In the transition from operation mode to configuration mode, the AVB-DMAC executes the following operations before the transition is completed. Read the operating mode status bits in the AVB-DMAC status register (CSR.OPS) to check that the transition to configuration mode has been completed.

- If the transfer of a frame between the reception FIFO and URAM is in progress, this is completed (other received frames remaining in the FIFO and any frames that are subsequently received by the E-MAC are discarded).
- If the transfer of a frame is in progress between the transmission FIFO and URAM, this is completed (frames for transmission remaining in the URAM will not be transmitted).
- All frames for transmission in the transmission FIFO are transferred to the E-MAC.

The CPU should not disable URAM transfers by CCC.DTSR nor prevent transmission by MAC when requesting transition from OPERATION to CONFIG, else EthernetAVB-IF cannot perform requested mode change.

Notes: When the operating mode shifts to configuration mode, all status registers are cleared.
When need status register information, the reception and transmission path can be individually disabled and can check the status before leaving operating mode with follow.
We recommend following the procedure below in the case of this transition.

1. Disable reception.
2. Since reception actually stopping after being disabled requires time, wait for an interval equivalent to that for reception of a maximum length packet.
3. Stop the software task that is generating data for transmission.
4. Wait until the receive process status bit (CSR.RPO) and the transmit process status bits (CSR.TPO0 to 3) in the AVB-DMAC status register are set to 0.

5. Capture all of the required status information.
6. Set the operating mode configuration bits in the AVB-DMAC mode register (CCC.OPC) to initiate the transition to configuration mode.

### (3) Leave RESET mode with additional configuration

When writing 01b (CONFIG) to **CCC.OPC** while EthernetAVB-IF is in RESET mode, it is possible to configure availability of gPTP support within CONFIG mode

To enable gPTP support in CONFIG mode use a 32 bit write access when setting **CCC.OPC** to 01b. This write should also set **CCC.GAC** to 1b and **CCC.CSEL** to intended configuration.

### (4) Operating Mode Transitions Due to Hardware

The following hardware factors can also initiate transitions of the AVB-DMAC operating mode.

#### (a) Hardware reset

Resetting of the LSI chip leads to resetting of the entire EthernetAVB-IF module. The operating mode shifts to reset mode.

#### (b) Transition during power-off by module standby

This transition is triggered by module standby of CPG during the power-off sequence.

The AVB-DMAC completes the bus master access in progress, and then shifts to reset mode. At this time, the operating mode configuration bits in the AVB-DMAC mode register (CCC.OPC) are set to B'00.

### 100.1.3.2 Common Control for Transmission and Reception

#### (1) Initialization Procedure

Figure 100.1.3.2.1 shows the overall initialization procedure in outline.

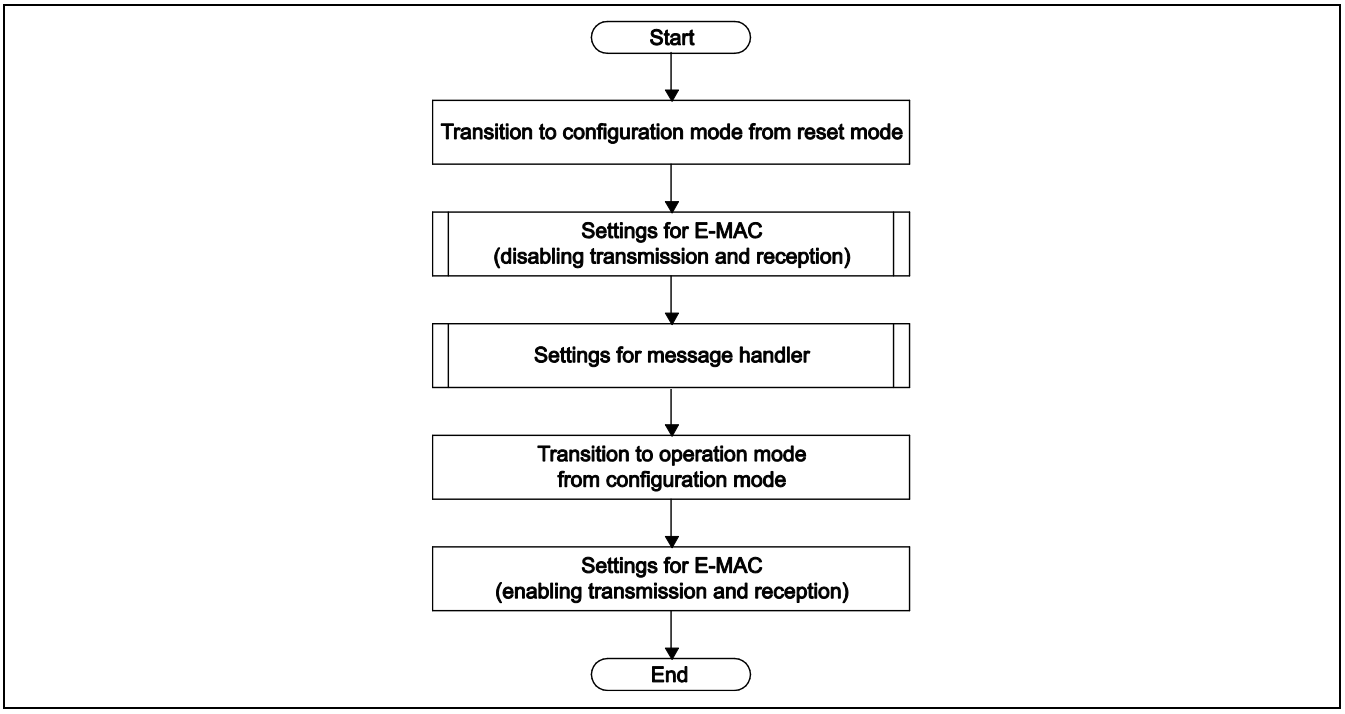

**Figure 100.1.3.2.1 Outline of the Initialization Procedure**

**(a) Initializing the Receiver Section**

Before starting reception, follow the procedure below.

Keep the operating mode to configuration mode, and do not enable reception until the settings for the AVB-DMAC are completed. However, there is a limitation that if it can be determined that no data is received, it is no problem to change the setting.

- Set the operating mode to configuration mode.
- Set AVB filtering for network control frames and AVB stream frames to suit the specifications of the product the chip will be used in.
- Create a descriptor chain for each queue to be used.
- Set the base address for table address in the descriptor base address table register (DBAT).
- Specify the maximum frame length with the receive frame length upper limit register (RFLR).
- Specify whether padding is to be used with the receive padding configuration register (RPC).
- Set the unread frame counter for each queue with unread frame counter registers (UFCVs) 0 to 4.

**(b) Initializing the Transmitter Section**

Figure 100.1.3.2.2 illustrates initialization of the transmitter section.

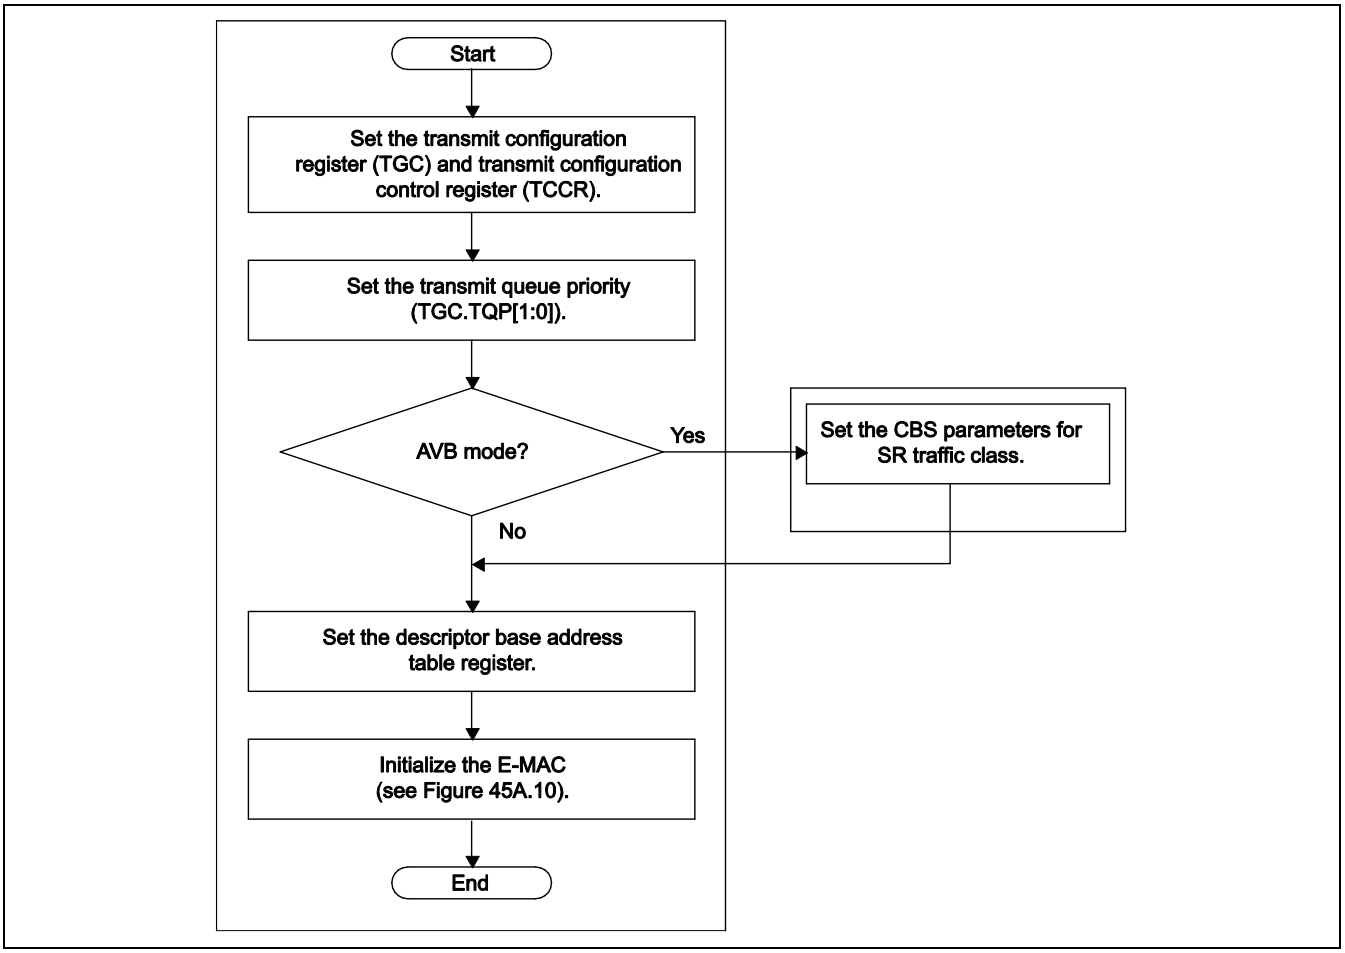

**Figure 100.1.3.2.2 Procedure for Initializing the Transmitter Section**

**(c) Initializing the E-MAC Section**

Figure 100.1.3.2.3 illustrates initialization of the E-MAC section.

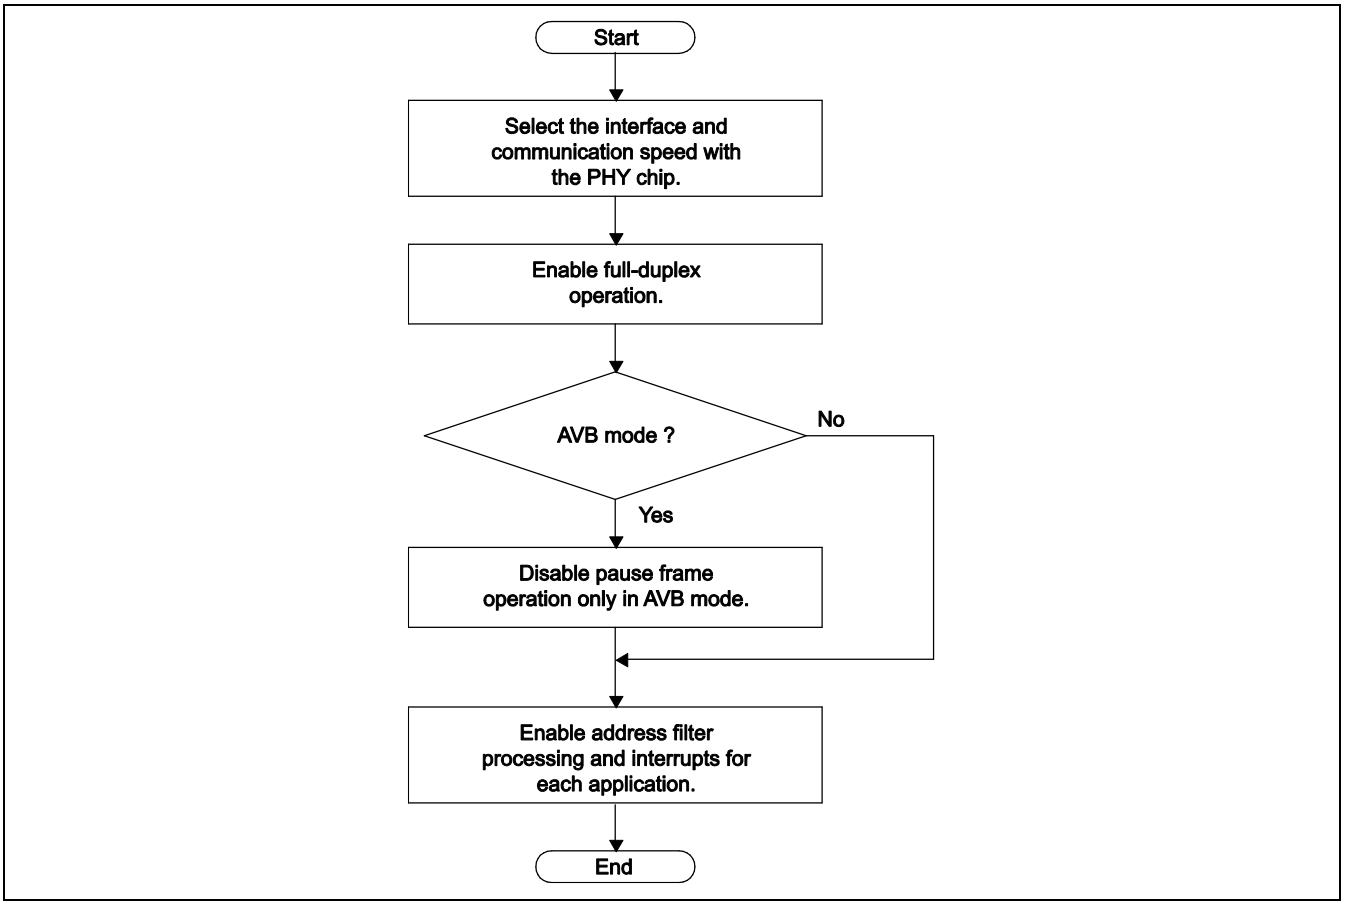

**Figure 100.1.3.2.3 Procedure for Initializing the E-MAC Section**

**(d) Initialization of the Application Unit**

Figure 100.1.3.2.4 illustrates initialization of the application unit.

For a description of how to set up the descriptors and the CBS traffic shaping parameters, see section 100.1.3.3 Descriptors, and section 100.1.3.6 CBS (Credit-Based Shaping).

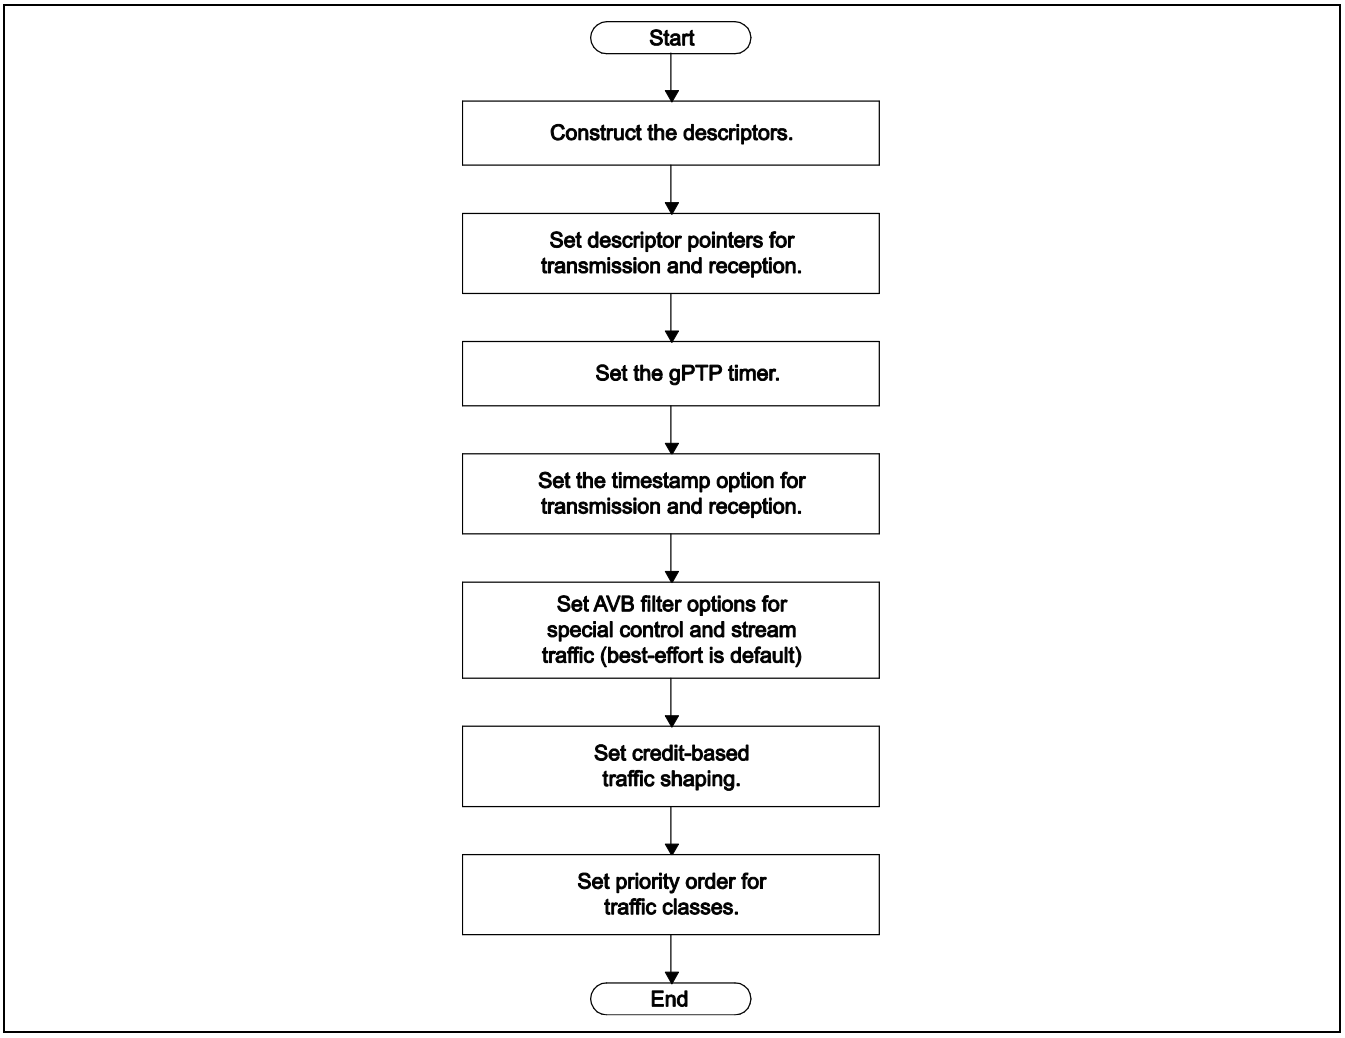

**Figure 100.1.3.2.4 Initializing the Sections for Use by the Application**

**(e) Relationship between Transmission Queue Numbers and Traffic Classes**

In fetching, the relationships between the transmission queues and traffic classes are fixed, so the priority specified by the transmit queue priority bits in the transmit configuration register (TGC.TQP) has no effect.

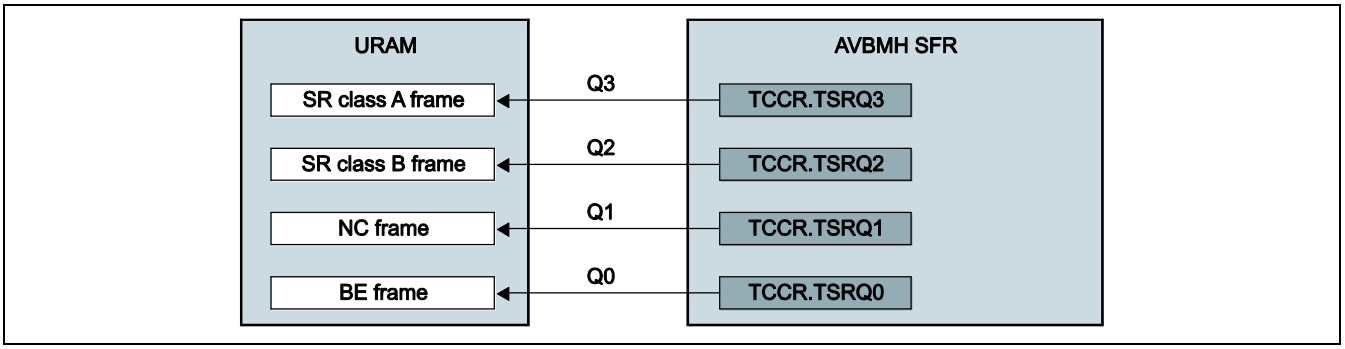

**Figure 100.1.3.2.5 Class Associations of Queues for the Scheduler**

In fetching, the credit values for stream classes A and B are not taken into account. Behavior depends on the setting of the transfer FIFO size configuration bits in the transfer configuration registers (TGC.TBDt) and on the frame size that can be fetched to the transmission FIFO.

When the transmit queue priority bit and enable credit based shaping bit in the transmit configuration register {TGC.TQP, TGC.ECBS} are B'00 or B'01, the priority order is Q3 → Q 2 → Q1 → Q0.

When the transmit queue priority bit and enable credit based shaping bit in the transmit configuration register {TGC.TQP, TGC.ECBS} are B'11, the priority order is Q1 → Q3 → Q2 → Q0.

### (2) Checking Integrity

The AVB-DMAC is capable of detecting and identifying errors produced in the processing of Ethernet frames and in the transfer of frame data for transmission and reception.

#### (a) Concept of Integrity Checking in Reception

The aim of integrity checking in reception is preventing the storage of error frames in the URAM. If an error frame is stored in the URAM, software can get information to identify the frame as an error frame.

Note: If a special descriptor chain is to be used for separation of received headers from the associated data, an error that breaks the sequence may lead to storage space for synchronization running out. In such cases, software interaction or re-synchronization via the EOS descriptor is required.

#### (b) Concept of Integrity Checking in Transmission

The purpose of integrity checking in transmission is to prevent the transmission of broken frames.

Since transmission of a frame by the E-MAC can neither be stopped nor disabled once it has started, this check involves intensive monitoring for problems that can arise during fetching.

#### (c) Items for Monitoring in Both Reception and Transmission

**Errors in access to the URAM for reading of descriptors**

The same descriptor may be processed again because the current descriptor address (CDARq.CDA) was not changed. If this problem occurs in a divided frame, the sequence may be broken.

**In reception**

- The received frame will be lost.
- The same problem will occur for the next frame of data received for the same queue.

**In transmission**

- The transmit start request bit in the transmit configuration control register (TCCR.TSRQt) is set to 0.
- The frame will be lost from the transmission FIFO.

Errors in access to read descriptors from the URAM are detected from the response signal of the AXI-Bus. EthernetAVB-IF flags only one access error per descriptor read.

**Illegal configuration of a descriptor by an application**

The same descriptor may be processed again because the current descriptor address (CDARq.CDA) was not changed. If this problem occurs in a divided frame, the sequence may be broken.

**In reception**

- The received frame will be lost.
- The same problem will occur for the next frame of data received for the same queue.

**In transmission**

- The transmit start request bit in the transmit configuration control register (TCCR.TSRQt) is set to 0.
- The frame will be lost from the transmission FIFO.

**Errors in access to the URAM for writing of descriptors**

As in the case where no error occurs, the current descriptor address (CDARq.CDA) and the transmit start request bit in the transmit configuration control register (TCCR.TSRQt) are updated.

As DESCR.DT was not updated, hardware and software synchronization may have been destroyed.

Errors in access to write descriptors to the URAM are detected from the response signal of the AXI-Bus.

**(d) Items for Monitoring in Reception**

**Errors in access to the URAM for writing of data or time stamps**

- As in the case where no error occurs, the current descriptor address (CDARq.CDA) is updated.
- DESCR.EI is set to indicate incorrect contents.
- This problem occurring in a divided frame may break the descriptor sequence, making the queue unusable.

Errors in access to write data or descriptors to the URAM are detected from the response signal of the AXI-Bus.

EthernetAVB-IF flags each access error individually, even they are related to same frame.

**Error of the Reception FIFO**

- Received frames are all invalidated.
- All frames stored as received frames are discarded. At this time, the number of frames and queue information cannot be captured.

If the reception FIFO RAM faults, AVB-DMAC detects the fault as error of the reception FIFO.

**Queue Synchronisation Fault of the Reception**

EthernetAVB-IF will not continue splitting frame across EOS descriptor. A queue synchronisation fault is detected when read descriptor with DESCR.DT = EOS at position where FMID, or FEND should be written

- RIS2.QFFr is set 1b
- CDARq.CDA is updated as in fault free operation.
- Neither CIARr.CIA nor LIARr.LIA is changed.
- Neither UFCVi.CVr nor RIS0.FRFr is changed.
- Received frame is lost. There is an incomplete frame (no FEND) in descriptor chain.

Note: Reading descriptor may be one or more storage elements ahead in descriptor chain.

