WPRNBSY command
0x00000000

(d) When DMAIE[15:12] is 0x4, 0x8, or 0xC, set DMAI_CONFIG and DMAW_CONFIG as follows before and after setting SLSP.SLSP_START bit to 1.

0x56009001 // Write 0x1000 to DMAI_CONFIG[15:0] with WPRNBSY command
0x00001000
0x56009401 // Write 0x1 to DMAW_CONFIG with WPRNBSY command
0x00000001

(Setting SLSP.SLSP_START to 1)

0x55009001 // Write 0x0000 to DMAI_CONFIG[15:0] with WPR command
0x00000000
0x56009401 // Write 0x0 to DMAW_CONFIG with WPRNBSY command
0x00000000

(9) WPRNBSY limitation after SLSP command

There must be an interval of several cycles between the setting of the SLSP register and the setting of the register whose trigger is specified as "ARI" in Table U33.3 by the WPRNBSY command. Therefore, choose one of the following methods to make the interval.

(a) Insert a SYNCS command between the setting of the SLSP register and the setting of the ARI-triggered register.

Example:
1, WPR (SLSP register)

2, SYNCS
3, WPRNBSY (ARI-triggered register)

(b) Insert at least one WPR command between the SLSP register setting and the ARI-triggered register setting or use the WPR command to set the ARI-triggered register.

Example 1:
1, WPR (SLSP register)
2, WPR (Some register)
3, WPRNBSY (ARI-triggered register)

Example 2:
1, WPR (SLSP register)
2, WPR (ARI-triggered register)

(c) Insert the required number of WPRNBSY commands between the SLSP register setting and the ARI-triggered register setting. The number of WPRNBSY commands required depends on the setting of the N field of WPRNBSY.
N field =1 …counts as 2cycle
N field =2 …counts as 3cycle
N field =3 …counts as 4cycle
N field =4 …counts as 5cycle
N field =5 or more …counts as 6cycle or more
A number of WPRNBSY instructions should be inserted so that the sum of inserted clock cycles reaches at least 6 cycles.

Example:
Insert WPRNBSY with N field =1 (2cycle) and N field =3 (4cycle)
1, WPR (SLSP register)
2, WPRNBSY, N field =1 (Some register)
3, WPRNBSY, N field =3 (Some register)
4, WPRNBSY (ARI-triggered register)

(10) Limitation overview

Table U33.55 Limitation overview

module(DMAI, DMAW, SUB, DMA3DC, DMAO, ARI)	function	Limitation	Reference
HI	Register Access	Accessing addresses not listed in this register list is prohibited. Operation cannot be guaranteed when accessing an address, which is not listed.	U33.1.3
HI	Register Access	Access size is 32-bit. Operation cannot be guaranteed when accessing by other than 32-bit.	U33.1.3
HI	Register Access	Operation cannot be guaranteed when writing to a register from CPU during IMP CNN execution.	U33.1.3

HI	Register Access	In the CNN register address area, offset addresses larger than 0x7000 are forbidden to access for read and write direction by WPR instruction and other IP.	U33.1.3
HI	Register Access	Read-only. The write value should be the same as the read value. Only modify the target bit (Read Modify Write) because the initial value should not be changed.	U33.1.3
IFID	CLW	CLW usage	U33.4.1
IFID	WPRNBSY	WPRNBSY can be only used if existing dependencies are not violated.	U33.4.3 U33.5.5.9
IFID	WPRNBSY	WPRNBSY limitation after SLSP command	U33.5.5.9
IFID	SLSP	Required settings for special DMAIE values	U33.5.5.8
IFID	WUP	Be sure to insert 8 or more instructions other than the WUP instruction between two WUP instructions in the CL.	U33.4.11 U33.3.8.2
IFID	WUP	Between 2 wake-up signals to the same module a SLP command must be scheduled for handshaking to the same one.	U33.3.8.2
IFID	SYNCS	If DMAO changes the memory to output make sure to wait for BUS busy.	U33.4.7.b
IFID	SYNCS	If disenabling a DMAO channel, make sure to wait for BUS busy.	U33.4.7.b
IFID	SYNCS	If changing DMAO output from packed to planar fast mode and disabling any of the channels 0,8,16 or 24 in the planar fast mode layer, make sure to wait for BUS busy.	U33.4.7.b
DMAW	Weight loading	start address is restricted to 512byte align, so the lower 9bit of DMAWSA should be set to 0.	U33.3.2.7
DMAW	Weight loading	When loading weight in depthwise mode (DMAWS.DMAWS_TYPE=B'0001), the CLW command with N field=B'00000 must be executed before starting the transfer by setting DMAWS.DMAWS_START to 1.	U33.3.2.7
DMAW	Weight loading	When wrap around is enable, keep following restriction DMAWWA_START*512 <= DMAWSA < DMAWWA_END*512	register map
DMAI	Kernel mode	Comply with the function limitation for each kernel mode	table U33.9
DMAI	Kernel mode	Only 1 of the following 3 operations is supported at a time: convolutional striding, dilated convolution	table U33.10

		and magnification.	
DMAI	Transfer modes	Comply to the supported transfer modes for each kernel mode.	table U33.11
DMAI	Picture parameter	Comply to the size setting restriction depending on magnification settings.	table U33.12 table U33.13 register map
DMAI	Picture parameter	Comply to the start address setting restrictions	table U33.14 table U33.17 table U33.18 register map
DMAI	Picture parameter	Comply to the stride setting restrictions	table U33.15 register map
DMAI	Picture parameter	DMAISA setting limitation for planar fast type	U33.5.5.2
DMAI	Picture parameter	Comply to the size setting dependencies between ARI and DMAI for x and y direction	register map
DMAI	Picture parameter	In case of 16*1x1 kernel mode, DMAILX must not be set larger than half of the setting for other kernel modes.	register map
DMAI	Common/Individual Setting	This individual setup is only supported for the 1*5x5 kernel mode and planar type format.	U33.3.2.6
DMAI	Common/Individual Setting	Set 0 to DMAICO in case of individual DMAISA setup.	U33.3.2.6
DMAI	Channel offset	Comply to the channel offset setting restrictions	table U33.16 register map
DMAI	Wrap around	Wrap-around is supported only for the packed type format (DMAIS_MODE=B'10).	U33.3.2.8
DMAI	Wrap around	Comply to the address settings when using wrap-around function	U33.3.2.8 table U33.20 register map
DMAI	Channel part	Comply to the limitations regarding part function usage for planar modes	U33.3.2.11
DMAI	Channel part	Weights setting limitation for 2*3x3 mode	U33.5.5.4
DMAI	Channel Enable	It is prohibited to run CNN with the DMAIE register set to 16'h0000. At least one channel must be enabled by setting DMAIE register.	U33.3.2.10
DMAI	Channel enable	When DMAIS_8TO16BIT_CONV=1, only even bits of DMAIE are available, and odd bits should be set to 0.	U33.3.2.10
DMAI	Channel enable	DMAIE setting limitation for 1*5x5 mode	U33.5.5.3 U33.3.2.10
DMAI	Padding	Supported range of padding function per kernel	table U33.24

		mode	
DMAI	Conv Stride	Supported range of convolution striding function per kernel mode	table U33.26
DMAI	Dilated conv	Supported range of dilated convolution per kernel mode (support only 1*5x5)	table U33.28
DMAI	Start pos	PADD_STRIDE_STARTPOS and ARI_LEN setting limitation	U33.5.5.6
DMAI	Start pos	Start position in x direction for 2*3x3 convolution mode requires setting the left padding to 0	register map
DMAI	Start pos	Start position in y direction for 2*3x3 convolution mode requires setting the top padding to 0	register map
DMAI	Start pos	Size in x-direction after magnification must be larger than start position in x direction.	register map
DMAI	Start pos	Size in y-direction after magnification must be larger than start position in y direction.	register map
DMAI	Padding	PADD_STRIDE_STARTPOS. PADDMODE=1 (identity padding) cannot be set together with DMAIPARAM.DMAIMM= 10 (repeat constant)	register map U33.5.5.5
DMA3DC	Picture parameter	Comply to alignment of DMA3DC start address	register map
DMA3DC	Picture parameter	DMA3DCL must be same as ARI_LEN for X/Y direction	register map
DMA3DC	Picture parameter	DMA3DCST must be set in 16 pixels units for s8 and s16 format, 8 pixels units for m16 format, and 4 pixels units for m32 format.	U33.3.3.2
DMA3DC	Format	Supported combinations of DMA3DCFM and ARIFM	U33.5.6
DMA3DC	Format	When {ARICSR[25], ARICSR[31]} = 2B'00, if 3DC_INPUT_USAGE=2/3 is used, only DMA3DCFM=m16/m32 are supported.	register map
DMA3DC	Format	When {ARICSR[25], ARICSR[31]} = 2B'01, if 3DC_INPUT_USAGE=2/3 is used, only DMA3DCFM=m16 is supported.	register map
DMA3DC	Format	Combination DMA3DCFM=s16 and ARICSR.ARIFM=s8 is not supported.	register map
DMA3DC	Format	Combination DMA3DCFM=s8 and ARICSR.ARIFM=s16 is not supported.	register map
DMA3DC	Format	DMA3DCFM must be set same in ARICSR and DMA3DCPARAM	register map
DMA3DC	SPMC	DMA3DC input data is only supported for SPMC1, not SPMC0	U33.3.3
DMA3DC	Channel enable	When DMA3DC is not used (DMA3DCS is not set), the DMA3DCE register must be set to	U33.3.3.4

		32H'0000_0000.	
DMA3DC	Channel enable	One of the bits 0-7 of DMA3DCEN must be ON when using DMA3DC.	U33.3.3.4
DMA3DC	Channel enable	If a bit in the ARIE register is set to 0, the corresponding bit in the DMA3DCE register must also be set to 0 (exception: ELTWISE MULT 16bit).	U33.3.3.4
DMA3DC	Shifter	No overflow check for SFTC, support of 32bit (8bit) and 41bit (16bit) for shifted output value	register map
SUB	Format	For convolution with s8/u8 FM and s16 WT. -Setting 0x1 in the DMAIS.DMAIS_8TO16BIT_CONV register to enable 8bpp to 16bpp conversion for FM -DMAIE can only be set to even bits, odd bits should be set to 0. -ARICSR.DMAIFM register must be set to 0x2 (s16).	U33.3.4.3
SUB	Format	When using DMAW to load weight data, DMAWS_FM register must be set to the same value as the ARICSR. ARIFM register.	U33.3.4.3
SUB	Format	Convolution with DMAIPARAM.DMAIFM=2B'10 (s16) and DMAWS.DMAWS_FM=1B'0 (s8) is not supported	U33.3.4.3
ARI	ALL subunits	ARIE bit 0 must be enabled	register map
ARI	Activation	Support for s8/s16/m16 with ARICSR.M16_VAL_AFTER_ACT set to 1. Not support for m16 with ARICSR.M16_VAL_AFTER_ACT set to 0 and m32.	U33.3.5.2
ARI	Activation	For RELU and BRELU and if not using an activation function, ACTIVATION_OUTPUT_PARAM and ACTIVATION_ZERO_POINT in post processing are not supported.	figure U33.32 figure U33.33
ARI	Activation	SFTM_ZERO_POINT for RELU and BRELU only used if ARICSR.ARIFM_AFTER_ACTIVATION is s8. User must set SFTM_ZERO_POINT to zero for s16/m16 with ARICSR.M16_VAL_AFTER_ACT set to 1.	table U33.35
ARI	Activation	ACTIVATION_ZERO_POINT for Post Processing only used if ARICSR.ARIFM_AFTER_ACTIVATION is s8.	table U33.45

		User must set it to zero for s16/m16 with ARICSR.M16_VAL_AFTER_ACT set to 1.	
ARI	Activation	For EXP(SOFTMAX) mode, the input data should be negative values only.	U33.3.5.2e
ARI	Activation	For BRELU, only ARI_BND.ARI_UPPER_BND is used. Leaky RELU, both ARI_BND.ARI_UPPER_BND and ARI_BND.ARI_LOWER_BND are used. Other modes do not use ARI_BND.ARI_UPPER_BND and ARI_BND.ARI_LOWER_BND.	U33.3.5.2b U33.3.5.2c
ARI	Activation	ACTIVATION_MULT_VAL and ACTIVATION_MULT_POST_SFT are only used for Leaky RELU.	U33.3.5.2
ARI	Channel pooling	Support for s8/s16, m16/m32 are not supported	U33.3.5.3
ARI	Channel pooling	The first channel of each channel pooling group must be enabled.	register map
ARI	XY pooling	Support for s8/s16, m16/m32 are not supported	U33.3.5.4
ARI	XY pooling	When using XY average pooling, XPOOL and YPOOL bits of the ARICSR register must be the same	U33.3.5.4b
ARI	XY pooling	ARI_XLEN must be greater than XPOOL and ARI_YLEN must be greater than YPOOL	register map
ARI	Format	16bit ARIFM and 8bit ARIFM_AFTER_ACTIVATION is not supported	table U33.48
ARI	Format	{ARICSR.MIX_MODE_2,ARICSR.MIX_MODE} = 2B'01 must work with DMAO format = 2 (mixmode 16bit)	register map
ARI	Format	{ARICSR.MIX_MODE_2,ARICSR.MIX_MODE} = 2B'11 must work with DMAO format = 3 (mixmode 32bit)	register map
ARI	Statistics	Support for s8/s16, m16/m32 are not supported	U33.3.7
ARI	Statistics	Performance counter do not support DMAW	register map
ARI	Statistics	Limited stall reason selection for DMAI and DMA3DC	register map
DMAO	Format	Only DMAO format conversion from s16 to s8 is supported, other combinations are not supported.	U33.3.6
DMAO	Format	Planar mode output is only supported for format s8/s16, m16 and m32 are not supported.	table U33.47
DMAO	Channel enable	DMAOE bit 0 must be enabled	U33.3.6

DMAO	Channel enable	Only channels which are active after channel pooling can be selected by DMAOE.	register map
DMAO	Channel part	DMAO channel part is not supported with DMAO mixed mode processing	table U33.47
DMAO	Channel offset	DMAO channel offset is not supported in DMAO packed mode	table U33.47
DMAO	Wrap around	DMAO wrap-around is only supported for DMAO packed mode when accessing to SPMC0	table U33.47
DMAO	Wrap around	Comply to the address settings when using wrap-around function	table U33.47 U33.3.6
DMAO	Picture parameter	CEILING(ARI_XLEN/(XPOOL+1),0) >= DMAO_X CEILING(ARI_YLEN/(YPOOL+1),0) >= DMAO_Y	U33.3.9 register map
DMAO	Picture parameter	For SPMC1 output, 0 < y <= 1024	U33.5.5.1
DMAO	SPMC access	Mixed mode output is only supported for SPMC1, not SPMC0	table U33.47
DMAO	SPMC access	Register dump output is only supported for SPMC1, not SPMC0	U33.3.7.3
DMAO	SPMC access	Planar fast type of planar format output is only supported for SPMC0, not SPMC1	table U33.47
DMAO	Register dump	DMAO and DMARD cannot run at the same time.	U33.3.7.3
DMAO	RmW	In case of DMAO_RMW=0 and packed mode, all not written data bytes of the 512byte data word are overwritten with 0, for planar mode, only not written data bytes of 8byte data words with at least 1 written data byte are overwritten with 0.	register map
DMAO	RmW / SPMC1 access	DMAOS.DMAOS_RMW must be 0 if using m16 or m32 and Slim-IMP DMAC or other non-CNN IP should not access at same time point.	U33.3.5.7
DMARD	Channel enable	At least 1 DMAOE bit must be enabled	U33.3.7.3
DMAI/DMAO/DMA3DC	packed	The horizontal stride DMAxST must be specified as multiple of 16 pixels.	U33.3.1.2
DMAW, DMAI, DMA3DC, DMAO, ARI	processing flow	Comply to CNN-IP processing flow	U33.3.9

U33.5.6 Format combinations

Table U33.56 shows all allowed format combinations.

Table U33.56 Possible format combinations among DMAI, DMA3DC, ARI and DMAO

group	DMAI			DMA 3DC	ARI							DMAO			stored channel		proc. channel		comment
	DMAIFM	DMAIS_8TO16BIT_CONV	DMAIS_PART	DMA3DCFM	ARIFM	MIXED_MODE	MIXED_MODE_2	DMAIFM	DMA3DCFM	3DC_INPUT_USAGE	ARIFM_AFTER_ACTIVATION	DMAOFM	ARIFM_AFTER_ACTIVATION	DMAOS_PART	packed input format	packed output format	processed input channel 1*	processed output channel

Note:
1* Number of input FM channels one run processing.

U33.5.7 Recommendations

(1) Channel enable setting in case of planar type of planar mode

It is recommended that consecutive input channels are enabled without disabling channels in between, because disenabled channels also consume time. This improves the performance as shown in following example. In case of 8x1x1 kernel in byte format and selecting 2 DMAI channels over DMAIE, case a and b is showing 2 examples with required cycles for loading the data for 1 row by DMAI.

a.) In case of DMAIE = 0x00000003, DMAI channel 0 and 1 are enabled, which means 16 channels (channel 0-15) are enabled and loading 1 row takes 16 cycles.
b.) In case of DMAIE = 0x00008001, DMAI channel 0 and 15 are enabled, which means 16 channels (channel 0-7 and 120-127) are enabled and loading 1 row takes 128 cycles.

(2) Channel enable setting in case of planar fast type of planar mode and packed mode

It is recommended that input channels are enabled in blocks or 4 channels (ch0-3, ch4-7, ch8-11, ch12-15), because blocks are getting loaded if at least 1 channel inside the block is enabled. This improves the performance as shown in following example. In case of 8x1x1 kernel in byte format and selecting 4 DMAI channels over DMAIE, case a and b is showing 2 examples with required cycles for loading 16byte per channel by DMAI.

a.) In case of DMAIE = 0x0000000f, DMAI channel 0 till 3 are enabled, which means 32 channels (channel 0-31) are enabled and loading 16 byte per channel takes 1 cycle.

b.) In case of DMAIE = 0x00001111, DMAI channel 0,4,8,12 are enabled, which means 32 channels (channel 0-7, 32-39, 64-71 and 96-103) are enabled and loading 16 byte per channel takes 4 cycles.

U33.6 Safety Mechanism

Note: The suitability of the safety mechanisms referenced in this manual will finally be judged during the safety analysis and safety assessment of the SoC. Therefore, the safety documentation shall always be considered as additional requirements for the system or software derived from the results of the safety analysis.

U33.6.1 EDC protection.

EDC (Error Detection Code) protection is implemented to SRAM, Bus interface and dedicated CNN/SPMC in IMPCNN. EDC check is always enabled. Note that all FUSA errors from the IMP CNN are merged and finally output to the ECM (For details, please refer U34. IMP-X7: U34.10.6 Safety Mechanism) through IMPSLV. AXI slave BUS EDC errors, AXI master EDC errors, CNN SPMC interface EDC error are merged to **IMP-X7 bus error** and SRAM EDC errors are merged to **IMP-X7 SRAM EDC error** of ECM module.

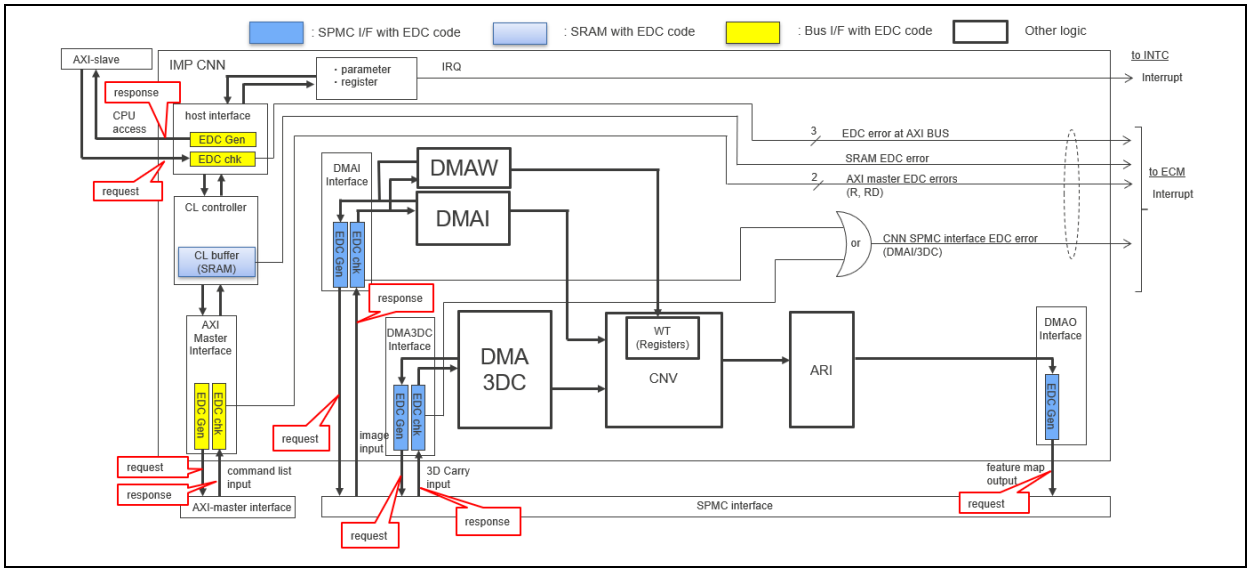

Figure U33.65 Block Diagram of IMPCNN (FUSA)

U34. IMP-X7_system

U34.1 Overview

The IMP-X7 consists of multiple modules and an Internal memory, each unit is connected by an IMP local bus. The IMP local bus allows each module to access any bank of internal memory (ScratchPad memory) at the same time. The configuration diagram of the IMP local bus is shown in Figure U34.1, and the address of each bank of the Internal memory is shown in Table U34.2.

Interrupts generated in each module can be controlled by the INT control logic of IMP-X7 and seven interrupts can be output to the interrupt controller (INTC). For the control method with INT control logic, refer to **U34.10 Operation**.

U34.1.1 Features

The IMP local bus specification of IMP-X7 is shown in Figure U34.1.

Table U34.1 IMP local bus Specification

Specification	(Module name in R-Car V4M)		
	SPMI	SPMC (High speed domain)	
Operating frequency	640 MHz	800 MHz	
Number of units	1	1	
Bus width	256 bits	256 bits / CNN dedicated 4096 bits	
Capacity (Internal memory)	2 Mbytes (256 Kbytes × 8 banks) *1 = 1 Mbytes In each bank access protection (secure regions scheme) is applied.	2 Mbytes SPMC0 Access protection (secure regions scheme) is applied.	0.5 Mbytes SPMC1 Access protection (secure regions scheme) is applied.

U34.1.2 Block Diagram

Figure U34.1 shows the internal implementation of the Gen4 IMP-X7.VDSP DMAC can access SPMC/SPMI memory with incremental transaction. Possible transaction sizes are 128-byte/256-byte and alignment shall be 32-byte. For the base address and use of VDSP, refer to the VDSP HWM.

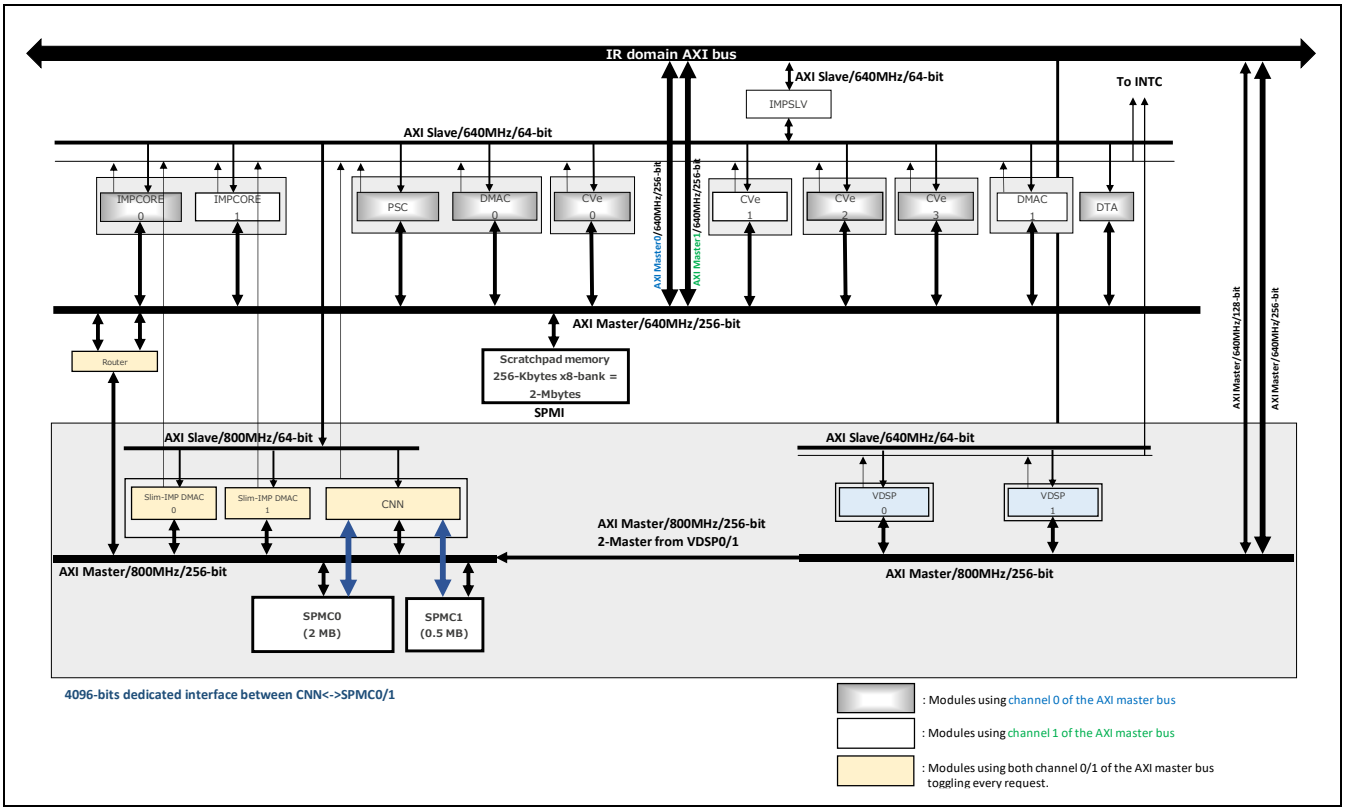

Figure U34.1 IMP-X7 IMP local bus arrangement

U34.1.3 Address map of Scratchpad Memory

The address map of each bank of Scratchpad memory (multi-bank Internal memory of the IMP-X7) is shown in Table U34.2.
When accessing below addresses from host CPU, these are accessed as registers by default. For example, start addresses of Scratchpad memory in Table U34.2 and base addresses of SPM registers in U34.8 are same. If user access these addresses by CPU, then they are accessed as registers which are described in U34.8. If user need to access these addresses by CPU as a Scratchpad memory, refer to the setting in U34.10.3.
IMP-X7 IPs like IMPcore, DMAC, Slim-IMP DMAC, IMPPSC, CVe, IMPCNN always access these addresses as Scratchpad memory. When VDSP access Scratchpad memory (SPMI/SPMC0/1) in IMP-X7, initially set 0 to the bit 31 of SPMCTRL4 (0xFFAB0F18) register in SPMC. Do not change this bit after setting to 0.