**(e) Items for Monitoring in Transmission**

**Errors in Access for Reading Data from the URAM**

- Data that have already been fetched are discarded from the transmission FIFO.
- When an error of this type occurs during processing of an FSINGLE or FEND descriptor:
  As in the case where no error occurs, the current descriptor address (CDARq.CDA) and the transmit start bit in the transmit configuration control register (TCCR.TSRQt) are updated. Fetching resumes after the error frame.
- When an error of this type occurs during processing of an FSTART or FMID descriptor:
  The current descriptor address (CDARq.CDA) is not updated.
  The transmit start bit in the transmit configuration control register (TCCR.TSRQt) is set to 0.

Errors in access to read data from the URAM are detected from the response signal of the AXI-Bus.

**Overflow of the Transmission FIFO**

- As in the case where no error occurs, the current descriptor address (CDARq.CDA) and the transmit start bit in the transmit configuration control register (TCCR.TSRQt) are updated. Fetching resumes after the error frame.
- The frame will be discarded from the FIFO.

**Frame size error during transmission**

— As in the case where no error occurs, the current descriptor address (CDARq.CDA) and the transmit start bit in the transmit configuration control register (TCCR.TSRQt) are updated. Fetching resumes after the error frame.

A transmit frame size error is detected when the size setting in one or more (in the case of a divided frame) descriptors for frame transmission is 1966 or more bytes. Such frames are cut out and transmitted.

**Damaged Data in the Transmission FIFO**

— Fetching is not affected by damaged data.
— Since damaged data from the FIFO is only detected during frame transmission, an error frame may be transmitted.

If damaged data in the transmission FIFO is an error due to the transmission FIFO, this is detected by the AVB-DMAC.

**(f) Items for Monitoring in gPTP**

**Access error while reading AVTP timestamps from Tx-Buffer RAM**

— AVTP timestamps are invalidated.
— gPTP unit ignores the issue. It uses the value as read for AVTP comparison.

An access error when reading timestamps from Tx-Buffer RAM is flagged to EthernetAVB-IF by external RAM protection logic.

### 100.1.3.3 Descriptors

#### (1) Data Representation in URAM

The AVB-DMAC transfers data for transmission and received data to and from the application software via the URAM.

The memory in the URAM for use by the AVB-DMAC is configured with control structures referred to as descriptors and associated areas to which the frame data are allocated. Dividing the memory into a control area and data area allows the flexible allocation of frame data to the URAM. This enables sharing of the areas to which frame data are allocated and the use of non-contiguous areas. Frame data can be copied without using the CPU. Arbitration that ensures hardware and software access to the memory area is also available without access to registers of the AVB-DMAC.

Figure 100.1.3.3.1 shows an example of the memory maps for descriptors and the descriptor data area in the URAM.

A descriptor consists of its type (DESCR.DT), which controls the descriptor functions, a descriptor pointer (DESCR.DPTR) indicating the start address for storage of the frame data in the descriptor area, and the data size field (DESCR.DS), indicating the amount of frame data. Post-processing interrupt generation can be set up for each descriptor. Enabling and disabling of the interrupt is controlled by the descriptor interrupt enable bits (DESCR.DIE).

The descriptor may also hold information related to content. This information does not affect general descriptor functions. It provides information other than the frame data proper, such as on the state of reception.

For details, see section 100.1.3.4(2) Setting Up Reception Descriptors, and section 100.1.3.5(2) Setting Up Transmission Descriptors.

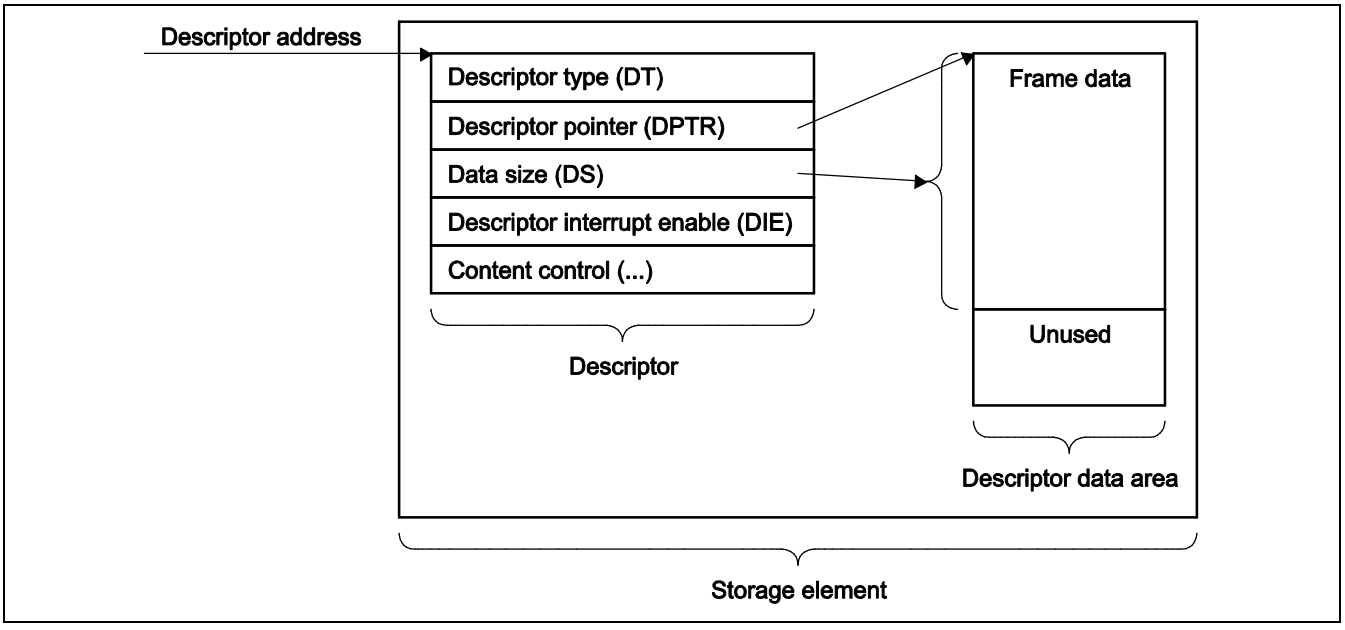

**Figure 100.1.3.3.1 Outline of Storage Element Used for Receive and Transmit Queues**

The descriptor must be aligned with a 8-bit boundary in the URAM.

Descriptors are generally configured of 64 bits, but are configured of 160 bits when reception and storage of gPTP time stamps is enabled.

The amount of data in the frame is defined by the data size bits (DESCR.DS). In reception, these bits indicate the upper limit on the size of frames to be received. If the data size is not aligned with a 32-bit boundary, the bytes to the next 32-bit boundary in the data area will be an unused area.

### (2) Using Descriptor Chains in Queues

Transmission and reception descriptors in the URAM are grouped into queues. Each queue handles frames so that they are transmitted in order of priority and received separately. A queue is capable of controlling one or more frames. Accordingly, multiple descriptors can be assigned to one queue. A combination of multiple descriptors is referred to as a descriptor chain.

For a descriptor chain, the three general descriptor types listed below are defined. For details on these descriptor types, see section 100.1.3.3(6) Descriptor Type.

- Descriptors that define frame data
- Descriptors that control the descriptor chain itself (e.g. LINK, EOS).
- Descriptors that arbitrate access by hardware or software

Figure 100.1.3.3.2 shows the two basic topologies for descriptor chains. In the simplified examples in the figure, all descriptors allocated to the chain are stored in the array.

- For a linear descriptor chain, the last descriptor in the array is a control descriptor indicating the end of the descriptors (e.g. EEMPTY).
- For a cyclic descriptor chain, the last descriptor in the array is a control descriptor that returns to the first descriptor in the array (e.g. LINK).

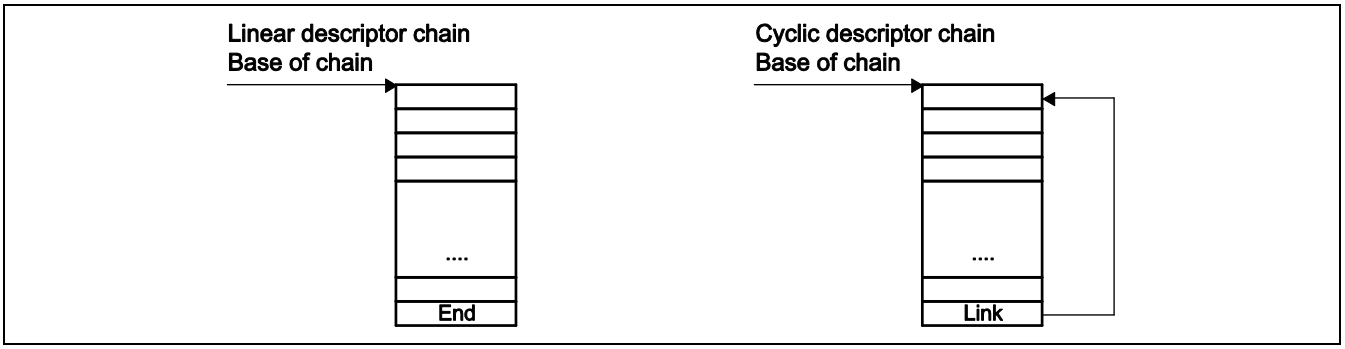

**Figure 100.1.3.3.2 Outline of the Basic Descriptor Chains**

The relationship between queues and descriptor chains is defined by the base addresses of chains. A queue is connected to one descriptor chain over one round of processing. There is also a method of switching to a different chain while in operation mode.

There are no restrictions on the number of link descriptors and their locations within the chain. The last descriptor of a designed chain determines the topology.

Which chain structure is to be used or which topology is suitable depends on the application. A description of how to design descriptor chains to suit various applications is given in section 100.1.3.4(2) Setting Up Reception Descriptors, and section 100.1.3.5(2) Setting Up Transmission Descriptors.

### (3) Descriptor Base Address Table

The base address table in the URAM contains the address of the first descriptor of all chains to be handled by the respective queues.

Entries 0 to 3 are used to access transmission queues 0 to 3. Subsequent entries are used to access reception queues. Entry 4 thus corresponds to reception queue 0.

The configuration of entries in the base address table is the same as the configuration of link descriptors. We recommend using the descriptor type (DESCR.DT) LINKFIX. Processing of this link descriptor does not change it, so it does not require updating. The first descriptor of a chain performs hardware and software synchronization. If the application requires hardware and software synchronization for the base addresses, use the descriptor type (DESCR.DT) LINK.

The CPU is only capable of using LINKFIX and LINK as descriptor types (DESCR.DT) of descriptors in the base address table.

Set the location of the base address table in the URAM in the descriptor base address table register (DBAT).

Figure 100.1.3.3.3 shows an example of a base address table for controlling four transmission and three reception queues. The boxes to the right of the table represent descriptor chains with the desired topologies.

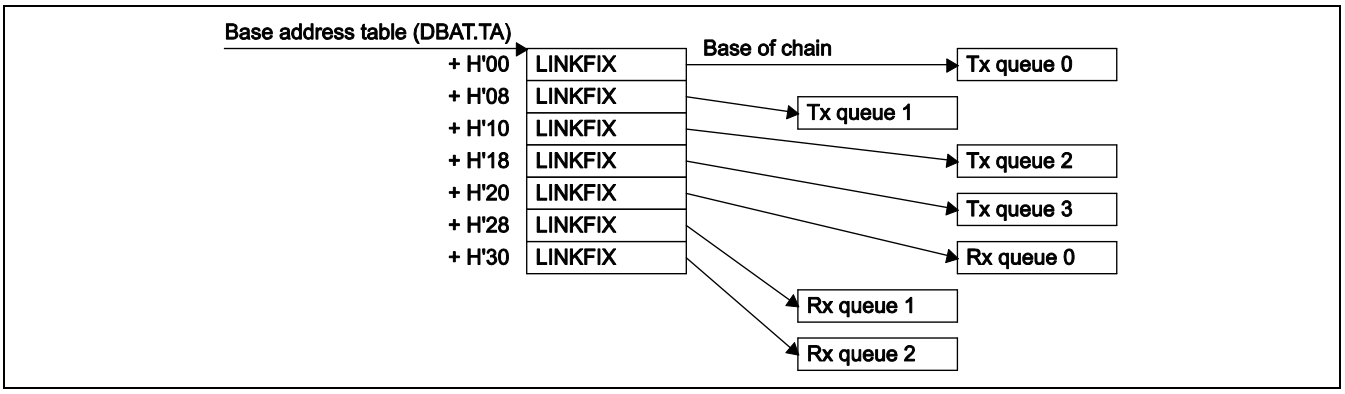

**Figure 100.1.3.3.3 Example of a Base Address Table for Reception and Transmission Queues**

Note: The size of the descriptors in the base address table is always eight bytes even if the queue itself includes extended descriptors.

### (4) Descriptor Chain Processing

The descriptor that is currently processed or will be processed when the related queue gets active is the current descriptor. The current descriptor address for use by a queue q can be checked in the current descriptor address register q (CDARq).

Current descriptors are stored in registers or in descriptors as described below in the given situations.

- In the descriptor base address table registers for all q queues (DBAT) (DBAT.TA+8*q) when the operating mode shifts to operation mode.
- In the descriptor base address table register (DBAT) (DBAT.TA+8*q) when a base address load request is issued for a queue q by setting the corresponding bit (DLR.LBAq) in the descriptor base address load request register (DLR).
- In DESCR.DPTR for a link descriptor (LINK, LINKFIX) to be processed.
- After a descriptor has been processed, the current descriptor for the same queue is incremented by the size of the descriptors being handled by the queue (8 bytes for normal descriptors and 20 bytes for extended descriptors). The AVB-DMAC updates the descriptor type and informs the CPU that the descriptor has been processed.

### (5) Descriptor Interrupts

A descriptor is able to issue a descriptor interrupt on completion of its processing. The setting of the descriptor interrupt enable bits (DESCR.DIE) in each descriptor selects disabling or generation of the descriptor interrupt.

EthernetAVB-IF provides two kinds of descriptor interrupts:
- Queue specific descriptor interrupt (1 per receive/transmit queue)
- Universal descriptor interrupt (15 shared between all receive/transmit queues)

The descriptor interrupt is a common resource that is shared between reception and transmission queues. Software control of the descriptor interrupt provides a flexible method of application-specific flag processing.

Figure 100.1.3.3.4 illustrates the way in which the AVB-DMAC generates descriptor interrupts (or sets bits in the descriptor interrupt status register (DIS.DPFi)). Processing of a descriptor with the value i in the descriptor interrupt enable bits (DESCR.DIE) leads to the corresponding bit in the descriptor interrupt status register (DIS.DPFi) being set.

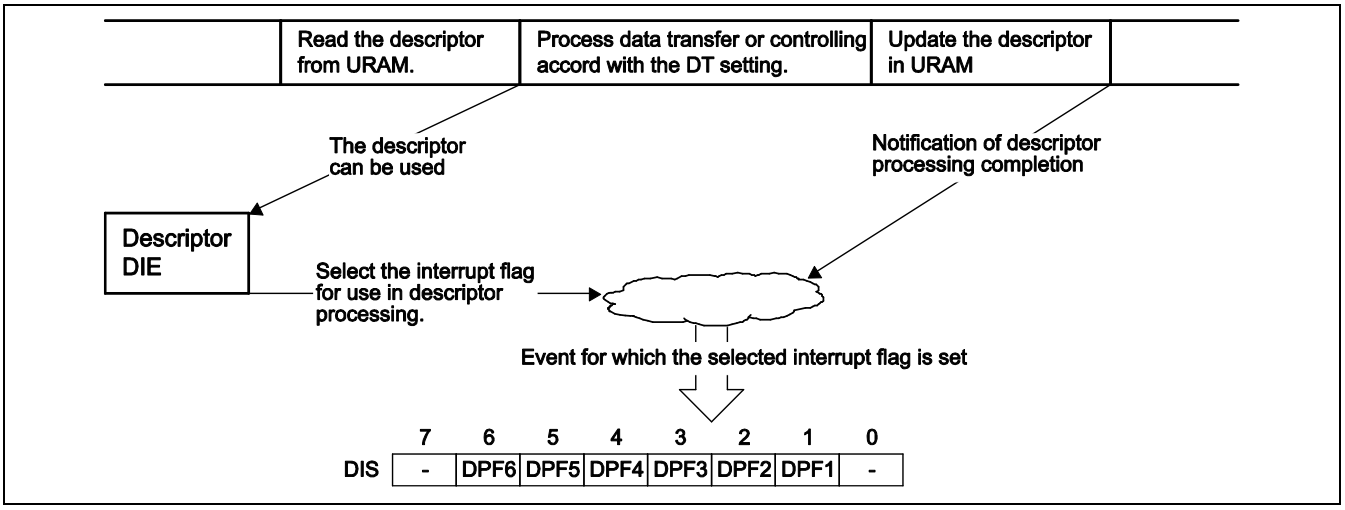

**Figure 100.1.3.3.4 Method of Descriptor Interrupt Generation**

### (6) Descriptor Type

The descriptor types (indicated by the DESCR.DT bits) supported by the AVB-DMAC fall into the following three categories.

- Definitions of frame data
- Control of descriptor chains
- Hardware and software arbitration

Table 100.10 is a summary of the descriptor types available for the AVB-DMAC. Entries under “Name” are the names of the descriptor types and the values under “DT” are the corresponding values to be set in the descriptor type field (DESCR.DT). A given descriptor may be handled differently according to whether it is in a transmission or reception queue, so the transmission and reception columns list the scopes of control and processing of the descriptor types.

The abbreviations defined below are used in the transmission and reception columns.

**Definition of SW:**

— The descriptor is processed by software.
— Software has access to and may modify the descriptor and descriptor data area.
— This descriptor cannot be changed by hardware (AVB-DMAC).

**Definition of HW:**

— The descriptor is processed by hardware (AVB-DMAC).
— Software must modify neither the descriptor nor the descriptor data area.
— Hardware (AVB-DMAC) processes this descriptor and subsequently changes the descriptor type.

**Invalid:**

This descriptor type is not used in transfer in the given direction (transmission or reception).

Do not write this value to the descriptor type (DESCR.DT) field for transfer in the given direction.

Hardware does not process these descriptor types in the cases listed as invalid. The current descriptor address (CDARq.CDA) will not be changed when processing of a queue for the given direction arrives at a descriptor with this type setting.

**Table 100.10 Summary of Descriptor Type**

| Name | DT | Description | Reception | Transmission |
|---|---|---|---|---|
| Frame data | | | | |
| FSTART | 5 | Frame Start<br>The descriptor points to valid data for a frame. The frame starts with the given data and continues with that indicated by the next descriptor. | SW | HW |
| FMID | 4 | Frame Middle<br>The descriptor points to valid data for a frame. The frame started with a previous descriptor and continues to the data indicated by the next descriptor. | SW | HW |
| FEND | 6 | Frame End<br>The descriptor points to valid data for a frame. The frame continues from the previous descriptor and ends with the data indicated by in this descriptor. | SW | HW |
| FSINGLE | 7 | Frame Single<br>The descriptor points to valid data for a complete frame. | SW | HW |
| Chain control | | | | |
| LINK | 8 | Link<br>Defines the next descriptor in the chain. | HW | HW |
| LINKFIX | 9 | Fixed Link<br>Same as LINK, but not changed by AVB-DMAC after processing. | SW | SW |
| EOS | 10 | End Of Set<br>Control element to split a descriptor chain. The chain stops and waits for user interaction. | HW | HW |
| HW/SW arbitration | | | | |
| FEMPTY | 12 | Frame Empty<br>A descriptor related to frame data but not containing valid data for a frame | HW | SW |
| FEMPTY_IS | 13 | Frame Empty Incremental Start<br>A descriptor related to frame data but not containing valid data for a frame.<br>DESCR.DPTR sets the base address of an “incremental data area” in the URAM. | HW | Invalid |
| FEMPTY_IC | 14 | Frame Empty Incremental Continue<br>A descriptor related to frame data but not containing valid data for a frame.<br>Data is stored to the incremental data area in the URAM. | HW | Invalid |
| FEMPTY_ND | 15 | Frame Empty No Data storage<br>A descriptor related to frame data but not containing valid data for a frame.<br>The descriptor is processed in the same way as FEMPTY but data are not stored in the URAM. | HW | Invalid |
| LEMPTY | 2 | Link Empty<br>A link descriptor for processing by the AVB-DMAC | SW | SW |
| EEMPTY | 3 | EOS Empty<br>An EOS descriptor for processing by the AVB-DMAC | SW | SW |
| DT0 | 0 | Reserved | Invalid | Invalid |
| DT1 | 1 | Reserved | Invalid | Invalid |
| DT11 | 11 | Reserved | Invalid | Invalid |

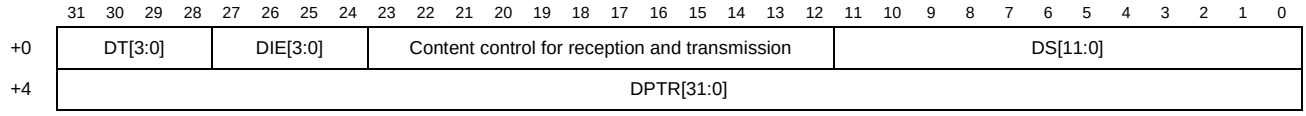
### (7) Layout of General Descriptors in the URAM

The AVB-DMAC updates processed descriptors in the URAM. The field to be changed in the descriptor being updated depends upon whether the direction is transmission or reception and the queue mode. Other fields will not be changed. There are no restrictions on the values set in unused descriptor fields (indicated by "—" in the figure).

#### (a) Frame Data Descriptors

The allocation of bits in the frame data descriptors (FSTART, FMID, FEND, and FSINGLE) is shown below.

- Normal descriptor (usable in both reception and transmission)



- Extended descriptor (usable only in reception)

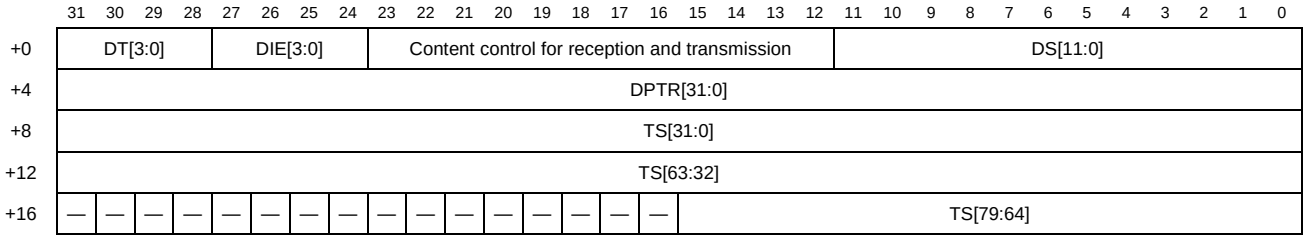


**Table 100.11 Contents of Frame Data Descriptors (DESCR)**

| Bit Name | Function |
|---|---|
| DT[3:0] | Descriptor Type<br>5: FSTART<br>4: FMID<br>6: FEND<br>7: FSINGLE<br>For details, see section 100.1.3.4(2) Setting Up Reception Descriptors, and section 100.1.3.5(2) Setting Up Transmission Descriptors. |
| DIE[3:0] | Descriptor Interrupt Enable<br>B'0000: Descriptor interrupt is disabled.<br>B'0001 to B'1111: The corresponding descriptor interrupt is generated (DIS.DPFi). |
| — | Content Control<br>For details, see section 100.1.3.4(2) Setting Up Reception Descriptors, and section 100.1.3.5(2) Setting Up Transmission Descriptors. |
| DS[11:0] | Data Size<br>Size of the data area/frame data for the descriptor (in bytes) |
| DPTR[31:0] | Descriptor Pointer<br>Pointer to the data area for the descriptor |
| TS[79:0] | Time Stamp<br>Time stamp of the received frame (only available in extended descriptors) |

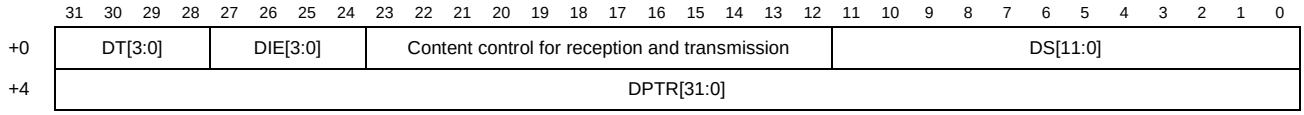
Note: Register an address aligned with a 32-bit boundary as the descriptor pointer (DESCR.DPTR).
Some bits in extended descriptors are reserved (The reserved bits (above DESCR.TS[79:64]) in an extended descriptor are set to H'0000 after the time stamp is stored).

**(b) Hardware/Software Arbitration Descriptors (Only for Reception)**

The allocation of bits in the descriptors for hardware/software arbitration (FEMPTY, FEMPTY_IS, FEMPTY_IC, and FEMPTY_ND) is shown below.

The allocation of bits in the arbitration descriptors for use in reception is the same as in frame data descriptors.

- Normal descriptor



- Extended descriptor (usable only in reception)

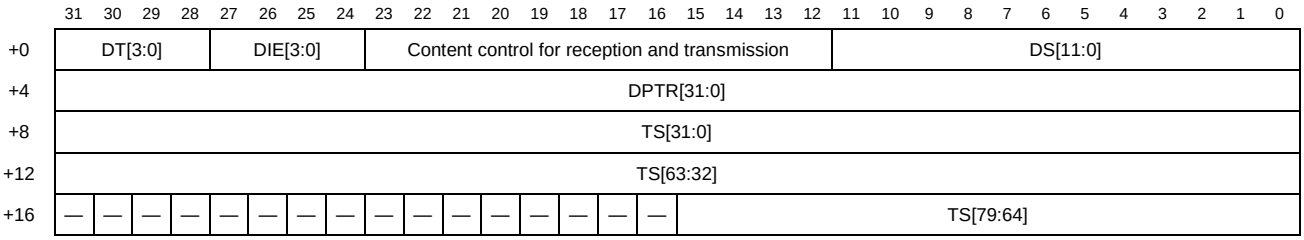


**Table 100.12 Contents of Hardware/Software Arbitration Descriptors (DESCR)**

| Bit Name | Function |
|---|---|
| DT[3:0] | Descriptor Type<br>12: FEMPTY<br>13: FEMPTY_IS<br>14: FEMPTY_IC<br>15: FEMPTY_ND<br>For details, see Table 100.10, Summary of Descriptor Types. |
| DIE[3:0] | Descriptor Interrupt Enable<br>B'0000: Descriptor interrupt is disabled.<br>B'0001 to B'1111: The corresponding descriptor interrupt is generated (DIS.DPFi). |
| — | Content Control<br>For details, see section 100.1.3.4(2) Setting Up Reception Descriptors, and section 100.1.3.5(2) Setting Up Transmission Descriptors. |
| DS[11:0] | Data Size<br>Size of the data area/frame data for the descriptor (in bytes) |
| DPTR[31:0] | Descriptor Pointer<br>Pointer to the data area for the descriptor |
| TS[79:0] | Time Stamp<br>Time stamp of the received frame (only available in extended descriptors) |

Note: Register an address aligned with a 32-bit boundary as the descriptor pointer (DESCR.DPTR).
When the descriptor is an extended descriptor, it has a 12-byte unused area.

In an FEMPTY descriptor, the descriptor type (DT), descriptor interrupt enable (DIE), data size (DS), and descriptor pointer (DPTR) fields are used.

In an FEMPTY_IS descriptor, the descriptor type (DT), descriptor interrupt enable (DIE), and descriptor pointer (DPTR) fields are used.

In an FEMPTY_IC descriptor, the descriptor type (DT) and descriptor interrupt enable (DIE) are used.

In an FEMPTY_ND descriptor, the descriptor type (DT), descriptor interrupt enable (DIE), and data size (DS) are used.

**(c) Link Descriptors**

The allocation of bits in the link descriptors (LINK and LINKFIX) is shown below.

- Normal descriptor

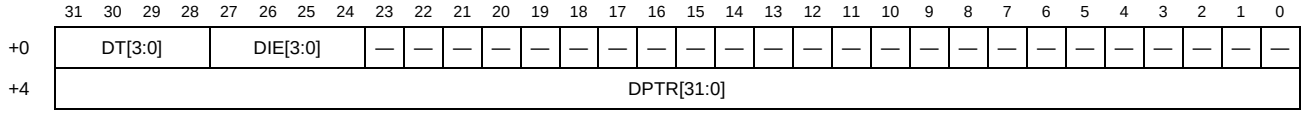

**Table 100.13 Contents of Link Descriptors (DESCR)**

| Bit Name | Function |
|---|---|
| DT[3:0] | Descriptor Type<br>8: LINK<br>9: LINKFIX<br>For details, see Table 100.10, Summary of Descriptor Types. |
| DIE[3:0] | Descriptor Interrupt Enable<br>B'0000: Descriptor interrupt is disabled.<br>B'0001 to B'1111: The corresponding descriptor interrupt is generated (DIS.DPFi). |
| DPTR[31:0] | Descriptor Pointer<br>Pointer to the data area for the descriptor<br>Register an address on a 32-bit boundary. |

Note: Register an address aligned with a 32-bit boundary as the descriptor pointer (DESCR.DPTR).

### (d) Other Descriptors

The allocation of bits in the other descriptors (EOS, FEMPTY (only for transmission), LEMPTY, and EEMPTY) is shown below.

| | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| +0 | DT[3:0] | | | | DIE[3:0] | | | | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| +4 | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |

**Table 100.14 Contents of Other Descriptors (DESCR)**

| Bit Name | Function |
|---|---|
| DT[3:0] | Descriptor Type<br>10: EOS<br>12: FEMPTY (only for transmission)<br>2: LEMPTY<br>3: EEMPTY<br>For details, see Table 100.10, Summary of Descriptor Types. |
| DIE[3:0] | Descriptor Interrupt Enable<br>B'0000: Descriptor interrupt is disabled.<br>B'0001 to B'1111: The corresponding descriptor interrupt is generated (DIS.DPFi). |

### (8) How to Use Frame Data Descriptors

The descriptor data area size field (DESCR.DS) can specify up to 2048 bytes of Ethernet frame data per data area. Settings higher than 2048 (bytes) cannot be made.

In general, Ethernet frames are not of uniform length. The AVB-DMAC is capable of dividing frame data into multiple descriptors in order to minimize the memory capacity for frame data. This function allows processing of frames that are longer than the limit for descriptor data areas. Division can also be applied to frames on the basis of their data structures.

To handle frames and descriptors, four descriptor types (DESCR.DT) as FSTART, FEND, FMID and FSINGLE are defined.

Figure 100.1.3.3.5 shows the mapping of frame data by frame data descriptors. The descriptor data areas are allocated to the URAM. For frames that require division into four or more data areas, additional FMID descriptors can be added as required.

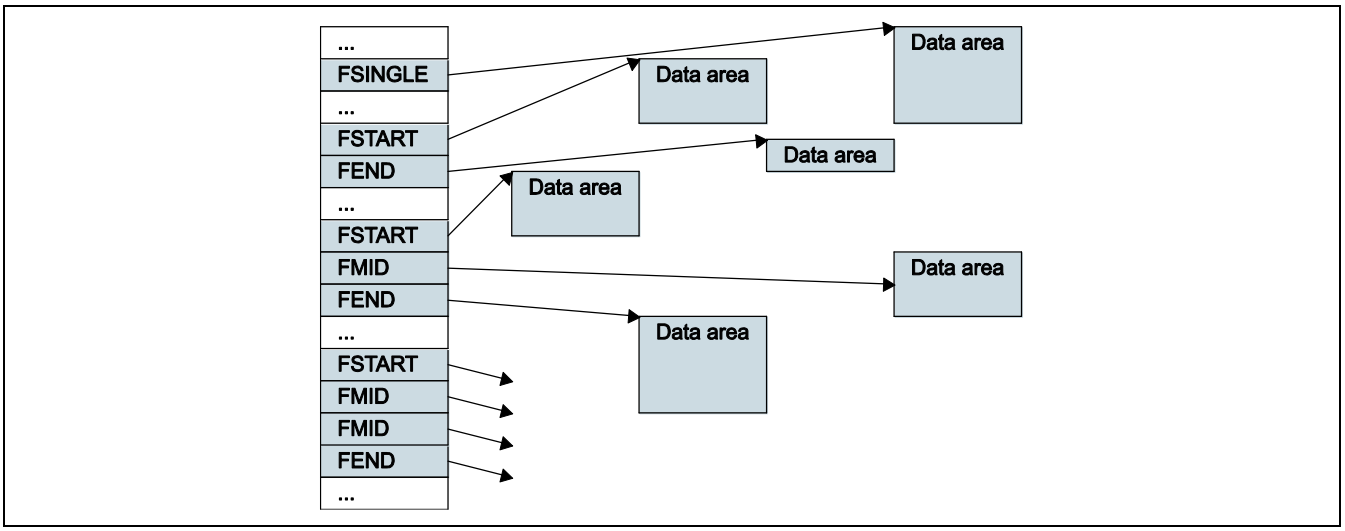

**Figure 100.1.3.3.5 Mapping of Frame Data**

For reception, set the descriptor data areas to the maximum size (i.e. give DESCR.DS its maximum value). The AVB-DMAC will store received frame data in the given area. If a received frame has more data than the maximum size, the AVB-DMAC will divide the data up.

For transmission, set the descriptor data area size field to the actual data size. The AVB-DMAC modifies the descriptor type (DESCR.DT) to FEMPTY after processing the relevant descriptor. The data size (DESCR.DS) and descriptor pointer (DESCR.PTR) fields retain their settings.

A descriptor data area including unused space produces an empty space between data areas. In reception, an “incremental data area” can be used to prevent empty spaces. For incremental data areas, see section 100.1.3.4(3)(b) Incremental Data Areas.

As well as reducing the memory capacity taken up by the descriptor area in the URAM, division into frames can be used to identify different sections of data (e.g. for separating a header and data).

### (9) How to Use Chain Control Descriptors

**Link Descriptors**

The link descriptors can be used to set up cyclic descriptor chains (for details, see section 100.1.3.3(2) Using Descriptor Chains in Queues)

After a LINK descriptor is processed, its descriptor type (DESCR.DT) is changed to LEMPTY. The descriptor pointer (DESCR.PTR) retains its setting.

After processing of a LINKFIX descriptor, the descriptor type (DESCR.DT) is not updated. Software can change the descriptor type (DESCR.DT), descriptor interrupt enable (DESCR.DIE), and descriptor pointer (DESCR.DPTR). However, DESCR.DT should not be modified by software. Take care to check the current descriptor address register (CDARq.CDA) before changing the descriptor pointer (DESCR.DPTR).

**EOS Descriptor**

Use the EOS descriptor to divide a descriptor chain into various segments. The queue can continue even after an EOS descriptor.

In transmission, the response to an EOS descriptor is clearing of the transmit start request bit in the transmit configuration control register (TCCR.TSRQq) to 0.

In reception, the response is generation of a receive queue full interrupt (RIS2.QFFr), although if the frame currently being received is being divided for storage (received data such as those where some storage is in FMID- or FEND-type frames), the data are not completely stored.

### (10) How to Use Hardware and Software Arbitration Descriptors

In hardware processing of descriptors, the empty descriptor types (FEMPTY, LEMPTY, and EEMPTY) are used to distinguish various descriptors. For software, they can be used to initiate checking for empty spaces, etc.

**FEMPTY, FEMPTY_IS, FEMPTY_IC, and FEMPTY_ND**

These descriptor types (DESCR.DT) are used for descriptors that do not contain effective data. Of these, only FEMPTY is used in transmission. The descriptor pointer of a FEMPTYxxx descriptor refers to a descriptor data area.

**LEMPTY**

This descriptor type (DESCR.DT) is assigned to LINK descriptors after they have been processed. The descriptor pointer (DESCR.DPTR) of an LEMPTY descriptor still points to the linked descriptor.

**EEMPTY**

This descriptor type (DESCR.DT) is assigned to EOS descriptors after they have been processed. The descriptor pointer (DESCR.DPTR) of an EEMPTY descriptor is not used.

### (11) Synchronization between Descriptor Access by Hardware and Software

The allocation of descriptor types (DESCR.DT) to the URAM can be used to set up the primary synchronization between hardware and software. By this, the number of CPU accesses to registers of EthernetAVB-IF can be minimized and performance can be increased.

Basic concepts of synchronization:

- Each descriptor type in the set is exclusively for processing by hardware or software, depending on the direction of transfer (see Table 100.10 Summary of Descriptor Type).
- Software must not change a descriptor assigned to hardware processing (the hardware does not change descriptors assigned to software processing).

In the case of software processing, the software must process the information in the descriptor and the corresponding frame data before changing the descriptor type. If a descriptor type for hardware is set in DESCR.DT, the software should not change any part of the descriptor or of the corresponding frame data.

### (12) Tips for Optimizing Performance in Handling Descriptors

The following items are recommended as ways to ensure the optimal use of data structures in the URAM.

They are not requirements, but using a different approach may increase the load on the system bus within the LSI chip.

- Register descriptors with 64-bit alignment (this does not apply to extended descriptors).
- While in operation mode, use LINKFIX instead of LINK whenever a descriptor need not be changed. Hardware modifies the descriptor type (DESCR.DT) fields of LINK descriptors.
- Frame data is accessed in blocks up to 128 bytes.
- The number of 128 byte borders (addresses H'x xx00 and H'x xx80) and frame data inside should be minimized.
- Design the descriptor chains in ways that minimize parallelism of processing. This helps in dividing the chains into segments allocated to different cache pages, and in arranging the different segments exclusively for access by software or hardware.
- Minimize the number of divided frames. This can reduce the overhead of descriptor handling.

### 100.1.3.4 Control in Reception

The point of the AVB-DMAC is to transfer data between the E-MAC and URAM without intervention by the CPU.

AVB-DMAC needs descriptors that define the amounts of frame data to be stored and the locations. After the E-MAC receives a frame, it stores the received frame data and the conditions of reception as the E-MAC state. If the descriptor is extended, the time stamp is also stored. For a description of how to set up descriptors for use in reception, see section 100.1.3.4(2) Setting Up Reception Descriptors.

The AVB-DMAC filters received frames to separate them into various classifications (separation filtering). More specifically, this is done to separate received frames into the various reception queues and to set the priorities of different classes of received frames. For more on separation filtering, see section 100.1.3.4(1)(a) Separation Filtering.

Figure 100.1.3.4.1 shows the reception data bus and the selection of queues for use in reception.

Each frame received from the E-MAC is stored in the reception FIFO; in parallel with this, the frame is analyzed to identify its type and the target queue number. After the E-MAC completes reception, the target queue number is generated and stored in the reception FIFO. Appending of a reception flag depends on the storage of one frame among the reception queues in the URAM, and the unread frame counter (UFC) is also associated with frame storage.

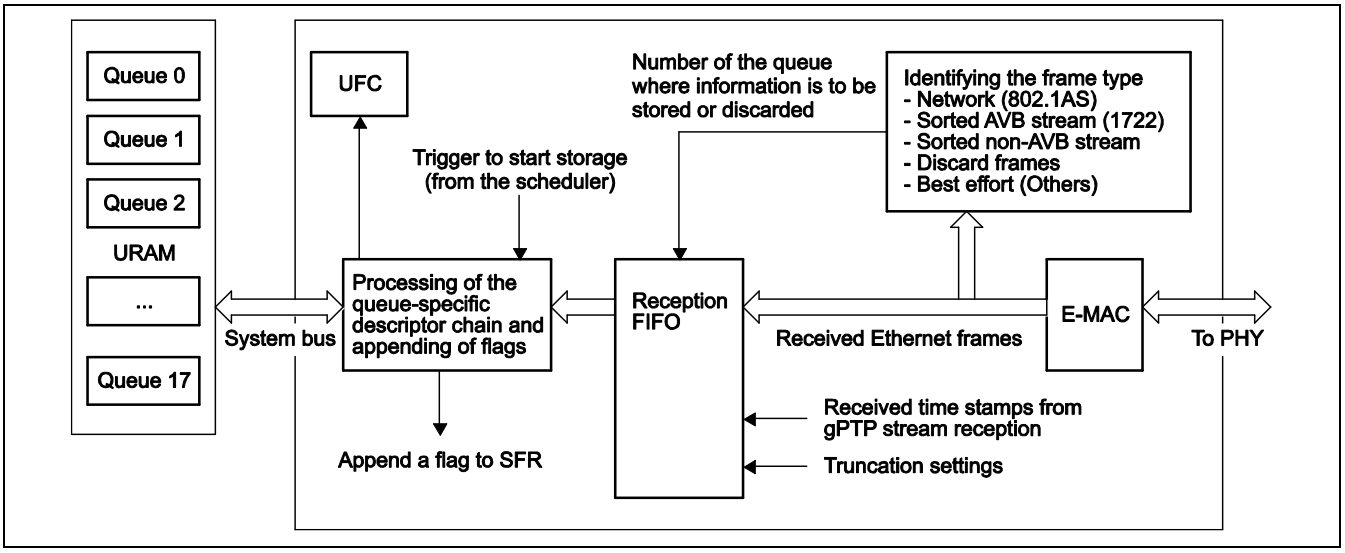

**Figure 100.1.3.4.1 Mechanism of General Reception Queue Selection**

### (1) Reception Queues

The AVB-DMAC applies its separation filtering mechanism to select the reception queue for storing a received frame. The AVB-DMAC stores all received frames in the URAM.

There are two conditions for the AVB-DMAC to discard a received frame.

- Detection of an error during reception by the E-MAC
  - Whether error frames are discarded or stored in reception queue 0 (best effort) depends on the setting of the error frame enable bit in the receive configuration register (RCR.EFFS). If error frames are to be stored (RCR.EFFS = 1), they are always stored in queue 0 (best effort). In this case, characteristics specific to the queue (e.g. truncation) will vary. If the storage of time stamps for reception queue 0 (best effort) is enabled (the time stamp enable bit in the receive configuration register RCR.ETS0 = 1), time stamps are stored even for error frames.
- Frame fails the separation filter
  - It depends on RCR.ESF if such frame is discarded or stored in receive queue 0 (best effort).

The flowchart in Figure 100.1.3.4.2 shows how the AVB-DMAC selects the reception queue in accord with the frame type, including judgment by the separation filter. Selection of the queue starts when the E-MAC completes frame reception. The result is storage of the frame in the proper queue or the frame being discarded.

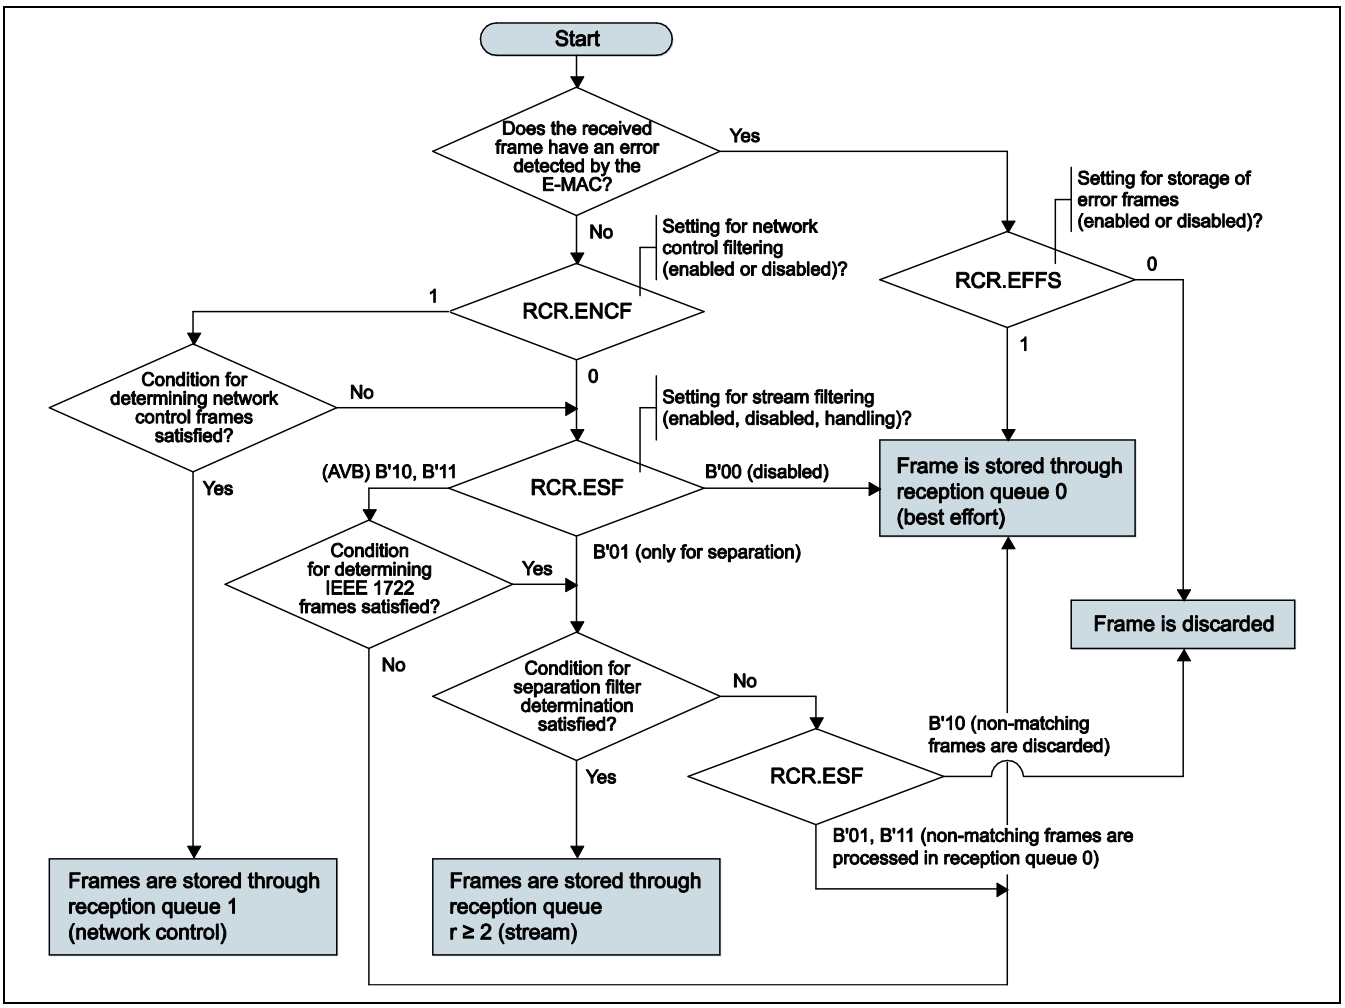

**Figure 100.1.3.4.2 Mechanism of Reception Queue Selection**

Notes on the meanings of entries in the flowchart

- "Condition for determining network control frames"
  The Ethernet destination address (DA) is 01:80:C2:00:00:0E.
  The Ethernet type (ET) is 88:F7.
- "Condition for determining IEEE 1722 frames"
  The Ethernet destination address (DA) is within the range from 91:E0:F0:00:00:00 to 91:E0:F0:00:FE:FF.
  The VLAN tagged TPID (tag protocol identifier) field (VL) is 81:00.
  The Ethernet type (ET) is 22:F0.
- "Condition for separation filter determination"
  See section 100.1.3.4(1)(a) Separation Filtering.

Figure 100.1.3.4.3 shows the allocation of bits related to the network and stream types in Ethernet frames. The preambles of Ethernet frames are not taken into account.

| Data bytes | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Network type | DA1 | DA2 | DA3 | DA4 | DA5 | DA6 | SA1 | SA2 | SA3 | SA4 | SA5 | SA6 | ET1 | ET2 | ... | ... | ... | ... | ... | ... |
| Stream type | DA1 | DA2 | DA3 | DA4 | DA5 | DA6 | SA1 | SA2 | SA3 | SA4 | SA5 | SA6 | VL1 | VL2 | - | - | ET1 | ET2 | ... | ... |

**Figure 100.1.3.4.3 Data Bytes of Ethernet Frames Used in Classification**

**(a) Separation Filtering**

Separation filtering involves the checking of up to 64 bits (eight successive bytes) in received Ethernet frames. The setting for the first byte (i.e. the setting of the separation filter offset configuration register (SFO.FBP)), selects the part of frames to be used in separation filtering. There is also a common filter mask (set in the separation filter mask configuration register (SFMi.CFM)) that can be freely set to reduce the number of bytes used in separation filtering or to mask particular bits.

**Examples**

To use one byte in separation, set separation filter mask configuration register 0 (SFM0.CFM) to H'0000 00FF and separation filter mask configuration register 1 (SFM1.CFM) to H'0000 0000.

To use seven bytes in separation, set separation filter mask configuration register 0 (SFM0.CFM) to H'FFFF FFFF and separation filter mask configuration register 1 (SFM1.CFM) to H'00FF FFFF.

Note: If bits at some positions are set to 0 in the separation mask, in order to match with the pattern, the bits at the corresponding positions of the pattern must also be set to 0. Only those bits in which the separation filter pattern configuration register (SFPi.FPs) setting is equal to the separation filter mask configuration register (SFMi.CFM) are sorted by matching with received data.

Figure 100.1.3.4.4 shows separation filtering. The selected data from a received frame (Rx_Frame[63:0]) are masked by the common filter mask. As a result, the selected frame data can be obtained. This value is compared with all filter patterns. The separation filter circuit in the AVB-DMAC selects the filter pattern that matches the queue having the lowest index s or selects a flag to indicate that there is no matching separation pattern.

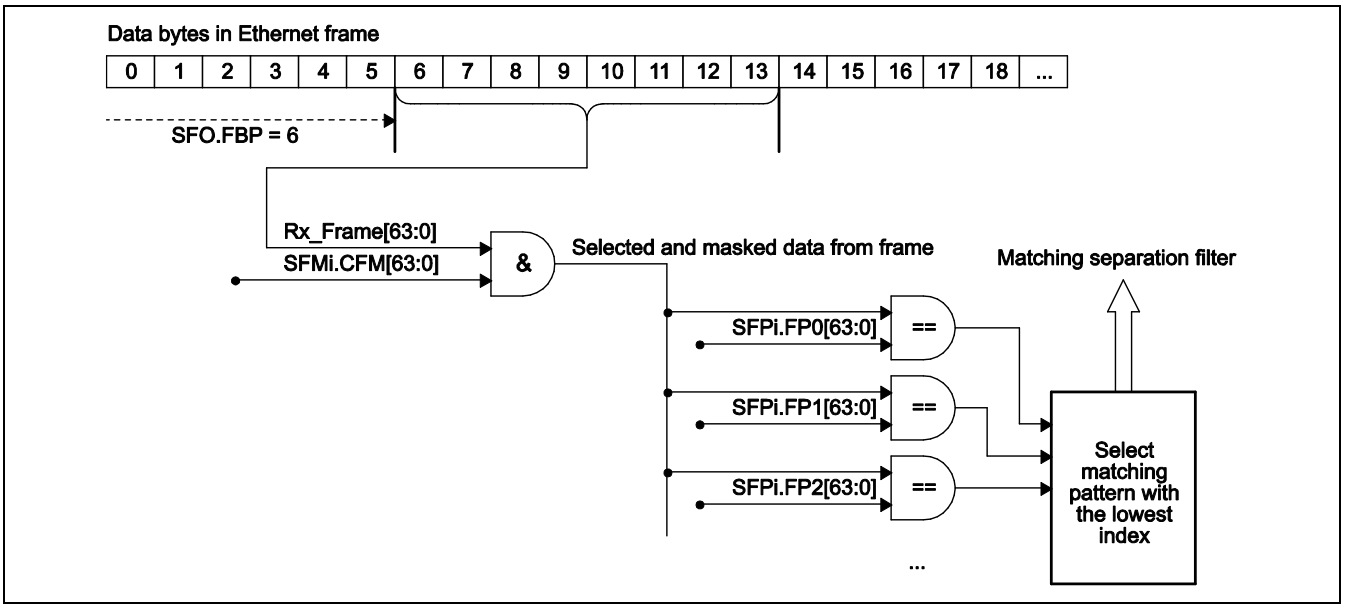

**Figure 100.1.3.4.4 Separation Filtering**

**(b) Separating Streams**

The AVB-DMAC applies separation filtering to sort frames received in streams. An AVB network has a concept of "Talker" and "Listener". A Talker is an end station that generates one or more streams. A Listener is an end station that has the role of being a sink for at least one stream. The various A/V streams are identified by 8-byte stream IDs.