Table U34.2 Address map of Scratchpad memory (SPMI, SPMC0/1)

Module	Scratchpad memory Bank number	Start address	End address	Size
SPMI	0	0xED200000	0xED23FFFF	256 KB
	1	0xED240000	0xED27FFFF	256 KB
	2	0xED280000	0xED2BFFFF	256 KB
	3	0xED2C0000	0xED2FFFFF	256 KB
	4	0xED300000	0xED33FFFF	256 KB
	5	0xED340000	0xED37FFFF	256 KB
	6	0xED380000	0xED3BFFFF	256 KB
	7	0xED3C0000	0xED3FFFFF	256 KB
SPMC0	-	0xED400000	0xED5FFFFF	2 MB
SPMC1	-	0xED600000	0xED67FFFF	0.5 MB

U34.2 Register Configuration (IMPSLV bus Registers)

These are the registers implemented in IMPSLV module in IMP-X7 local bus. Do not access to any address other than those listed Register Configuration. Otherwise, correct operation is not guaranteed.

Base Address Name	Base Address
IMPSLV	H'FF90 0000

[Legend]
Initial value : Register value after a reset (hardware reset : This reset is to reset all the logic including bus interface)
— : Undefined value
R/W : Readable/writable. The written value can be read.
R/WC1 : Readable/writable. Writing 1 initializes the bit. Writing 0 to the bit is ignored.
R : Read-only. The write value should always be 0.

—All the registers of IMPSLV can be reset by CPG software reset.
— For the bits that are not assigned:
a) For reserved bits of read only register, always read initial value before preset (initial setting).
b) For reserved bits of read/write register, always read initial value before preset (initial setting) and write value should always be read value after preset.

Refer to R-CarV4M_UM_U34_IMP-X7_System_IMPSLV_r0p40.xlsx.

U34.3 Register Description (IMPSLV bus Registers)

Refer to R-CarV4M_UM_U34_IMP-X7_System_IMPSLV_r0p40.xlsx.

U34.4 Register Configuration (SPMI bus Registers)

These are the registers implemented in SPMI module in IMP-X7 local bus. Do not access to any address other than those listed Register Configuration. Otherwise, correct operation is not guaranteed.

Base Address Name	Base Address
SPMI	H'FFA8 C000

[Legend]
Initial value : Register value after a reset (hardware reset : This reset is to reset all the logic including bus interface)
— : Undefined value
R/W : Readable/writable. The written value can be read.
R/WC1 : Readable/writable. Writing 1 initializes the bit. Writing 0 to the bit is ignored.
R : Read-only. The write value should always be 0.

- All the registers of SPMI can be reset by CPG software reset.
- For the bits that are not assigned:
  a) For reserved bits of read only register, always read initial value before preset (initial setting).
  b) For reserved bits of read/write register, always read initial value before preset (initial setting) and write value should always be read value after preset.

Refer to R-CarV4M_UM_U34_IMP-X7_System_SPMI_r1p00.xlsx.

U34.5 Register Description (SPMI bus Registers)

Refer to R-CarV4M_UM_U34_IMP-X7_System_SPMI_r1p00.xlsx.

U34.6 Register Configuration (SPMC bus Registers)

These are the registers implemented in SPMC module in IMP-X7 local bus. Do not access to any address other than those listed Register Configuration. Otherwise, correct operation is not guaranteed.

Base Address Name	Base Address
SPMC	H'FFAB 0000

[Legend]
Initial value : Register value after a reset (hardware reset : This reset is to reset all the logic including bus interface)
— : Undefined value
R/W : Readable/writable. The written value can be read.
R/WC1 : Readable/writable. Writing 1 initializes the bit. Writing 0 to the bit is ignored.
R : Read-only. The write value should always be 0.

— All the registers of SPMC can be reset by CPG software reset.
— For the bits that are not assigned:
  a) For reserved bits of read only register, always read initial value before preset (initial setting).
  b) For reserved bits of read/write register, always read initial value before preset (initial setting) and write value should always be read value after preset.

Refer to R-CarV4M_UM_U34_IMP-X7_System_SPMC_r1p00.xlsx.

U34.7 Register Description (SPMC bus Registers)

Refer to R-CarV4M_UM_U34_IMP-X7_System_SPMC_r1p00.xlsx.

U34.8 Register Configuration Scratchpad Memory (SPM Registers)

These are the registers implemented in Scratchpad Memory (SPM) module in IMP-X7. Do not access to any address other than those listed Register Configuration. Otherwise, correct operation is not guaranteed.

Base Address Name	Base Address
SPMI bank0 – bank7 By default, 4-byte CPU access to Scratchpad memory as a register.	0xED20_0000 0xED24_0000 0xED28_0000 0xED2C_0000 0xED30_0000 0xED34_0000 0xED38_0000 0xED3C_0000
SPMC0/1 By default, 4-byte CPU access to Scratchpad memory as a register.	0xED40_0000 0xED60_0000

[Legend]
Initial value : Register value after a reset (hardware reset : This reset is to reset all the logic including bus interface)
－ : Undefined value
R/W : Readable/writable. The written value can be read.
R/WC1 : Readable/writable. Writing 1 initializes the bit. Writing 0 to the bit is ignored.
R : Read-only. The write value should always be 0.
W : Write-only. The read value should always be 0.

— All the registers of SPM can be reset by CPG software reset.
— For the bits that are not assigned:
  a) For reserved bits of read only register, always read initial value before preset (initial setting).
  b) For reserved bits of read/write register, always read initial value before preset (initial setting) and write value should always be read value after preset.

Refer to R-CarV4M_UM_U34_IMP-X7_System_SPM_r0p70.xlsx.

U34.9 Register Description Scratchpad Memory (SPM Registers)

Refer to R-CarV4M_UM_U34_IMP-X7_System_SPM_r0p70.xlsx.

U34.10 Operation

U34.10.1 Initial setting

IMP local bus needs following setting initially and again if it meets the preset condition in Table U34.3.

Table U34.3 Initial setting IMP local bus

Preset IMP local bus	Register name	Address	Initial set value	Preset condition
	PRESET Register [IMPSLV]	0xFF90_2000	0x0000000A	Power on C4 or IMPSLV reset release
	PRESET Register [SPMI]	0xFFA8_E000	0x0000000A	Power on C4 or SPMI reset release
	Master Bus ConTRoL120 [SPMI]	0xFFA8_C868	0x00030000	Power on C4 or SPMI reset release
	Master Bus ConTRoL130 [SPMI]	0xFFA8_D028	0x00030000	Power on A2CN0 or SPMC reset release
	PRESET Register [SPMC]	0xFFAB_2000	0x00000009	Power on A2CN0 or SPMC reset release

U34.10.2 Secure region for IMP-X7

Before using IMP subsystem, region ID related to IMP subsystem setting is necessary. For the region ID setting refer to the HWM for the 18.AXI-Bus secure protection using region ID.

U34.10.3 Initialization of Scratchpad memory

Scratchpad Memory initialization is necessary after preset in U34.U34.10.1.
For initialization of the Scratchpad memory SPMI and SPMC0/1 all banks with single setting, refer to registers and setting value in Table U34.4. Read the INITSTS (0xED400004) register to confirm the initializing status. If read value of the memory initializing status register bit 1 is 1, the initialization is finished. INITSTS register shall be accessed as register (SPMI SPMCTRL4 bit 31 shall be 1) to confirm the Scratchpad memory initialization. When Scratchpad memory address is accessed by host CPU, it is accessed as a register in default setting.

Only SPMC0/1 Scratchpad Memory initialization setting is enough if only Pseudo-Power on A2CN0 and preset SPMC.

To access SPMI and SPMC0/1 as Scratchpad memory by CPU (Only 4-byte access is possible), set 0 to the SPMCTRL4 register bit 31 in SPMI. Before changing SPMCTRL4 register bit 31, confirm that there is no access to SPMI/SPMC0/1 memory and registers by outside HOST (CPU etc.) except IMP subsystem.

The order of register setting is SPMI initialization register and SPMC initialization register. In case of EDC/ECC mode first disable the ECM error register in ECM, initialize the memory and enable the ECM errors. In case user want to initialize the each scpatchpad memory bank, set the ScratchPadMemory ConTRL (SPMCTRL) register of each Scratchpad memory bank and read the InITializng STatuS (INITSTS) register by CPU to confirm the memory initialization. In this case, it is user responsibility to confirm that target bank of initialization is not in use.

Table U34.4 Memory initialization registers

Register name	Address	Setting value
ScratchPadMemory ConTRoL eXtra0 (SPMCTRLX0) [SPMI]	0xFFA8_E300	0x80000000
ScratchPadMemory ConTRoL eXtra0 (SPMCTRLX0) [SPMC]	0xFFAB_2300	0x80000000

U34.10.4 Interrupt control

In IMP-X7, number of interrupts output to the INTC is 3, as shown in Figure U34.2. With the INT control logic, it is possible to control interrupts generated in each module.

Interrupts generated in each module are reflected in the Interrupt Status Register (INTSTS) of INT control logic. Interrupts generated in each module can be grouped by selecting arbitrary modules of IMP-X7 with INT control logic. The modules to be grouped can be selected with the G00INTSEL to G02INTSEL registers.

For each group of interrupts, the GROUP00 to GROUP02 bits of the INTSTS register corresponding to the group are set to 1 when all interrupts of the grouped modules have occurred.

Further, if at least one interrupt of a grouped module is cleared, the GROUP00 to GROUP02 bits of the INTSTS register corresponding to the group becomes 0.

An example of operation of the GROUP00 bit when IMP CNN, Cve0, IMP core 0 is selected for the G00INTSEL register is shown below.

- When all three module interrupts have occurred, the G00INTS bit = "1".
- The GROUP00 bit = "0" when one of the three module interrupts is cleared.
- The value of the GROUP00 bit does not change when an interrupt occurs in a module other than 3 modules.
- The value of the GROUP00 bit does not change when an interrupt of a module other than 3 modules is cleared.

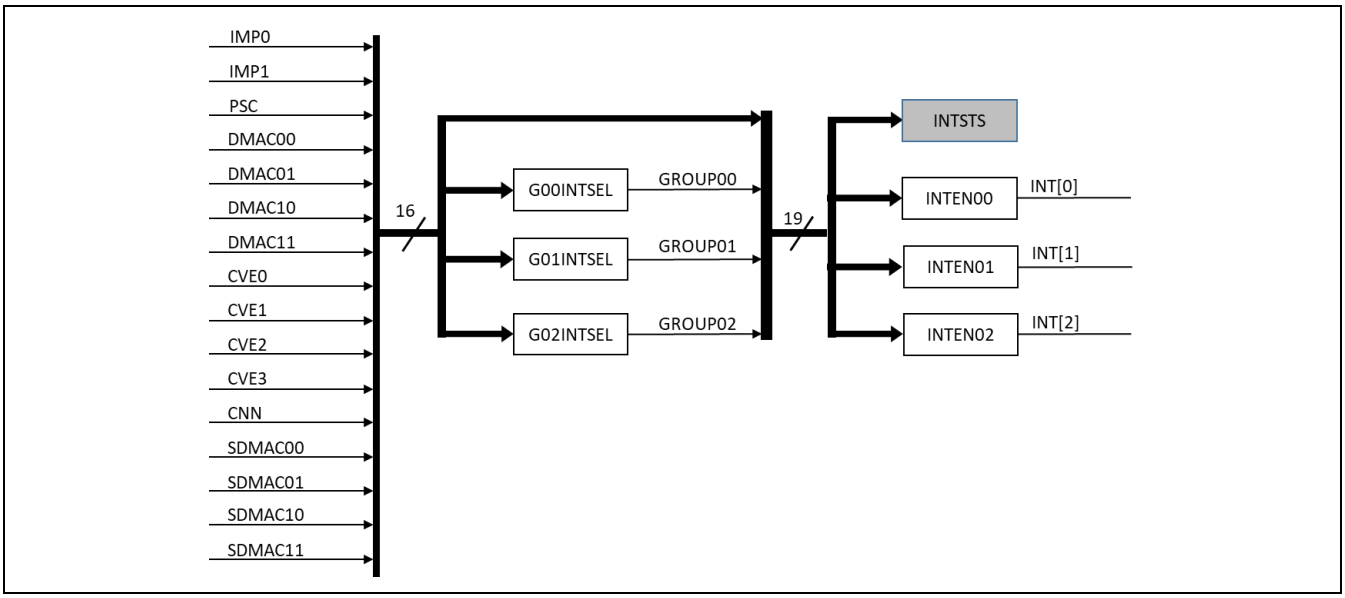

Figure U34.2 INT control logic

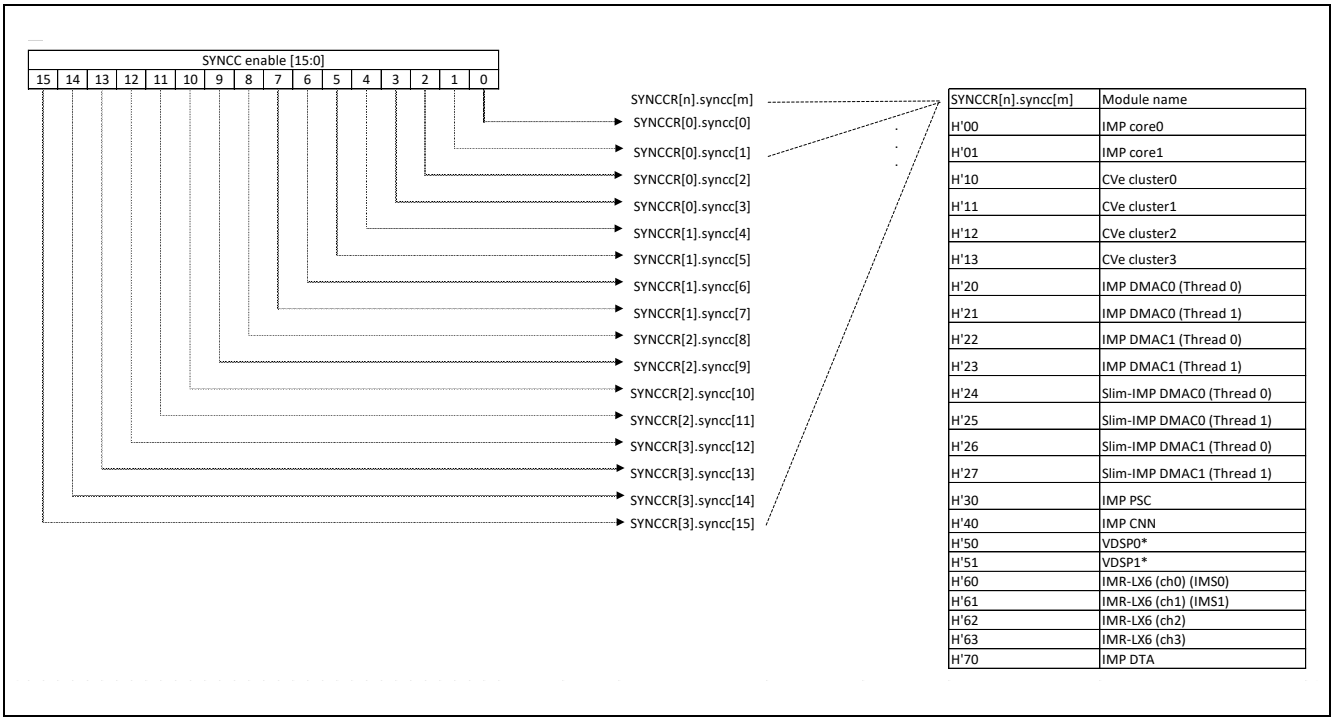
U34.10.5 Inter Module Synchronization

The synchronization system between modules is the system that synchronizes the control of each CL Controller by specifying the target module and executing the WUP instruction and the SLP instruction for IMP core, CVe core, IMP DMAC, IMP PSC, IMP CNN, slim-IMP DMAC, VDSP and IMP DTA.

For the WUP instruction and the SLP instruction in for different IPs of IMP-X7 sub-system, refer to refer to the individual HWM of IP. For target module specification, refer to the next section.

U34.10.5.1 Target module specification

The target modules in WUP instruction and SLP instruction are specified by the SYNCC enable field as shown in Figure U34.3. The target module corresponds to the module specified by SYNCCR[n].syncc[m], which has 1 set in each bit of the SYNCC enable field. Settings not described in below figure are prohibited.



SYNCCR[n].syncc[m]	Module name
H'00	IMP core0
H'01	IMP core1
H'10	CVe cluster0
H'11	CVe cluster1
H'12	CVe cluster2
H'13	CVe cluster3
H'20	IMP DMAC0 (Thread 0)
H'21	IMP DMAC0 (Thread 1)
H'22	IMP DMAC1 (Thread 0)
H'23	IMP DMAC1 (Thread 1)
H'24	Slim-IMP DMAC0 (Thread 0)
H'25	Slim-IMP DMAC0 (Thread 1)
H'26	Slim-IMP DMAC1 (Thread 0)
H'27	Slim-IMP DMAC1 (Thread 1)
H'30	IMP PSC
H'40	IMP CNN
H'50	VDSP0*
H'51	VDSP1*
H'60	IMR-LX6 (ch0) (IMS0)
H'61	IMR-LX6 (ch1) (IMS1)
H'62	IMR-LX6 (ch2)
H'63	IMR-LX6 (ch3)
H'70	IMP DTA

Figure U34.3 Specification of target module in WUP instruction and SLP instruction

For example, when the following are specified,

SYNCC enable field :B’0000000001001001
SYNCCR0.syncc0 :H’01
SYNCCR0.syncc3 :H’20
SYNCCR1.syncc6 :H’10

Target modules are IMP core1, IMP DMAC (Thread 0) and CVe cluster0.

By using WUP and SLP instructions, it is possible to synchronize between modules shown in Figure U34.3. It is possible to issue the WUP signal mutually with the module shown in Figure U34.3.

Notes

1. Specifying multiple identical modules is prohibited when specifying the target module.

   For example, as below, specifying IMP core1 more than one time as target module is prohibited.

   SYNCC enable field : B'0000000000001001
   SYNCCR0.syncc0 : H'01 (IMP core1)
   SYNCCR0.syncc3 : H'01 (IMP core1)

2. IMR-LX6 (IMR) can only WUP/SLP with IMPDMAC and Slim-IMP DMAC
3. SYNCCR register must be set before executing the WUP and SLP instruction.
4. For WUP sending, SYNCCR register of receiving module need to be set before executing the WUP instruction.

5. IMP component number for IMPDTA are as follows.

0 : IMP Core 0
1 : IMP Core 1
2 : CVe 0
3 : CVe 1
4 : CVe 2
5 : CVe 3
6 : IMPDMAC 0 (Thread 0)
7 : IMPDMAC 0 (Thread 1)
8 : IMPDMAC 1 (Thread 0)
9 : IMPDMAC 1 (Thread 1)
10 : Slim-IMPDMAC 0 (Thread 0)
11 : Slim-IMPDMAC 0 (Thread 1)
12 : Slim-IMPDMAC 1 (Thread 0)
13 : Slim-IMPDMAC 1 (Thread 1)
14 : IMPPSC
15 : IMPCNN

6. The policy of the WUP/SLP with VDSP is a little different than other modules. For the WUP/SLP with VDSP, follow the below guideline. IPs (For example: IMP core, CVe, IMP CNN, IMPPSC, IMPDMAC, Slim-IMP DMAC) communicate with VDSP as described in figure below. Selection of the communication type is user responsibility. Note that IMR and IMP DTA cannot communicate with VDSP. Refer to the VDSP HWM for the interrupt mapping.

   a) As shown in Figure U34.4, For example, if user select Polling-based communication between IMPCNN and VDSP0

      - First select the poling-based communication writing IMPSLV.DSP0CT[0] = 0.
      - Clear the DSP0CSTS[17] by writing 0 by CPU. Then start the VDSP0 and IMPCNN by CPU. When IMPCNN sends WUP to the VDSP0 then DSP0CSTS[17] status will become 1.
      - VDSP0 reads DSP0CSTS[17] status and starts its operation if DSP0CSTS[17] status = 1.
      - VDSP0 sends WUP to the IMPCNN and clears the DSP0CSTS[17] by writing DSP0CTRM[17] = 1 (Writing 0 to DSP0CTRM[17] is prohibited).
      - IMPCNN process will continue from SLP state when it receives WUP from the VDSP0.

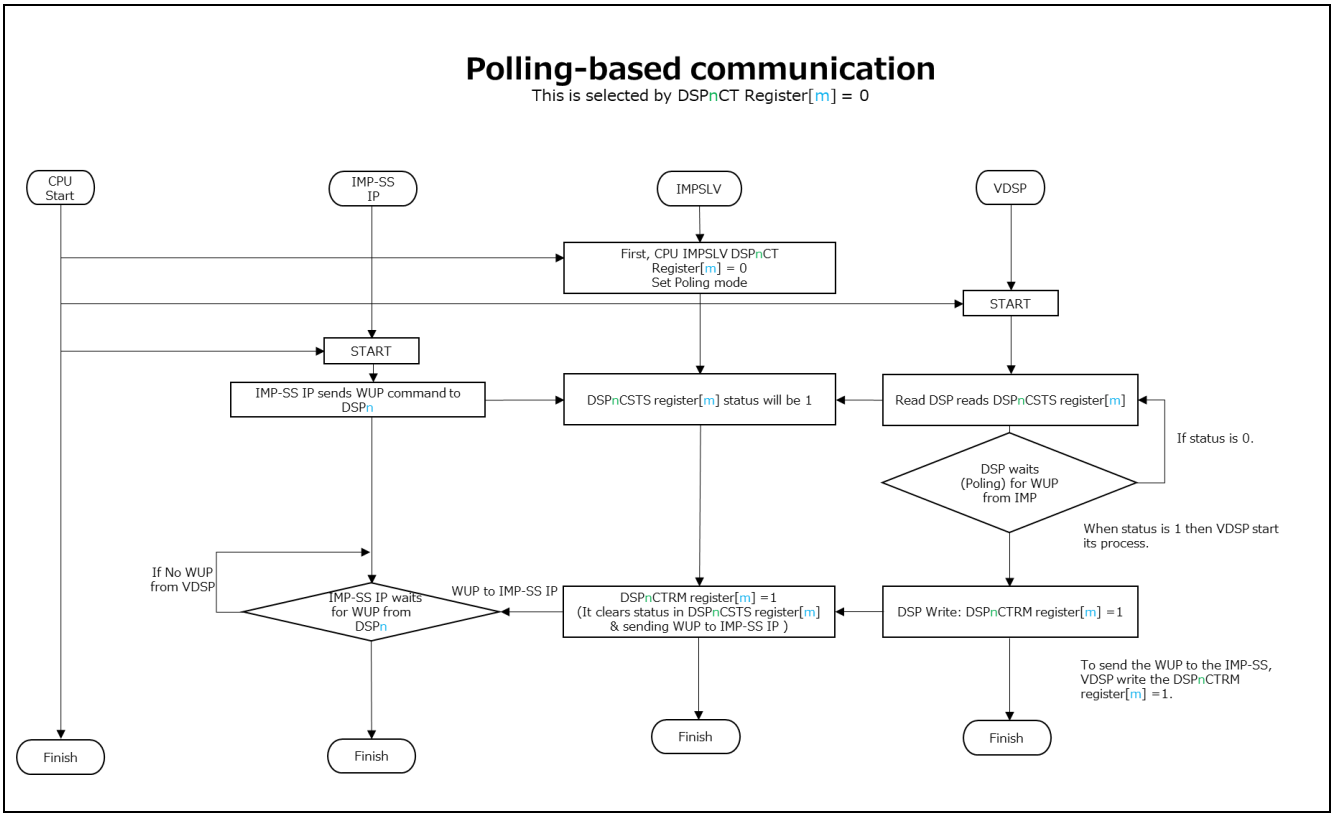


Figure U34.4 Polling-based WUP/SLP communication with VDSP
[n=0~1] [m=0~12]

b) As shown in Figure U34.5, For example, if user select interrupt-based communication between IMPCNN and VDSP0

- First select the interrupt-based communication writing IMPSLV.DSP0CT[0] = 1.
- Clear the DSP0CSTS[17] by writing 0 by CPU. Then start the VDSP0 and IMPCNN by CPU. When IMPCNN sends WUP to the VDSP0 then DSP0CSTS[17] status will become 1 and an interrupt will assert to VDSP0.
- VDSP0 will receives the interrupt and starts its operation after handling the interrupt.
- VDSP0 sends WUP to the IMPCNN and clears the DSP0CSTS[17] by writing DSP0CTRM[17] = 1 (Writing 0 to DSP0CTRM[17] is prohibited).
- IMPCNN process will continue from SLP state when it receives WUP from the VDSP0.