The number of end stations within an AVB network and their roles differ with the application.

The stream ID is a general pattern of the AVB network for identifying one stream. Figure 100.1.3.4.5 shows the bit allocation of bits in IEEE1722 Ethernet frames and stream ID fields.

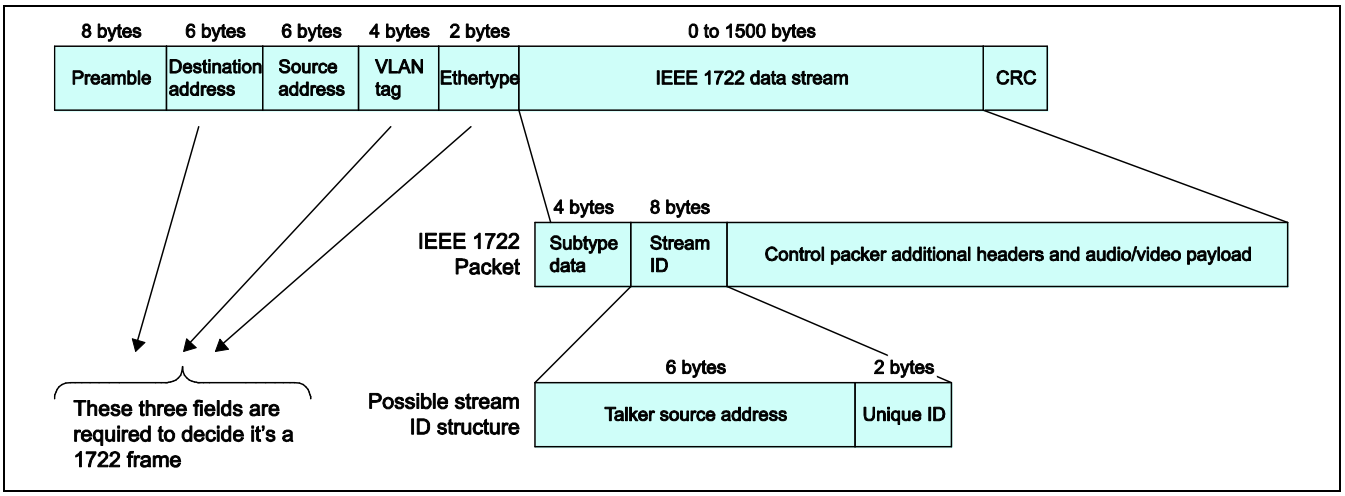

**Figure 100.1.3.4.5 IEEE 1722 Frame Layout and Stream ID**

The IEEE 1722 standard stipulates that the stream ID field starts from the 23rd byte (not counting the preamble). Accordingly, set the separation filter offset (SFO.FBP) to 22 in operations on IEEE 1722 streams. Set the separation filter mask (SFMi) and separation filter pattern (SFPi) in accord with the specification of the product in which the chip is being used.

Example: In the example of a stream ID shown in Figure 100.1.3.4.5, the current application divides the field into the talker source address and the unique stream ID. The unique ID is used to differentiate between multiple streams from the same talker. Based on this, there are two settings for separation filter masking:

- To divide various streams into individual queues, set SFM0.CFM to H'FFFF FFFF and SFM1.CFM to H'FFFF FFFF.
- To divide streams from various talkers into individual queues, set SFM0.CFM to H'FFFF FFFF and SFM1.CFM to H'0000 FFFF. This excludes the unique ID from the filter condition.

**(c) Reconfiguration of separation filter during OPERATION**

In CONFIG mode the initial separation filter configuration is defined. To prevent inconsistent filter results during OPERATION direct parameter change is not possible; instead update mechanism by **SFVi.LV** and **SFL.LC** should be used.

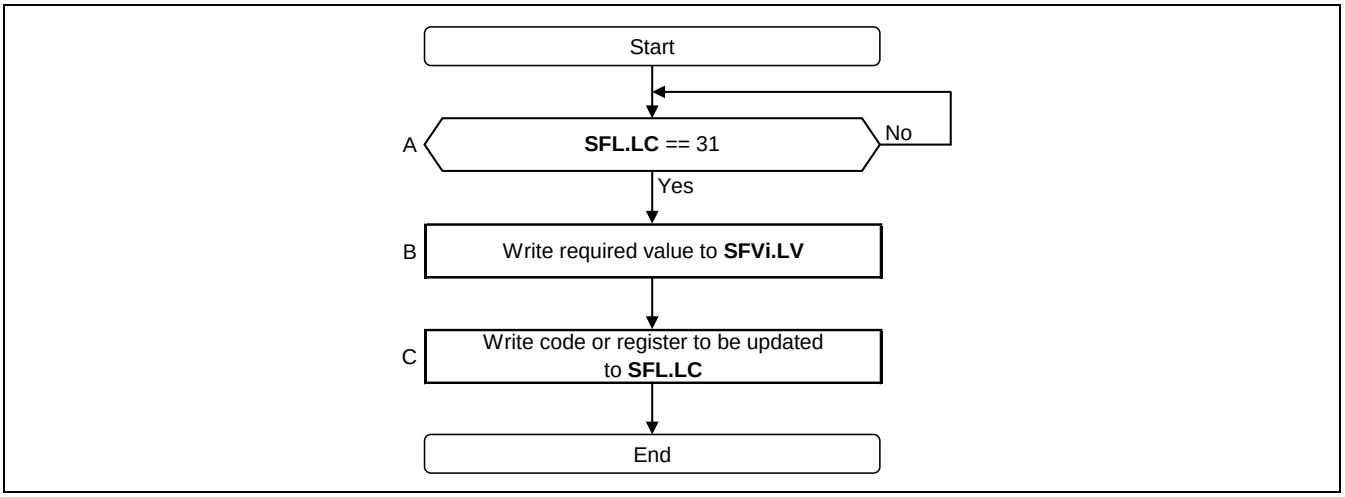

**Figure 100.1.3.4.6 SW flow to update separation filter during OPERATION**

When reconfigure separation filter, EthernetAVB-IF guarantees consistent classification for one received frame. If reconfiguration requires a sequence of parameter changes, CPU has to order reconfiguration based on application demand.

EthernetAVB-IF updates filter configurations when no frame reception is handled. In worse case the update is delayed by one frame reception. Exact duration depends on PHY speed and frame size. By reading **SFL.LC** CPU can observe when a previous update has been processed.

Note: Frame classification happens during frame reception and storage into internal Rx-FIFO. There may be frames with old classification pending in Rx-FIFO or under storage to URAM when filter reconfiguration is accepted.

### (2) Setting Up Reception Descriptors

For reception, the descriptor mechanism is essentially as described in section 100.1.3.3 Descriptors.

This section describes memory operations that are especially required in handling reception queues.

#### (a) Reception Descriptor Type

The type of a descriptor is defined by the descriptor type (DESCR.DT) field.

Table 100.15 shows the descriptor types used in reception.

**Table 100.15 Descriptor Types in Reception**

| Descriptor Type (DESCR.DT) | Operation | Write-back |
|---|---|---|
| Frame Start (FSTART) | Condition for data not being stored in a reception queue:<br>The RIS2.QFFr bit indicates that queue r is full and the received frame is not stored.<br>Descriptor processing proceeds again in response to further reception. | Not changed |
| Frame Middle (FMID) | Same as FSTART | Not changed |
| Frame End (FEND) | Same as FSTART | Not changed |
| Frame Single (FSINGLE) | Same as FSTART | Not changed |
| Link (LINK) | Processing proceeds to the descriptor specified by DESCR.DPTR. | LEMPTY |
| Fixed Link (LINKFIX) | Same as LINK | Not changed |
| End Of Set (EOS) | A stop point defined by software has been reached.<br>A descriptor of this type within a divided frame (writing of FMID or FEND) stops the frame being stored and the frame is lost. RIS2.QFFr indicates that the frame has been lost.<br>If this happens at the start of a frame (writing of FSTART or FSINGLE), storing of frames starts from the next descriptor.<br>In either case, processing shifts to the next descriptor in the chain. | EEMPTY |
| Frame Empty (FEMPTY) | The descriptor can be used to store received data.<br>Up to DESCR.DS bytes are stored in the descriptor data area.<br>For details, see section 100.1.3.4(3)(a) Storing Frame Data in the Descriptor Data Area. | FSTART, FMID, FEND, or FSINGLE |
| Frame Empty Incremental Start (FEMPTY_IS) | The descriptor can be used to store received data.<br>All data for the frame are stored in the descriptor data area.<br>DESCR.DPTR indicates the base address of the incremental data area.<br>For details, see section 100.1.3.4(3)(b) Incremental Data Areas. | FEND or FSINGLE |
| Frame Empty Incremental Continue (FEMPTY_IC) | The descriptor can be used to store received data.<br>The remaining bytes of frame data are stored in the descriptor data area.<br>DESCR.DPTR is undefined, but is written back at the start position within the incremental data area after processing.<br>For details, see section 100.1.3.4(3)(b) Incremental Data Areas. | FEND or FSINGLE |
| Frame Empty No Data storage (FEMPTY_ND) | The descriptor can be used to store received data.<br>Up to DESCR.DS bytes are captured from the reception FIFO but not stored. After processing, DESCR.DS is written back as 0.<br>For details, see section 100.1.3.4(3)(b) Incremental Data Areas. | FSTART, FMID, FEND or FSINGLE |
| Link Empty (LEMPTY) | Same as FSTART | Not changed |
| EOS Empty (EEMPTY) | Same as FSTART | Not changed |

**(b) Configuration of Reception Frame Data Descriptors**

Figure 100.1.3.4.7 shows the configuration of descriptors for use with reception queues. The reception-specific fields are the same whether the descriptor is normal or extended. The reception-specific fields (DESCR.MSC, DESCR.PS, DESCR.EI, and DESCR.TR) are described in Table 100.16.

For the other fields and the descriptor types, see section 100.1.3.3(6) Descriptor Type.

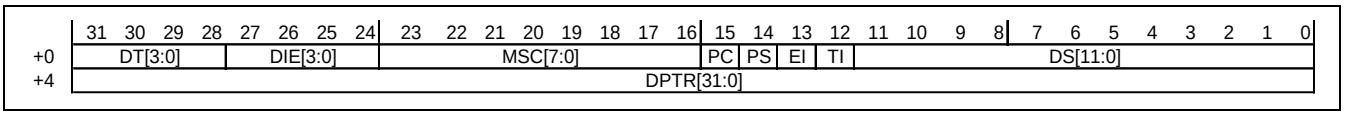

**Figure 100.1.3.4.7 Configuration of Descriptor for a Received Frame**

**Table 100.16 Configuration of a Received Descriptor**

| Bit Name | Function |
|---|---|
| MSC | E-MAC Status Code<br>These bits indicate errors in reception detected by the E-MAC.<br>In the case of a divided frame, these bits are set to the same value within all descriptors for the frame data. Details of the bits are as follows.<br>MSC[7]: Received frame has a multicast address.<br>MSC[6]: Carrier extend error<br>MSC[5]: Carrier sense error<br>MSC[4]: Received frame has alignment error.<br>MSC[3]: Received frame is too long.<br>MSC[2]: Received frame is too short<br>MSC[1]: Error in frame reception (PHY detects an error)<br>MSC[0]: Received frame has a CRC error. |
| PC | Payload Crc status<br>This register is functional safety use only. |
| PS | Padding Selection<br>These bits specify whether frame data are to be padded when stored in the incremental data area.<br>Insertion of padding data is in accord with the settings in the RPC register.<br>0: Padding is not to be inserted.<br>1: Padding data may be inserted. This depends on the RPC settings. |
| EI | Error Indication<br>This bit indicates the detection of an error in frame data while a frame was being stored.<br>The bit is set to 1 for a descriptor in which an error has been detected. If the descriptor is for a divided frame, storage of the frame is aborted.<br>0: No error<br>1: Error is detected |
| TI | Truncation Indication<br>This bit indicates whether frame data received from the E-MAC have been truncated before being stored.<br>These bits are set to the same value within all frame data descriptors for a divided frame.<br>0: Data have not been truncated.<br>1: Data have been truncated. |

Note: The RCR.EFFS bit specifies whether or not frames with errors detected by the E-MAC are to be stored in the URAM. When the storing of error frames is disabled, error codes are not written to DESCR.MSC.

### (3) Reception Processing

After initialization, the AVB-DMAC is able to select the proper reception queue and store received frames in the data area in the URAM as indicated by the descriptor. The AVB-DMAC continues to store received data in the URAM as long as space is available for descriptors and data areas.

Received frames are classified and stored in the reception FIFO in accord with the algorithm described in section 100.1.3.4(1)(a) Separation Filtering.

If the reception FIFO contains even one frame, storing is executed to the reception queue.

If there is even one empty data descriptor in a queue for which reception has started, the storage of frame data starts. Received frames for a queue that is already full (there is no empty frame descriptor or the UFC stop level has been reached) are discarded from the reception FIFO. This ensures that one queue being full does not prevent the storage of data in the other queues.

#### (a) Storing Frame Data in the Descriptor Data Area

Frame data for storage are assumed to be in either of the two patterns described below.

- The data for an entire frame will fit in the descriptor data area.
  - In this case, the descriptor type (DESCR.DT) is FSINGLE.
- Frame data to be stored in the descriptor data area arrive in divided form.
  - In this case, FSTART is written to the descriptor type (DESCR.DT) bits of the first descriptor of the frame data to arrive and FMID and FEND are written to the type bits of descriptors for subsequent data.

The descriptor type is updated by the AVB-DMAC in the last step of descriptor processing, so software can always access the descriptor assigned to DESCR.DT.

When normal synchronization mode is used, the CPU can write FEMPTYxxx directly to the descriptor type field after processing the stored element. Do not change the descriptor or any part of the descriptor data area after FEMPTYxxx is written to DESCR.DT.

**Storing Frame Data for a Whole Single Frame**

For a frame with an FSINGLE descriptor, all data for the frame are held at the position defined by DESCR.DPTR. DESCR.DS indicates the length of the received frame.

If DESCR.DS is bigger than the actual size of a received frame, the FSINGLE descriptor is stored in place of the FEMPTY or FEMPTY_ND descriptor after processing.

Also, the FSINGLE descriptor is stored in place of the FEMPTY_IS or FEMPTY_IC descriptor, which always hold the descriptor data area greater than all frame data in Rx-FIFO after processing.

**Storing Frame Data as Divided Frames**

Divided frames are handled in the same way as a single frame. A frame stored with divided descriptors must be recombined before use. DESCR.EI and DESCR.DS are only valid in the last descriptor of the sequence for a divided frame.

Note: If the data area size setting in DESCR.DS is not a multiple of four, the number of bytes set in DESCR.DS is fetched from the reception FIFO and the remaining bytes are used as the next storage area.

After a received frame is divided into different descriptors, each storage element is handled separately, and the descriptor type is assigned by software after processing. Accordingly, an error frame (FEMPTYxxx instead of FMID or FEND) may exist while a descriptor chain is being processed. In such a case, the CPU must postpone processing of the error frame to the next trigger point.

**No Data are Stored**

The application specification may lead to some types of received frames being unimportant (for example, when the application only requires stream data from the Ethernet frames). Storing frames in divided form makes separating out the unnecessary parts of Ethernet frames possible.

If part of a divided frame is not required, use the FEMPTY_ND descriptor for that part so that it is not stored in the URAM. Not storing the data negates the need for bandwidth on the data bus, improving the overall performance.

When an FEMPTY_ND descriptor is processed, DESCR.DS is set to 0. This brings the frame data section of the descriptor into agreement with the FEMPTY type. DESCR.DS = 0 is for the unique identification of the descriptor after writing.

**(b) Incremental Data Areas**

Secure space in the URAM for storing received data. Even when data are placed in the URAM area such that all descriptor data areas of a chain are contiguous, a received frame being shorter than the descriptor data area will lead to an empty space. Figure 100.1.3.4.8 shows an example of settings and the memory map.

Certain applications require that data areas be contiguous (e.g. when received data are to be processed other than by hardware as the A/V codec module). When the length of received frames differs (e.g. when payloads vary between having one or two A/V packages), the use of a static pointer in the descriptor produces empty spaces in the data area. This may necessitate direct additional processing to remove the empty spaces.

Accordingly, and to reduce the CPU load imposed by copying data, the AVB-DMAC supports an “incremental data area” function.

When incremental data areas are in use, all descriptors use a common data area for storage. One descriptor (FEMPTY_IS) defines the base address of the incremental data area and the next descriptor (FEMPTY_IC) within the descriptor chain holds received data. Figure 100.1.3.4.9 shows an example of settings and the memory map.

Use of an incremental data area does not reduce the memory space in the individual descriptor data areas.

The hardware and software synchronization strategy and performance are also not changed.

It is also possible to divide a frame up among various descriptors in a way that reflects its structure (e.g. one descriptor for the Ethernet header and one for the data payload).

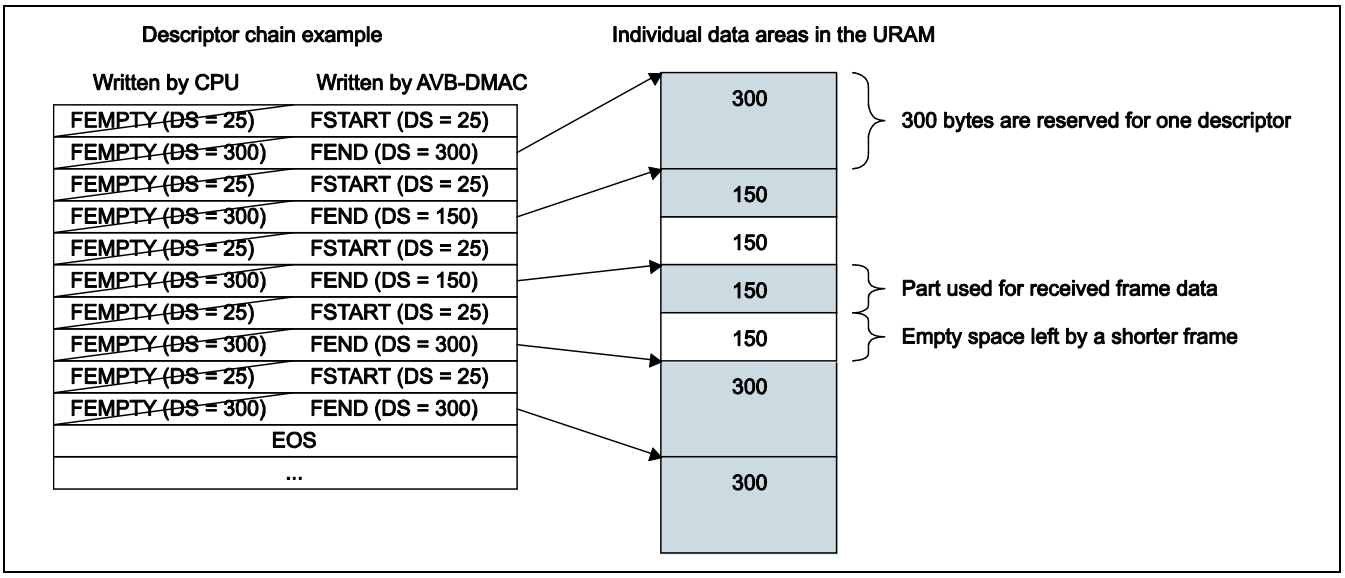

**Figure 100.1.3.4.8 A Reception Queue Using Individual Descriptor Data Areas**

Figure 100.1.3.4.8 and Figure 100.1.3.4.9 show how control of the data storage areas by a descriptor chain varies according to whether individual or incremental data areas are in use. The chains are configured for storing received frames consisting of a 25-byte header (which is treated as one descriptor; and is outside the scope) and a 150- or 300-byte payload (whether one or two 150-byte payload packages are transmitted with one Ethernet frame depends on the data source).

In Figure 100.1.3.4.8, the EOS descriptor is added as an example of a re-synchronization point. If the frame source transmits a frame containing more than 325 bytes, the frame will be divided among three descriptors, meaning that synchronization of the header and data sequences is lost. Despite this, however, the frame is not divided across the EOS descriptor, so recovery is automatic without software interaction. The EOS is not required with the incremental descriptors because all data being processed are always stored while an incremental data area is in use.

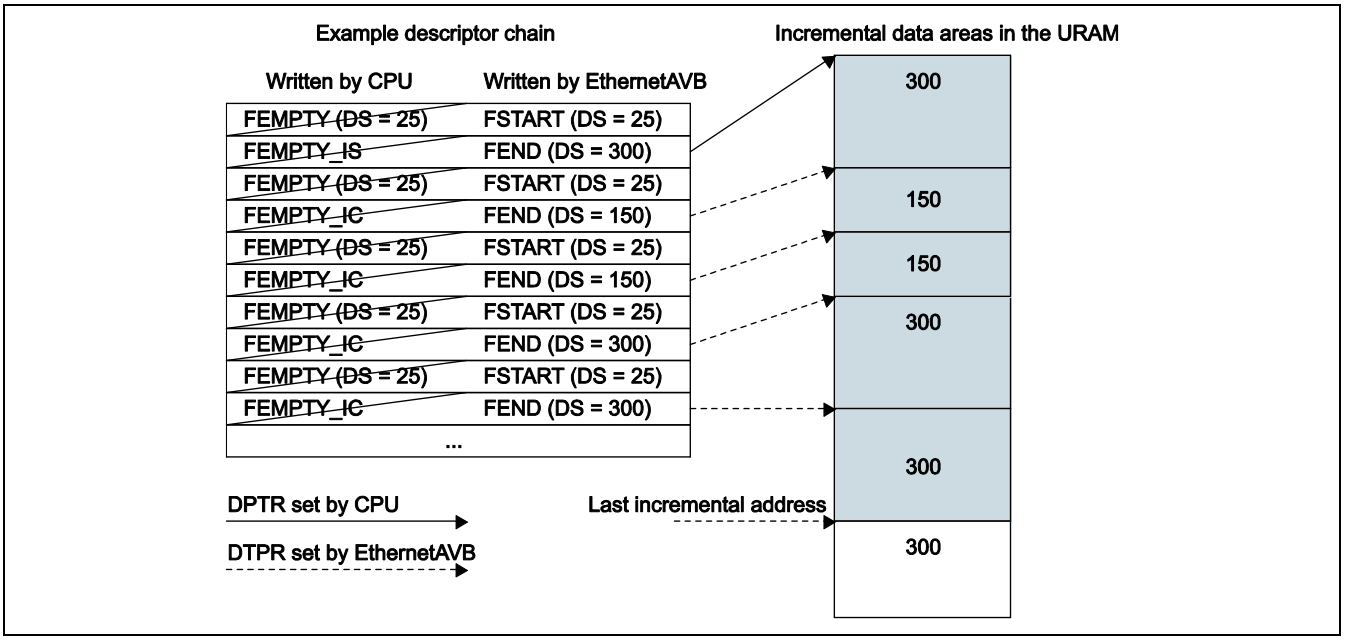

**Figure 100.1.3.4.9 Reception Queue Using a Common Incremental Data Area**

As Figure 100.1.3.4.9 shows, when data are stored in an incremental data area, the descriptor pointers in the FEMPTY_IC descriptors (DESCR.DPTR) are updated. Accordingly, the resulting FEND or FSINGLE descriptor is in the same format as after writing to an FEMPTY descriptor.

Software captures received data from an incremental data area, which has no empty storage areas between frame data. The only empty space is that at the end of the incremental data area. The sizes of incremental data areas and of blocks of data for storage in incremental data areas must be multiples of four bytes. When the amount of data for storage in an incremental data area is not a multiple of four bytes, from one to three bytes of empty space will be produced. DESCR.DS can be read to check for such empty spaces.

CPU cannot restrict directly the amount of received data stored by an incremental descriptor (FEMPTY_IS, FEMPTY_IC) as this is possible for other descriptors (FEMPTY, FEMPTY_ND) by DESCR.DS. Incremental descriptors store always all received data.

**Setting Up an Incremental Data Area**

A descriptor chain in the incremental data area having N descriptors (one FEMPTY_IS and N-1 FEMPTY_IC) means that the incremental storage area of N times of maximum frame size is needed.

As Figure 100.1.3.4.9 shows, DESCR.DPTR of an FEMPTY_IS descriptor indicates the base address of the incremental data area. The next FEMPTY_IS descriptor in the chain indicates the processing step where data must be stored in the incremental data area.

**Processing an Incremental Data Area Based on Descriptors**

Since data processing by the CPU is the same regardless of how the AVB-DMAC stores the data, data stored in an incremental data area do not require any special handling.

**Padding**

Use padding for received frame data that are not aligned correctly in the specified memory structure. Padding can be set individually for each descriptor. Accordingly, in the reception of divided frames, padding can be restricted to only those frames that require it (e.g. A/V payload data.)

Padding can also be used to optimize system performance in an incremental data area (e.g. to prevent inefficient access by aligning received data with 32-byte boundaries in the incremental data area), as well as to fulfill application-specific requirements for specified memory structures (e.g. formats required by other modules that will be processing the received data).

Padding can only be used in an incremental data area.

The value H'0000 0000 is always used in padding.

Padding is the addition of the number of words (from one to seven 32-bit words) set in the stored padding counter in the receive padding configuration register (RPC.PCNT). This padding is repeatedly inserted in accord with the value in the stored data counter (RPC.DCNT) (from one to 255 32-bit words). When the stored data counter (RPC.DCNT) reaches 0, however, padding is not repeated.

The first word of padding is always inserted at the position specified by DESCR.DPTR. When divided frames are in use, a padding word can be inserted at any byte position, and padding is handled on a 32-bit basis (e.g. an incremental data area where the first descriptor is for a 42-byte header data and the second descriptor holds padded payload data).

The next figure shows a general example of how padding is inserted and an example of setting up padding. A indicates frame data A received by the E-MAC, and B indicates the frame data stored in the descriptor data area (32-bit word units).

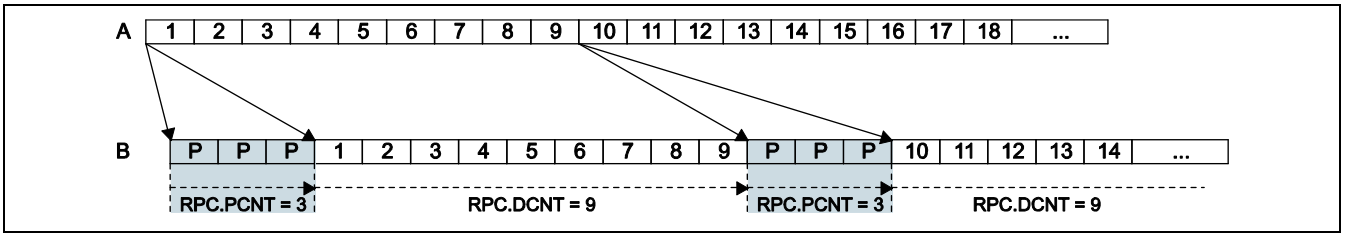

**Figure 100.1.3.4.10 Example of a Padding Setting**

Both padding and received frame data are counted in the descriptor size (DESCR.DS).

**(c) Mode with Write-Back**

Constructing a descriptor chain requires software (see Figure 100.1.3.4.11).

In the example in the figure, the variable SWdescr (software descriptor pointer) is a structure to identify a descriptor being processed. SWdescr must be initialized after operation mode is entered and a descriptor base address load request (DLR.LBAq) is executed (condition for starting the flow of software operations).

The frame_processing() function processes the stored data. The function can use SWdescr.DT to check whether processing of a frame is completed. How frame data are processed differs with the application, so create functions that handle processing in accord with the specification.

The processing section is common to all modes of reception. The number of frames processed in response to each trigger can be restricted. When multiple frames have to be processed in a batch, waiting for individual trigger boxes must be skipped for these frames.

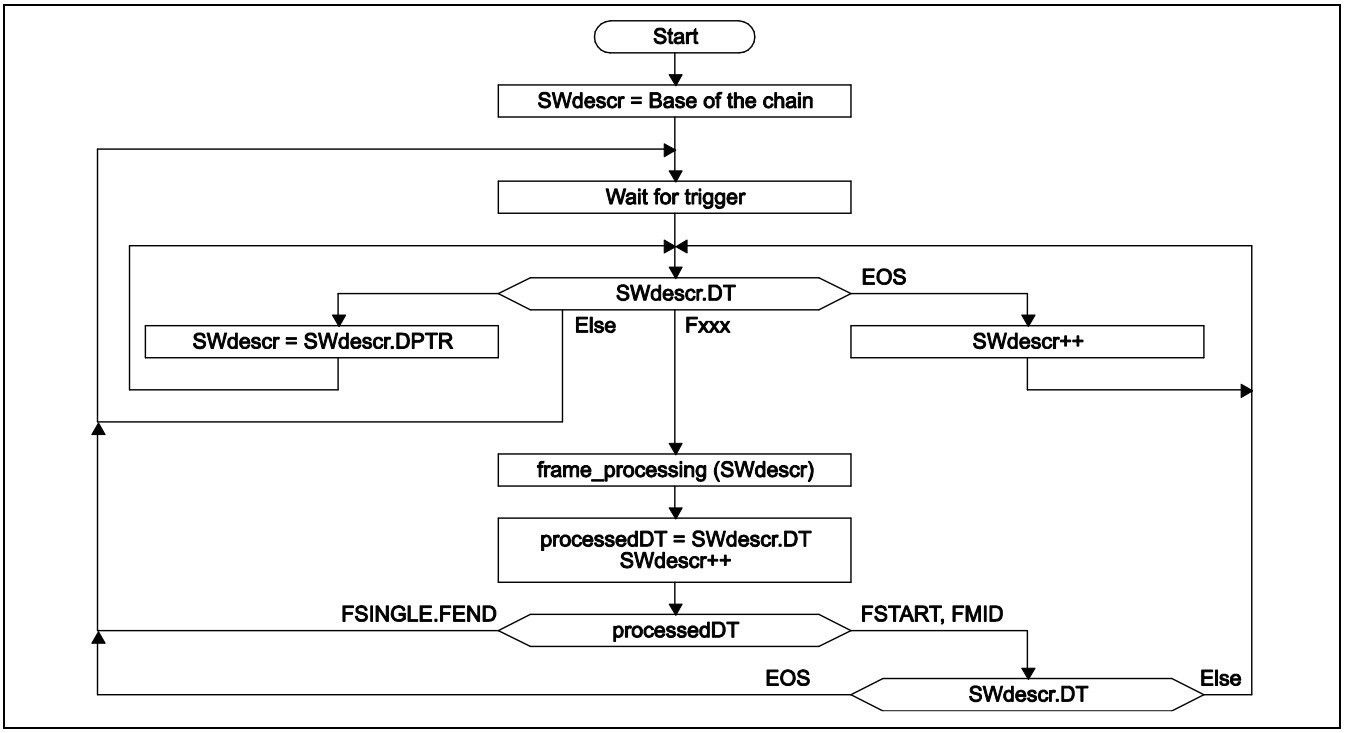

**Figure 100.1.3.4.11 Flow of Reception Descriptor Processing (with Write-Back)**

**(d) Support for Reception Time Stamps**

Capturing reception time stamps is essential for IEEE 802.1AS time synchronization. Other types of received frames may also require that a reception time stamp be appended; this depends on the application. The AVB-DMAC supports reception time stamps based on the gPTP timer by storing time stamps, which have been captured when Start Frame Delimiter (SFD) of a received frame is arrived, in the last frame data descriptor (FEND or FSINGLE). For the gPTP timer, see section 100.1.3.7(1) gPTP Timer.

When time stamps are to be stored, use extended descriptors for the entire reception queue. Furthermore, time stamps are always stored for reception queue 1 (network control). Time stamps for reception queue 0 (best effort) and reception queue r ($r \geq 2$; for stream data) can be selected by the time stamp enable bits in the receive configuration register (RCR.ETS0 or RCR.ETS2).

### (4) Unread Frame Counters

Each reception queue has an unread frame counter (UFCVi). Use the unread frame counter configuration bits in the receive queue configuration register (RQCi.UFCCr) to select from among the four warning and stop levels for each unread frame counter. The 0 setting disables the stop and warning functions. For how to set this up, see Figure 100.1.3.4.12.

Operations of the AVB-DMAC (hardware) and CPU (software) drive an unread frame counter (UFC) in the following ways.

- The hardware indicates that it has added a new frame to the descriptor chain for the queue (this increments the counter).
- Software indicates how many frames from the descriptor chain it has processed by writing to the corresponding bits of the unread frame counter decrement register for the queue (this decrements the register by the number written).

The unread frame counter is based on the number of frames stored in the URAM and is only incremented by one even when a received frame is divided into different descriptors. Failure in storing a descriptor chain requires care because this may unread frame counter may fail in synchronization as described in section 100.1.3.4(4)(a) Unread Frame (UFC) Synchronization Failure.

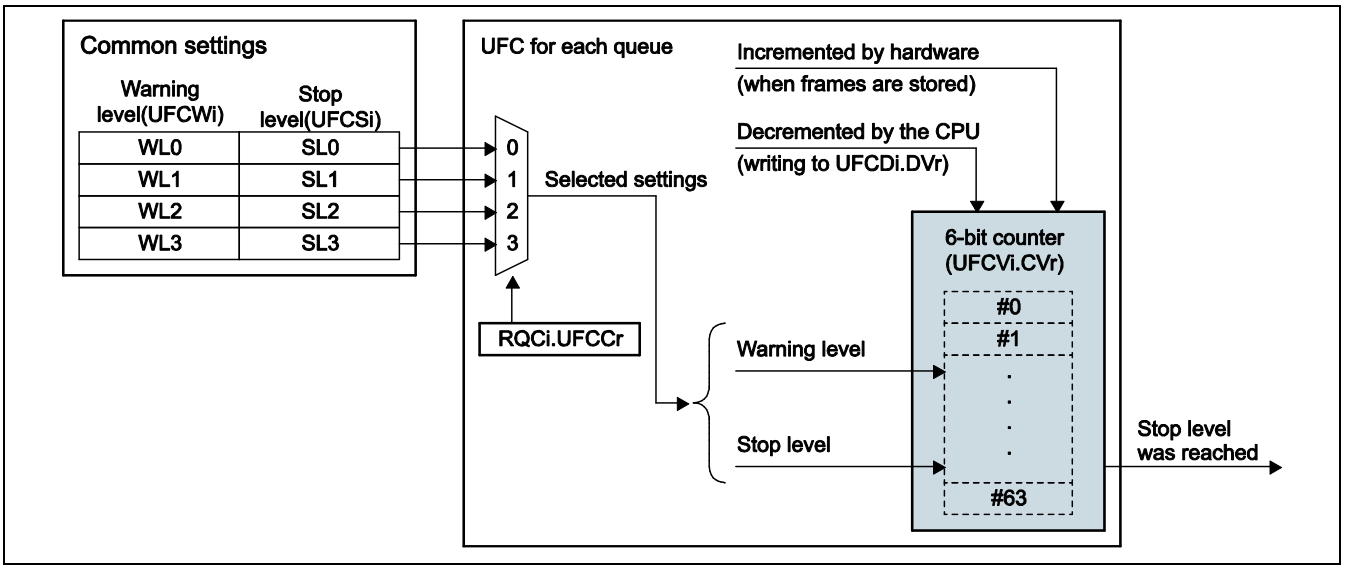

**Figure 100.1.3.4.12 Overview of an Unread Frame Counter**

Unless synchronization of hardware and software is lost, the current unread frame counter value (UFCVi.CVr) indicates the number of unread frames in the queue.

The indicator that the stop level has been reached prevents the storage of further received frames in the descriptor chain. Selecting 0 as the stop level disables this function. Otherwise, further received frames for the queue are discarded once its unread frame counter reaches the stop level. Activation of the unread frame counter stop function is indicating by setting of the receive queue full interrupt flag in the receive interrupt status register 2 (RIS2.QFFr).

Set the unread frame counter warning level configuration register (UFCW) and the unread frame counter stop level configuration register (UFCS) for each reception queue that will use the unread frame counter function while the current operating mode is configuration mode.

**(a) Unread Frame (UFC) Synchronization Failure**

The unread frame counters do not recognize failure to store a frame in the URAM. In other words, the AVB-DMAC increments the counter for a queue each time it captures a frame for that queue from the reception FIFO whether or not it succeeds in storing the frame normally in the descriptor chain.

In general, synchronization of hardware and software fails under the following conditions.

- An unread frame counter reaching its maximum value
  When the value of a counter in an unread frame counter register i (UFCVi) (i = 0 to 4) reaches 63, synchronization for the corresponding queue can fail.
  The CPU can only judge that a failure in synchronization has not occurred when the stop level is set to 63.
- A queue not having enough space for a descriptor
  In this case, the corresponding receive queue full interrupt flag (RIS2.QFFr) in receive interrupt status register 2 (RIS2) is set.
  If an unread frame counter reaches its stop level while synchronization remains normal, the receive queue full interrupt flag (RIS2.QFFr) in the receive interrupt status register 2 (RIS2) is set. Software must respond to this.
- A problem occurring during access to memory

The result of a failure in synchronization is the unread frame counter indicating that the corresponding descriptor chain may contain more available frames than it actually can. To retrieve the correct starting point for operations, use the descriptor base address load request (DLR.LBAq) for the given queue.

### 100.1.3.5 Transmission Control

Areas in the URAM for storing transmission descriptors must also be secured (for descriptors, see section 100.1.3.3 Descriptors).

The AVB-DMAC fetches data from the URAM in accord with the procedure the descriptor describes. The descriptor also retains tag information once the frame has been fetched for transmission. The tag information is used to maintain the relationships between status and time stamps for the software and the AVB-DMAC. The status and time stamp information for transmitted frames remains accessible after their transmission is completed.

#### (1) Transmission Modes

The AVB-DMAC has two modes of transmission.

- AVB transmission mode
  This mode is selected by the priority level setting for the transmission queue in the transmit configuration register (setting of the {TGC.TQP, TGC.ECBS} bits) being B'01 or B'11.
- Non-AVB transmission mode
  This mode is selected by the priority level setting for the transmission queue in the transmit configuration register (setting of the {TGC.TQP, TGC.ECBS} bits) being B'00.

**(a) AVB Transmission Mode**

AVB transmission supports the control of traffic through the output port to implement various traffic classes.

**Support for Traffic Classes and Associated Priority**

When transmission is in AVB transmission mode, streams of traffic are transmitted in accord with the part of the AVB specification called Forwarding and Queuing for Time Sensitive Streams (FQTSS; for details on this, see the IEEE 802.1Q standard).

In the AVB specification, at least one queue for a reserving stream under the Stream Reservation Protocol (SR stream) and at least one queue for a non-SR stream are present, and the queues for SR traffic is Highest priority queue.

The AVB-DMAC supports four traffic classes: SR class A, SR class B, network control (NC) traffic (gPTP frames), and best effort (BE) traffic. Allocating a specific queue to network control (NC) frames ensures the control of synchronization.

The AVB-DMAC realizes compliance with the AVB standards by handling queues with the following architecture (in terms of traffic classes).

- Four transmission queues (Q3, Q2, Q1, and Q0) are available.
- Q3 and Q2 are for SR streams (one each for class A and class B).
- Q1 is for low-bandwidth network control (NC) traffic (gPTP frames)
- Q0 is for other types of traffic (MSRPDU*1, MVRPDU*2, best effort (BE), etc.)

Notes: 1. MSRPDU: Multiple Stream Registration Protocol Data Unit
2. MVRPDU: Multiple VLAN Registration Protocol Data Unit

Fetching from queues proceeds in order of priority of the above traffic types. Three systems of priority are available through the setting of the transmit queue priority bit and enable credit based shaping bit in the transmit configuration register (TGC.TQP and TGC.ECBS). In the default priority scheme, which is called AVB mode 1 (selected by {TGC.TQP, TGC.ECBS} = B'01), operation of the AVB-DMAC is fully in accord with the AVB specification. AVB mode 2 (transmit queue priority bits {TGC.TQP, TGC.ECBS} = B'11) is an alternative priority scheme and varies from the AVB specification. Using this scheme thus requires more care. The other setting is for non-AVB-mode transmission.

**Table 100.17 Default and Alternative Priority Orders in AVB Transmission Mode**

| Priority Schemes (AVB Mode) | Priority Order of Queues |
|---|---|
| Default | Q3 (SR class A) > Q2 (SR class B) > Q1 (NC) > Q0 (BE) |
| Alternative | Q1 (NC) > Q3 (SR class A) > Q2 (SR class B) > Q0 (BE) |

**Transmission Selecting Algorithm and CBS**

The algorithm the AVB-DMAC applies to select frames for transmission is in accord with the specifications under section 8.6.8, Transmission selection, of the IEEE 802.1Q standard. For AVB mode, the CBS (credit-based shaping) algorithm is applied to the class A and class B SR queues (Q3 and Q2). Use of the CBS enables correct handling of the priorities of transmission from the SR queues. For the CBS algorithm, see section 100.1.3.6 CBS (Credit-Based Shaping).

When the following conditions both hold, transmission from an SR queue (Q3 or Q2) proceeds at the specified time.

- The queue contains at least one frame ready for transmission.
- The queue has available credit.
- Unless an SR queue satisfies the above conditions, a higher priority queue is not present (not ready for transmission).

A non-SR queue (Q1 or Q0) is selected if the conditions below both hold.

- The queue contains at least one frame ready for transmission.
- As well as the above condition, a higher priority queue is not present (not ready for transmission).

Figure 100.1.3.5.1 and Figure 100.1.3.5.2 are flowcharts of selection for transmission in AVB mode 1 (default) and AVB mode 2 (alternative).

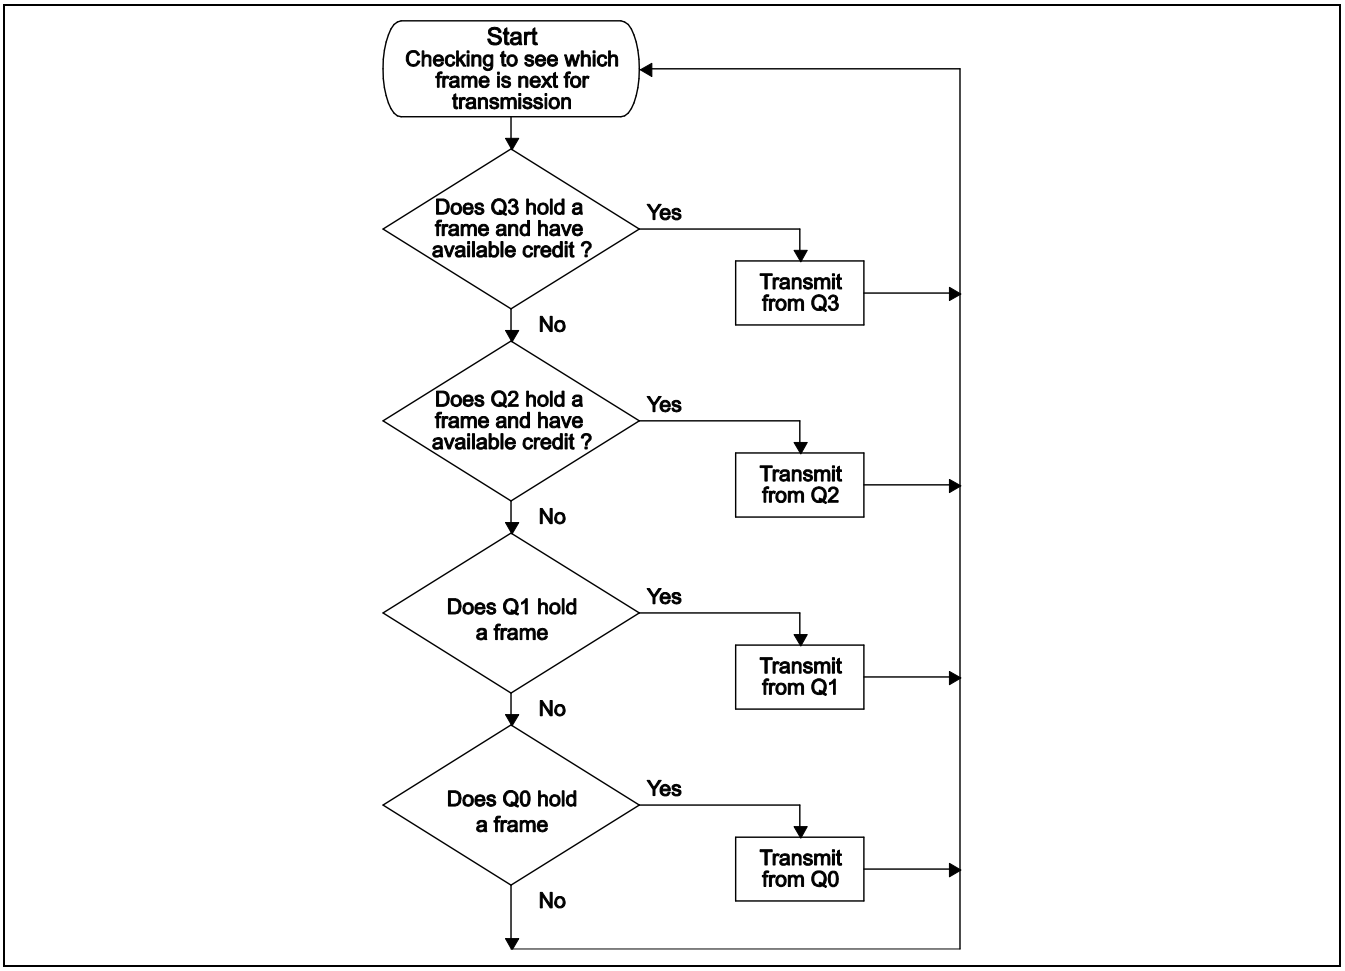

**Figure 100.1.3.5.1 Flow of Selection for Transmission in AVB Mode 1 (Default)**

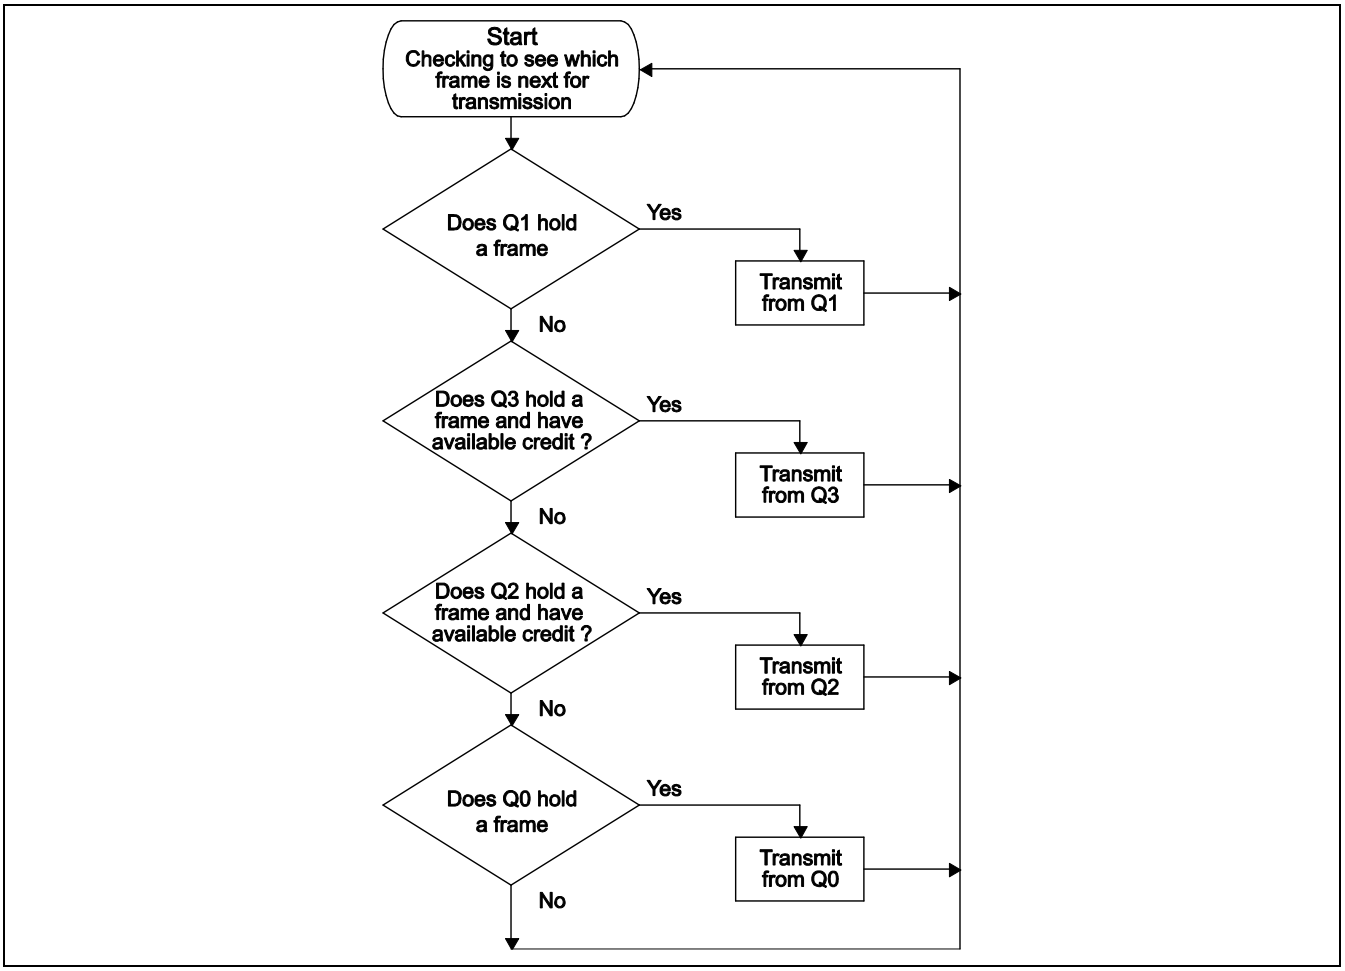

**Figure 100.1.3.5.2 Flow of Selection for Transmission in AVB Mode 2 (Alternative)**

**(b) Non-AVB Transmission Mode**

In non-AVB transmission mode, an absolute priority scheme is used. The SR class is not supported and the CBS algorithm is not used.

In non-AVB transmission mode (when the transmit queue priority bit and enable credit based shaping bit in the transmit configuration register {TGC.TQP, TGC.ECBS} are B'00), data is fetched for transmission in a strict order of priority (Q3 > Q2 > Q1 > Q0).

Figure 100.1.3.5.3 shows the flow of selection in non-AVB transmission mode.