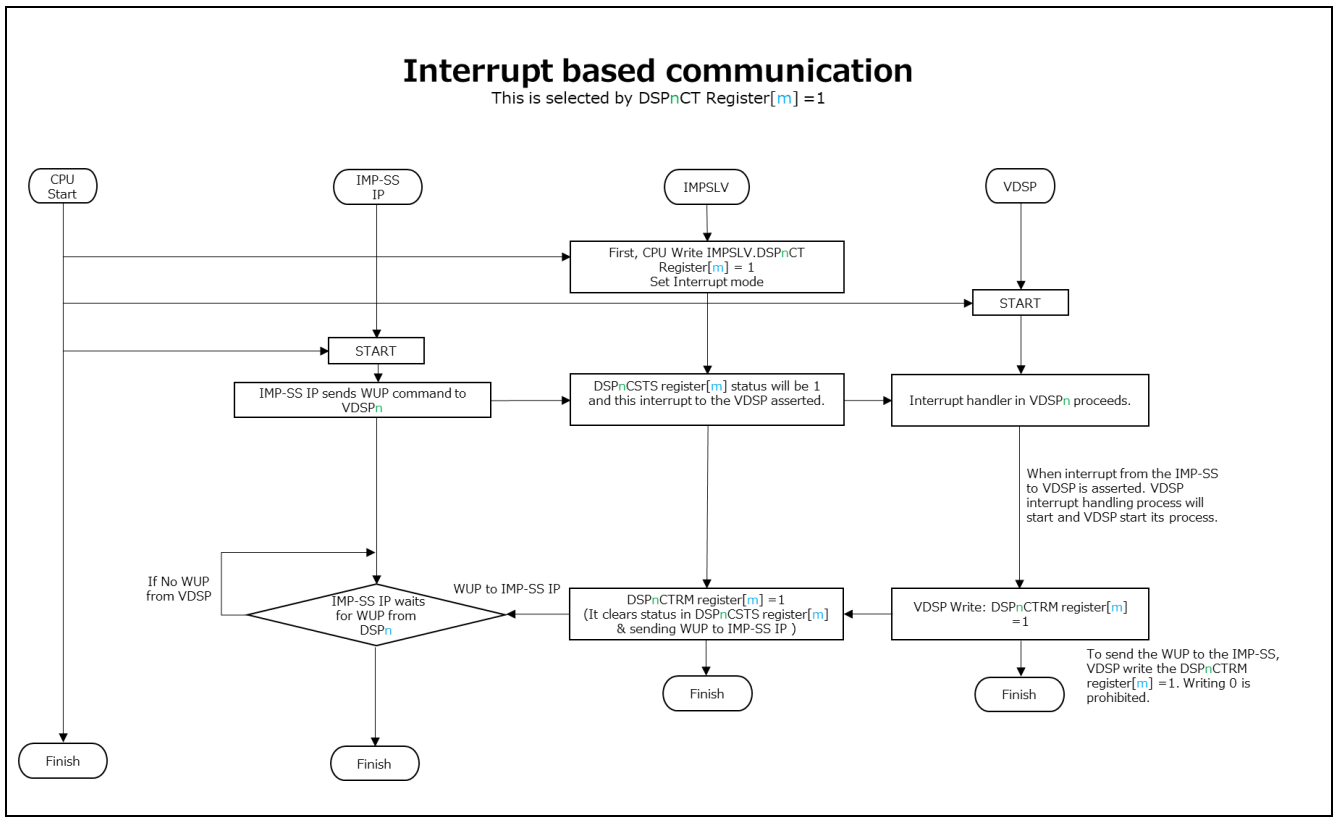

Figure U34.5 Interrupt-based WUP/SLP communication with VDSP [n=0~1] [m=0~12]

U34.10.5.2 Operations

Figure U34.6 and Figure U34.7 show examples of release from the sleep state in inter-module synchronization.

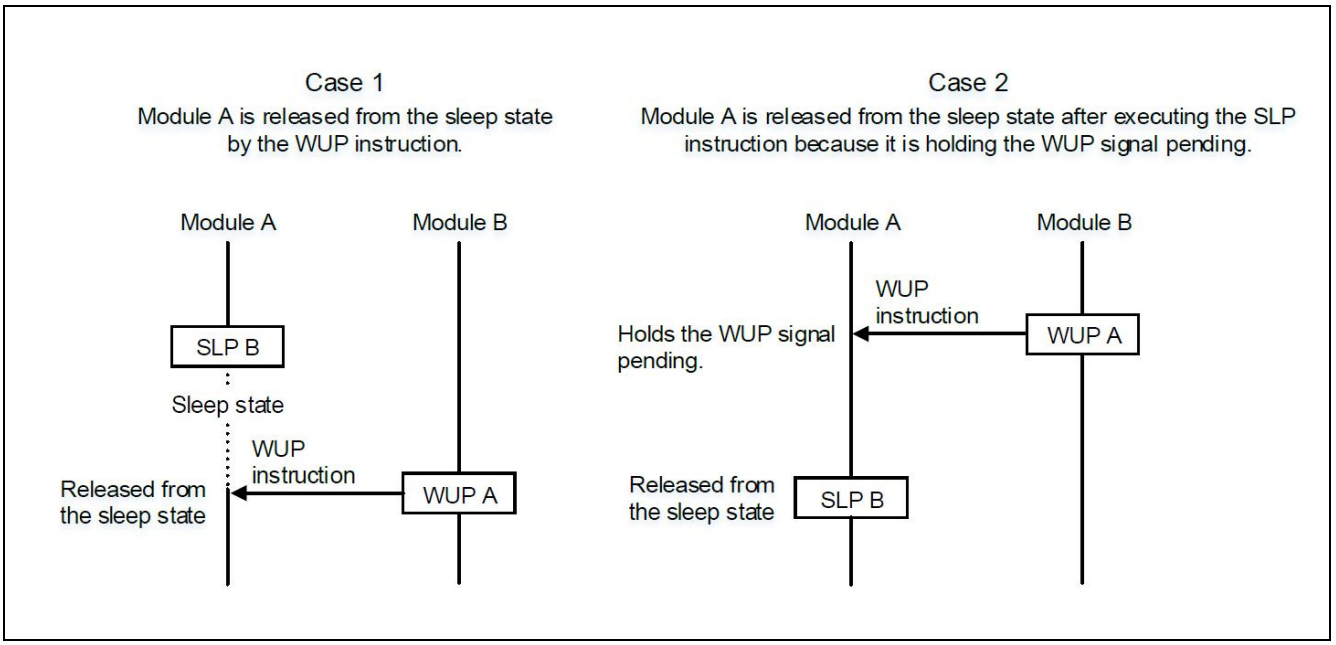

Figure U34.6 Examples of Release from the Sleep State in Inter-Module Synchronization (Between Two Modules)

Case 1 Figure U34.6 in is an example of releasing module A from the sleep state when module B executes the WUP instruction. Module A is placed in the sleep state by execution of the SLP instruction. Module A is then released from the sleep state once module B executes the WUP instruction.
Case 2 is an example of releasing module A from the sleep state by the pending WUP signal from module B. If module B executes the WUP instruction when module A is not in the sleep state, module A holds the WUP signal pending. When the subsequent SLP instruction is executed, module A is immediately released from the sleep state because the pending WUP signal is effective.

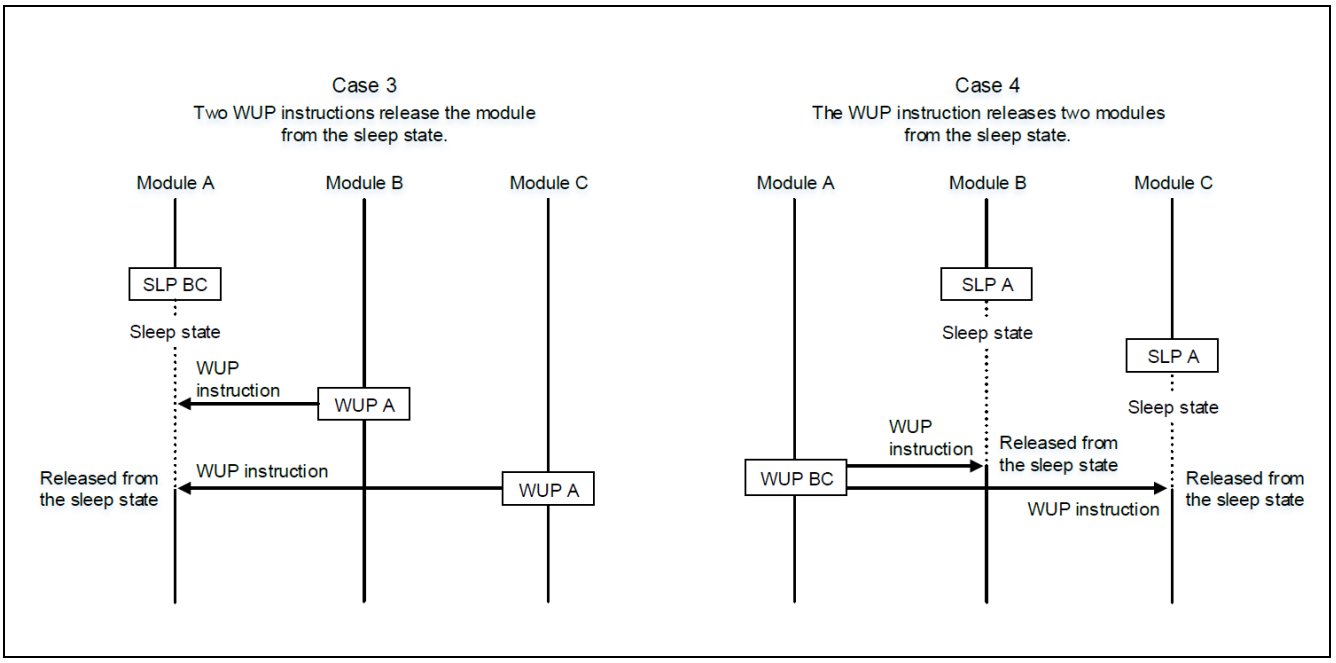

Figure U34.7 Examples of Release from the Sleep State in Inter-Module Synchronization (between Three Modules)

Case 3 in Figure U34.7 is an example of releasing module A from the sleep state when modules B and C execute the WUP instruction. Module A is placed in the sleep state by execution of the SLP instruction with modules B and C specified. Module A is then released from the sleep state in response to the WUP instructions executed by both modules B and C.
Case 4 is an example of releasing modules B and C from the sleep state when module A executes the WUP instruction. Modules B and C are placed in the sleep state by execution of the SLP instruction with module A specified. Modules B and C are then released from the sleep state when module A executes the WUP instruction with modules B and C specified.
These steps of release from the sleep state can also be applied to synchronization between four or more modules.

Figure U34.8 shows examples of synchronizing multiple modules in inter-module synchronization.

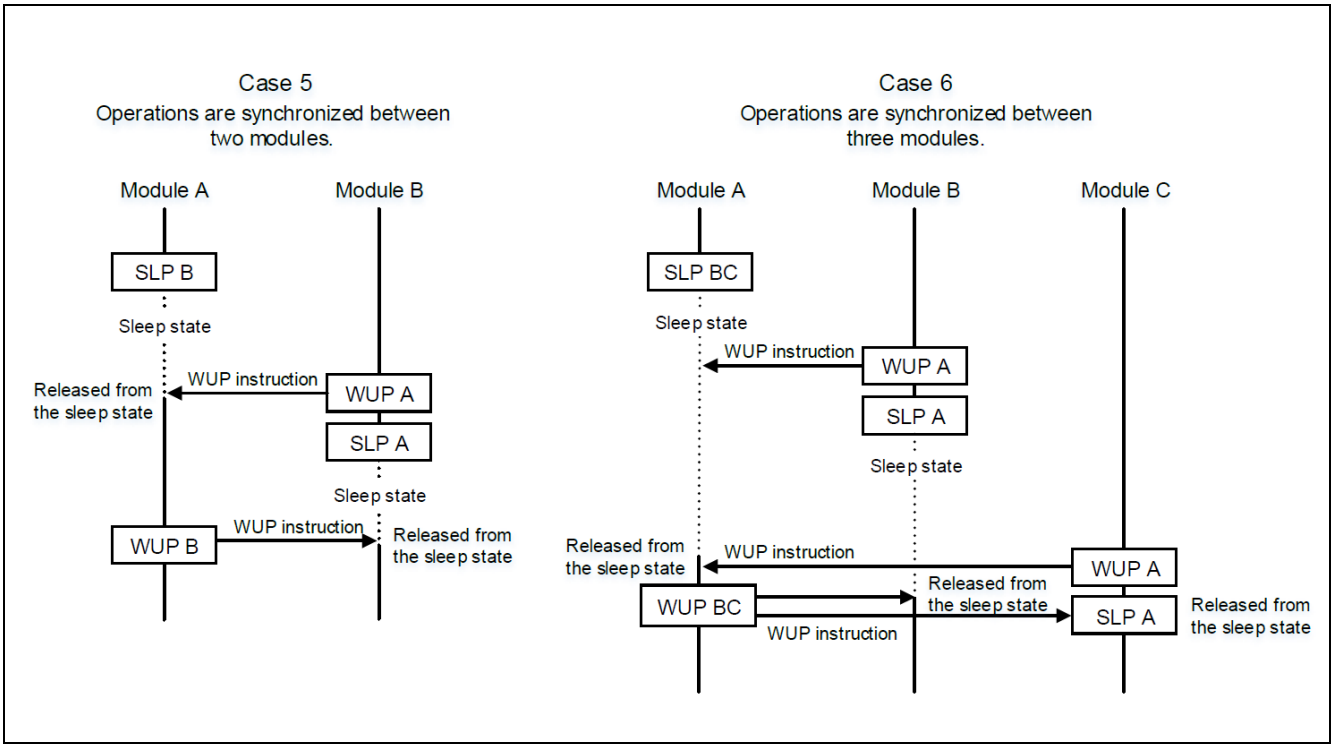

Figure U34.8 Synchronization of Multiple Modules in Inter-Module Synchronization

To synchronize operations of multiple modules, select a module as the key module and execute the following steps in the key module and the other modules.

- The key module executes the SLP instruction and then the WUP instruction with the other modules specified.
- The other modules execute the WUP instruction and then the SLP instruction with the key module specified.

Before the key module executes the WUP instruction, the key module has been released from the sleep state that was entered by execution of the SLP instruction and the other modules have executed the WUP instruction. The other modules then execute the SLP instruction, and the key module executes the WUP instruction; this synchronizes the operations of these modules.

Case 5 in Figure U34.8 is an example of synchronizing operations between two modules.
Module A is the key module and module B is the other module. Executing the following steps synchronizes operations of modules A and B.

- Module A executes the SLP instruction and then the WUP instruction with module B specified.
- Module B executes the WUP instruction and then the SLP instruction with module A specified.

Case 6 in Figure U34.8 is an example of synchronizing operations between three modules.
Module A is the key module and modules B and C are the other modules. Executing the following steps synchronizes the operations of modules A, B, and C.

- Module A executes the SLP instruction and then the WUP instruction with modules B and C specified.
- Modules B and C execute the WUP instruction and then the SLP instruction with module A specified.

The steps in case 6 can also be applied to synchronization between four or more modules.

Figure U34.9 shows a case where execution of the WUP instruction is made to wait in inter-module synchronization.

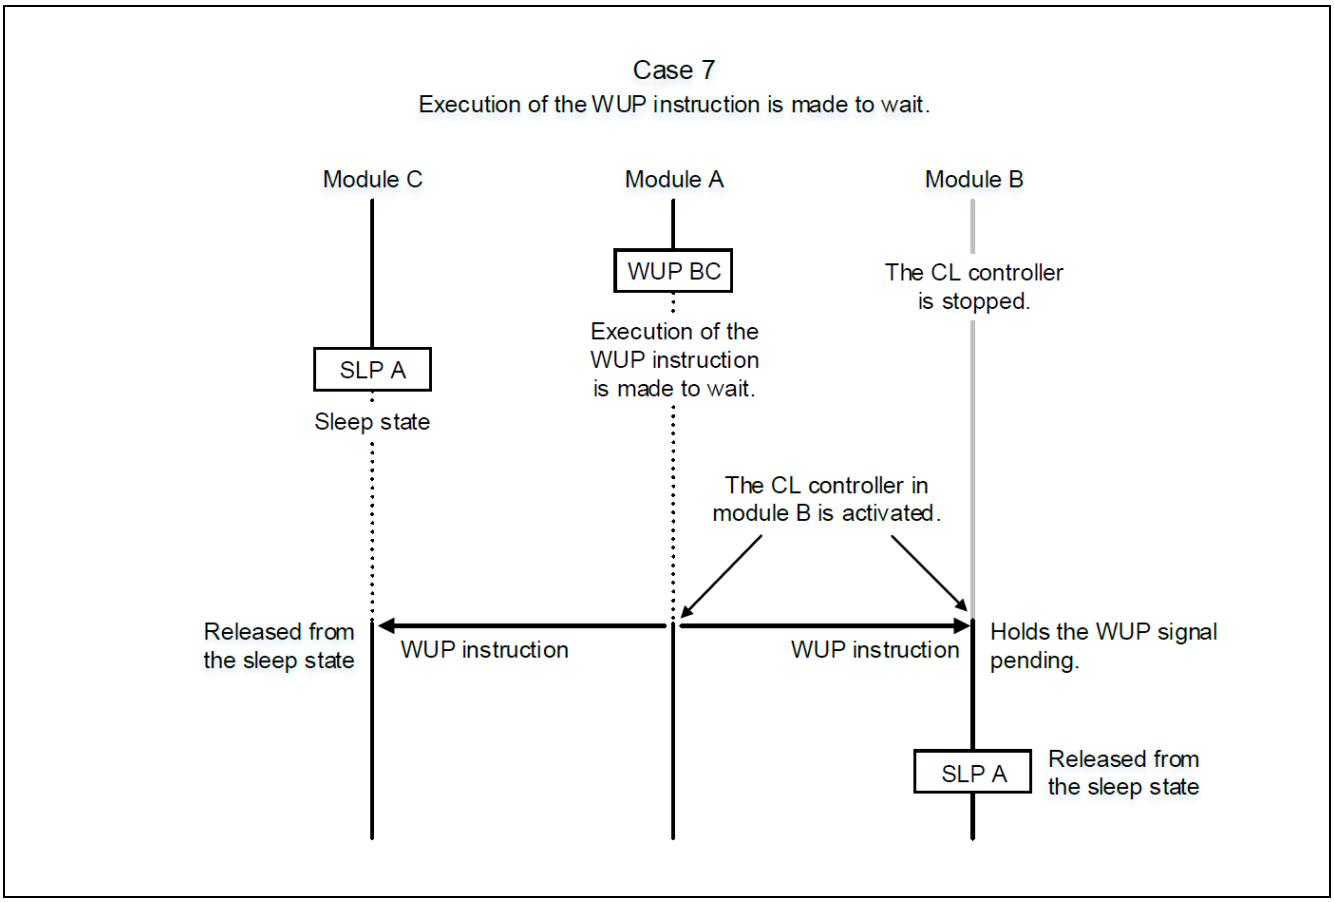

Figure U34.9 Case where Execution of the WUP Instruction is Made to Wait

In case 7 in Figure U34.9, execution of the WUP instruction is made to wait. Module A attempts to execute the WUP instruction with module B specified, but execution of the WUP instruction in module A is made to wait because the CL controller in module B is stopped. When the CL controller in module B is activated, module A can execute the WUP instruction.

U34.10.5.3 Prohibitions

The following two operations are prohibited in inter-module synchronization. This section describes examples of the prohibitions.

- Prohibited operation 1: Execution of the WUP instruction for a module that is holding the WUP signal pending.
- Prohibited operation 2: Execution of the TRAP instruction in a module that is holding the WUP signal pending.

In inter-module synchronization, execution of the WUP instruction for a module that is holding the WUP signal pending is prohibited (prohibited operation 1). Figure U34.10 shows prohibited operation 1 and an example of a workaround in one situation.
While module B is holding the WUP signal pending after module A has executed the WUP instruction for module B, module A must not execute the WUP instruction again for module B before the pending WUP signal is cleared.
To execute the WUP instruction for a single module multiple times, synchronize the current module with the target module and then execute the second WUP instruction.

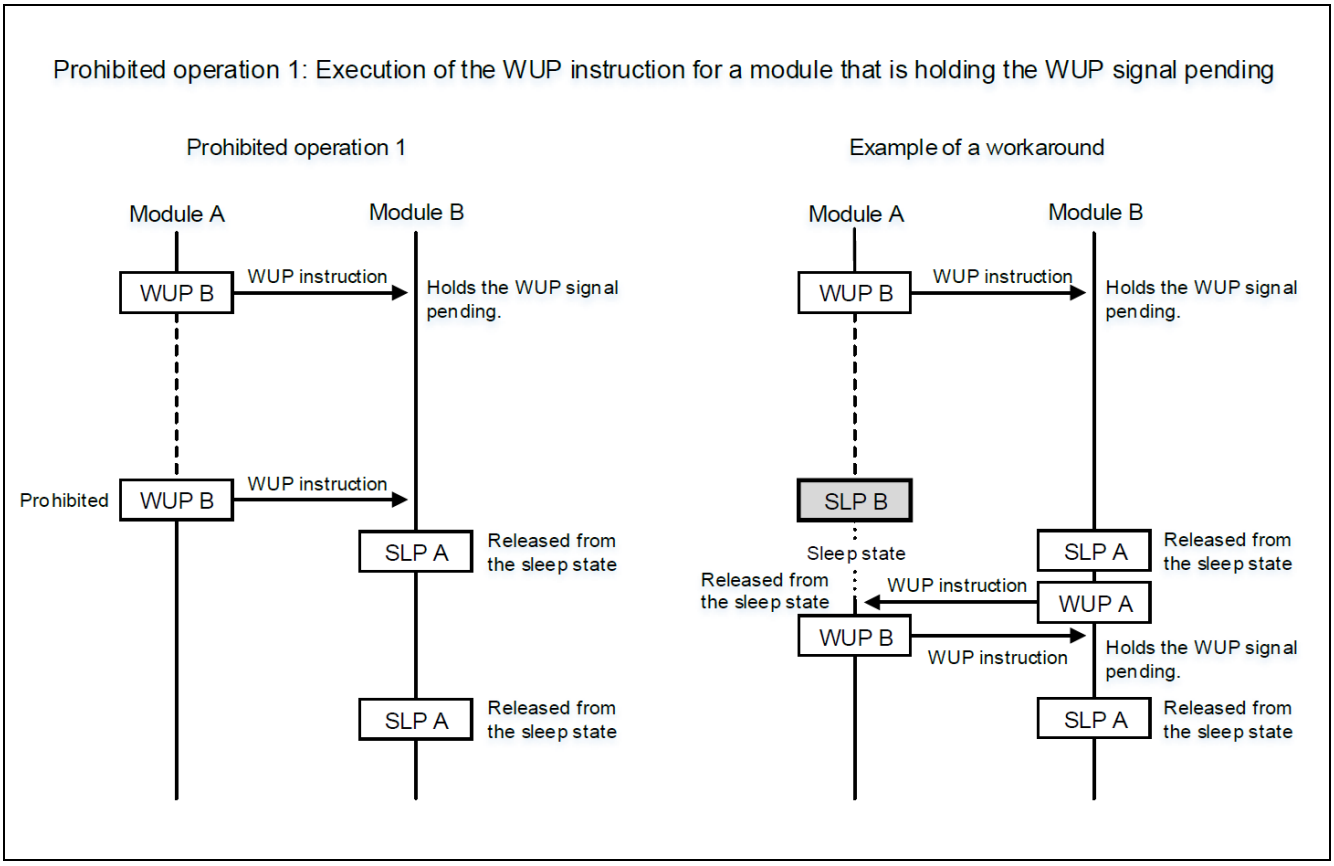

Figure U34.10 Prohibited Operation 1 and Example of a Workaround

In inter-module synchronization, execution of the TRAP instruction in a module that is holding the WUP signal pending is prohibited (prohibited operation 2). Figure U34.11 shows prohibited operation 2 and an example of a workaround in one situation.
While module A is holding the WUP signal pending after module B has executed the WUP instruction for module A, module A must not execute the TRAP instruction.
Module A must first execute the SLP instruction to clear the pending WUP signal and then execute the TRAP instruction.

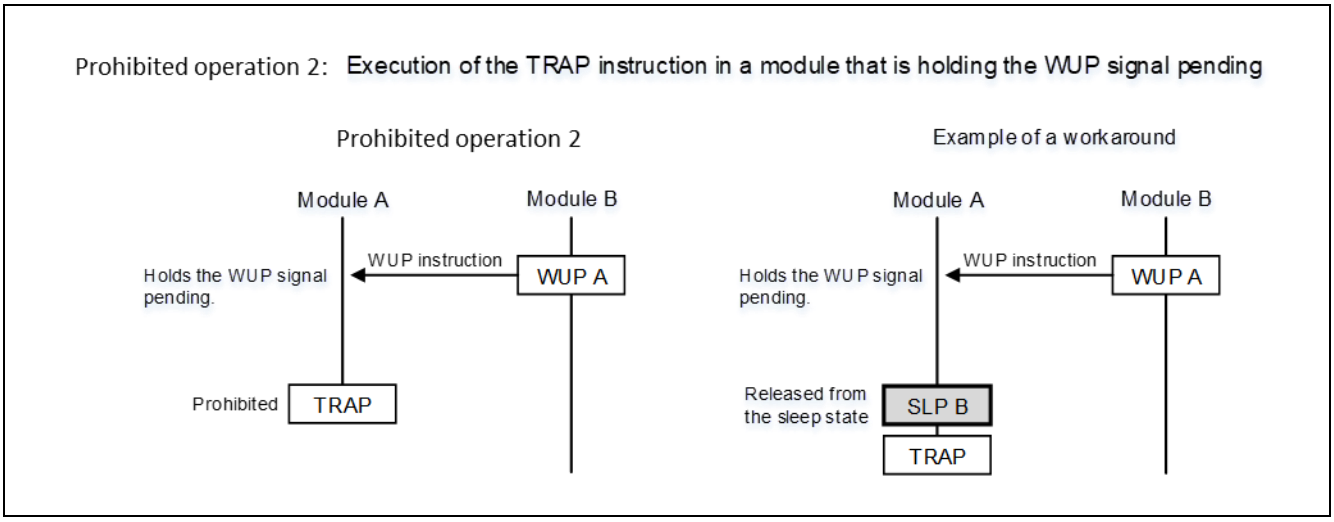

Figure U34.11 Prohibited Operation 2 and Example of a Workaround

U34.10.5.4 Possible Combinations of Modules for Inter-Module Synchronization

U34.10.6 Safety Mechanism

U34.10.6.1 Block diagram of safety mechanism

Note: The suitability of the safety mechanisms referenced in this manual will finally be judged during the safety analysis and safety assessment of the SoC. Therefore, the safety documentation shall always be considered as additional requirements for the system or software derived from the results of the safety analysis.