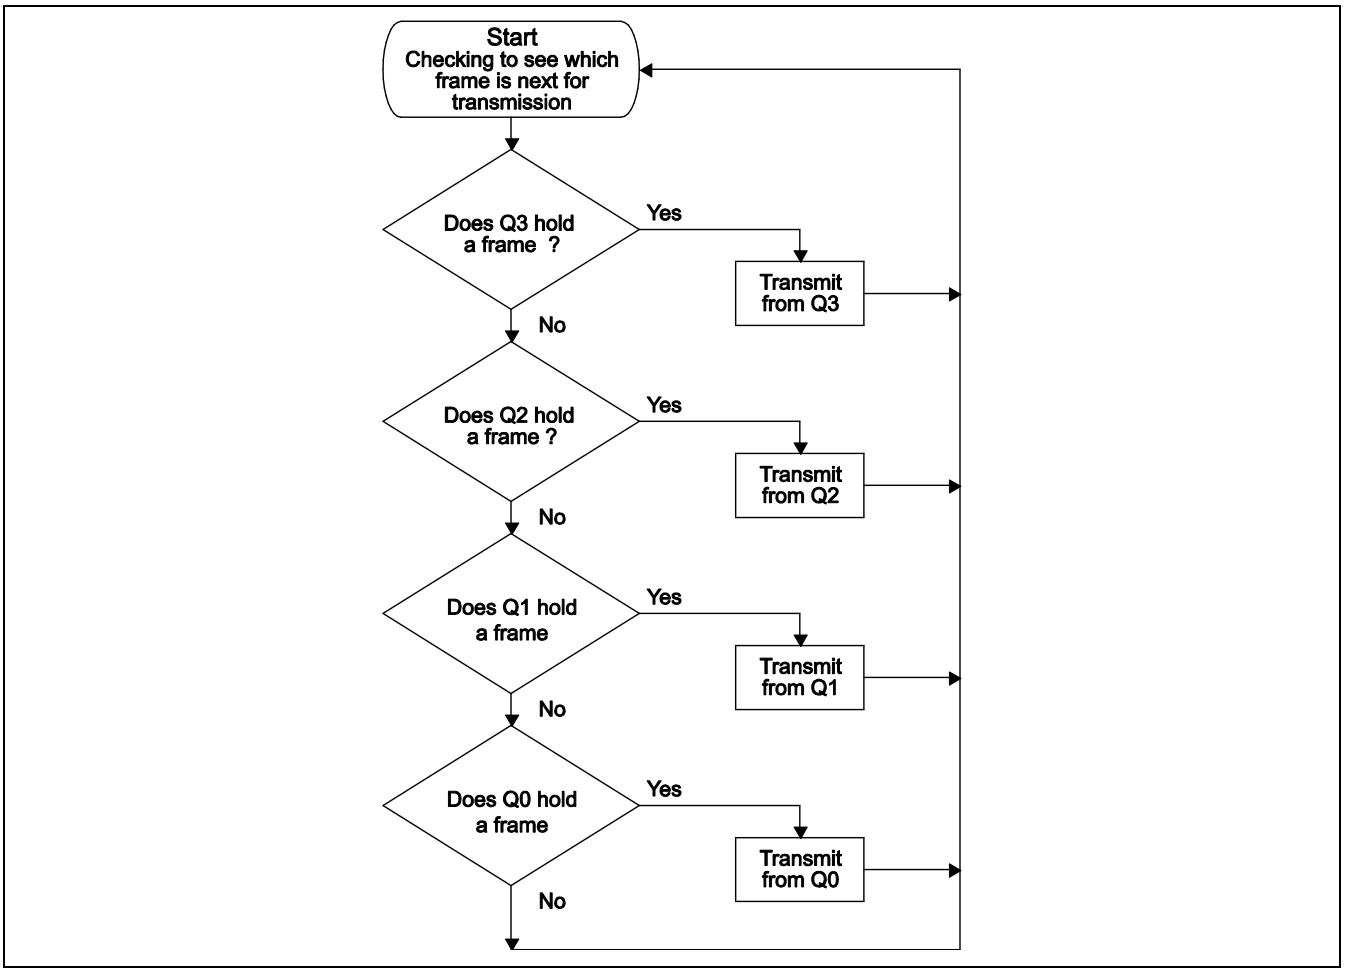

**Figure 100.1.3.5.3 Flow of Selection for Transmission in Non-AVB Mode**

**(c) Setting the Size of the Transmission FIFO**

The transmission FIFO is made up of 122 clusters. Each cluster can hold up to 128 bytes.

The size of the part of the transmission FIFO for use by each of the four transmission queues can be set by the corresponding transmit queue configuration q bits in the transmit control register (TGC.TBDq). The setting of TGC.TBDq is fixed to 2.

**General Usage Examples:**

Q0: Frames containing up to 1500 bytes → 1500/128 = 11.7 → 12 clusters
Q1: Frames containing up to 1024 bytes → 1024/128 = 8.0 → 8 clusters
Q3: Frames containing up to 1996 bytes → 1996/128 = 15.6 → 16 clusters
Q4: Frames containing up to 1996 bytes → 1996/128 = 15.6 → 16 clusters
When the depth of all transmission queues is 2, only the following number of clusters is required.
$2 \times (12 + 8 + 16 + 16) + 16 = 2 \times 52 + 16 = 120$

In the worst case (each of the transmission queues holds 1996 bytes), $2 \times 64 + 16 = 144$ clusters are required, so the maximum length of transmission frames must be less than 1996 bytes for some queues.

### (2) Setting Up Transmission Descriptors

#### (a) Transmission Descriptor Type

The type of a descriptor is defined by the descriptor type (DESCR.DT) field.

Table 100.18 shows the descriptor types used in transmission.

**Table 100.18 Descriptor Types in Transmission**

| Descriptor Type (DESCR.DT) | Operation | Write-back |
|---|---|---|
| Frame Start (FSTART) | The AVB-DMAC fetches the first of the data for the divided frame and proceeds to processing of the next descriptor. | FEMPTY |
| Frame Middle (FMID) | The AVB-DMAC fetches the second or subsequent data for the divided frame and proceeds to processing of the next descriptor. | FEMPTY |
| Frame End (FEND) | The AVB-DMAC fetches the last of the data for the divided frame.<br>The frame of data that has been fetched to the transmission FIFO is ready for transmission by the E-MAC, and then the AVB-DMAC proceeds to processing of the next descriptor. | FEMPTY |
| Frame Single (FSINGLE) | The AVB-DMAC fetches the frame of data.<br>The frame of data that has been fetched to the transmission FIFO is ready for transmission by the E-MAC, and then the AVB-DMAC proceeds to processing of the next descriptor. | FEMPTY |
| Link (LINK) | Processing proceeds to the descriptor specified by DESCR.DPTR. | LEMPTY |
| Fixed Link (LINKFIX) | Same as LINK | Not changed |
| End Of Set (EOS) | This is a transmission stop point defined by software<br>This leads to clearing of the transmit start request bit (TCCR.TSRQt), which stops transmission.<br>When the TCCR.TSRQt is again set to 1 (a new transmission start request is issued), processing proceeds to the next descriptor. | EEMPTY |
| Frame Empty (FEMPTY) | No frame data are ready for transmission<br>This leads to clearing of the transmit start request bit (TCCR.TSRQt), which stops transmission.<br>When the TCCR.TSRQt is again set to 1 (a new transmission start request is issued), processing starts at this descriptor. | Not changed |
| Link Empty (LEMPTY) | Same as FEMPTY | Not changed |
| EOS Empty (EEMPTY) | Same as FEMPTY | Not changed |

**(b) Configuration of Transmission Frame Data Descriptors**

Figure 100.1.3.5.4 shows the configuration of descriptors for use with transmission queues. The transmission-specific fields (DESCR.MSR, DESCR.TSR, and DESCR.TAG) are described in Table 100.19.

For the other fields and the descriptor types, see section 100.1.3.3(6) Descriptor Type.

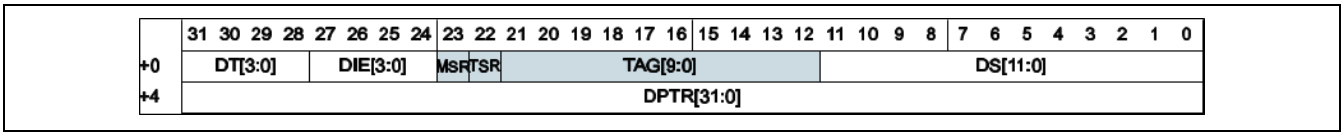

**Figure 100.1.3.5.4 Configuration of Descriptor for a Transmitted Frame**

**Table 100.19 Configuration of a Transmission Descriptor**

| Bit Name | Function |
|---|---|
| MSR | MAC Status storage Request<br>This bit configures if E-MAC transmission status of the frame is stored in E-MAC status FIFO.<br>0b: No status information is stored<br>1b: Status information is to be kept for this frame in MAC status FIFO<br>This bit is considered only if DESCR.DT = FEND or FSINGLE.<br>Note: If there is error during transmission of frame by E-MAC then status is always stored. |
| TSR | Time Stamp Store Request<br>This bit specifies whether the transmission time stamp is to be stored within the EthernetAVB-IF module.<br>0: The time stamp status FIFO within the EthernetAVB-IF module does not retain a transmission time stamp.<br>1: The time stamp status FIFO within the EthernetAVB-IF module retains a transmission time stamp.<br>This bit is available while the current DESCR.DT is FEND or FSINGLE. |
| TAG | Frame Tag<br>This TAG field is used to associate each frame data with a time stamp. Frame TAG is not required but is recommended.<br>This bit is available while the current DESCR.DT is FEND or FSINGLE. |

For the time stamp FIFO function, see section 100.1.3.5(4) Time Stamping in Transmission.

### (3) Transmission

#### (a) Transmitting Frames

Setting the transmit start request bit in the transmit configuration control register (TCCR.TSRQt) starts the transfer of frames from the corresponding transmission queue.

The descriptor in the current descriptor address (CDARq.CDA) for the queue t (with q = t) is read first.

If this descriptor is a descriptor for frame transmission (FSINGLE, etc.), the AVB-DMAC fetches the frame data from the data area indicated by the descriptor, writes FEMPTY back to the descriptor type (DESCR.DT) bits to indicate completion of this processing, then proceeds to processing of the next descriptor.

If the descriptor is not for transmission, processing is as dictated by the given descriptor (for these descriptors, see the descriptions in section 100.1.3.3 Descriptors).

If a base address load request is issued for a descriptor chain while it is being processed (by setting 1 in the LBAq bit for transmission queue q that is currently being processed in the descriptor base address load request register, DLR), processing proceeds to the new descriptor chain. Changing the chain does not interrupt frame fetching, but note that frames that have not been fetched from the old chain remain where they are.

Figure 100.1.3.5.5 shows descriptor processing during transmission.

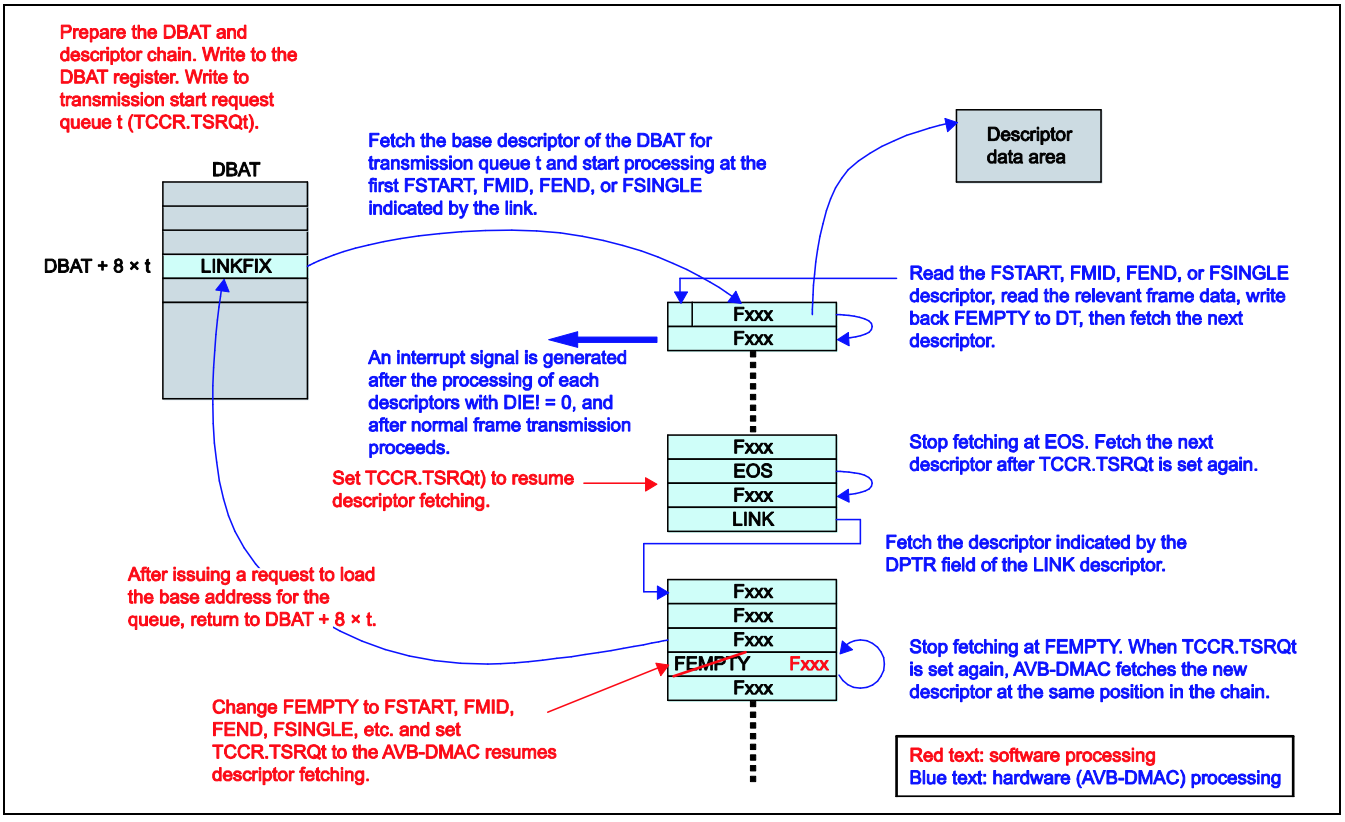

**Figure 100.1.3.5.5 Descriptor Processing During Transmission**

**(b) Examples of Descriptor Usage**

**Immediate Frame Transmission**

Immediate frame transmission is a pattern in which fetching by the AVB-DMAC starts whenever software adds data to a queue. FEMPTY descriptors are used as stop points to keep the hardware and software in synchronization.

Create descriptor chains that have FEMTPY descriptors at the stop points.

Figure 100.1.3.5.6 shows the flow for software implementing this pattern. SW should read back written descriptor between changing FEMPTY descriptor before writing to TCCR.TSRQt.

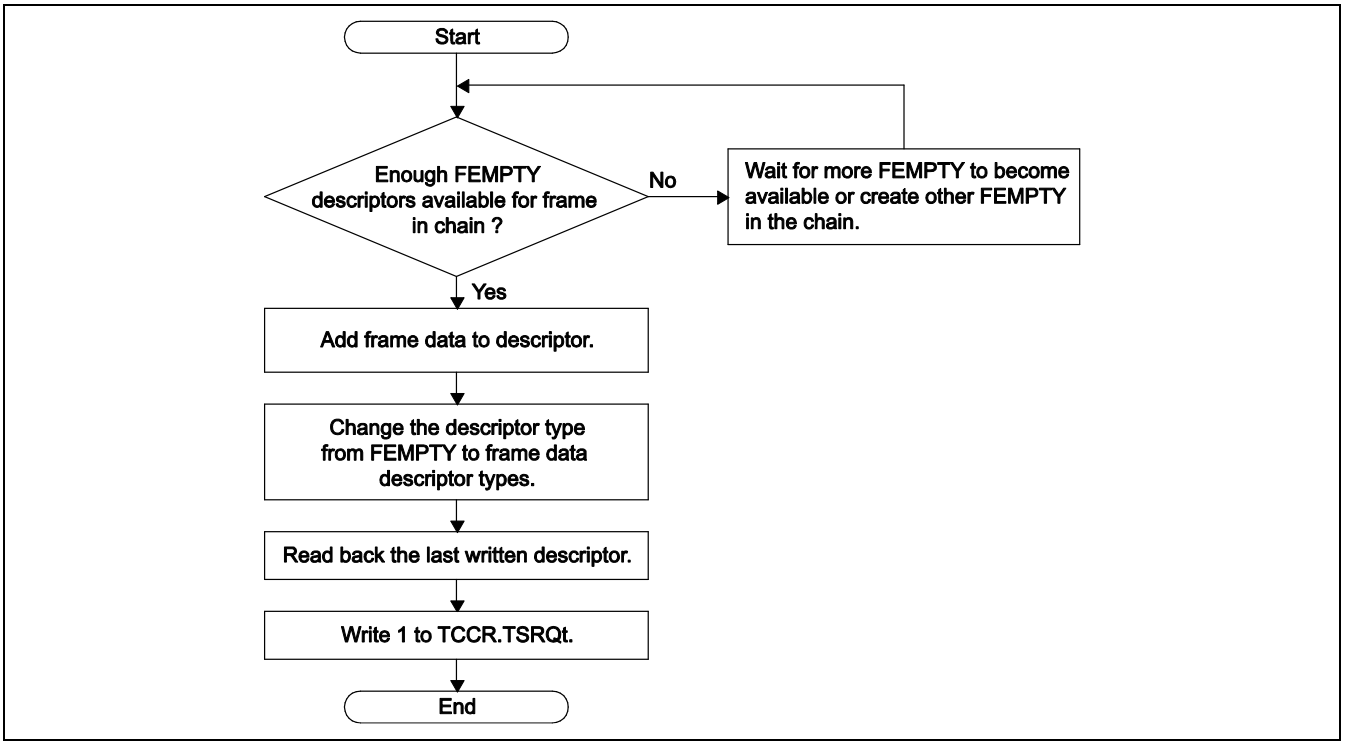

**Figure 100.1.3.5.6 Software Flow for Immediate Frame Transmission**

Figure 100.1.3.5.7 shows software and AVB-DMAC operations for immediate frame transmission.

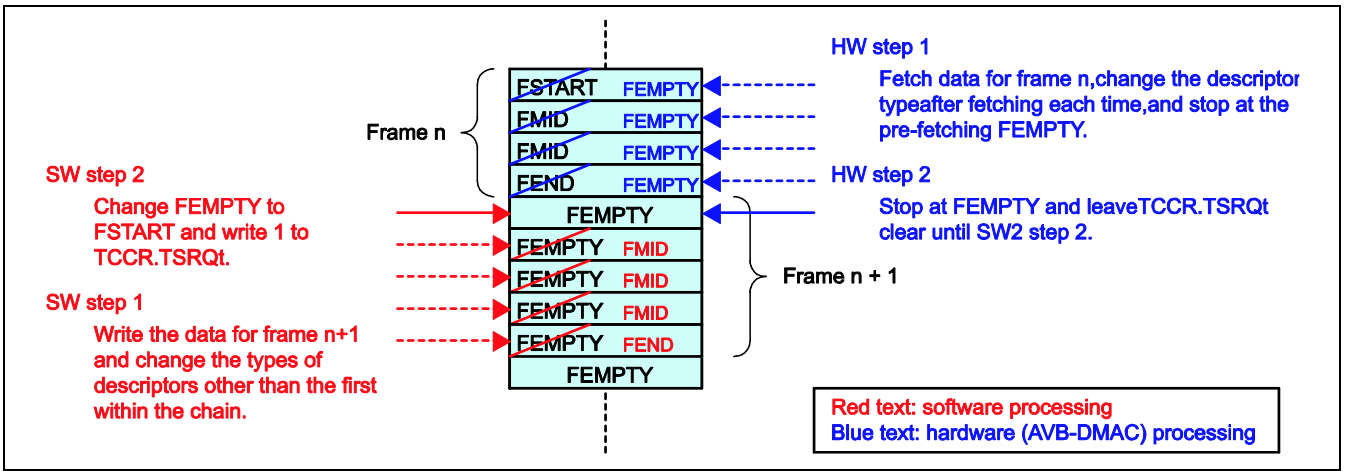

**Figure 100.1.3.5.7 Software and AVB-DMAC Operations for Immediate Frame Transmission**

**Frame Set Transmission with Changing of the Active Descriptor Chain**

This pattern is used when data are transmitted with a delay for software control to secure bandwidth or for other reasons, rather than immediately transmitted. EOS descriptors are used for the stop points. Start by creating a descriptor chain that has a FEMPTY descriptor as its stop point.

Figure 100.1.3.5.8 shows the software flow in this pattern.

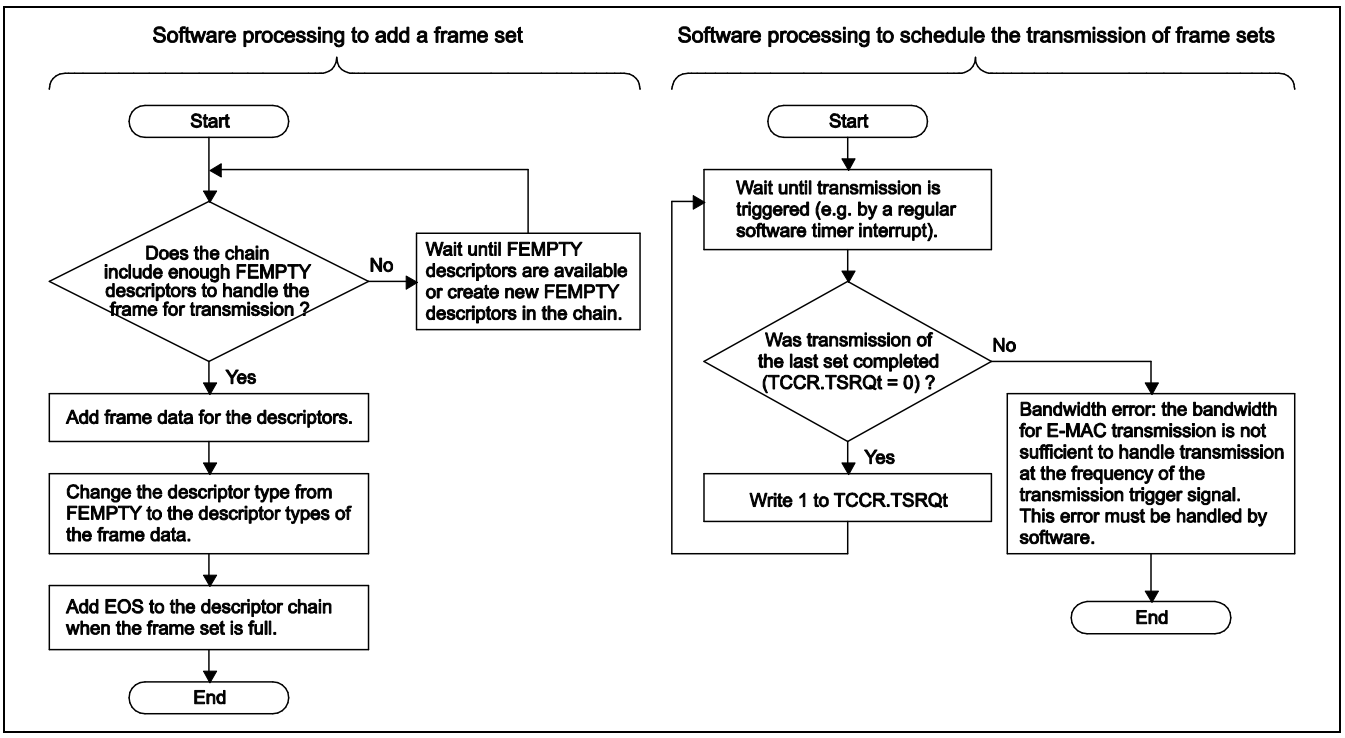

**Figure 100.1.3.5.8 Software Flow for Frame Set Transmission with Changing of the Active Descriptor Chain**

Figure 100.1.3.5.9 shows software and AVB-DMAC operations for frame set transmission.

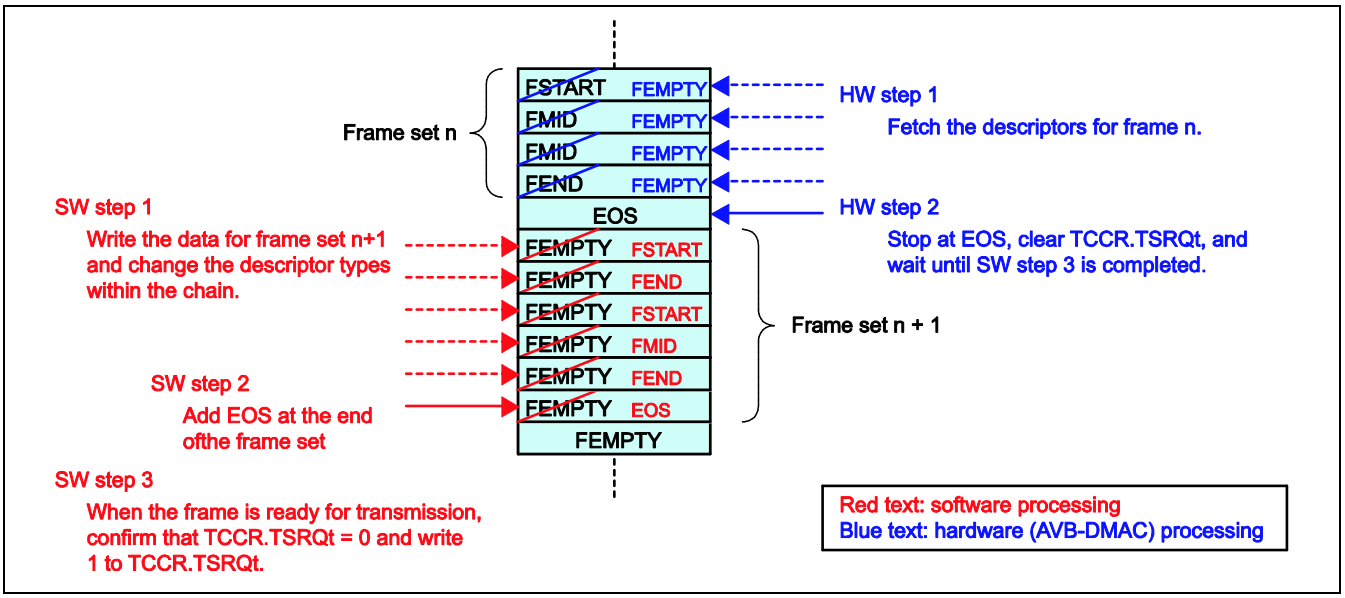

**Figure 100.1.3.5.9 SW and AVB-DMAC Operations for Frame Set Transmission with Changing of the Active Descriptor Chain**

**Frame Set Transmission Using a Shadow Descriptor Chain**

This pattern is used when data are transmitted with a delay for software control to secure bandwidth or for other reasons, rather than immediately transmitted. Two or more descriptor chains are used. The chains are classified as active or shadow chains. EOS descriptors are used for the stop points.

Create descriptor chains that have FEMPTY descriptors at the stop points.