Below figures describes the hardware description of IMP-X7 System safety mechanism. Refer to the Figure U34.13 for hardware description of redundant logic of register slice.

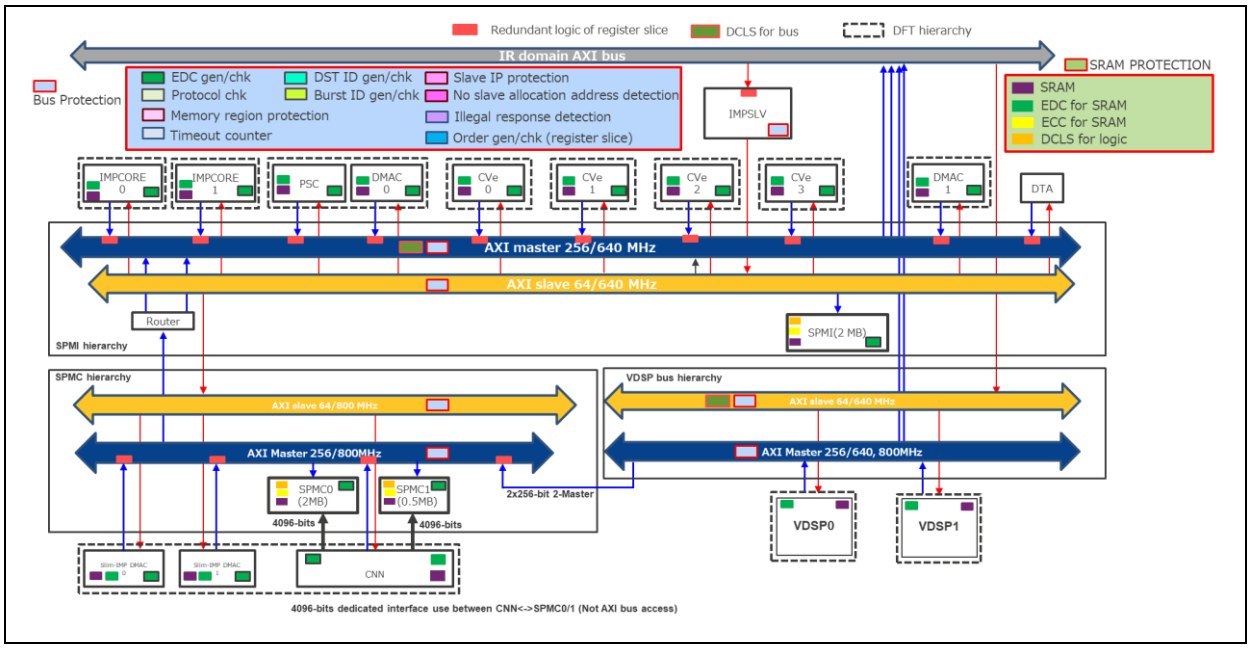

Figure U34.12 Block Diagram of IMP-X7 (FUSA)

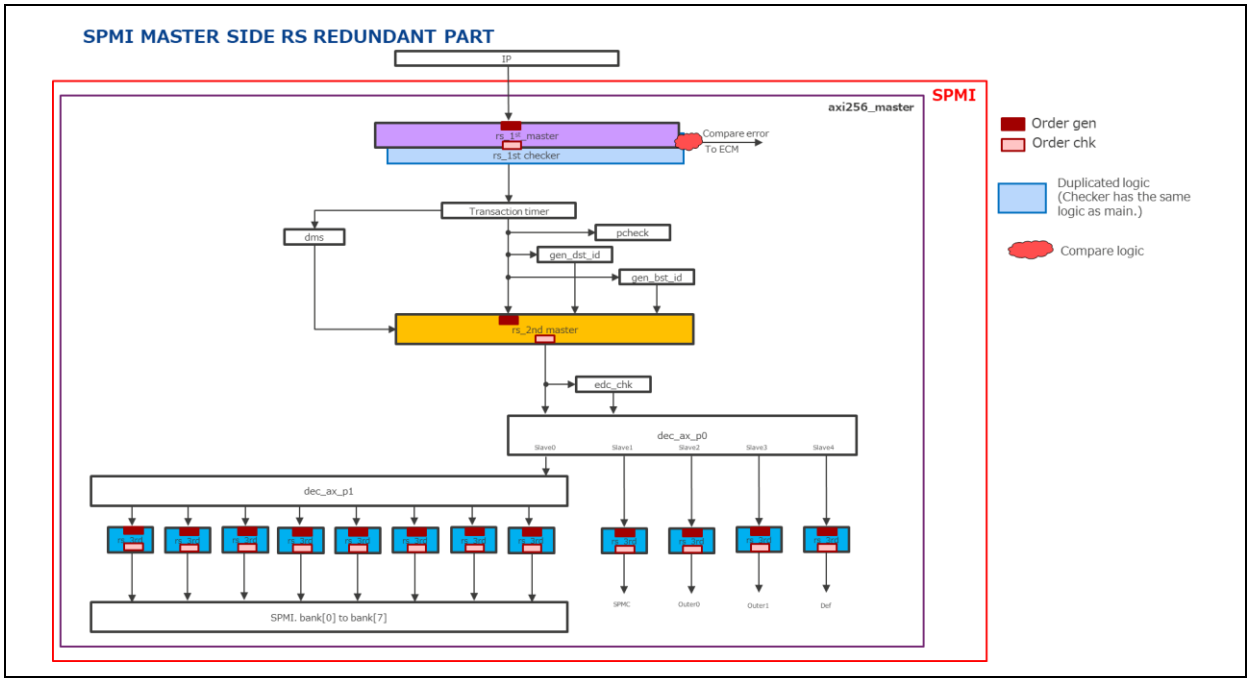

Figure U34.13 Hardware description for Redundant logic of register slice (Example. SPMI hierarchy)

U34.10.6.2 Setting for functional safety

1. Error Correction Code (ECC)

ECC protection is applied to the SRAM for Scratchpad memory (multi-bank Internal memory). To run in ECC mode initialization of the the Scratchpad memory is required. Refer to **U34.10.3** for details of Scratchpad memory initialization.

a) Error count threshold setting

Set the error threshold register for ECC error correction. For the module SPMI and SPMC following register setting is necessary.

Table U34.5 Error thresholding registers

Register name	Address
ScratchPadMemory ConTRoL4 (SPMCTRL4) -SPMI	0xFFA8_CF18
ScratchPadMemory ConTRoL4 (SPMCTRL4) -SPMC	0xFFAB_0F18

2. Timeout setting

The IMP subsystem local AXI bus has a Request and Response Timeout function that counts latency cycles from transaction request to transaction finish. When this counter exceeds a threshold waiting time, it is recognized as wrong operation of the bus controller and bus error corresponding to the domain to which the IP belongs will occur.

Below are the examples of Timeout function threshold setting.
If TIMESCALE[3:0] in SPMI register is set to N, the counter will count using the frequency obtained by dividing the SPMI clock by 2^N.
For example, if TIMESCALE[3:0]= 6 and SPMI is 640MHz, it counts at 640MHz/64 = 10MHz. Each waiting time in register is set to H’2710 (=10000) cycles at which the threshold at 10MHz is 1 ms.
If TIMESCALE0[3:0] in SPMC register is set to N, the counter will count using the frequency obtained by dividing the SPMC clock by 2^N.
For example, if TIMESCALE0[3:0]= 7 and SPMC is 800MHz, it counts at 800MHz/128 = 6.25MHz. Each waiting time in register is set to H’186a (=6250) cycles at which the threshold at 6.25MHz is 1 ms.

3. IMP local AXI bus protection

There are following safety mechanisms inside IMP local AXI Bus system.

- EDC checker/generator on data, address, and side information for IMP local bus
- Protocol checker
- Memory region protection
- Timeout checker
- Destination ID generator/checker
- Burst ID generator/checker
- Slave IP protection for internal IMP modules
- No slave allocation address detection for IMP local bus
- Illegal response detection for IMP local bus
- Order generator/checker

For the detailed of the (above listed safety mechanisms) refer to the HWM AXI bus of safety mechanism of the **Safety Mechanism for AXI-bus.**

U34.10.6.3 How to analyse the ECM error

All the FUSA errors are listed below (a total of 4 errors). To confirm the error occurred to the ECM, read the Functional Safety Error Board (FSERRBRD: H'FF9000C0) register bits 19 to 16, bit 7 and bits 1 to 0 of IMPSLV. Following errors can be analysed from the reading.

- IMP-X7 Scratchpad memory DCLS error
- IMP-X7 bus error
- IMP-X7 SRAM ECC error
- IMP-X7 SRAM EDC error

To confirm the ECM error of SPMI, SPMC and each IP, read the following registers in corresponding module.

- SPMI : Functional Safety Error Board (FSERRBRD)
- SPMI : Check the Error STatuS for IP[n] (IPnERRSTS) (n= 0-11) SPMI registers for IP side error.
- SPMI : Error SUMmary n (ERRSUMn) (n= 0-6)
- SPMI : ScratchPadMemory Error n (SPMERRn) (n= 0-1)

- SPMC : Functional Safety Error Board (FSERRBRD)
- SPMC : Check the Error STatuS for IP[n] (IPnERRSTS) (n= 0-3) SPMC registers for IP side error.
- SPMC : Error SUMmary n (ERRSUMn) (n= 0-6)
- SPMC : ScratchPadMemory Error n (SPMERRn) (n= 0-1)

Note: In case of SPMI/SPMC0/1, following signals are not compared by DCLS core between DCLS master instance and DCLS checker instance of Scratchpad memory.

- AXI256 read data
- DATA SRAM write data
- CNN dedicated interface read data.

U34.10.6.4 Error injection and confirm the Error in ECM

IMP-X7 supports error injection for the in IMPSLV, SPMI and SPMC hierarchy so that error connected to the ECM can be confirmed by injecting the pseudo error. Note that all FUSA error from the IMP IPs (IMP core, IMP DMAC, Slim-IMP DMAC, IMPCNN, CVe), SPMI and SPMC are merged and finally output to the ECM through IMPSLV. Set the dms bit of SPMCTRLX0 register before error injection in scratchpad memory.

Figure U34.14 shows the general example of EDC/ECC error injection procedure in IMP-X7.

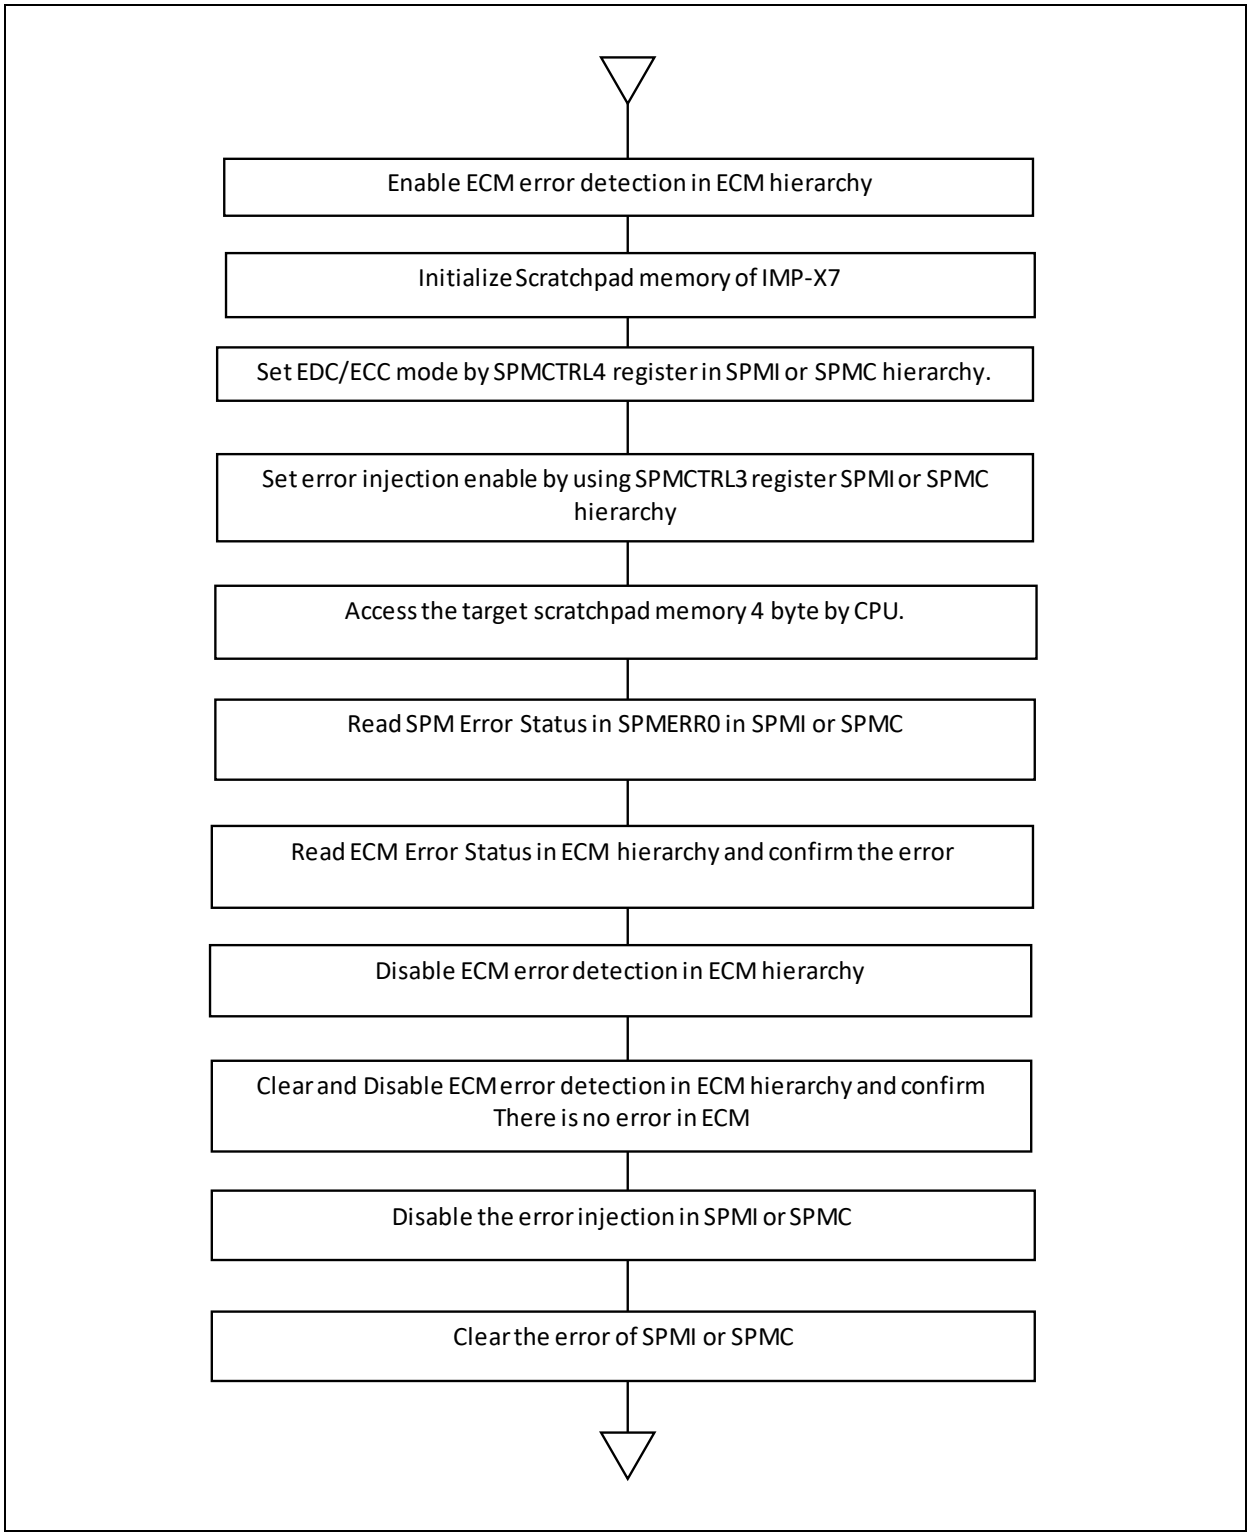

Figure U34.14 General procedure of Error injection and confirm pseudo error to ECM

U34.11 Usage notes

U34.11.1 Command list pre-fetch maximum data size information for IMP-X7 IP

IMP-X7 IPs (IMP core, CVe, IMP DMAC, Slim-IMP DMAC, IMP PSC, IMPCNN) has pre-fetch function of command list.
The maximum pre-fetch data size for IMP core, CVe, IMP DMAC, Slim-IMP DMAC, IMP PSC is 640-bytes. Therefore, CL must be placed in memory block so that 640-bytes space is available for maximum pre-fetch after the TRAP/RET/GOSUB/JUMP instruction.

In case of IMP CNN, the maximum pre-fetch data size for each IP is 36-Kbytes. Therefore, CL must be placed in memory block so that 36-Kbytes space is available for maximum pre-fetch after the TRAP/RET/GOSUB/JUMP instruction.

Note: It is prohibited to compress the Command List (CL), so place the CL including maximum pre-fetch data area only to the uncompressed region.

U34.11.2 Command list pre-fetch alignment information for IMP-X7 IP

Pre-fetch of CL buffer in IMP-X7 IPs (IMP CNN, IMP core, CVe, IMP DMAC, Slim-IMP DMAC, IMP PSC) take place with 128-byte unit alignment. Therefore, to achieve efficient buffering and pre-fetch data transfer, it is recommended to use memory addresses with 128-byte unit alignment for CL start address, GOSUB address and JUMP address for these IPs. In the case of IMP CNN, additionally, pre-fetch of CL buffer take place with 4-Kbyte unit alignment. Therefore, the recommended memory address alignment is a 4-Kbyte unit for IMP CNN.
When using GOSUB or JUMP instructions, there is a possibility of a pre-fetch data invalidation of data which was already pre-fetched prior to the GOSUB or JUMP instructions. Therefore, pre-fetch data transfer efficiency might be affected by it.

U36. Debug Trace Agent (IMP DTA)

U36.1 Overview

U36.1.1 Features

The IMP-X7 Debug and Trace Agent (IMP DTA) supports debugging of the IMP-X7 sub system. The IMP-X7 sub system consists of several independent components like CV engine, legacy IMP core, iDMA, Pyramidal Scaler. These components can synchronize each other by using a simple trigger mechanism. Each component can trigger another component. Each component can decide which component can trigger it.
To debug this synchronization between the different components the Debug and Trace Agent can interrupt processing of a component or of several components. Additionally, the debug and trace agent will inform the external debug module which component is now stopped and automatically send status updates to the STM trace module.
If IMPDTA is not enabled, each incoming WUP trigger will result in a KICK output trigger to the corresponding IMP component. If IMPDTA is enabled, each incoming WUP trigger will result in a KICK output trigger to the correspondent IMP component either in the next cycle or after the status had been successfully send out to the STM trace module, which can be connected over a direct connection to the DTA. This will reduce the influence of the debug and trace agent to the IMP subsystem behaviour.

U36.1.2 Block diagram

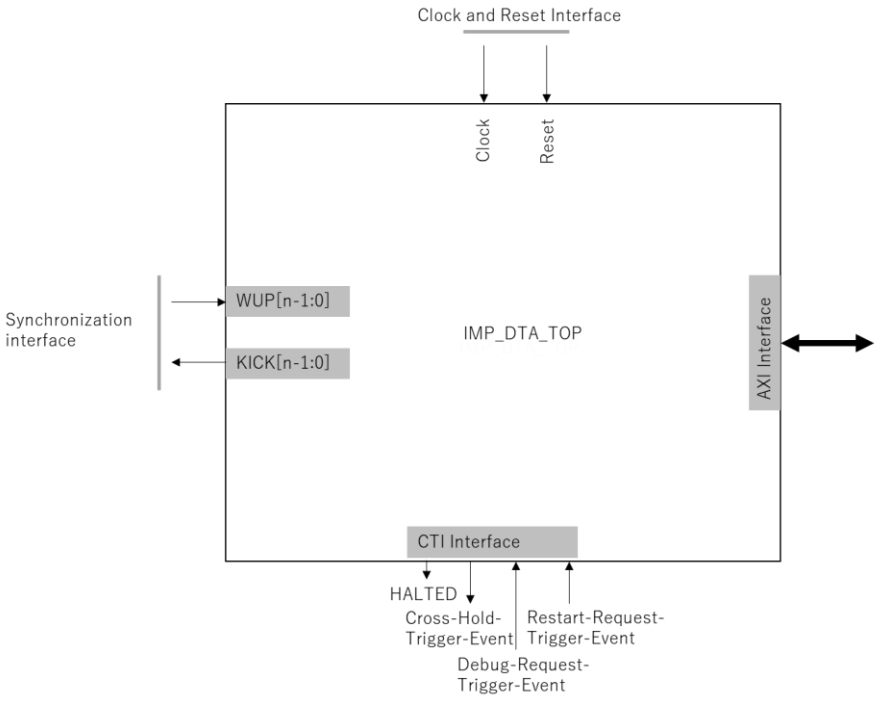

Figure U36.1 IMP_DTA_TOP Block Diagram

The Debug Trace Agent uses a standard AXI interface for register configuration. The AXI interface is also used for transferring the trace information to the CoreSight system. This trace information can be either sent out

over the general available 256bit AXI interface or over a 64-bit AXI interface to a bus directly connected to the STM.
The wakeup (WUP) and kick signals are used for the handshaking with the IMP-X7 components.

U36.1.3 Configuration Process

Software process flow:

1. Reset Release
2. Configure Registers
   a. IMPDTAIDn
   b. IMPDTANDEVCNTLIMITn
   c. IMPDTADBCTRLn
   d. IMPDTACTRL
3. Set IMPDTACTRL.EN bit ‘1’
4. Wait until the configured components are stopped
5. To restart the components, use IMPDTACTRL.GLBKICK/IMPDTADBCTRLn.KICK

Note: Before disabling the component or the different debug modes, the SW must check the status of each component (IMPDTASTATn) to avoid any deadlock situation.

U36.1.4 DTA Register Configuration

Table U36.1 DTA Register Configuration Table for Fourth Generation R-Car Series Products

Register Name	Symbol	Access Possible From CP-R/ CP-W[*1]	Value after Reset	Offset Address	RESET
Control register	IMPDTACTRL	1/1	0x0	0x0000	✓
OPC value register	IMPDTAOPC	1/1	0x0052E900	0x000C	✓
Break configuration register	IMPDTADBCTRLn[*2]	1/1	0	n * 0x0040 + 0x10	✓
Event counter target register	IMPDTAEVCNTLIMITn[*2]	1/1	0	n * 0x0040 + 0x14	✓
ID number register	IMPDTAIDn[*2]	1/1	0	n * 0x0040 + 0x18	✓
Debug Status register	IMPDTASTATn[*2]	1/1	0	n * 0x0040 + 0x1C	✓
Event counter register	IMPDTAEVCNTVALn[*2]	1/1	0	n * 0x0040 + 0x20	✓

Note: 1. CP = central processor, R = read, W = write

2. n: IMP Component number, range is 0..17 (Refer to U34. IMP-X7 System, Inter module synchronization for the details about the component connections.)

U36.2 Register Description

[Legend]
Initial value: Register value after a reset
-: Undefined value
R/W: Readable/writable. The written value can be read.
R: Read-only. The write value should be the same as the read value.
-/W: Write-only. The read value is undefined.

Function for control registers is not defined when using values other than the defined values or values outside the defined areas.

U36.2.1 IMPDTACTRL register

This register configures the IMP_DTA IP.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
CP: R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	AXIM_SEL	GLBKICK	GLBBRK	GLBDBMODE	EN
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
CP: R/W	R	R	R	R	R	R	R	R	R	R	R	R/W	-/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	-	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0. If a value other than 0 is written, correct operation cannot be guaranteed.
4	AXIM_SEL	0	R/W	AXI bus select signal 0: AXIM256 (Default) 1: AXIM64 (direct connection) Selection must be done before DTA is used.
3	GLBKICK	0	W	Global KICK 0: no function 1: triggers a KICK pulse on all KICK signals. Switches to ‘0’ after 1 SYCLK cycle
2	GLBBRK	0	R/W	Global Break 0: disabled 1: all Components will be stopped
1	GLBDBMODE	0	R/W	Global Debug Mode 0: Disabled 1: Enabled
0	EN	0	R/W	IMPDTA enable: 0: disabled 1: enabled IP does not start before setting this bit to ‘1’. Other register configuration shall be done before.

U36.2.2 IMPDTAOPC register

This register contains the OPC value for the AXI interface, low and high part.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	IMPDTAOPC															
Initial value:	0	0	0	0	0	0	0	0	0	1	0	1	0	0	1	0
CP: R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	IMPDTAOPC															
Initial value:	1	1	1	0	1	0	0	1	0	0	0	0	0	0	0	0
CP: R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	IMPDTAOPC	All 0x0052E900	R	Reserved. These bits are always read as 0x0052E900. The write value should always be 0x0052E900. If a value other than 0x0052E900 is written, correct operation cannot be guaranteed.