Figure 100.1.3.5.10 shows the flow for software implementing this pattern.

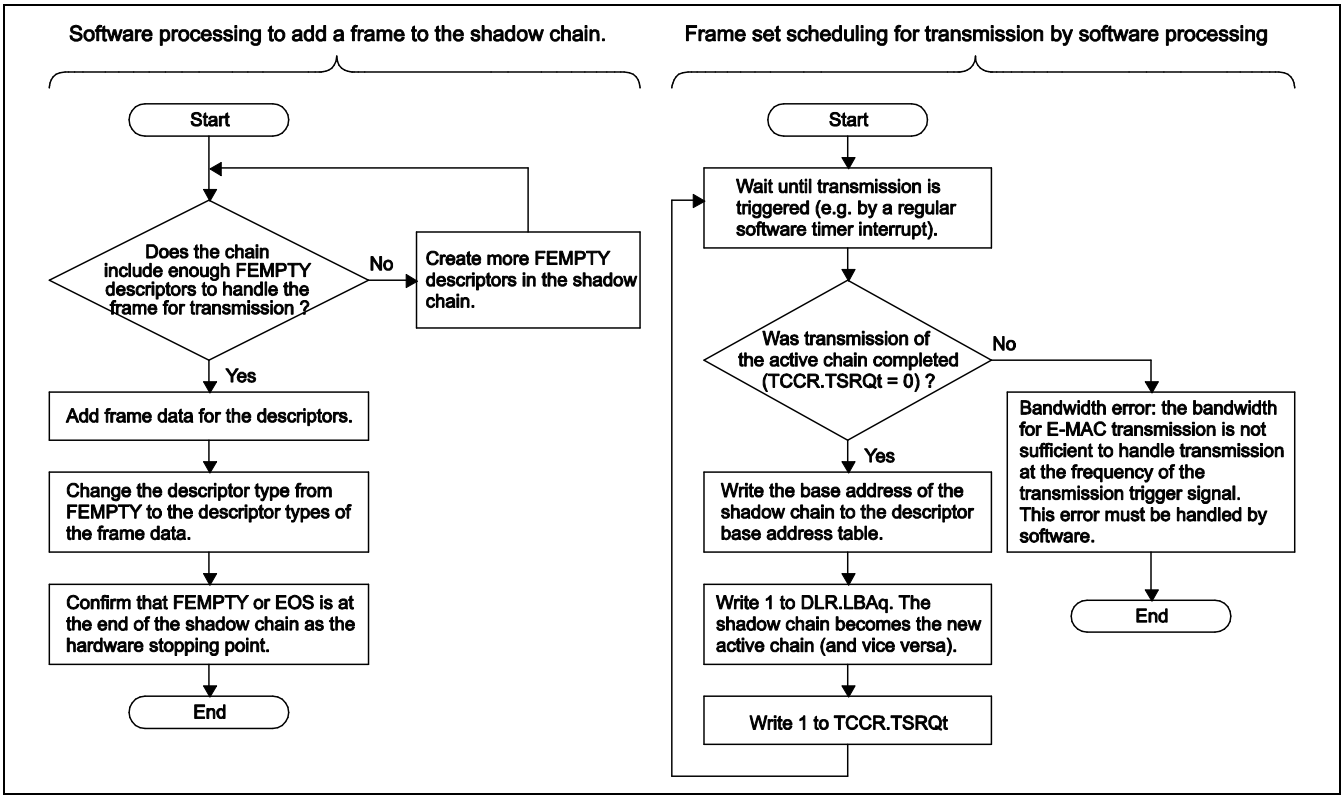

**Figure 100.1.3.5.10 Software Flow for Frame Set Transmission Using the Shadow Descriptor Chain**

Figure 100.1.3.5.11 shows software and AVB-DMAC operations for frame set transmission.

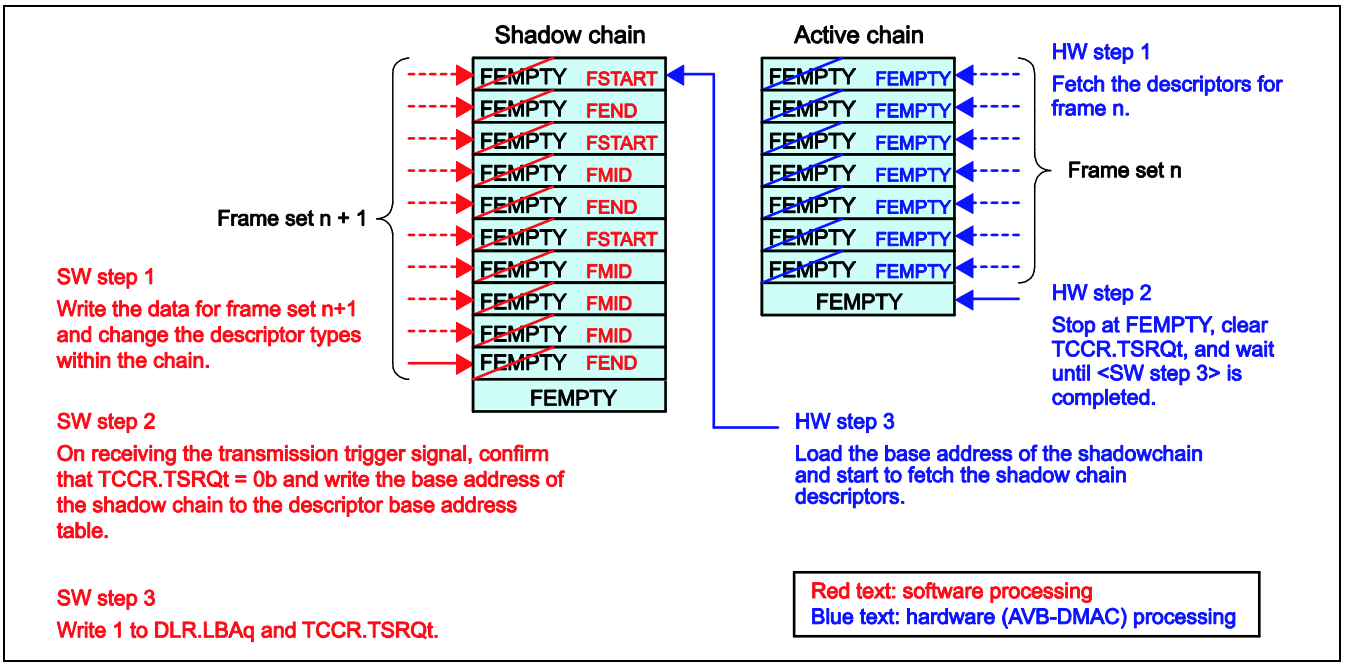

**Figure 100.1.3.5.11 SW and AVB-DMAC Operations for Frame Set Transmission Using the Shadow Descriptor Chain**

### (4) Time Stamping in Transmission

Transmission time stamps are important in satisfying the requirements for timing and synchronization of the IEEE 802.1AS standard. Reference to this information can also be useful to other applications and in testing. The AVB-DMAC supports the storage of time stamps for transmitted frames. The time-stamp values are based on the gPTP timer and are captured at the same time as sending of the Start of Frame Delimiter (SFD) for transmitted frames.

When the time stamp storage request field (DESCR.TSR) is set to 1, selecting storage of a time stamp, the tag number defined in the tag field (DESCR.TAG) of the last descriptor (FEND or FSINGLE) for the frame being transmitted is stored with the time stamp. This eases identification and association. The time-stamp FIFO is accessible at any time.

Figure 100.1.3.5.12 shows the mechanism supporting transmission time stamping.

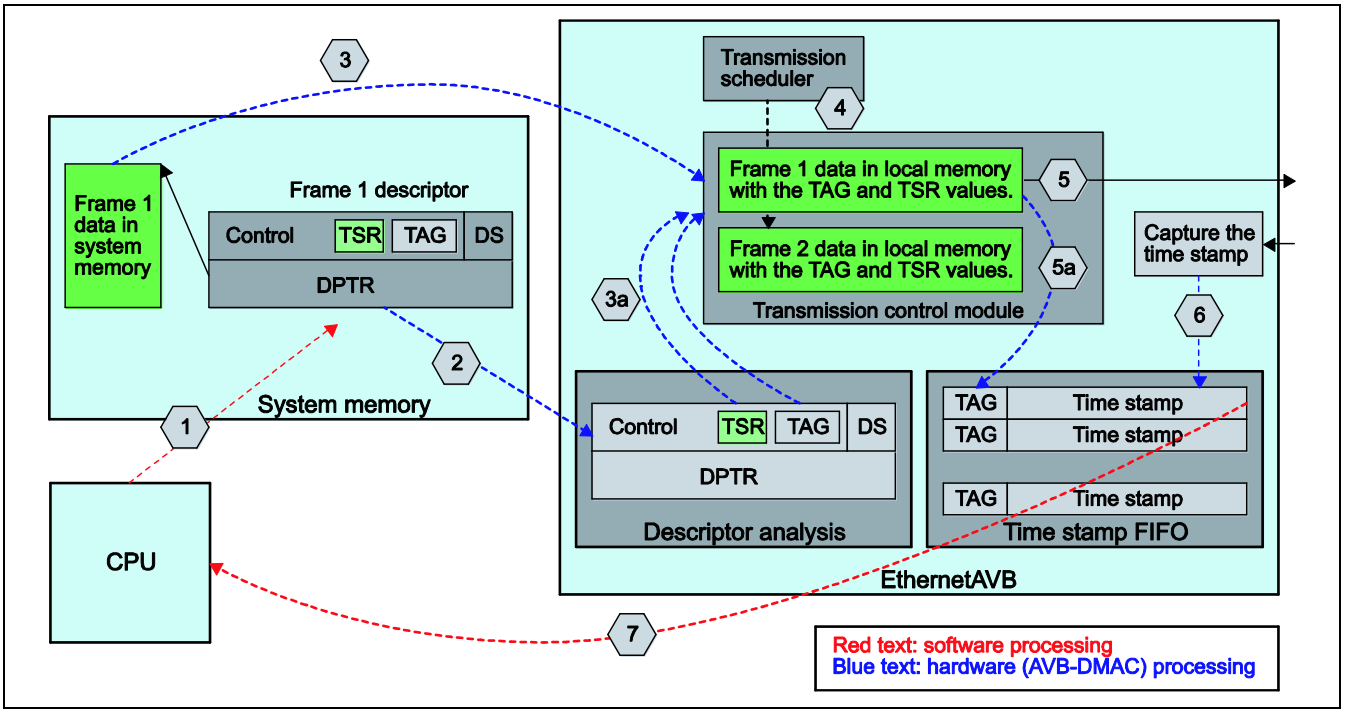

**Figure 100.1.3.5.12 Mechanism to Support Transmission Time Stamps**

The method of using this function is described below:

1. Secure space in the URAM for the frame requiring time stamping.
   Write the tag number of the frame to the frame tag field (DESCR.TAG) and set the time stamp storage request field (DESCR.TSR) to 1.
2. The AVB-DMAC fetches and analyzes the descriptor. The time stamp storage request field (DESCR.TSR) is 1, so it recognizes that transmitting this frame also requires storage of the time stamp.
3. The AVB-DMAC fetches the data for frame 1 and temporarily stores the frame in internal memory for scheduling.
   3a: The frame tag field (DESCR.TAG) and time stamp storage request field (DESCR.TSR) are stored with the fetched data.)
4. Under the control of priority settings according to credit-based shaping (CBS) or another scheme, the transmission scheduler decides it is time to transmit frame 1.
5. Transmission of frame 1 starts.
   5a: Frame 1's tag is stored in the time-stamp FIFO.
6. The gPTP time stamp is captured at the start of frame delimiter (SFD) for transmission and stored with the tag in the time-stamp FIFO when the frame is completely transmitted. An interrupt is generated to indicate existence of new timestamp information. For this to happen, the descriptor interrupt control register (DIC) must be set beforehand.
7. The entry can now be read from the time-stamp FIFO.

Use the time-stamp FIFO for the timing and synchronization of frames with IEEE 802.1AS compliance.

Time stamping can also be used with other frames, but take care not to allow the time-stamp FIFO to overflow. When the FIFO is full, further time stamps supplied to it are lost.

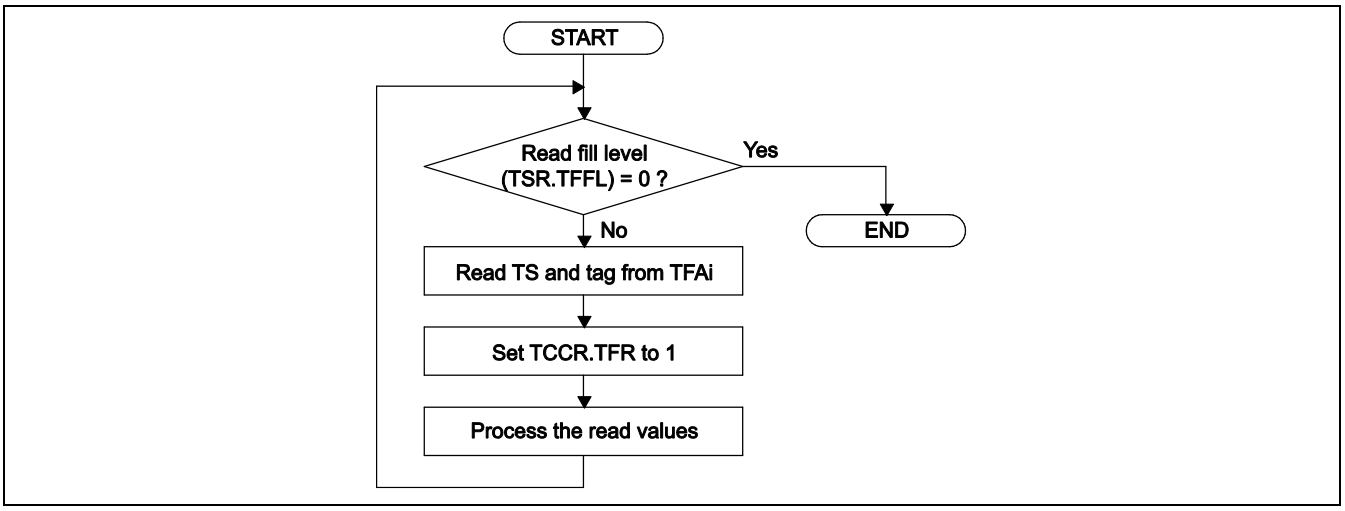

**Figure 100.1.3.5.13 Flow of Transmission Time Stamping**

### (5) Ending Transmission

Figure 100.1.3.5.14 shows the procedure for ending transmission.

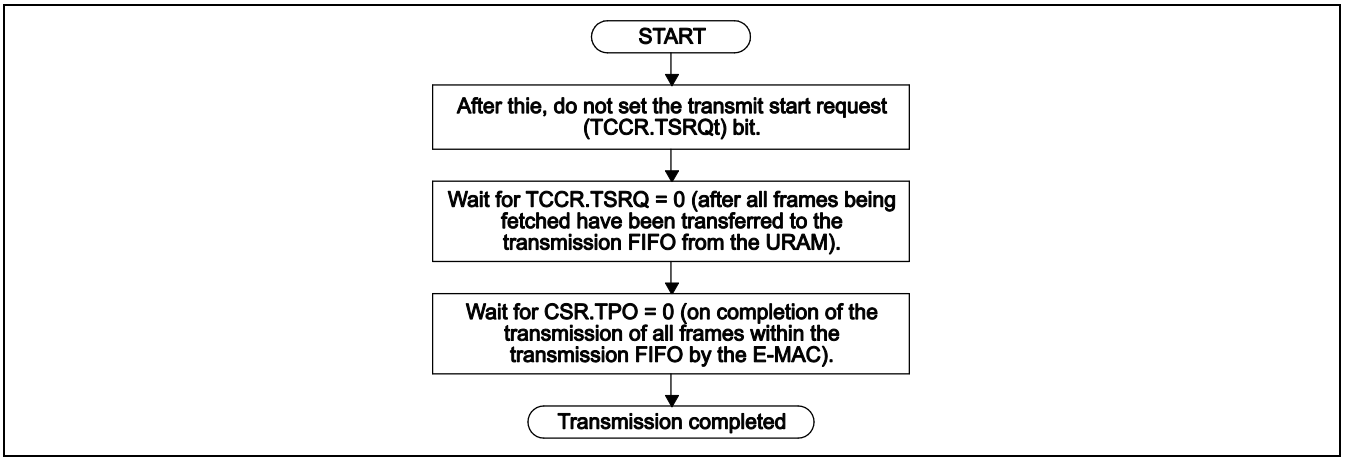

**Figure 100.1.3.5.14 Procedures for Ending Transmission**

### 100.1.3.6 CBS (Credit-Based Shaping)

In AVB transmission mode (i.e. when the transmit queue priority bit and enable credit based shaping bit in the transmit configuration register {TGC.TQP, TGC.ECBS} are B'01 or B'11), transmission queues Q3 and Q2 are respectively assigned to class A and class B stream traffic and the CBS (Credit Based Shaping) algorithm is used to select the transmission queues in order to satisfy the Forwarding and Queuing for Time Sensitive Streams (FQTSS) specification (see section 8.6.8 or section 34 in IEEE 802.1Q).

The CBS algorithm is based on the concept of transmission credit for each queue. Credit can be thought of as the degree to which a queue has the “right” to transmit at a given time. Actually, in AVB transmission mode as specified in IEEE 802.1Q, queues that are subject to the CBS algorithm are able to transmit when the following conditions are met.

At least one frame is stored in the queue.

The credit for the queue is 0 or a positive value.

The credit for a transmission queue is incremented while one or more frames from the queue are present in the transmission FIFO but transmission of these frames is not proceeding. This state is indicated by the transmission process status bit for queue t in the AVB-DMAC status register (CSR.TPOt). The credit is decremented while transmission of a frame from the queue is in progress. This mechanism is used to control transmission so that the transmission of frames from the queues for each of the traffic classes does not exceed the specified maximum bandwidths.

IEEE 802.1Q defines the following parameters for queues under the control of the CBS algorithm.

**portTransmitRate:** Maximum transmission data rate of an external port. The E-MAC determines this parameter.

**bandwidthFraction:** Maximum fraction of portTransmitRate that can be used for a queue.

**idleSlope**: Rate of change of credit for a queue when transmission of frames from the queue is not proceeding so the credit value (in bits per second) is increasing. idleSlope is also equal to the maximum fraction of the total bandwidth (portTransmitRate) that is available to the given queue under a specified condition (frames from the queue can be placed in a continuous stream. See Annex L of IEEE 802.Q.
idleSlope = bandwidthFraction × portTransmitRate

**sendSlope**: Rate of change of credit for a queue while transmission of a frame from the queue is in progress so the credit value is decreasing.
The value of sendSlope is defined as follows:
sendSlope = idleSlope – portTransmitRate

Furthermore, the values below are used to define individual traffic classes (or queues for the classes) under control of the algorithm. See Annex L of IEEE 802.Q.

**maxFrameSize:** Maximum size of frames (in bits) of the corresponding traffic class that can be transmitted from a port

**maxInterferenceSize:** Maximum burst size (in bits) by which delays for the corresponding traffic class can be allowed

**hiCredit:** Maximum credit value (positive number). Can be calculated by using the following equation: hiCredit = maxInterferenceSize × (idleSlope / portTransmitRate)

**loCredit:** Minimum credit value (negative number). Can be calculated by using the following equation:
loCredit = maxFrameSize × (sendSlope / portTransmitRate)

Figure 100.1.3.6.1 shows how the CBS algorithm works and the meaning of the above parameters.

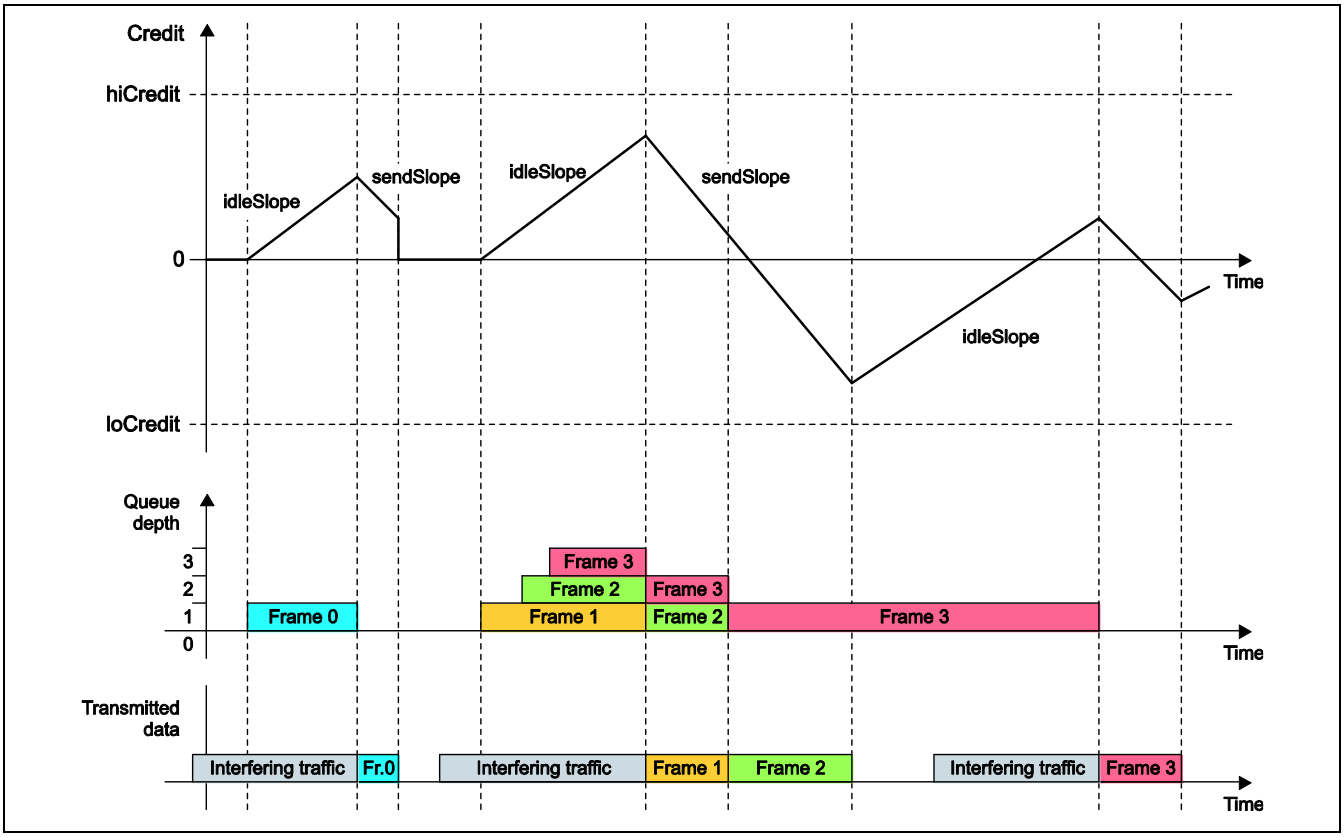

**Figure 100.1.3.6.1 CBS (Credit-Based Shaping) Operation**

Figure 100.1.3.6.2 shows the implementation of CBS in the AVB-DMAC.

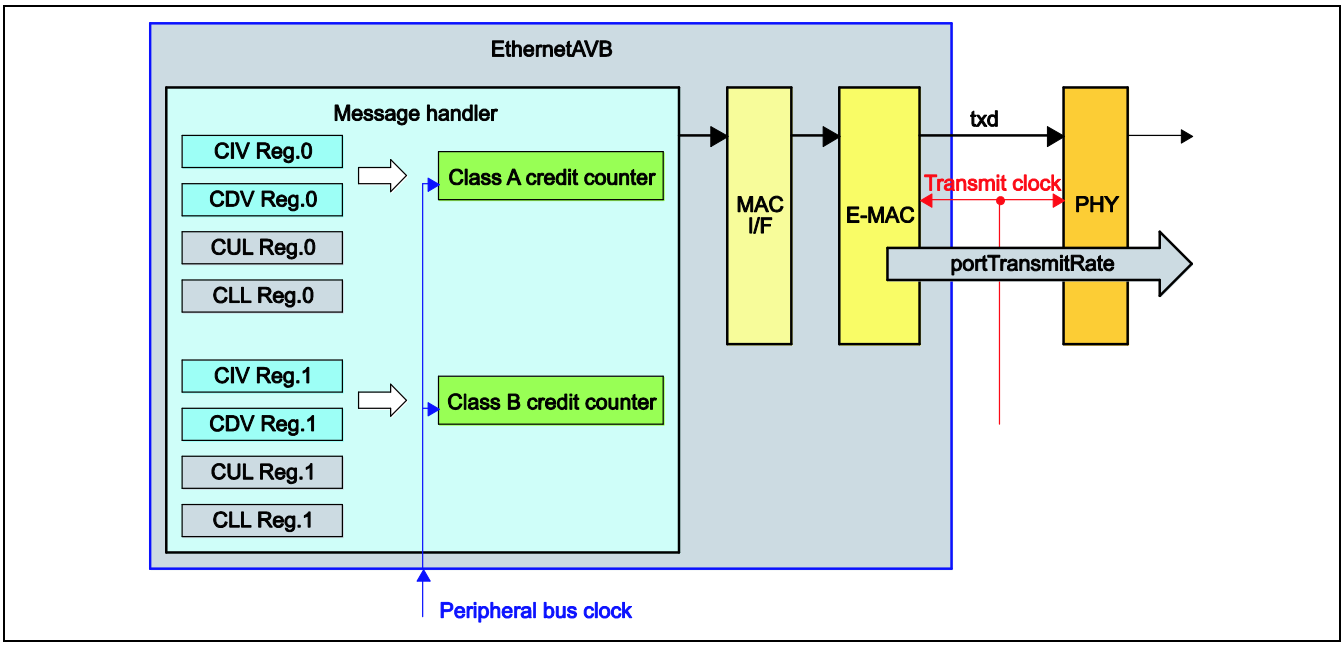

**Figure 100.1.3.6.2 CBS (Credit-Based Shaping) Operation in the AVB-DMAC**

The above implementation is based on “credit counters” for the respective traffic classes (SR class A and class B). The following parameters apply for these classes.