U36.2.3 IMPDTADBCTRLn register

This register configures the debug behavior for component n.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
CP: R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	DLY_KICK	MSGEN	KICK	EVCNTRES	TraceEN	DBMODE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
CP: R/W	R	R	R	R	R	R	R	R	R	R	R/W	R/W	-/W	-/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 6	-	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0. If a value other than 0 is written, correct operation cannot be guaranteed.
5	DLY_KICK	0	R/W	DLY_KICK 0: KICK is directly sent out 1: KICK is delayed till message has been successfully sent out over AXI bus to STM Selection must be done before DTA is used.
4	MSGEN	0	R/W	Message EN 0: Only Trace information (32bit CNTVAL) will be sent if wake up trigger received and TraceEN set 1: User message and trace information will be sent if wake up trigger received and TraceEN set (Upper 8bit: message, lower 24bit: lower 24bit of 32bit CNTVAL)
3	KICK	0	-/W	Kick 1: Kick 0: No Kick
2	EVCNTRES	0	-/W	Event Counter Reset 1: Counter reset 0: no function Switches to '0' after 1 SYCLK cycle.
1	TraceEN	0	R/W	Trace EN 0: disabled 1: Trace information will be sent if wake up trigger received
0	DBMODE	0	R/W	Individual Debug Mode: 0: Disabled 1: Enabled

U36.2.4 IMPDTAEVCNTLIMITn register

This register configures the event counter limit of component n.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	LIMIT															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
CP: R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	LIMIT															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
CP: R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0,	LIMIT	0	R/W	Node counter target value. The component will be stopped if the global and individual debug mode is enabled, and the event counter reaches the LIMIT.

U36.2.5 IMPDTAIDn register

This register configures the trace ID of component n.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	TRCMSG							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
CP: R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TRCID															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
CP: R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	-	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0. If a value other than 0 is written, correct operation cannot be guaranteed.
23 to 16	TRCMSG	0	R/W	User trace message for this component
15 to 0	TRCID	0	R/W	Configures the trace ID for this component

U36.2.6 IMPDTASTATn register

This register shows the current debug status of component n.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
CP: R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	BRK	GLBBRK
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
CP: R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	-	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0. If a value other than 0 is written, correct operation cannot be guaranteed.
1	BRK	0	R	1: Component is stopped due to individual break. Bit is cleared if KICK is executed
0	GLBBRK	0	R	1: Component is stopped due to global break. Bit is cleared if KICK or GLBKICK is executed

U36.2.7 IMPDTAEVCNTVALn register

This register shows the current event counter value of component n.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CNTVAL															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
CP: R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CNTVAL															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
CP: R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0,	CNTVAL	0	R	Shows the current event counter value.

U36.3 Operation

Each synchronization interface is assigned to 1 core process. The individual core processes are configured by the global configuration registers and by the individual configuration registers.

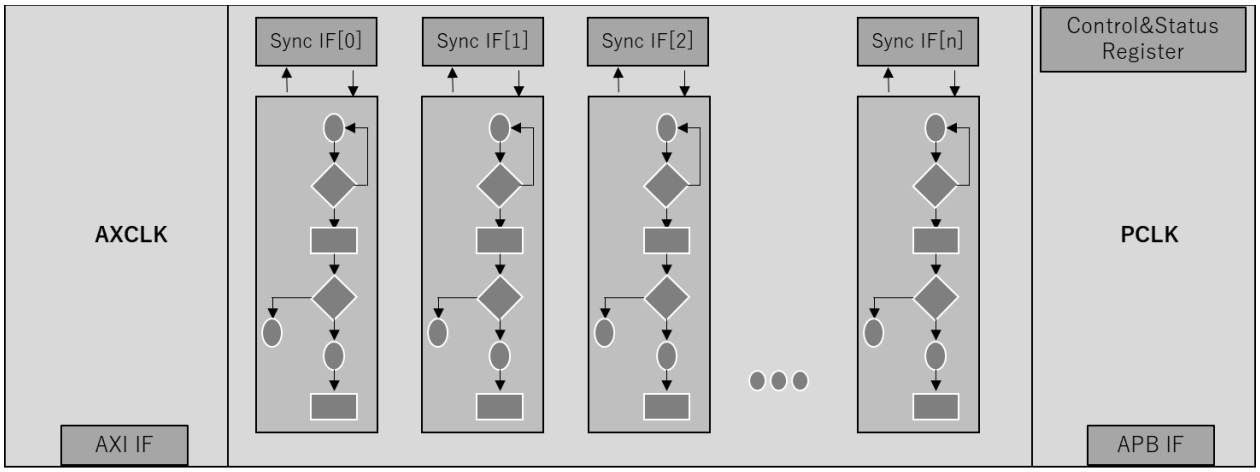

Figure U36.2 Assignment of Synchronization Interfaces to Core Processes

The core process is separated into 2 levels:

1) Configuration level
2) Break processing level

The configuration level is 1 single global process for all synchronization interfaces.

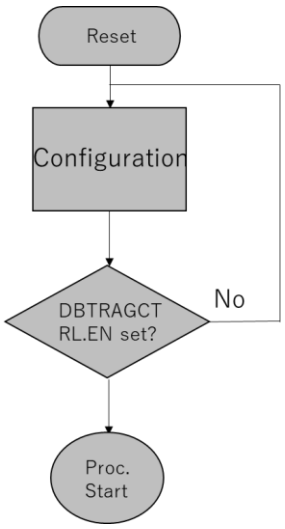

Figure U36.3 Flow diagram of configuration level process

The break processing level is implemented as several independent processes, 1 process for each synchronization interface. Figure U36.4 shows the break processing level for synchronization interface/process.

After initialization is done, the DTA is waiting for a WUP signal from other IMP sub modules. When such WUP is received, an internal event counter is increased, and a trace command is sent out to CoreSight system if desired. After, global and local debug mode settings are checked and depending on their settings and the setting of a global or local break point, the DTA unit goes in a global or local wait state from which it can be restarted by receiving a global or local KICK.

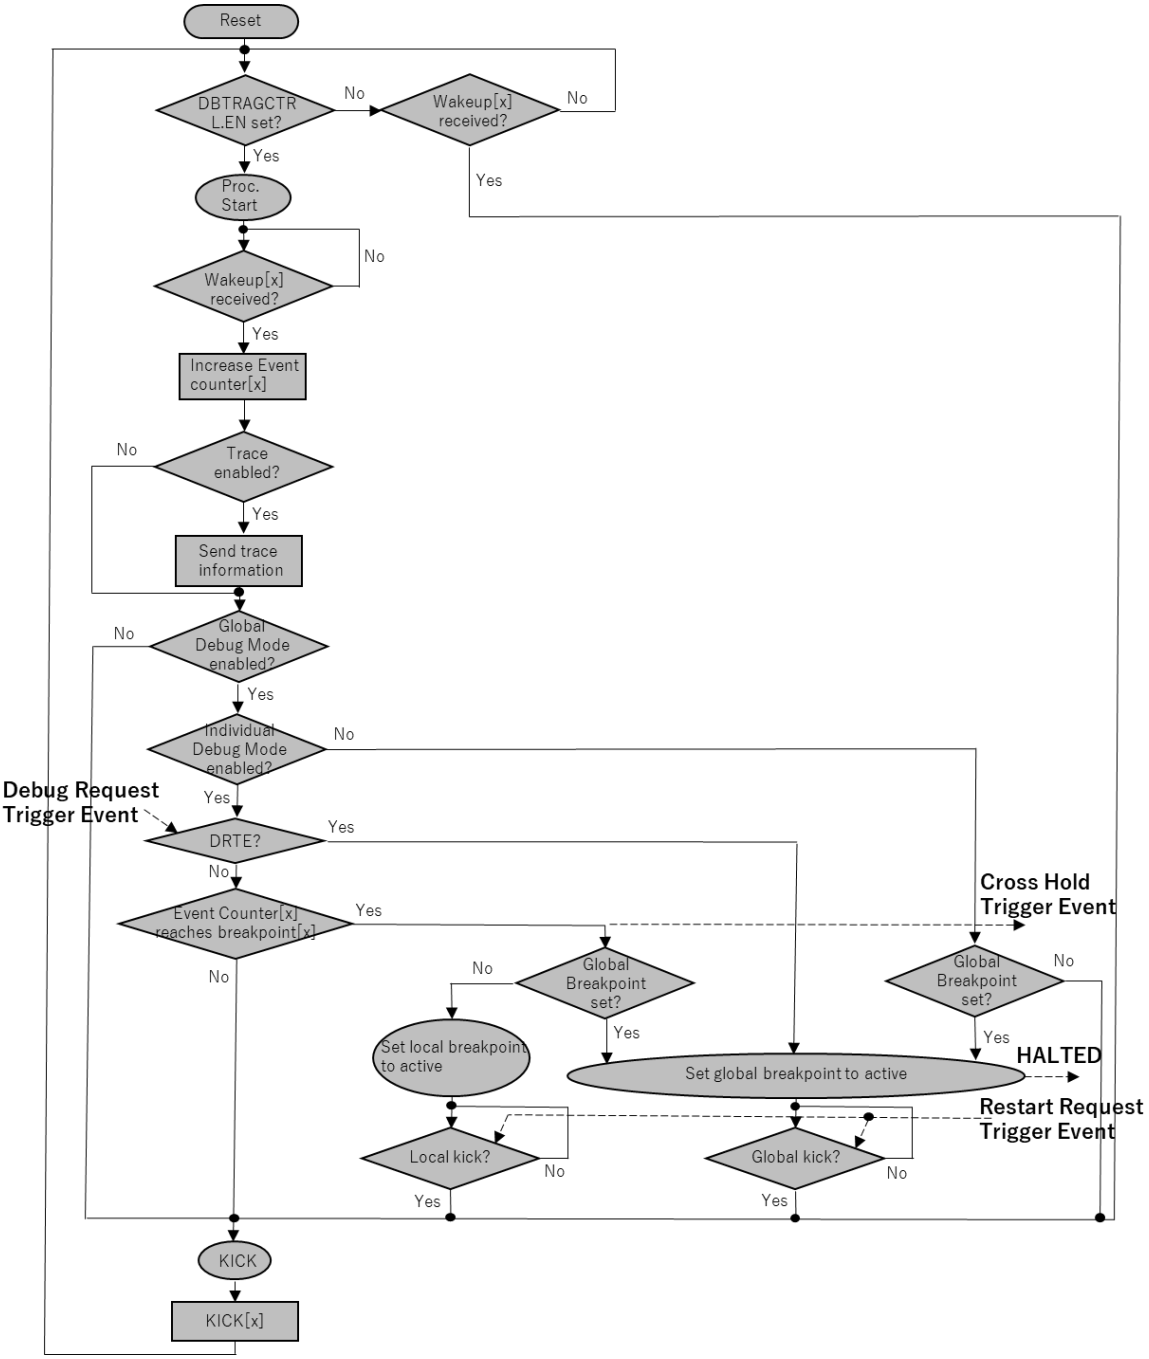

Figure U36.4 Flow Diagram of break processing level process

If the IMP DTA is not enabled (EN bit of IMPDTACTRL register is 0), it sends a KICK whenever a wakeup is received. For synchronization with the Cross Trigger Module, the following 4 signals were added:

Cross Hold Trigger Event: Informs Cross Trigger Module of a break of an individual debug mode enabled IMP-X7 component.
Debug Request Trigger Event: Global breakpoint request is set for all enabled IMP-X7 components.
HALTED: Informs Cross Trigger Module that no component is running anymore, they are either not enabled or stopped due to local or global breakpoint.
Restart Request Trigger Event: All enabled components waiting in local or global break are restarted again.

U36.4 Usage Notes

U36.4.1 Synchronized system between modules

The synchronization between DTA and other IMP sub modules works as follows. The other IMP sub modules using their WUP/SLP CL commands to get in synchronization with the DTA module. The DTA module does not have such WUP/SLP CL commands, instead, an acknowledge KICK to a received WUP signal is directly in the receiving following clock cycle sent back as WUP to the calling IMP sub module to wake up that sub module from SLP state. A SLP does not exist in the DTA unit.
NOTE: Please make sure that the DTA unit is started before receiving any WUP signals from other IMP sub modules, otherwise, it can cause a hang-up.

U36.4.2 Power shutdown

For power shutdown, refer to the Section 58.7.1 Shutting Down the Power Supply of IMP-X7 manual.

U36.4.3 Module Standby Mode

For module standby mode, refer to the Section 58.7.2 Module Standby Mode of IMP-X7 manual.

U36.4.4 CPG Software Reset

For software reset of CPG, refer to the Section 58.7.3 Software Reset by the Clock Pulse Generator (CPG) of IMP-X7 manual.

U36.5 Safety Mechanism

Note: The suitability of the safety mechanisms referenced in this manual will finally be judged during the safety analysis and safety assessment of the SoC. Therefore, the safety documentation shall always be considered as additional requirements for the system or software derived from the results of the safety analysis.

U36.5.1 Block diagram for FuSa

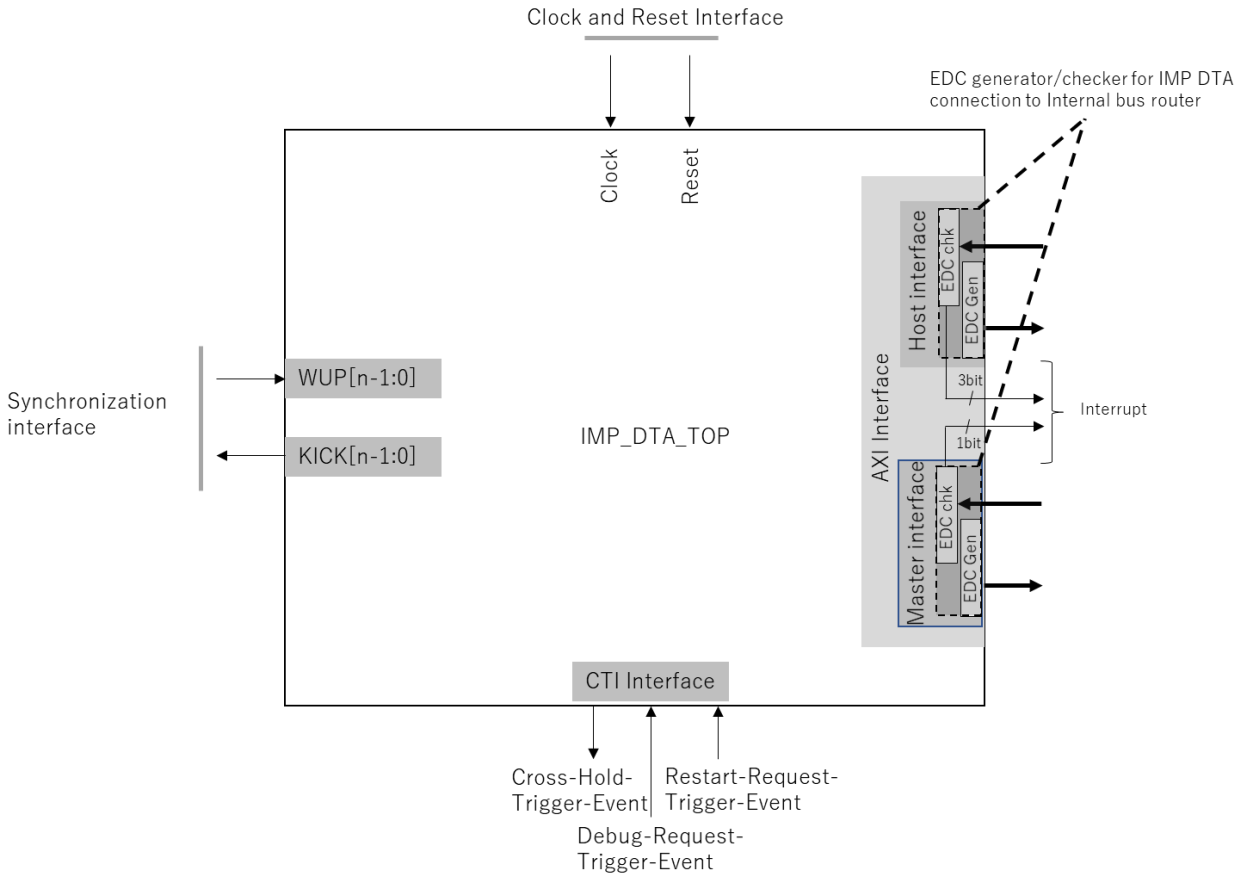

Figure U36.5 DTA Block diagram for FuSa

U36.5.2 Bus I/F

Bus EDC is implemented inside DTA.

U39. Vision DSP (VDSP)

This chapter describes the Vision DSP (VDSP).

The VDSP has parallel execution performance by 8-way VLIW architecture which allows it to handle a variety of applications.

The vector processing unit adopts the SIMD architecture, and up to 512 8-bit x 8-bit MACs (multiply-accumulate arithmetic units), includes up to 128 16-bit x 16-bit MACs, up to 32 single-precision floating-point MACs.

For the details refer to the implementation guide of CEVA-SP500™ core. Note that chapter number of the implementation guide of CEVA-SP500™ might be different according to the version of guide.

U39.1 Overview

U39.1.1 Features

VDSP supports the following features

- 2 VDSPs with CEVA-SP500™ core are available
- The following memories are implemented in each core of VDSP.
  1. 256KByte of internal data memory
  2. 8KByte of internal program memory
  3. 64KByte of instruction cache memory
- It can be started from the instructions from the external memory or its own instruction RAM by specifying the reset vector address
- VDSP PDMA (Program DMA) and DDMA (Data DMA)
- Can access IMP subsystem registers using 4 byte access.
- WatchDog Timer is implemented for functional safety (FUSA) .
- Supports the Cross Trigger Interface.
- All CEVA-SP500™ cores of the VDSP can be debugged using CEVA® toolchain
- Support Runtime Test and power down for each VDSP.
- VDSP can access to other VDSP's memory regions.

Below is the CEVA-SP500™ Configuration table.

Table U39.1 CEVA-SP500™ HW Configuration

Configuration	Setting	Remarks
Type	CEVA-SP500™	512 MAC configration
BTB_WAY	4	Branch target buffer n-way
BTB_SIZE	256	btb total entries
BASIC_FULL	BASIC	BASIC + extensions. FULL
VPU_FXP_UNITS	512	CEVA-SP500™ has 512 8x8 fix point mac
LVPU	TRUE	Light VPU as assitance to main VPU (LVCU Light vector computation unit)
SPU_FLP_Type	BOTH	16 & 32 bit operations (HP, SP)
SPU_FLP_Units	2	
VPU_Non_Linear_Units	16	Unit count of INV, SQRT,... (Basic 16, Full-extended 32)
VPU_FLP_Units	SP32	
VRF	24	# of 512b vectors (Basic 24, Full 32)
Program_TCM	8KB	Internal program memory
Program_CACHE	64KB	Instruction cache memory
Data_TCM	256KB	Internal data memory
EDP_width	256bit	External Data master AXI interface (EDP) width (bits)
EDAP_width	128bit	External Data slave AXI interface (EDAP) width (bits)
EPP_width	128bit	External Program master AXI interface (EPP) width (bits)
Additional_AXI_Masters	1port	AXI Master internal-256 bit
ECC_WIDTH	32bit	SRAM ECC is implemented for 32-bit alignment(7-bit) code
NUM_TIMERS	4	One VDSP has 4 Timers
RTT	Internal	Real Time Trace (excludes VCU); location of ETM-R4 trace bus interface
ENH_SAFETY	TRUE	Enhance safety.
Number of ICU	2ch	Interrupt control unit

U39.1.1.1 **Block Diagram**

The following figures show the block diagram of the VDSP subsystem and one VDSP.

The VDSP subsystem consists of 2 VDSPs with CEVA-SP500 ™. The CPU can access the registers in the 2 VDSP via "AXI Slave / SVD1_IRϕ / 64-bit" of the IR domain AXI bus.

Each VDSP can access the DDR-SDRAM via "AXI Master / SVD1_IRϕ / 128-bit" for instructions, and "AXI Master / SVD1_IRϕ / 256-bit" for data.

In addition, each VDSP can access the SPMI/SPMC memory in IMP-subsystem to share data with IPs in the IMP-subsystem via "AXI Master / IMPAD1ϕ / 256-bit". Refer U34.IMP-X7_System HWM for IMP-subsystem.

U39.2 Register Description

[Legend]

Initial value	: Register value after a reset (hardware reset : This reset is to reset all the logic including bus interface)
-	: Reserved. The write value should always be 0.
R/W	: Readable/writable. The written value can be read.
W	: Write-only. The read value is not guaranteed.
R	: Read-only. The write value should always be 0.

Refer : R-CarV4M_UM_U39_VDSP_r0p50.xlsx

Bits not listed in the referenced file above are reserved read-only bits.

U39.3 Operation

U39.3.1 Data DMA Debug Match for Breakpoint Generation

The data DMA (DDMA) can output a debug match indication when a configured address matches the address of the current DDMA transaction.

A match can be done on either an internal TCM address or an external AXI addresses. It can also be done for DDMA transfer direction (upload, download, or IIT).

The DDMA debug match indication is an output at the top level of the SensPro™ where it is called DDMA_MATCH.

The address match indication is cleared either by software writing to the register of the SensPro™ or by asserting an input at the top level of the SensPro™ where it is called DDMA_MATCH_ACK.

For more details about the DDMA_MATCH and DDMA_MATCH_ACK, see “3.9.8 DMA Breakpoint Generation” of “SensPro™ Architecture Specification Volume III (MSS)”.

To clear this indication useing DDMA_MATCH_ACK, set the DDMA_EXT_ACK bit in the DDMA_CNTRL register to 1 and then 0.

To also clear interrupts to INTC or other DSPs, set the OIC_ * _DDMA_DBG_MATCH bit in the OUT_INT_CLR_I or OUT_INT_CLR_D registers to 1.

The DDMA debug match indication also goes to the OCEM and is connected to the Stand-Alone External Breakpoint input (SA_EXT4). This means that the DDMA debug match can trigger a breakpoint in the OCEM, if the OCEM is configured to accept that external breakpoint.

If configured, the OCEM acknowledges the DDMA debug match indication automatically.

For more details about the configuration registers in the OCEM, see the SensPro™ Debug Unit Reference Guide in the release package.

The DDMA address match is triggered when the actual read or write has been completed.

For example, if triggering on the internal address during a DDMA download, the DDMA can perform the memory write over several cycles because of contention issues with higher priority sources on one or more banks.

In this case, the DDMA debug match indication is not asserted until the DDMA has completed the entire write to all banks.

Figure U39.3.1 shows the DDMA_MATCH, the DDMA_MATCH_ACK, and the OCEM acknowledge.

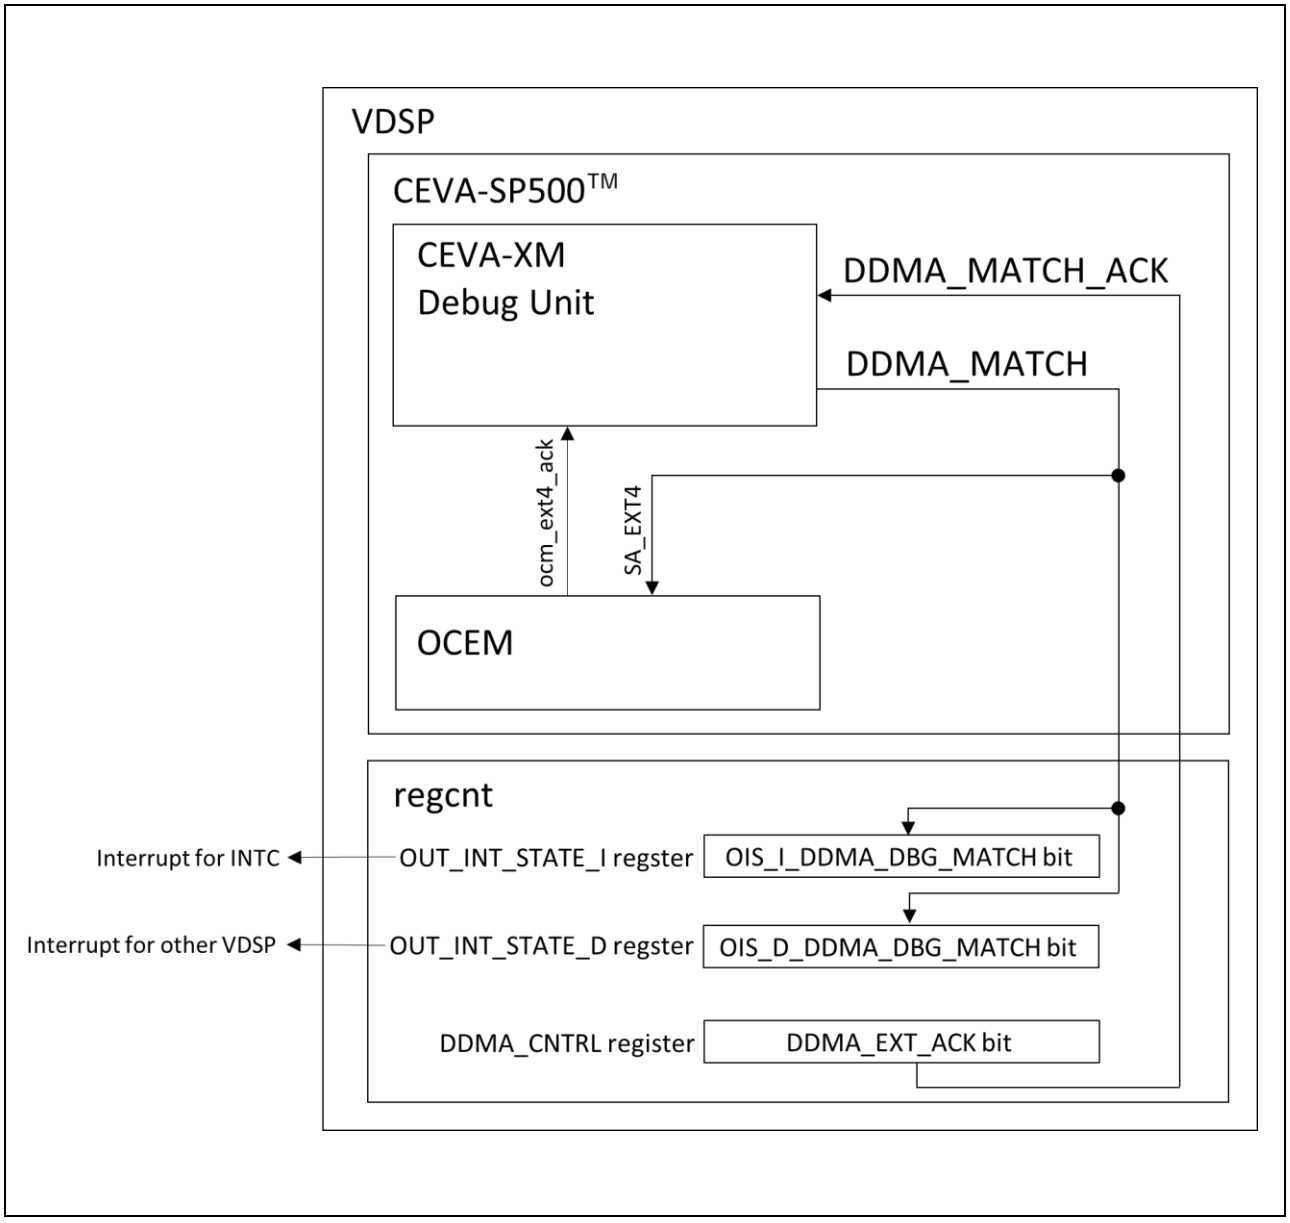

Figure U39.3.1 DDMA Debug Match Indication

Figure U39.3.2 shows an example of a debug match indication and the subsequent acknowledgements.

Note: The input of the external acknowledgment DDMA_MATCH_ACK is used by the synchronized ext_ddma_dbg_match_ack to clear the match indication.

ddma_edp_rd_addr_r : Read Address signals to the EDP port by the DDMA transfer

ddma_edp_rd_r : Read-Address-valid signal to the EDP port by the DDMA transfer

edp_axb_rready : Read-Address-ready signal from the EDP port

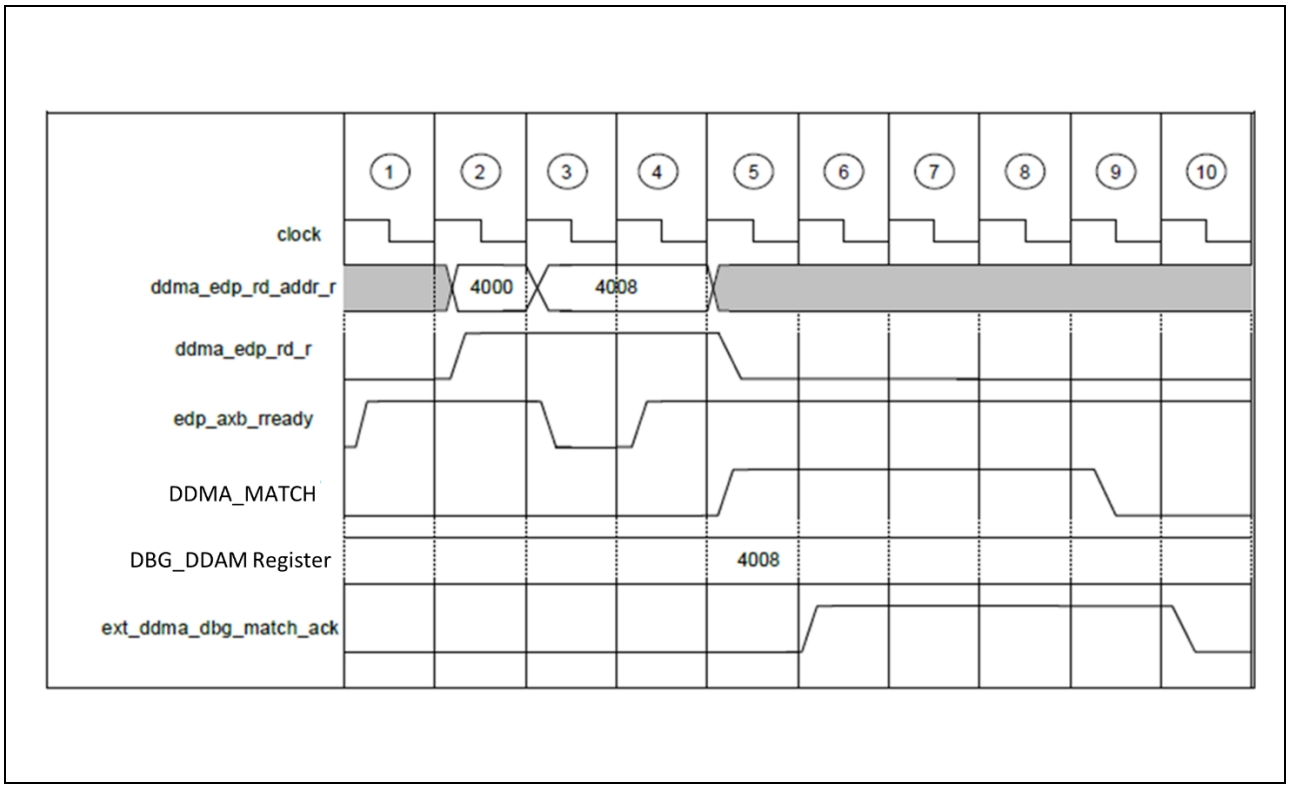

Figure U39.3.2 DDMA Debug Match Indication Timing Diagram

U39.3.2 Program Memory Cache Invalidate Strap.

Figure U39.3.3 shows the PMSS cache invalidate strap pin sequence.

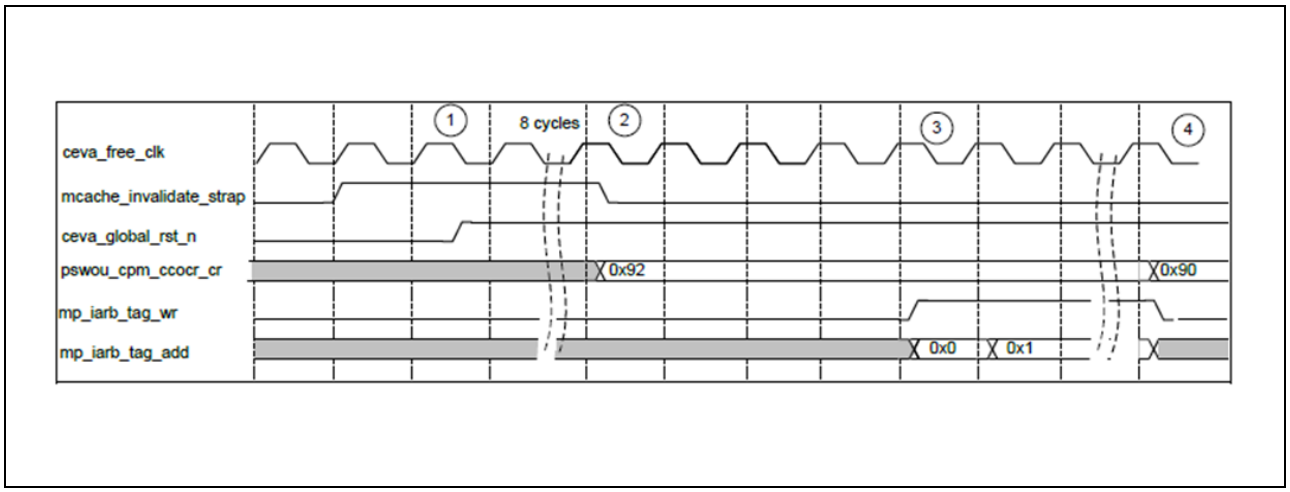

Figure U39.3.3 PMSS Cache Invalidate Strap pin

The transaction sequence is as follows:

1) Global reset is released.
2) After eight cycles, the PMSS CCOCR register is configured to start the entire cache invalidation process.
3) Four cycles later, the cache invalidation process begins.
4) When the entire cache has been invalidated, bit 1 in the CCOCRregister is reset, and the user can begin working with the cache

The PMSS cache invalidate strapping signal should be high and stable when the external reset is de-asserted. To enable the PMSS to start the cache invalidate process, the PMSS cache invalidate strap pin should be held for eight cycles after the reset is released. The process is done automatically by setting the software operation of the PMSS to invalidate the entire cache. This strap is active when either the global (ceva_global_rst_n) or system (ceva_sys_rst_n) resets are released.

U39.3.3 SPMI/SPMC access Method through internal router (DACU)

Data DMA (DDMA) of VDSP can access Scratchpad memory (SPMI/SPMC) in IMP-X7. Accessing SPMI/SPMC other than DDMA is prohibited.

When DDMA access to SPMI/SPMC, it is necessary to set the AXIM0 port in D_ADD*_START register in CEVA-SP500™. VDSP cannot access SPMI/SPMC from the EDP port.

Refer SensPro™ Architecture Specification Volume III(MSS), 3.4 Data Access Control Unit for details on how to set the D_ADD*_START register. Refer to U34.1.3 Address map in U34.IMP-X7_system for the SPMI/SPMC address. When VDSP access Scratchpad memory (SPMI/SPMC0/1) in IMP-X7, initially set 0 to the bit 31 of SPMCTRL4 (0xFFAB0F18) registers in SPMC. Do not change this bit after setting to 0.

Refer SensPro™ Architecture Specification Volume III(MSS), 3.9 Data DMA for details on how to use DDMA. When using DDMA, follow the restrictions described in U39.4.13 AXI Usage.

An example of setting the D_ADD*_START register when using the entire SPMI/SPMC area (0xED30_0000 to 0xED5F_FFFF) is shown below.

1) Set D_ADD1_START register to 0x002ED300

REGION_START[19:0]	=	0xED300 (Start address, 4KB unit)
REGION_MID[27:20]	=	0x02 (AXIM0 port)
INACTIVE[28]	=	0x0 (Active)
DPRAW[29]	=	0x0

2) Set D_ADD2_START register to 0x080ED600

REGION_START[19:0]	=	0xED600 (End address, 4KB unit)
REGION_MID[27:20]	=	0x80 (Blank region)
INACTIVE[28]	=	0x0 (Active)
DPRAW[29]	=	0x0

U39.3.3.1 DDMA SPMI/SPMC transfer data

Below are the example in which Data DMA (DDMA) of VDSP taranfer the data form SPMC to IDM of VDSP.

a) Linear data transfer from SPMC to IDM

Set the D_ADD*_START register to select the SPMC region. In below example, D_ADD3_START is used.

- First release the vdsp*_global DSP reset.
- Set **P_PDEA**[*1] = **0x0000 0000 // pload_stop=1->0**
- Set **ICU_ACU_LOCK**[*1] = **0x0000 0008 // External masters can configure the DACU**
- Set **D_ADD3_START**[*1] = **0x002E D400 // SPMC (AXIM0)**
- Set **MSS_DDTC**[*1] = **0x0000 0400 // (1024 bytes) data**
- Set **MSS_DDEA**[*1] = **0xED40 0000 // Data DMA SPMC used as source**
- Set **MSS_DDIA**[*1] = **0x1000 0000 // IDM address used by DMA as destination**
- Set **MSS_DDCL**[*1] = **0x0000 00A0 // (8 transfers (INCR)), Transfer from the external memory to the IDM**

Wait for the DMA transfer end.

Note 1 : Refer "SensPro™ Architecture Specification Volume III (MSS)" for details of these registers.

b) Two dimensional data transfer from SPMC to IDM

Set the D_ADD*_START register to select the SPMC region. In below example, D_ADD3_START is used.

- First release the vdsp*_global DSP reset.
- Set **P_PDEA**[*1] = **0x0000 0000 // pload_stop=1->0**
- Set **ICU_ACU_LOCK**[*1] = **0x0000 0008 // External masters can configure the DACU**
- Set **D_ADD3_START**[*1] = **0x002E D400 // SPMC (AXIM0)**
- Set **MSS_2DCFG1**[*1] = **0x0000 0001 // Select two dimensional transfer indication**
- Set **MSS_2DCFG2**[*1] = **0x0010 0040 // [WIDTHxHEIGHT(64x16=1024 bytes)] data**
- Set **MSS_2DCFG3**[*1] = **0x0040 0000 // Set EXT_STRIDE**
- Set **MSS_DDEA**[*1] = **0xED40 0000 // Data DMA SPMC used as source**
- Set **MSS_DDIA**[*1] = **0x1000 0000 // IDM address used by DMA as destination**
- Set **MSS_DDCL**[*1] = **0x0000 00A0 // (8 transfers (INCR)), Transfer from the external memory to the IDM**

Wait for the DMA transfer end.

Note 1: Refer "SensPro™ Architecture Specification Volume III (MSS)" for details of these registers.

U39.4.4 Interrupt to INTC

Table U39.9 Interrupt to INTC table.

n=0-1

For INTC interrupt output Name (OR of unmasked bits)	VDSP regiser in the regcnt (Each enabled bit holds the entered "1".)		CEVA-SP500™ Interrupt output
	Regiser neme	Bit Name	
intreq_dspp***n***timer	OUT_INT_STATE_I[n]	OIS_I_TIMER00	TIMER0_OUT

		OIS_I_TIMER01	TIMER1_OUT
		OIS_I_TIMER02	TIMER2_OUT
		OIS_I_TIMER03	TIMER3_OUT
intreq_dspp***n***[1]		OIS_I_DDMA_DBG_MATCH	DDMA_MATCH

The intreq_dspp***n***timer interrupt to INTC outputs the OR of the OIS_I_TIMER00 to 03 bits of the OUT_INT_STATE_I[n] register, and the intreq_dspp***n***[1] interrupt outputs the OIS_I_DDMA_DBG_MATCH bit of the OUT_INT_STATE_I[n] register.

The interrupt output by CEVA-SP500™ is input to the OUT_INT_STATE_I[n] register in the REGCNT of each VDSPn when the corresponding bit is enabled by the OUT_INT_EN_I[n] register, and holds the input "1".

Each bit in the OUT_INT_STATE_I[n] register is cleared by writing "1" to the corresponding bit in the OUT_INT_CLR_I[n] register.
Note that the interrupt output factor of the CEVA-SP500™ must be cleared first in order to clear the interrupt.

Each bit in the OUT_INT_STATE_I[n] register can be excluded from the interrupt factor by setting the corresponding bit in the OUT_INT_MSK_I[n] register to "1".

U39.4.5 Interrupt to ECM

Table U39.10 Interrupt to ECM table.

Notes:

1. Internal data Memory must be initialized before being read. Please refer to "2.2 Error Correction and Detection (ECC)" of SensPro Hardware Safety Mechanism Specification.
2. Internal Program Memory must be initialized before being read. Please refer to "2.2 Error Correction and Detection (ECC)" of SensPro Hardware Safety Mechanism Specification. Entire Program Cache must be invalidated by configuring P_CCOCR register before it is enabled. Please refer to "2.10.3.5.2 Entire-Cache Operation" of SensPro Architecture Spcification Volume III (MSS) for the operation flow.
3. Internal Program Memory must be initialized before being read. Please reer to "2.2 Error Correction and Detection (ECC)" of SensPro Hardware Safety Mechanism Specification.

U39.4.6 Interrupts between VDSPs

Table U39.11 Interrupts between VDSPs table.

VDSPn.CEVA-SP500™ Interrupt input Name	VDSP Interrupt output Name	Notes
VDSP1.EXT_INT[1]	dspp0_internal_int	See “Table U39.12 Interrupt to other VDSP table”.
VDSP0.EXT_INT[1]	dspp1_internal_int	

Table U39.12 Interrupt to other VDSP table.

n=0-1

For othe VDSP Interrupt output Name (OR of unmasked bits)	VDSP regiser in the regcnt (Each enabled bit holds the entered "1".)		CEVA-SP500™ Interrupt output
	Regiser Neme	Bit Name	
dspp***n***_internal_int	OUT_INT_STATE_D[n]	OIS_D_TIMER00	TIMER0_OUT
		OIS_D_TIMER01	TIMER1_OUT
		OIS_D_TIMER02	TIMER2_OUT
		OIS_D_TIMER03	TIMER3_OUT
		OIS_D_DDMA_DBG_MATCH	DDMA_MATCH

The dspp***n***_internal_int interrupt to the other VDSP outputs the OR of the all bits of the OUT_INT_STATE_D[n] register.

The interrupt output by CEVA-SP500™ is input to the OUT_INT_STATE_D[n] register in the REGCNT of each VDSPn when the corresponding bit is enabled by the OUT_INT_EN_D[n] register, and holds the input "1".

Each bit in the OUT_INT_STATE_D[n] register is cleared by writing "1" to the corresponding bit in the OUT_INT_CLR_D[n] register.
Note that the interrupt output factor of the CEVA-SP500™ must be cleared first in order to clear the interrupt.

Each bit in the OUT_INT_STATE_D[n] register can be excluded from the interrupt factor by setting the corresponding bit in the OUT_INT_MSK_D[n] register to "1".

U39.4.7 VDSP startup method

This chapter describes how to start the DSP. There are the following 3 patterns for boot method.

1) Start from the vector address set in register RST_VEC_ADDR.
2) Start from internal program memory after fetching a program from external memory.
3) Preload a program into the program cache memory and boot from the cache memory.

Before booting the VDSP, turn on the power of the VDSP according to the following procedure.

1) Assert the following VDSP resets by using CPG register. See Refer to Table U39.6 for details.

   (In no particular order)

   - WR_RESET
   - OCEM RESET
   - CORE RESET
   - SYS RESET
   - GLOBAL RESET

2) Turn on the power of VDSP by the register of SYSC.

For CPG and SYSC registers, refer to the HW manual for CPG and SYSC.

U39.4.7.1 Start from the vector address set in register RST_VEC_ADDR

1) Release the following VDSP resets by using CPG register. See Refer to Table U39.6 for details.

   (In no particular order)

   - Reset registers in regcnt
   - Reset debugging interface

   Then, confirm that the reset has been released in the CPG registers.

2) Set the PLOAD_STOP bit in register DSP_CONTROL to 0.
3) If it is necessary to set a unique Core ID for each VDSP, set the CORE_ID register.
4) Set the reset vector in the register RST_VEC_ADDR.

   - Initial value 0x00000000
   - External Memory address 0x40000000～0xBFFFFFFF (SDRAM Area 2GB)

   If RST_VEC_ADDR is set to initial value (0x00000000), the DSP boots from the Internal Program Memory, please refer to U39.4.7.2 for how to boot from the Internal Program Memory.

5) Release the following VDSP resets by using CPG register. See Refer to Table U39.6 for details.

   (In no particular order)

   - GLOBAL RESET
   - SYS RESET
   - CORE RESET

   Then, confirm that the reset has been released in the CPG registers.

6) RST_VEC_ADDR register should not be changed during reset release.

U39.4.7.2 Start from internal program memory after fetching a program from external memory

1) Release the following VDSP resets by using CPG register. See Refer to Table U39.6 for details.
(In no particular order)
・Reset registers in regcnt
・Reset debugging interface
Then, confirm that the reset has been released in the CPG registers.
2) Set the PLOAD_STOP bit in register DSP_CONTROL to 0.
3) If it is necessary to set a unique Core ID for each VDSP, set the CORE_ID register.
4) Release the following VDSP resets by using CPG register. See Refer to Table U39.6 for details.
(In no particular order)
・GLOBAL RESET
・SYS RESET
Then, confirm that the reset has been released in the CPG registers
5) Activate the PDMA in CEVA-SP500™ to transfer the boot program from external memory to Internal Program Memory. For more information on PDMA, see the “2.11 Program Direct Memory Access” chapter of “SensPro™ Architecture Specification Volume III (MSS)”. The maximum size of the program that can be transferred is 8KByte.
6) After confirming the completion of program download by PDMA in the register P_PDTC inside the DSP, release the following VDSP resets by using CPG register. See Refer to Table U39.6 for details.
・CORE RESET
Then, confirm that the reset has been released in the CPG registers

U39.4.7.3 Preload a program into the program cache memory and boot from the cache memory

1) Release the following VDSP resets by using CPG register. See Refer to Table U39.6 for details.
(In no particular order)
・Reset registers in regcnt
・Reset debugging interface
Then, confirm that the reset has been released in the CPG registers.
2) Set the PLOAD_STOP bit in register DSP_CONTROL to 0.
3) If it is necessary to set a unique Core ID for each VDSP set the CORE_ID register.
4) Set the reset vector in the register RST_VEC_ADDR.
・Initial value 0x00000000
・External Memory address 0x40000000～0xBFFFFFFF (SDRAM Area 2GB)

If RST_VEC_ADDR is set to initial value (0x00000000), the DSP boots from the Internal Program Memory, please refer to U39.4.7.2 for how to boot from the Internal Program Memory.

5) Release the following VDSP resets by using CPG register. See Refer to Table U39.6 for details.

(In no particular order)

・GLOBAL RESET

・SYS RESET

Then, confirm that the reset has been released in the CPG registers.

6) Transfer the boot program from external memory to program cache memory by controlling the registers of CEVA-SP500™.

a) Invalidate cache:

Set to P_L1ICO = '1' , P_OT = "0100", P_OS = '1' in P_CCOCR register (0x4e4).

b) Confirm completion of cache invalidation:

Read P_ACTIVE and P_L1ICO = '0' in P_CCOCR register (0x4e4).

c) Enable cache:

Set L1IC bit ='1' in P_ADD0_ATT0 registor (0x424).

d) Set the Start Address for pre-fetch to P_CCOSA in the P_CCOSAR register (0x4e0).

e) Start the pre-fetch:

Set to P_L1ICO = '1', P_OT = "0001", P_OS = '0', P_NOBPL = "0100" in P_CCOCR register (0x4e4).

f) Confirm completion of pre-fetch:

Read P_ACTIVE and P_L1ICO = '0' in P_CCOCR register (0x4e4).

7) Release the following VDSP resets by using CPG register. See Refer to Table U39.6 for details.

・CORE RESET

Then, confirm that the reset has been released in the CPG registers.

8) RST_VEC_ADDR register should not be changed during reset release.

U39.4.8 VDSP stop method

This chapter describes how to stop the VDSP.

To stop the VDSP, transition the PSU (Power Scaling Unit) of CEVA-SP500™ core to the following special modes.

- Light Sleep Mode : The core clock is shut down while memories and ports are enabled to provide upload or download.
- Standby Mode : The core clock and memory clocks are shut down.

To enter Light Sleep Mode / Standby Mode, user need to execute a “psu {lightsleep / standby}” CEVA-SP500™ instruction.

PSU mode can be confirmed by each bit of VDSP wrapper register PSU_STATE as shown in the table below. Refer U39.2 Register Description for PSU_STATE register.

Table U39.13 PSU_STATE values in each PSU mode.

PSU mode	PSU_STATE register
Light Sleep	When the transition to Light Sleep mode is completed, the LIGHT_SLP_MD bit becomes "1".
Standby	When the transition to Standby mode is completed, the STANDBY_MD bit becomes "1".

VDSP can perform “U39.4.10 Power shutdown”, “U39.4.11 Module Standby Mode”, or “U39.4.12 CPG Software Reset” only in the Standby Mode of the PSU mode.

To transition to the Standby Mode of the PSU mode, follow the steps below.

1) Execute psu {standby} instruction of the CEVA-SP500™ in the VDSP.
2) Confirm that the STANDBY_MD bit of the VDSP wrapper register PSU_STATE set to "1".

Note:

For details of each mode and transition method, refer to the following Power Scaling Unit and "4.6 Power Scaling Unit" of "SensPro™ Architecture Specification Volume III (MSS)"

The following sections describe the Power Scaling Unit (PSU). The PSU has the following modes:

- **Free Run**: Related to unit clock control. All clocks to all units are toggling.
- **Dynamic Power Save (DPS)**: Related to unit clock control. Each unit asserts active and gets a clock according to its active status (this is the reset value).
- **Light Sleep**: Related to unit clock control. No core units get clocks.
- **Standby**: Related to unit clock control. No core units or system units (for example, DMSS or PMSS) get clocks.

The modes are changed by writing to the **PSVM** register in the PSU, via the *psu* instruction.

The interrupt can be a wakeup trigger to the PSU for recovery from Light Sleep and Standby mode.

For details about the restrictions and limitations for switching between these modes, see the SensPro™ *Architecture Specification*.

U39.4.9 Bridge for APB / ATB / CTI (csdbgxm)

APB, ATB and Cross trigger interface go through a bridge called "csbgxm". See Chapter “170 Debug and Trace” for more information on this bridge.

U39.4.10 Power shutdown

1. Do not attempt access to the registers of the modules in a domain to which the supply of power has been shut down.
2. Before shutting down the power supply to a domain, ensure that no modules in the target domain are operating. Operation cannot be guaranteed if the power supply is shut down while any of the modules is operating.
3. Before Power shutdown in the VDSP, confirm VDSP is Standby mode as describe in “U39.4.8 VDSP stop method”.

For power shutdown, refer to chapter 11. SYSC, Shutting Down the Power Supply.

U39.4.11 Module Standby Mode

Table U39.14 Module Stop Control Comparison table

Register Name (9.2.3 Module Stop Control Register)	bit	Bit Name	Notes
MSTPCR28	30	vdsp1_csb	VDSP1, dsp_top block
	21	vdsp0_csb	VDSP0, dsp_top block
	2	vdsp1_bus	VDSP1, AXI router block
	1	vdsp0_bus	VDSP0, AXI router block

1. Do not attempt access to the registers of the modules in a domain that is in the module standby mode.
2. Before releasing a domain from the module standby mode, be sure to reset the target domain by a software reset from the clock pulse generator. Otherwise, reset the modules once they are released from the module standby mode.
3. Before placing a domain in the module standby mode, ensure that none of the modules in the target domain are operating. Operation cannot be guaranteed if a target domain is placed in the module standby mode while any of its modules is operating.

For module standby mode, refer to chapter 09.Module_standby_Software_reset , Module Standby Mode.

U39.4.12 CPG Software Reset

1. Do not attempt access to the registers of the modules in a domain to which a software reset is being applied by the clock pulse generator.
2. Before applying a software reset to a target domain by using the CPG, ensure that none of the modules in the domain are operating. A software reset applied to a target domain by the CPG is equivalent to a power-on reset. Accordingly, operation cannot be guaranteed if a domain is reset while any of its modules is operating.

For software reset of CPG, refer to chapter 09.Module_standby_Software_reset, Software Reset by the Clock Pulse Generator (CPG).

U39.4.13 AXI Usage

U39.4.13.1 Max Burst Length

D_ADD0_ATT1.DABSZ (CPM Address 0x928), D_ADDx_ATT1.DABSZ or MSS_DDCL (CPM Address 0x68c).BSZ should be set in such a manner that maximum burst length does not exceed the 8 transfers. P_SYS_OU_C (CPM Address 0x404).PDMA_BSZ should be set in such a manner that maximum burst size for PDMA transactions is B'10: 8 beats. Otherwise operation cannot be guaranteed. Refer "SensPro™ Architecture Specification Volume III (MSS)" for the details of D_ADD0_ATT1, D_ADDx_ATT1 and MSS_DDCL registers. Note that, when VDSP DMAC access SPMI/SPMC memory of IMP-Subsystem, only incremental transaction is allowed and possible transaction are 128-byte/256-byte and alignment shall be 32-byte. Refer U34.IMP-X7_System HWM for SPMI/SPMC address map. One transaction must always access within one BANK of SPMI/SPMC.

U39.4.13.2 Max Outstanding (OS)

When using DDMA, the efficiency of data transfer may vary depending on the setting of read and write outstanding numbers at D_ADD0_ATT1.DADOL/D_ADD0_ATT1.DAUOL or D_ADDx_ATT1.DADOL/D_ADDx_ATT1.DAUOL or MSS_DACC.DOL/MSS_DACC.UOL registers. The recommended outstanding setting for maximum data transfer efficiency is 16-outstanding for both read and write transactions. An outstanding setting greater than 16 cannot be used.

When using PDMA, the efficiency of data transfer may vary depending on the setting of outstanding numbers at P_SYS_OU_C.PDMA_OS (CPM Address 0x404) register. The recommended outstanding setting for maximum data transfer efficiency is 8-outstanding for PDMA.

U39.4.13.3 Prohibit Narrow Access with DDMA

D_ADD0_ATT1.EXACT_RD (CPM Address 0x928), D_ADDx_ATT1.EXACT_RD should be set to 0 to prevent Narrow access when using DDMA on the Ceva-SP500™. Refer "SensPro™ Architecture Specification Volume III (MSS)" for the details of D_ADD0_ATT1 and D_ADDx_ATT1 registers.

U39.4.13.4 Other AXI attribute settings

External AXI bus does not support the exclusive access, therefore do not use AXI Exclusive Access for read and write when using the program or the PDMA/DDMA. For the details, refer "SensPro™ Architecture Specification Volume III (MSS), 3.13.2 External Memory Exclusive Access Synchronization".

Also, the external AXI bus must be accessed by a transaction with AxCACHE = 0x0010, Therefore always set L2A_WR and L2A_RD = 4'b0010 in the D_ADD0_ATT1 or D_ADDx_ATT1 register. And always set P_L2A = 4'b0010 in the P_ADD0_ATT0 or P_ADDx_ATT0 register.

The CEVA-SP500™ has two privilege levels, "Supervisor mode" and "User mode," which determine the value of AxPROT at the AXI Master Port. However, external AXI buses handle these privilege levels as "user mode," regardless of User (unprivileged) access or Supervisor (privileged) access from CEVA-SP500™.

Note: The External AXI bus explained in this chapter are EDP, EPP and AXIM0 described in Figure U39.1.1.

U39.4.14 JTAG Usage

The JTAG interface of the VDSP is cascaded with up to 2 VDSPs. Before using the JTAG interface, the DBGEN input of the VDSP must be set to 1. Please refer to Chapter "170 Debug and Trace" for the setting method.

Also, it is necessary to set the JTAG_BYP_METH register (0xC003C) as shown in the table below, depending on the number of VDSPs implemented.

Table U39.15 Register settings for the JTAG interface

Number of VDSP	JTAG_BYP_METH register (0xC003C)	
	JTAG_METHOD bit	JTAG_BYPASS[2:0] bits
1	VDSP0: 1’b1	VDSP0: 3’b000
2	VDSP0: 1’b0 VDSP1: 1’b0	VDSP0: 3’b110 VDSP1: 3’b111

U39.4.15 ATB Usage

Set the ETMTRACEIDR register of the ETM-R4 built into the VDSP to a value between 0x01 and 0x6F. The ETM-R4 can be configured via the APB interface. For more information about APB, Refer to Chapter "170 Debug and Trace" for details.

U39.4.16 Interrupt Mapping

The mapping of the VDSP interrupt inputs is shown in the table below.

Table U39.16 Interrupt Mapping table

n = 0 - 1

Interrupt Number	CEVA-SP500™ Interrupt Name	VDSPn Interrupt input	Notes
0-8	Internal Interrupt		See "4.2.5 Internal Interrupt Map" of "SensPro™ Architecture Specification Volume III (MSS)" for details.
9-32	-		-
33	EXT_INT[1]	VDSP1 : dspp0_internal_int VDSP0 : dspp1_internal_int	See Table U39.12 Interrupt to other VDSP table. See OUT_INT_STATE_D register in chapter "Register Description" for interrupt factors.
34-35	-		
36	EXT_INT[4]	IMP core0	See “U34.10.4 Interrupt control” of "U34.IMP-X7_system" for details.
37	EXT_INT[5]	IMP core1	
38	-		
39	-		
40	EXT_INT[8]	CVe0

54-63	-		-

U39.4.17 DMA Queue manager (QMAN)

- Four queues are configurable per DSP
- Programmable queue location and size (either direct access to the IDM or access to the external memory) is supported.
- Separate descriptor push and activation stages are supported; tasks pushed to the queue are later enabled according to the system state.
- Descriptor activation is controlled by software activation.
- Task descriptors are pulled from queues.
- Tasks are split into programmable chunk sizes per queue.
- Priority of queues arbitrating for DDMA access is based either on preconfigured queue priority or on priority in the task descriptor.
- Queues with the same priority arbitrate according to the data packet order of execution.
- Queues with the same priority and same execution order arbitrate using a round-robin policy. Tasks are activated only if the source and destination are ready for a chunk/task transaction (using buffer management).
- Several tasks can be bundled into a task frame.

U39.4.18 Unsupported CEVA-SP500™ features

VDSP does not support the following CEVA-SP500™ features. Do not use these functions.

- Exclusive external memory access synchronization, which uses an AXI interface.
- Multi-core messaging interface (MCCI)
- IDM Snooping mechanism
- Queue manager (QMAN) with VDSP multiple cores

U39.5 Safety Mechanism

U39.5.1 Functional Safety

VDSP is equipped with the following Safety Mechanism.

- The Runtime test detects a failure in the Logic section.
- For Memory, 1-bit error correction and 2-bit error detection are performed.
- Anomaly is detected by the watchdog timer.

The block diagram of FUSA is shown below.

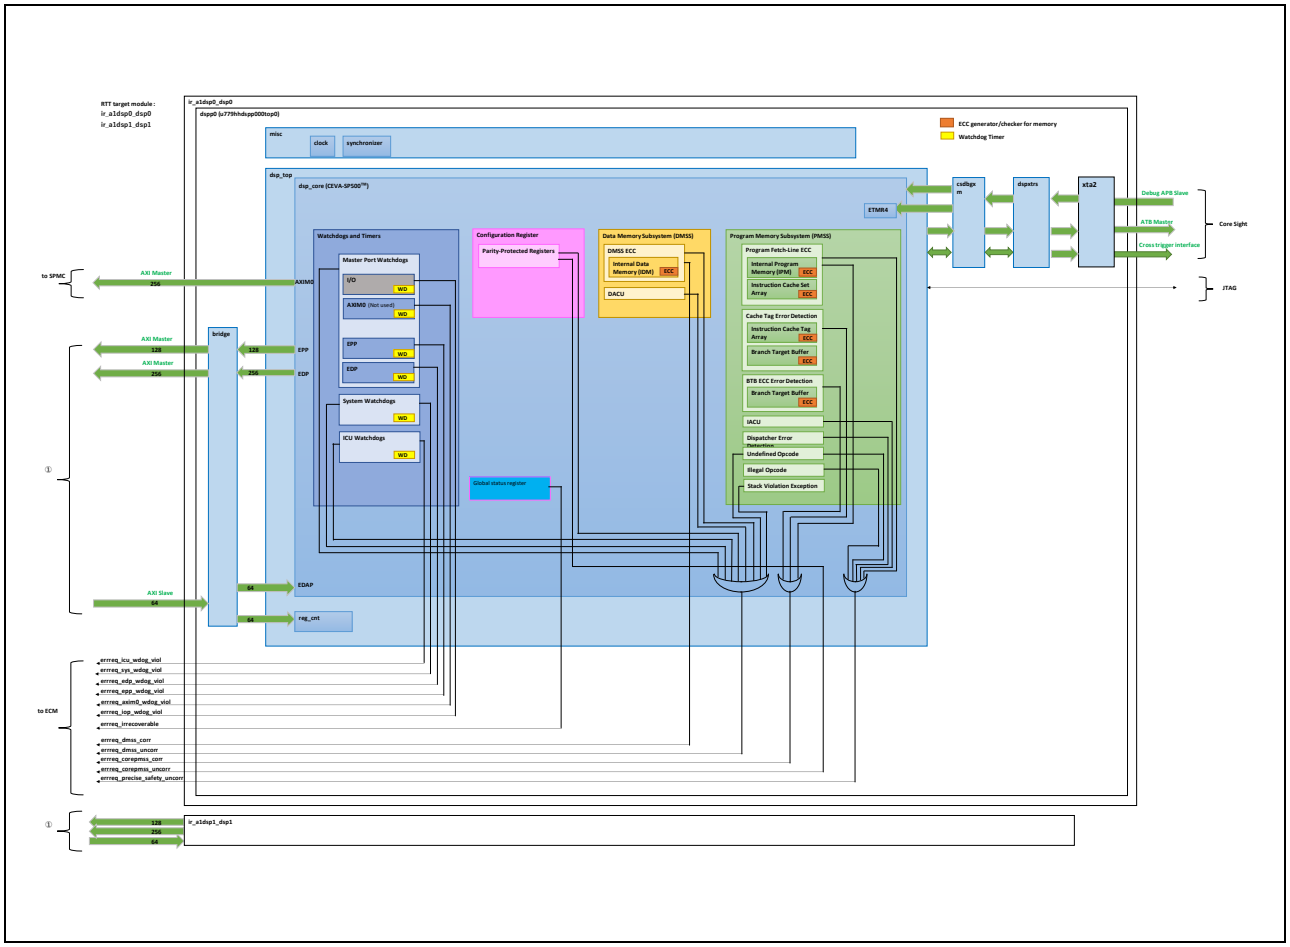

Figure U39.5.1 FUSA block diagram(1)

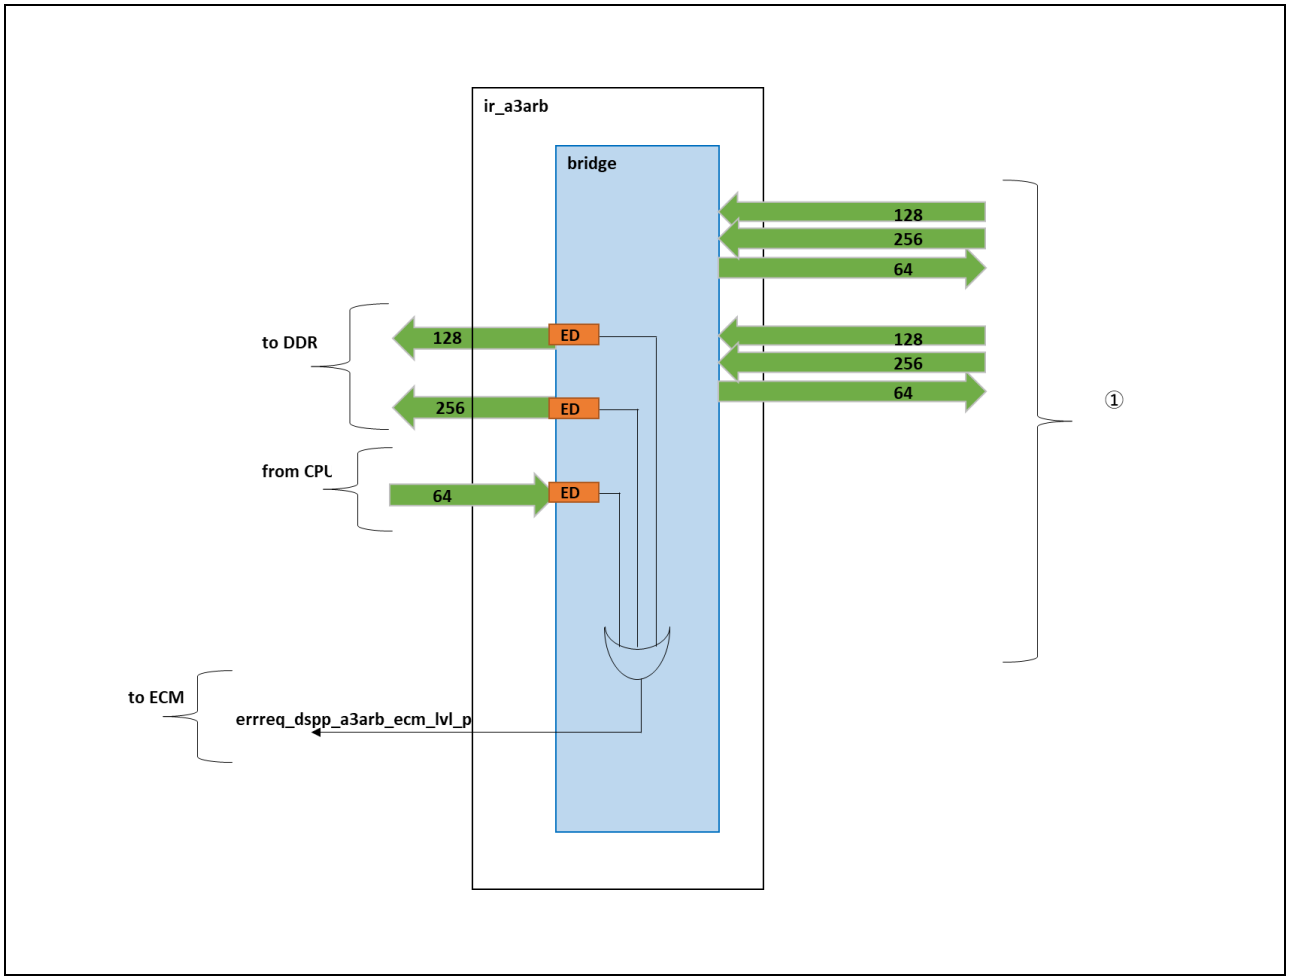

Figure U39.5.2 FUSA block diagram(2)

The following signal is output as an interrupt signal addressed to ECM.

Table U39.17 Table of ECM errors

Error name	Description	Comments
errreq_corepmss_uncorr	Core and PMSS uncorrectable safety error	For a detailed description of these interrupt signals, please refer to “SensPro™ Hardware Safety Manual”.
errreq_corepmss_corr	Core and PMSS correctable safety error	
errreq_dmss_uncorr	DMSS uncorrectable safety error	
errreq_dmss_corr	DMSS correctable safety error	
errreq_irrecoverable	Irrecoverable error in non-secure mode	
errreq_precise_safety_uncorr	Core uncorrectable precise error	
errreq_epp_wdog_viol	Indicates EPP Watchdog timeout	
errreq_edp_wdog_viol	Indicates EDP Watchdog timeout	
errreq_axim0_wdog_viol	Indicates AXIM0 Watchdog timeout	
errreq_sys_wd_int	Indicates System Watchdog min/max violation	
errreq_icu_wdog_viol	cevasp_icu_wdog_viol_r	
a3arb intreq_ecm	Bus EDC error on a3arb	errreq_dspp_a3arb_ecm_lvl_p

U39.5.2 Region ID

For the VDSP subsystem secure protection, set the region ID using the RGID(R,W)_AXIDSPx registers / RGIDM_DSPxx registers located in the IR domain AXI bus interfaces, and the SPMI/SPMC slave region ID control registers located in the SPMI/SPMC bus interface of the IMP-subsystem.

To set the region ID on the slave side where the VDSP interfaces with the bus IR domain AXI bus via AXI Slave 64-bit, set the bit corresponding to the allowed region ID in the RGID(R,W)_AXIDSPx register to "1". Also write 0xFFFF to the RGID(R,W)_DSPPS register.

To set the region ID on the master side where the VDSP interfaces with the bus IR domain AXI bus via AXI Master 128-bit or AXI Master 256-bit, set the region ID value in the RGIDM_DSPx0 or RGIDM_DSPx1 registers.

The SPMC slave region ID control register need to be set when VDSP accesses to the SPMI/SPMC memory.

The following figures show the Region ID implementation for VDSP subsystem.

Refer to the chapter “User's Manual 18.2 Register description" for the details of RGID(R,W)_AXIDSPx , RGID(R,W)_DSPPS , and RGIDM_DSPxx registers. Refer to the chapter “User's Manual 18.5.9 Region ID protection” about the Region ID protection.

Refer to the chapter "U34.10.2 Secure region for IMP-X7" for the details of the SPMI/SPMC slave region ID control registers.

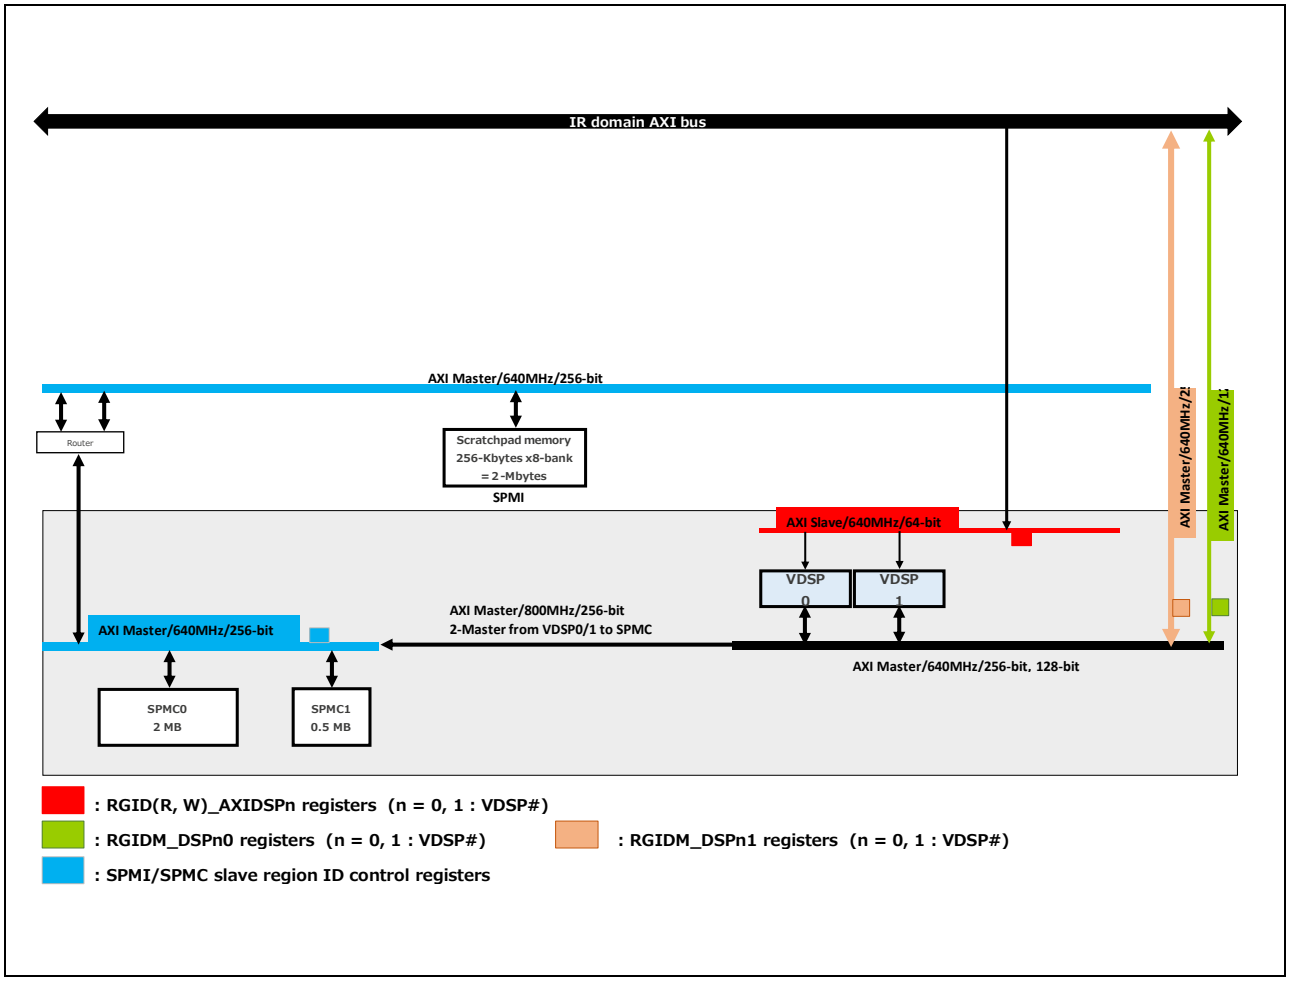

Figure U39.5.2 Region ID registers implementation for VDSP

U61. DDR PHY

U61.1 Overview

DDRPHY provides the functionality to interface DBSC5 (external bus controller) to a high-speed DRAM device - LPDDR5 / LPDDR4X. DDRPHY consists of 2channel block (DDRPHYn, n=0/1), and each channel has x16bitDQ.

U61.1.1 Functions and Features

(1) Basic Functions

- Alignment of DRAM commands to the DRAM clock
- Timing control for write data and write data clock/strobe placement
- Read data capture using DRAM generated data strobe and re-synchronization
- Support multiple leveling/training function
- Support DBI mode only
- Support IO calibration
- Support DRAM Backup Mode
- Support DFS (Dynamic Frequency Scaling) function

(2) LPDDR5 Configuration

- Compliant with JEDEC JESD209-5B
- Supported maximum bit width is 32bit – x32bit x 1pcs
- Supported rank is 1rank and 2rank
- Supported Data Rate 1600Mbps(min) - 6400Mbps(max)@1rank / 5500Mbps(max)@2rank
- Supported total memory size is up to 8GByte

(3) LPDDR4X Configuration

- Compliant with JEDEC JESD209-4C and JEDEC JESD209-4-1A
- Supported maximum bit width is 32bit – x32bit x 1pcs
- Supported rank is 1rank and 2rank
- Supported Data Rate is 1066Mbps(min) - 4266Mbps(max)@1rank / 4266Mbps(max)@2rank

  Supported total memory size is up to 8GByte

U61.1.4 Connected Module

Table U61-2. Connected Modules

Module Name	Connected Module Name	Connected Module Function
DDRPHY	DBSC5	External Bus Controller for SDRAM
	CPG	Output clocks
	Module Standby	Control to stop clocks
	Software Reset	Execute software reset

U61.1.5 Register Configuration

DDRPHY Parameters are assigned to bit and bit fields of DDRPHY Registers, and access to DDRPHY Registers is through access to DBSC5 Registers.
Table U61-3 shows the DBSC5 Registers which are used to access to DDRPHY Registers.

Table U61-3. DBSC Registers to access to DDRPHY Registers

Register Name	Abbreviation	Bit Name	R/W	Address	Initial value	Access Size
PHY Unit Register Address for DDRPHY0	dbpdrga0	pra0[15:0]	R/W	H'E679_0624	H'0000 0000	32
PHY Unit Register Access for DDRPHY0	dbpdrgd0	prd0[31:0]	R/W	H'E679_0628	H'0000 0000	32
PHY Unit Register Address for DDRPHY1	dbpdrga1	pra1[15:0]	R/W	H'E679_0664	H'0000 0000	32
PHY Unit Register Access for DDRPHY1	dbpdrgd1	prd1[31:0]	R/W	H'E679_0668	H'0000 0000	32

U61.2 Register Description

For detailed DDRPHY Register Description, refer to the following document.

- ***LPDDR5 : R-Car V4M Initialization Sequence of LPDDR5 interface***
- ***LPDDR4X : R-Car V4M Initialization Sequence of LPDDR4X interface***

U61.3 Operation

U61.3.1 Initialization and Training Sequence

(1) Main Flow of Initialization Sequence

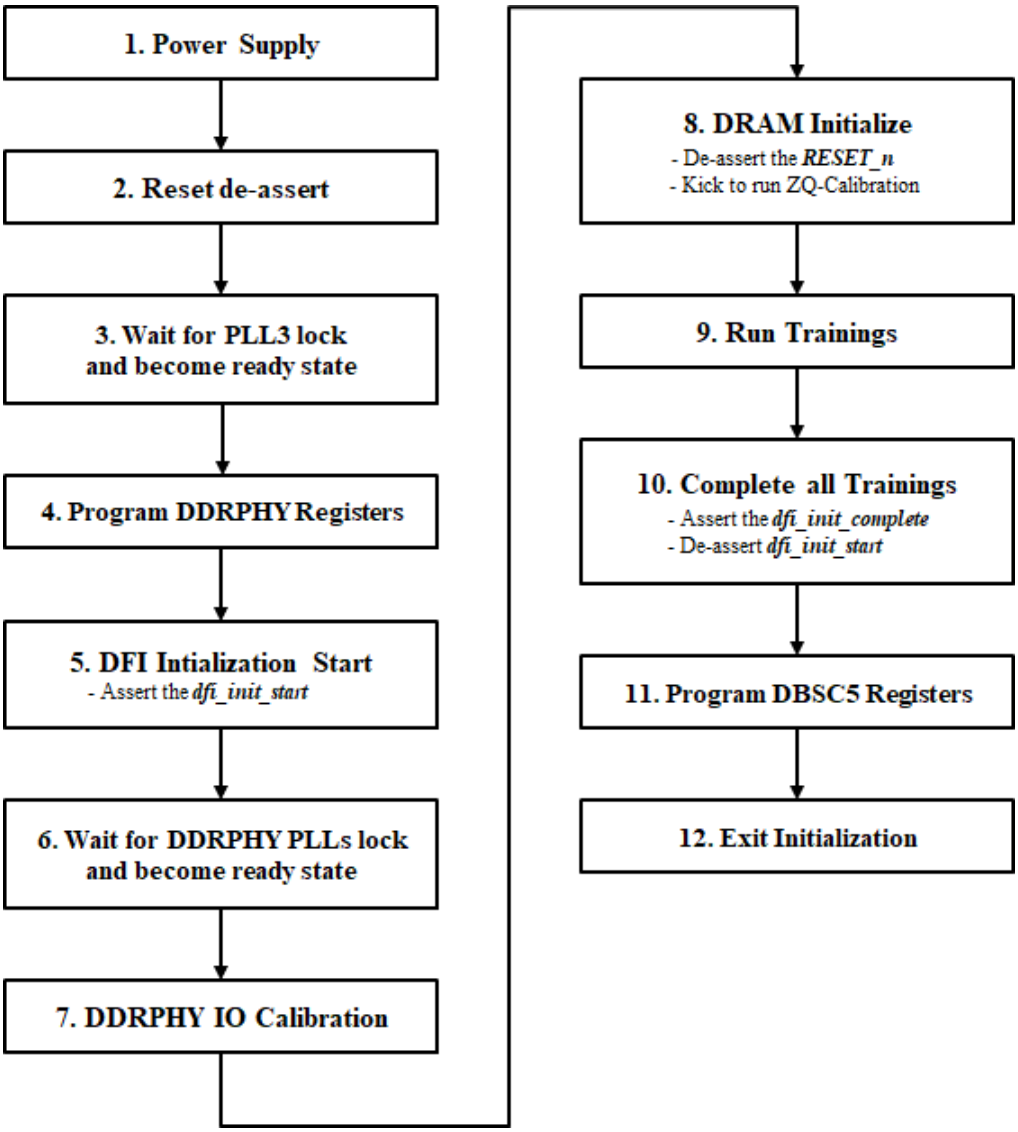

Figure U61-2. Main Flow of Initialization Sequence

(2) Training Sequence

Refer to the following Application Note.

- ***LPDDR5: R-Car V4M Initialization Sequence of LPDDR5 interface***
- ***LPDDR4X: R-Car V4M Initialization Sequence of LPDDR4X interface***

U61.3.2 DRAM Backup Mode

DRAM: Self-Refresh + DDRPHY: Power off (Power-On = VDDQX_DDRn/VDDQVA_DDRn (n=0,1) only)

DRAM devices have a function called Self Refresh, which automatically refreshes the memory contents without being controlled by other devices while there is no need to access DRAM. In this document, making DRAM enter the Self Refresh Mode is called the DRAM Backup function.
While DRAM is being backed up, DRAM cannot be accessed but the DRAM controller does not need to control DRAM refresh operations; the power supply to the controller can be turned off and the entire system can enter a low-power state. To shift DRAM to the Self Refresh mode, the DRAM controller should issue a self-refresh command to the target DRAM. Driving the CKE signal high or driving the RESET# signal low makes DRAM exit the Self Refresh Mode and cancels the DRAM Backup Mode.

For detailed DRAM Backup Mode function, refer to the following document.

- ***33.4.1 (3) SDRAM Power-supply Backup Mode***
- ***33.4.1 (4) Recovery from SDRAM Power-supply Backup Mode***

U61.3.3 Clock Supply Path for DDRPHY

Figure U61-3 shows clock supply path to the external DRAM and the DFI-IF clock between DBSC5 and DDRPHY.

The clock to external DRAM is generated by PLL3 – ZB3φ. ZB3φ is multiplied by PLL in DDRPHY. PLL3 can be set in both 'Integer multiplication mode' and 'Fractional multiplication mode'.
For detailed PLL3 setting Description, refer to the following section.

- ***8.1.5.3 PLL3 Multiplication Ratio***

The clock for the DFI-IF is ZB3D2φ. It's generated by dividing ZB3φ. The divider ratio is set by DFICKM in the DBSC5 register domain.
- DFICKM (DBSYSCONF2A[9])
  0 : LPDDR4X - ZB3D2φ = ZB3φ x 1/2
  1 : LPDDR5 - ZB3D2φ = ZB3φ x 1
Note) Clock Monitor setting for ZB3D2φ need to be set according to DFICKM.

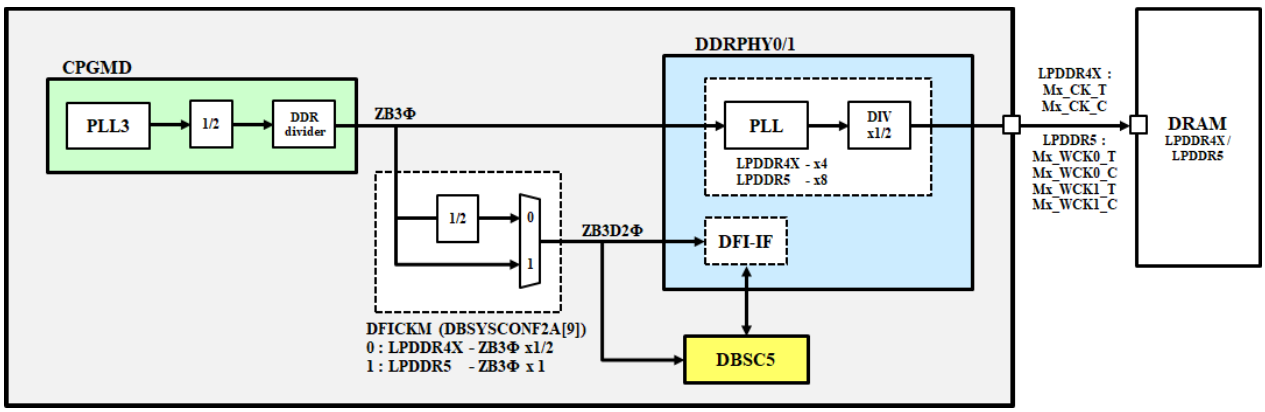

Figure U61-3 Clock supply path to external DRAM

U61.3.4 DFS

(1) DFS Function Overview

DDRPHY supports DFS (Dynamic Frequency Scaling) function for Low Power mode. DRAM clock frequency changes between high-speed operation on Full-Run mode and medium speed operation on Low-Power mode automatically according to the system condition to optimize the power.

- DFS operation is realized by executing the sequence shown in 'Figure U61-5' by System-SW.
- In the case of using DFS function, initialization training is performed both at high speed and at medium speed. Both registers and training parameters are stored in DDRPHY and these parameters can be changed automatically according to the frequency mode during DFS operation.
- When the frequency is changed by DFS operation, it is necessary to enter the DRAM into Self-Refresh with Power-Down mode because the clock supply to the DRAM is temporarily stopped.
- It is necessary to execute some pre-processing before DFS operation.
  i.e) Disable DRAM access, Disable Periodic-training

(2) DFS Frequency Specification

Table U61-4 shows the frequency combinations that can be set in the DFS function. Frequency changing is realized by setting the DDR divider after the PLL3 on the CPGMD.

Table U61-4. DFS Frequency

DRAM	Frequency Mode	Mode			
		Full-Run Mode		Low-Power Mode	
		DDR divider N	High Speed	DDR divider N	Medium Speed
LPDDR5	6400Mbps	2	6400Mbps	8	1600Mbps
	6000Mbps	2	6000Mbps	6	2000Mbps
	5500Mbps	2	5500Mbps	6	1833Mbps
	4800Mbps	2	4800Mbps	6	1600Mbps
LPDDR4X	4266Mbps	2	4266Mbps	6	1422Mbps
	3200Mbps	2	3200Mbps	4	1600Mbps
	3733Mbps	2	3733Mbps	6	1244Mbps

Note) LPDDR4X - 2133Mbps mode can't be used on DFS function.

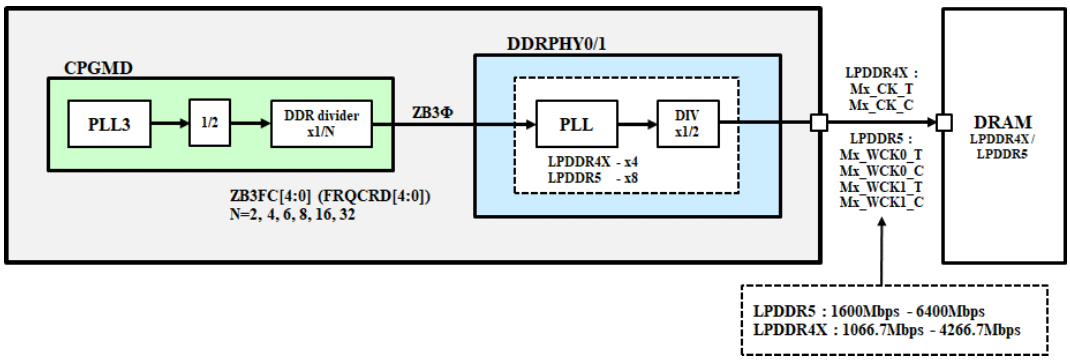

Figure U61-4 DFS Frequency Generation

(3) DFS Sequence

Figure U61-5 shows the DFS sequence.

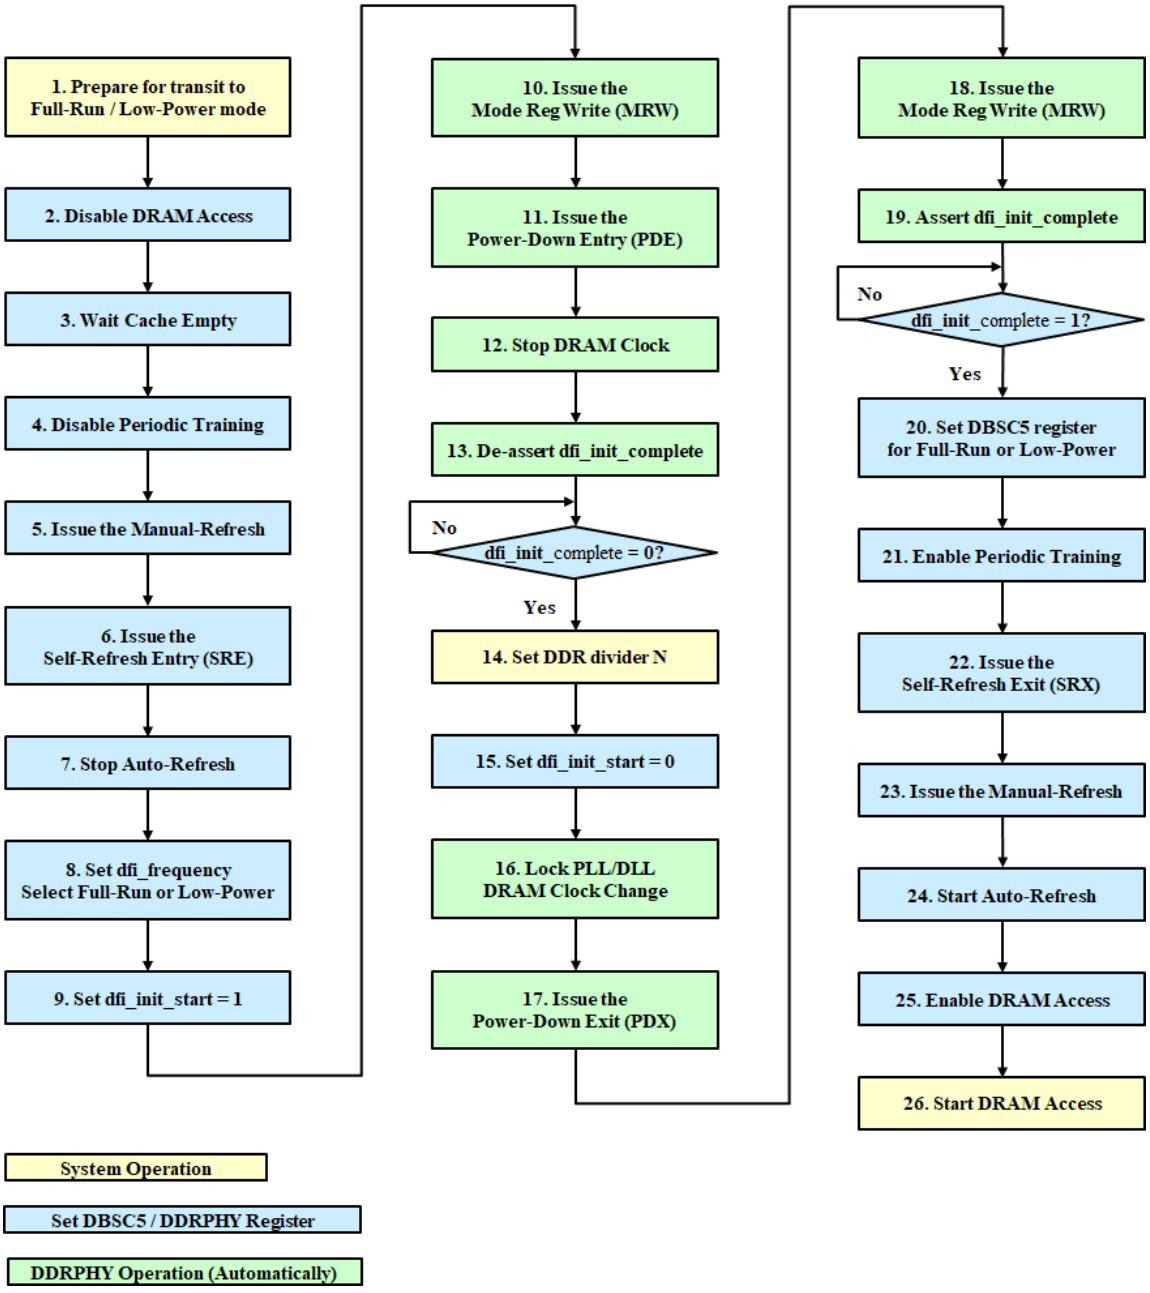

Figure U61-5 DFS Sequence

U61.4 Usage Notes

U61.4.1 Connection of DRAM

(1) Connection of LPDDR5

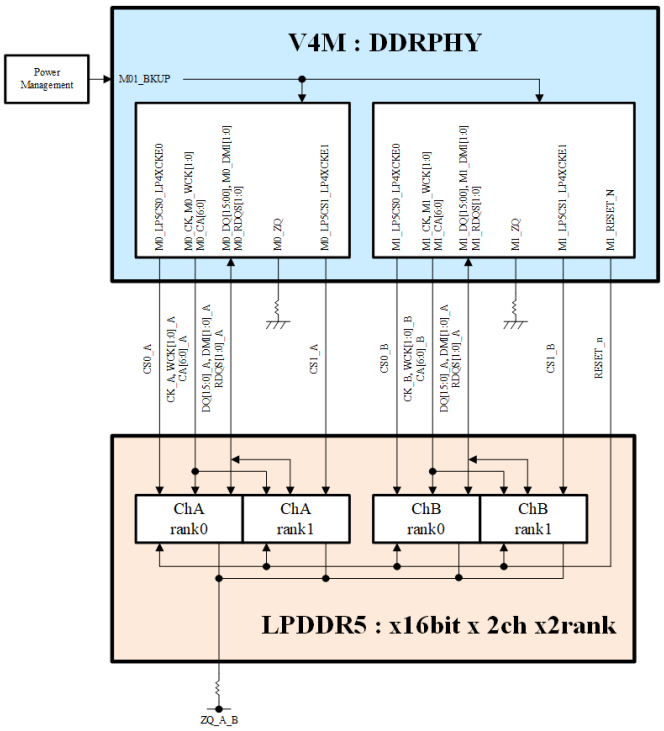

Figure U61-6 LPDDR5 connection Example: x32bit x2rank x1pcs

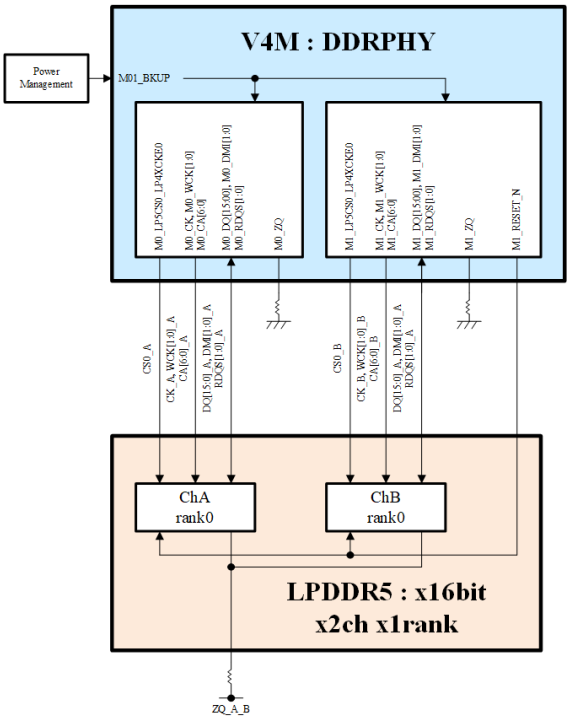

Figure U61-7 LPDDR5 connection Example: x32bit x 1rank x1pcs

(2) Connection of LPDDR4X

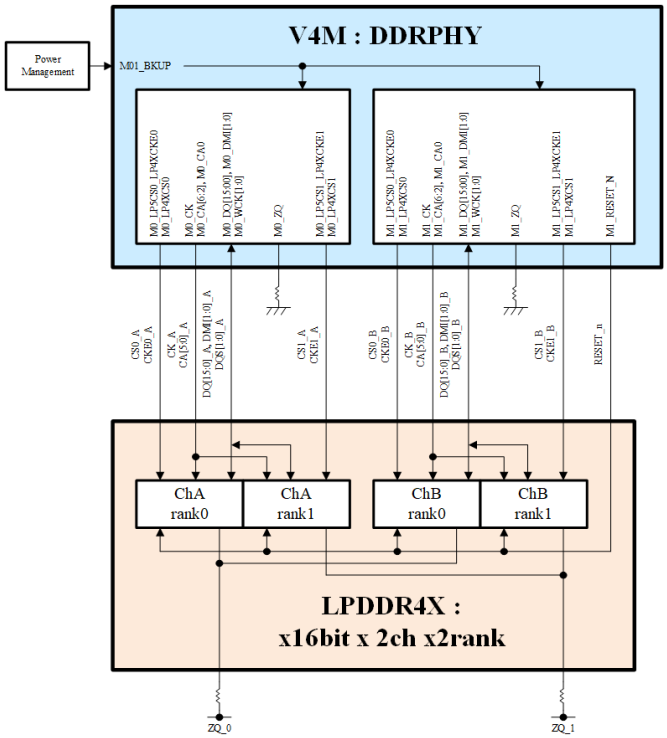

Figure U61-8 LPDDR4X connection Example: x32bit x2rank x1pcs

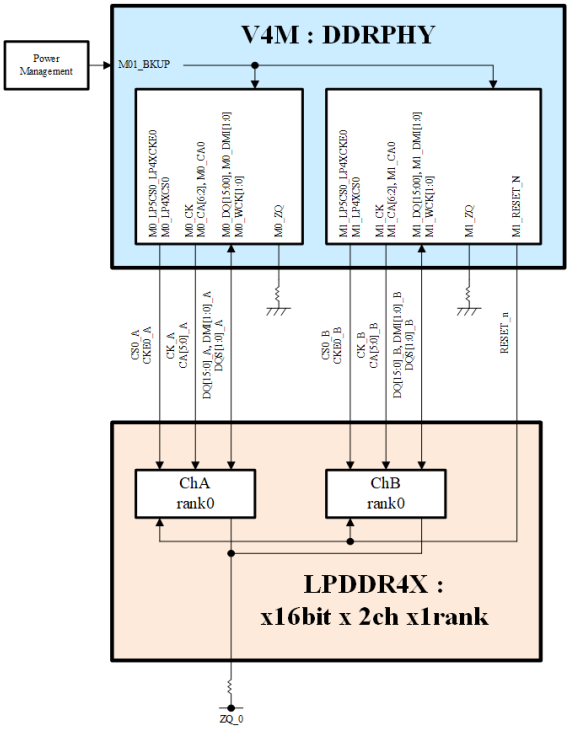

Figure U61-9 LPDDR4X connection Example: x32bit x1rank x1pcs

U61.4.2 Mode Setting

(1) DRAM Mode

DRAM Mode is set by MD pin – MD22/MD27.

Table U61-5. DRAM Mode Setting

MD27	MD22	DRAM Mode
0	0	LPDDR5
0	1	LPDDR4X
1	0	Reserved
1	1	Reserved

(2) DRAM Frequency Mode

DRAM Frequency Mode is set by MD pin – MD17/MD19. PLL. PLL3 and clock dividers for DDRPHY clock are set by CPG module according to EXTAL frequency and below table.

Table U61-6. DRAM Frequency Mode Setting

MD19	MD17	LPDDR5	LPDDR4X
0	0	6400Mbps	4266Mbps
0	1	6000Mbps	3733Mbps
1	0	5500Mbps	3200Mbps
1	1	4800Mbps	2133Mbps

U61.4.3 Module Stop and Software Reset

Module Standby (MSTP) and Software Reset (SRST) are supplied to pair of DDRPHY0/DDRPHY1 by Reset module. SRST initializes DDRPHY module by setting the software reset register bit. MSTP stops clock supply to DDRPHY by setting module stop register bit.

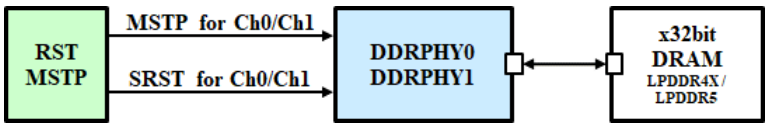

Figure U61-10 Module Stop and Software Reset supply to DDRPHY

U61.4.4 Signal Swapping Function

The following rules apply to swapping data signaling between DDRPHY and DRAM connection.

- DQ Byte group can be swapped within Ch. All signals related to a Byte group are re-mapped when DQ Byte swapping is enabled. DQ Byte group is consisted of 8xDQ/1xDMI/1xWCK/1xRDQS.
- DQ bits and DMI can be swapped within DQ Byte group.
- CA signals can be swapped within Ch.

- CS signals can be swapped within Ch.
- CKE signals can be swapped within Ch.

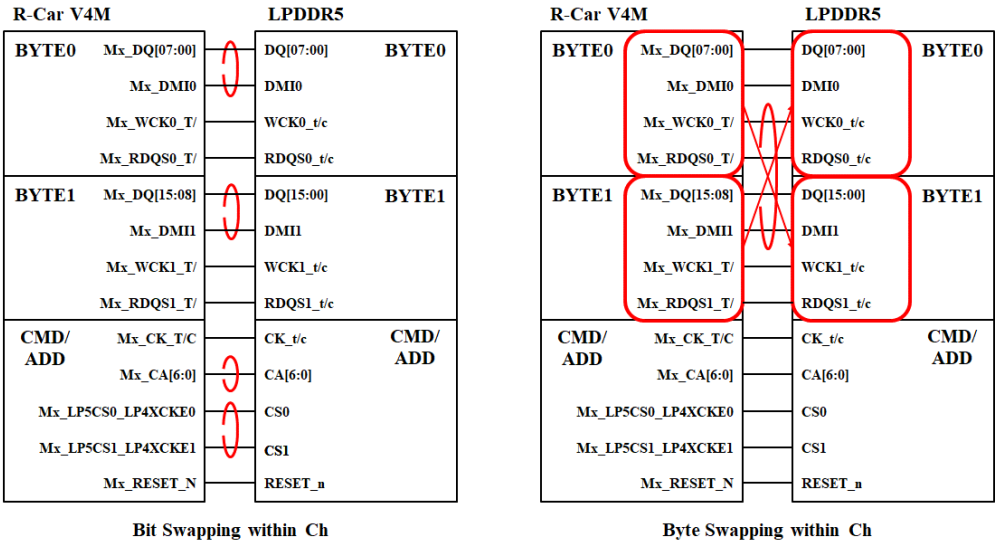

Figure U61-11 LPDDR5 Swapping Function

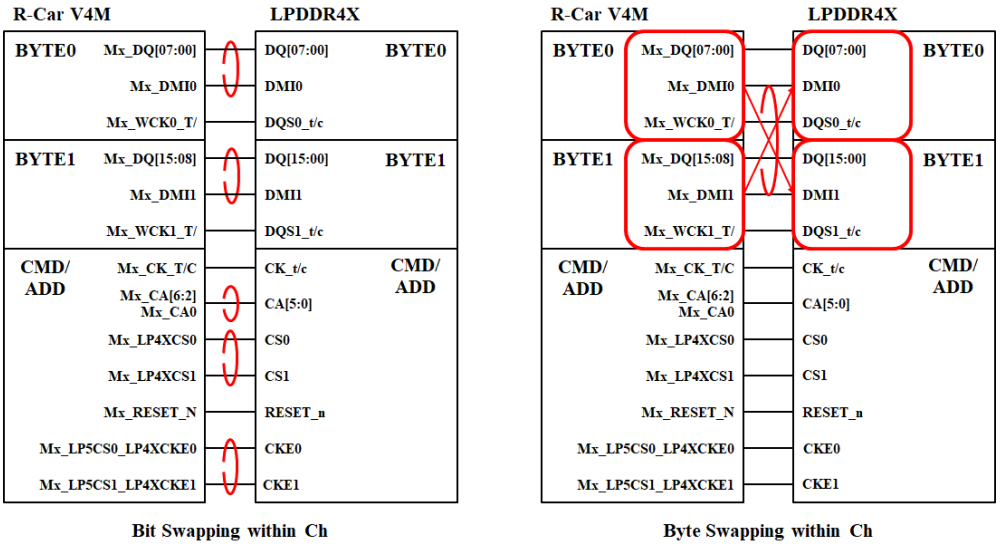

Note) : Mx_CA1 can't be used for LPDDR4X. Please use Mx_CA6 instead of Mx_CA1.

Figure U61-12 LPDDR4X Swapping Function

U61.4.5 DBI Mode

DBI (Data Bus Inversion) is supported in DDRPHY. DDRPHY requires DBSC5 to perform DBI generation and decode, DDRPHY only passes the DBI information between DBSC5 and DRAM devices. DBI mode should be enable from the point of view of supply noise reduction.

U61.5 Safety Mechanisms

DDRPHY has no safety mechanisms. DRAM access errors are protected by ECC protection function which DBSC5 performs.

For detailed ECC protection function, refer to the following section.

- ***33.5 Safety Mechanism***