CBS increment value (CIV): Signed positive number
The credit is incremented by this amount every high-speed peripheral bus clock cycle while a frame from the queue is pending but transmission has not started (idleSlope).

CBS decrement value (CDV): Signed negative number
The credit is decremented by this amount every high-speed peripheral bus clock cycle while transmission of a frame from the queue is proceeding (sendSlope).

The CBS increment value (CIV) and CBS decrement value (CDV) are defined as follows.

CIV = idleSlope × Mfactor
CDV = sendSlope × Mfactor

Mfactor is a multiplier factor to ensure accuracy for CIV and CDV. CIV and CDV are calculated by using the following equations.

CIV = (portTransmitRate/HPϕ) × bwFraction × Mfactor
CDV = (portTransmitRate/HPϕ) × (bwFraction – 1) × Mfactor

HPϕ is the frequency of the high-speed peripheral bus clock. The credit counters are driven by the high-speed peripheral bus clock, so calculating the slope parameters for CBS requires (1/HPϕ).

Use software to prepare Mfactor for the CBS parameters. All queues for the same class must have the same Mfactor for all CBS parameters. Mfactor for a specified class c can be changed during operation, unless transmission is pending for that class (i.e. the transmit process status bit in the AVB-DMAC status register (CSR.TPOt) = 0). At that time, the credit counter values for class A and class B are 0. Note that the credit value will not match a new incrementation or decrementation parameter if Mfactor is changed while the credit counter value is non-zero. Mfactor is not present in the AVB-DMAC registers.

Set the CIV and CDV parameters in the CBS increment value registers (CIVRc) and the CBS decrement value registers (CDVRc). These are treated as dynamic settings since they should be updated when streams are registered and erased in accord with IEEE 802.1Qat.

The AVB-DMAC also has CBS upper limit registers (CULc) (the upper limit registers for classes A and B) and CBS lower limit registers (CLLc) (the lower limit registers for classes A and B). Set Mfactor to match the credit value and set the upper limit (hiCredit) and the lower limit (loCredit) for each class as defined above.

CUL = hiCredit × Mfactor = maxInterferenceSize × bwFraction × Mfactor
CLL = loCredit × Mfactor = maxFrameSize × (bwFraction – 1) × Mfactor

**Example:**

Assume that portTransmitRate = 100 Mbps, HPϕ = 133.33 MHz and bwFraction = 3%. Then idleSlope and sendSlope represented as one bit vs. cycles of the high-speed peripheral bus clock are as follows.

idleSlope = (portTransmitRate/HPϕ) × bwFraction = 100/133.33 (Mbps/MHz) × 3% = 0.023 bit per high-speed peripheral bus clock cycle
sendSlope = idleSlope – (portTransmitRate / HPϕ) = –0.727 bits per high-speed peripheral bus clock cycle
Let Mfactor be 100, then CIV and CDV parameters are determined as follows.

CIV = idleSlope × Mfactor = 2.3
CDV = sendSlope × Mfactor = –72.7

Note : 133MHz is calculation example. Need to replace with S0D8_HSC $\phi$ and calculate.

### (1) Restrictions on CIV, CDV and Mfactor

The maximum value (the minimum value for negative numbers) up to which the credit counter will not overflow determines the maximum values of CIV and CDV that can be set in the CBS registers. This maximum credit value is equivalent to the worst case of the hiCredit value, and the maximum values for class A and class B are calculated as follows.

**<Conditions>**

- Class A maximum value (hiCredit_max_classA)
  classA bwFraction ≅ 100%
  Maintaining the proper relations in the transmission priority order requires waiting for a period equivalent to the maximum frame size.
  hiCredit_max_classA ≅ maxInterferenceSize for class A = Interference due to one max. sized frame = header + max. size payload + CRC (2000 bytes) + preamble (8 bytes) + IFG (12 bytes) + processing_delay (≅80 bytes) ≅ 2100 bytes
- Class B maximum value (hiCredit_max_classB)
  classB bwFraction ≅ 100%
  Maintaining the proper relations in the transmission priority order requires waiting for a period equivalent to the maximum size of frames in the class A transmission queue and other transmission queues.
  hiCredit_max_classB ≅ maxInterferenceSize for class B = Interference due to two max-size frames = 2 × hiCredit_max_classA ≅ 4200 bytes

hiCredit_max_classA = 16800

hiCredit_max_classB = 33600

The maximum values that can be selected with Mfactor for the 32-bit signed counter without overflow are:

Mfactor_max_classA = $2^{31}$–1 / hiCredit_max_classA ≅ 127826 and
Mfactor_max_classB = $2^{31}$–1 / hiCredit_max_classB ≅ 63913.

A high degree of accuracy can be achieved even with a low bandwidth. In class B, bandwidthFraction = 0.05% and the bandwidth error < 0.1%.

The maximum value of CIV is calculated from the following equation.

CIV = idleSlope x Mfactor = (portTransmitRate / HPϕ) × bandwidthFraction × Mfactor

When Mfactor is the maximum value and bandwidthFraction is the maximum value (up to 100%):

CIV_max_classA = (portTransmitRate / HPϕ) × Mfactor_max_classA and
CIV_max_classB = (portTransmitRate / HPϕ) × Mfactor_max_classB.

The maximum values when portTransmitRate = 1000 Mbps and HPϕ = 133.33 MHz are as follows:

CIV_max_classA ≅ 958719

CIV_max_classB ≅ 479359

These values in the table are the limits of CIV up to which the 32-bit credit counter will not overflow. The CIV parameters are implemented as 16 bits + a sign bit, so a further limit of CIV ≤ 65535 applies to both class A and class B.

Note : 133MHz is calculation example. Need to replace with S0D8_HSCφ and calculate.

### (2) Credit Incrementation during Inter-Frame Gaps (IFGs)

The inter-frame gap (IFG) after a frame is transmitted is not treated as part of frame transmission by the CBS credit counter. During an IFG, the credit is incremented for all SR queues that have pending frames or negative credit. Figure 100.1.3.6.3 illustrates credit operations during IFGs.

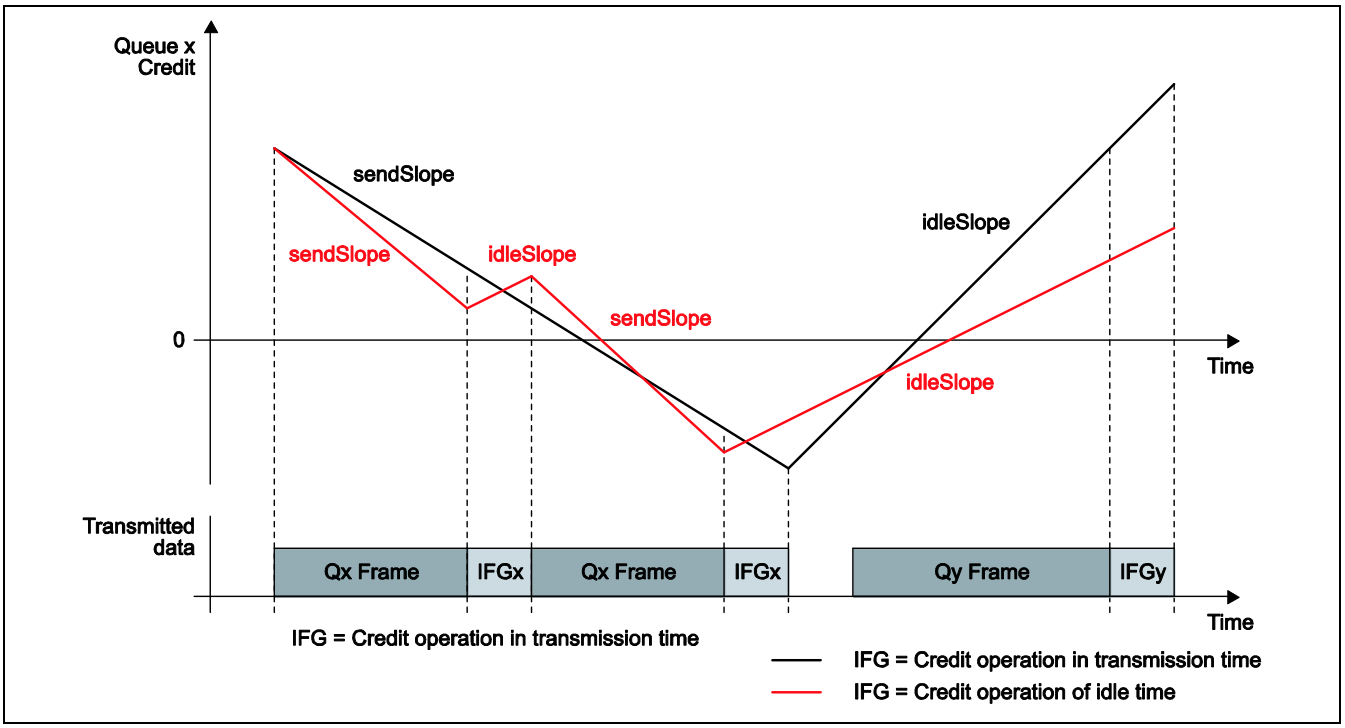

**Figure 100.1.3.6.3 Credit Operations during IFGs**

Accordingly, the IFG need not be included in calculation of the bandwidth requirements for the specified SR class when deciding the idleSlope, sendSlope, and CIV and CDV parameters. However, IFG must also be included in the calculation in order to confirm that the total bandwidth allocated to all SR classes does not exceed 100% of portTransmitRate. This is described in *Section 35.2.2.8.4* of *IEEE 802.1Q*.

### (3) Example

The case of a class A 48-kHz stereo audio stream among Ethernet frames is described as an example.

After every class A measurement interval (125 µs), 80 octets consisting of two sets of six 32-bit samples plus a 32-octet header are stored as audio data within a frame. The IEEE 802.3 also imposes a 42-octet media-specific framing overhead (an 8-octet preamble, 14-octet IEEE 802.3 header, 4-octet IEEE 802.1Q priority/VID Tag, 4-octet CRC, and 12-octet IFG) are also added. Accordingly, the total frame size is 80 + 42 = 122, and one such frame is transmitted after every class measurement interval.

This represents a total bandwidth of about 7.8 Mbits per second (122 octets × 8 bits per octet × 8000 frames per second) for this class. If the E-MAC is assumed to run at 1 Gbps (portTransmitRate), this is equivalent to the allocation of about 0.78% of the total bandwidth to each class A queue. If other traffic classes are to share the total transmission bandwidth, checking that this 0.78% allocation does not lead to the total allocation of bandwidth being greater than 100% of portTransmitRate is required.

To obtain the CIV and CDV parameters for a given class, the IFG must not be taken into account in calculation of the frame size must not include the IFG. For this case, therefore, we obtain an 80-bit payload + 30-bit overhead = 110-octet measurement interval for the class → the total bandwidth for the class = 7.04 Mbps = 0.704% of portTransmitRate.

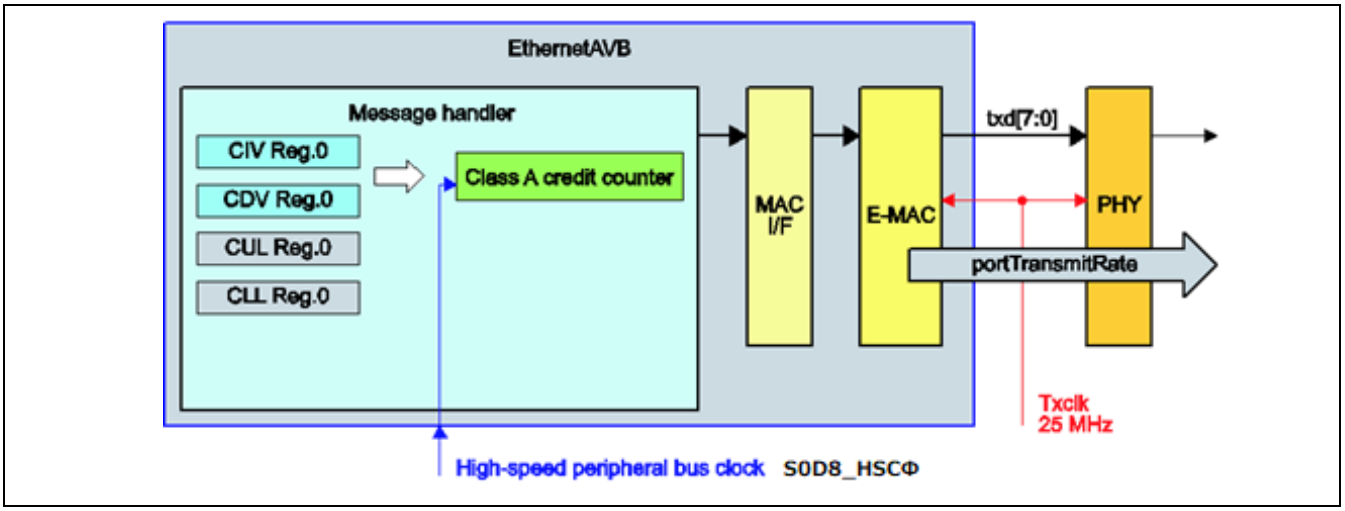

**Figure 100.1.3.6.4 Example of CBS Settings**

Given that:

- the E-MAC runs at 1000 Mbps, so portTransmitRate = 1000 Mbps and
- high-speed peripheral bus clock (operating clock for the credit counter) frequency = 133.33 MHz, securing a bandwidth of 7.04 Mbits/sec for class A requires configuring the CBS parameters as follows.
  bandwidthFraction = 0.704%
  idleSlope = (portTransmitRate / HPϕ) × bandwidthFraction ≅ 0.0528 bits per high-speed peripheral bus clock cycle
  sendSlope = idleSlope – (portTransmitRate / HPϕ) ≅ –7.44739 bits per high-speed peripheral bus clock cycle

When Mfactor = 100000, the parameters are as follows.

- CIV = idleSlope × Mfactor = 5280 bits per high-speed peripheral bus clock cycle
- CDV = sendSlope × Mfactor = 744739bits per high-speed peripheral bus clock cycle

These are the final values for setting in the CIVR1 and CDVR1 registers.

Note : 133MHz is calculation example. Need to replace with S0D8_HSCφ and calculate.

### 100.1.3.7 Flow Control

The EthernetAVB-IF does not support flow control in the specification. Flow control is only effective when transmitting and receiving only normal (non-AVB) packets.

The E-MAC supports flow control for full-duplex operation in compliance with the IEEE 802.3 standards. This flow control is applicable to both reception and transmission. In regard to the transmission of PAUSE frames, flow control operates in the following ways.

(1) PAUSE Frame Transmission

PAUSE frames can also be transmitted in response to software operations. Writing a timer value to the manual PAUSE frame register (MPR) starts the transmission of a PAUSE frame. This only causes the transmission of one PAUSE frame.

(2) PAUSE Frame Reception

After reception of a PAUSE frame, transmission of the next frame does not proceed until the time indicated by the Timer value elapses. However, transmission of a frame currently being transmitted continues. PAUSE frames are only received while the RXF bit in the E-MAC mode register (ECMR) is set to 1. The number of received PAUSE frames is counted.

(3) PAUSE Frames with the Timer Value 0

The setting of the 0-time PAUSE frame enable bit (ECMR.ZPF) enables or disables the reception of PAUSE frames with the TIME parameter value 0.

- When control of PAUSE frames with the TIME parameter value 0 is disabled

  PAUSE frames with the TIME parameter value 0 are not transmitted. Received PAUSE frames with the TIME parameter value 0 are discarded.

### 100.1.3.8 Magic Packet Detection

The E-MAC has a Magic Packet detection function. This function provides a facility for host devices and other sources to start other peripheral devices connected to a LAN. A peripheral device that handles Magic Packets starts itself in response to receiving a Magic Packet.

When a Magic Packet is detected, data from broadcast packets that were previously being received are stored in the FIFO and the E-MAC is notified of the receiving status. To return to normal operation from the associated interrupt processing, the E-MAC and AVB-DMAC must be initialized by using the operating mode configuration bit in the AVB-DMAC mode register (CCC.OPC) to set the operating mode to reset mode.

Magic Packets are received regardless of the destination address. As a result, the AVB_MAGIC pin is only enabled in the case of a match with the destination address specified in the Magic Packet.

The procedure for using the Magic Packet detection function with this LSI chip is as follows.

1. Use the various interrupt enabling and masking registers to disable the output of interrupts from interrupt sources.
2. Set the Magic Packet detection enable bit in the E-MAC mode register (ECMR.MPDE).
3. Set the Magic Packet detection interrupt enable bit in the E-MAC interrupt enable register (ECSIPR.MPDIP) to enable the interrupt.
4. Place the CPU in sleep mode as required.
5. An interrupt is conveyed to the CPU on detection of a Magic Packet.
6. The AVB_MAGIC pin notifies connected devices of Magic Packet detection.

Note: The Magic Packet detection interrupt status can be read in the E-MAC status register (ECSR.MPD). The bit can be cleared by setting the E-MAC status register Magic Packet TM detection bit (ECSR.MPD) to 1.

But EthernetAVB-IF can’t detect 2nd or later Magic PacketTM and the AVB_MAGIC pin can be negated though the bit is cleared.

The AVB_MAGIC pin can be negated and EthernetAVB-IF can detect MAGIC PacketTM again according to below way.

1) Hardware reset — set reset pin in the R-Car series to reset signal.
2) Software reset — set mstp/srst register for EthernetAVB-IF to software reset mode.
3) Software reset register in AVB — set AVB DMAC mode register Operating Mode Configuration bits (CCC.OPC) to reset mode.

#### 100.1.3.9 Interrupts

For details, refer to the “Interrupt Controller” section in the manual.

The interrupts of EthernetAVB-IF are indicated by individual flags **DIS**, **EIS**, **RISi**, **TIS**, and **GIS**. Each interrupt is controllable by the corresponding interrupt enable bit. The status flags are independent from this enable bits.

Additionally grouped interrupt status available in **ISS** and **EIS.QFS**. The summary status allows CPU to locate the interrupt source with a minimum number of read accesses to EthernetAVB-IF.

EthernetAVB-IF interrupts are combined to 4 groups of interrupt lines for request an interrupt service by CPU. Interrupt requests in group 0 and 1 are only generated in OPERATION mode. Interrupt requests in group 2 are only generated in OPERATION mode and in CONFIG mode if gPTP support is enabled (**CCC.GAC**). Interrupt request on line 3 depends on E-MAC configuration and can be generated in CONFIG, OPERATION and STANDBY mode.

Interrupt lines are level output and each line is asserted when at least one of the interrupt status registers bits belonging to the group associated with that line is set to 1b, and the corresponding enable bit in the related interrupt control register is also set to 1b.

For **ISS** bits the combined flag/enable is used. The green dots in detailed interrupt figures in detailed interrupt line description illustrates the point where status information for **ISS** is taken.

**Table 100.25 Interrupt assignment**

| Interrupt Name | Cause of interrupt |
|---|---|
| Ethernet AVB.ch0 | Line0_Rx[0] |
| Ethernet AVB.ch1 | Line0_Rx[1] |
| Ethernet AVB.ch2 | Line0_Rx[2] |
| Ethernet AVB.ch3 | Line0_Rx[3] |
| Ethernet AVB.ch4 | Line0_Rx[4] |
| Ethernet AVB.ch5 | Line0_Rx[5] |
| Ethernet AVB.ch6 | Line0_Rx[6] |
| Ethernet AVB.ch7 | Line0_Rx[7] |
| Ethernet AVB.ch8 | Line0_Rx[8] |
| Ethernet AVB.ch9 | Line0_Rx[9] |
| Ethernet AVB.ch10 | Line0_Rx[10] |
| Ethernet AVB.ch11 | Line0_Rx[11] |
| Ethernet AVB.ch12 | Line0_Rx[12] |
| Ethernet AVB.ch13 | Line0_Rx[13] |
| Ethernet AVB.ch14 | Line0_Rx[14] |
| Ethernet AVB.ch15 | Line0_Rx[15] |
| Ethernet AVB.ch16 | Line0_Rx[16] |
| Ethernet AVB.ch17 | Line0_Rx[17] |
| Ethernet AVB.ch18 | Line0_Tx[0] |
| Ethernet AVB.ch19 | Line0_Tx[1] |

| Interrupt Name | Cause of interrupt |
|---|---|
| Ethernet AVB.ch20 | Line0_Tx[2] |
| Ethernet AVB.ch21 | Line0_Tx[3] |
| Ethernet AVB.ch22 | Line0_DiA \| Line1_A \| Line2_A |

| Ethernet AVB.ch24 | Line 3 |
| EtherAVB TX RAM EDC Error | * |
| EtherAVB RX RAM EDC Error | * |

*This interrupt is functional safety use only.

### (1) Concurrent interrupt enable support

The interrupt enable bits can be directly modified by writing the interrupt control registers (**xxC.yyE**). If concurrent processes enable/disable interrupts located in same interrupt control register inter-process communication is required. To reduce SW overhead there are dedicated registers available controlling conflict free enable/disable of interrupts.

To enable an interrupt CPU should write 1b to the corresponding bit (**xxE.yyS**) in the enable register. Because written 0b have no effect, there is no side effect to concurrent processes.

To disable an interrupt CPU should write 1b to the corresponding bit (**xxD.yyD**) in the disable register. Because written 0b have no effect, there is no side effect to concurrent processes.

The current interrupt enable status is readable in **xxC.yyE**.

Grouping of interrupts for each interrupt line is as described in following sub-chapters.

### (2) Group 0 (Data related interrupts)

This group consists on:

Frame received interrupts **RIS0.FRFr** (for each received frame stored in URAM)
Receive warning interrupts **RIS1.RWFr** (when Unread Frame Counter reaches warning level)
Descriptor processed interrupts **RIS3.RDPFr** (for reception)Frame transmitted interrupts **TIS.FTFt** (for completion of frame transmission by E-MAC)
Descriptor processed interrupts **TIS.TDPFr** (for transmission)
Descriptor processed interrupts **DIS.DPFi** (for reception and transmission)

By reading **ISS**, CPU get an overview of all data related interrupts (**ISS.FRM**, **ISS.RWM**, **ISS.DPMi, ISS.FTM**).

Interrupt group 0 consists on these 24 interrupt lines:

Line0_Rx[17:0]
Line0_Tx[3:0]
Line0_DiA (Share the interrupt line : Group0.Line0_DiA, Group1.Line1_A, Group2.Line2_A)
Line0_DiB (Share the interrupt line : Group0.Line0_DiB, Group1.Line1_B, Group2.Line2_B)

**(a) Reception interrupts**

There are 18 dedicated interrupt lines flagging frame reception. For the queue full flag it is configurable by **CIE.RQFM** if these notification are part of the queue specific reception interrupt lines or part of the error interrupt lines (group 1).

There is a common interrupt enable (**CIE.CRIE**) for all reception lines.

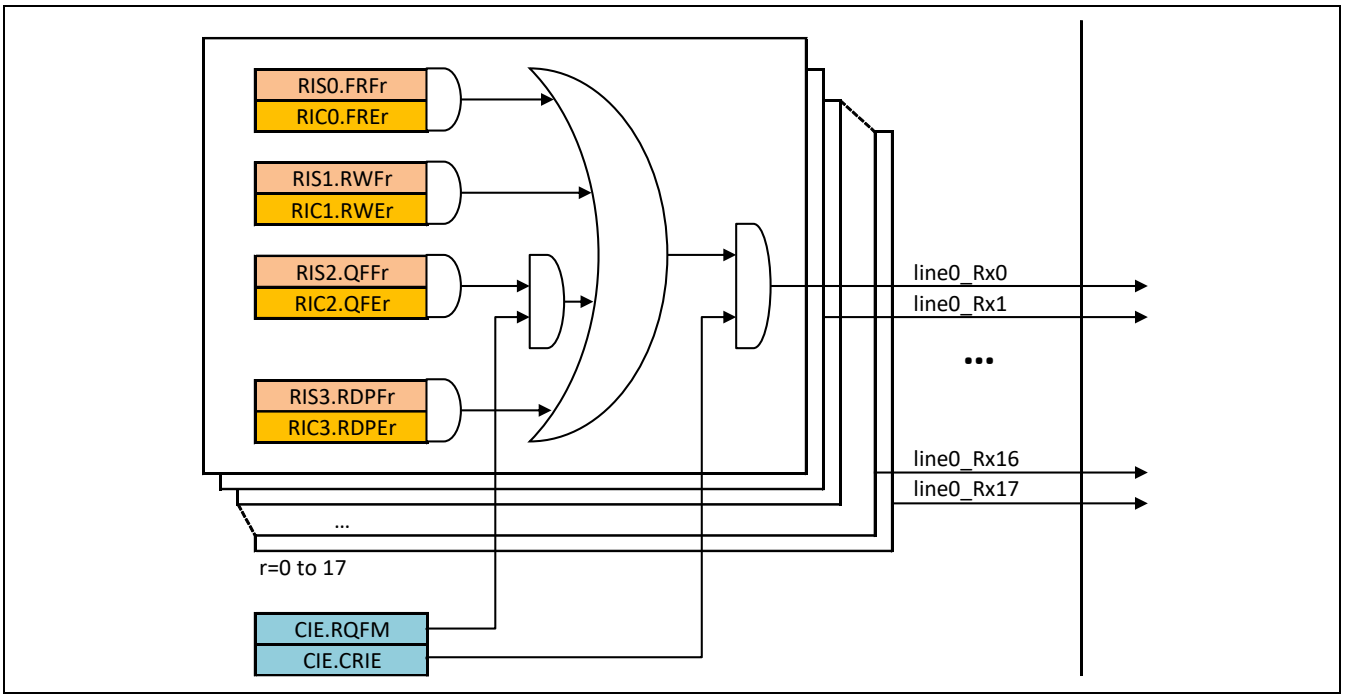

**Figure 100.1.3.11.1 Interrupt group 0, reception interrupt lines**

**(b) Transmission interrupts**

There are 4 dedicated interrupt lines flagging frame transmission.

There is a common interrupt enable (**CIE.CTIE**) for all reception lines.

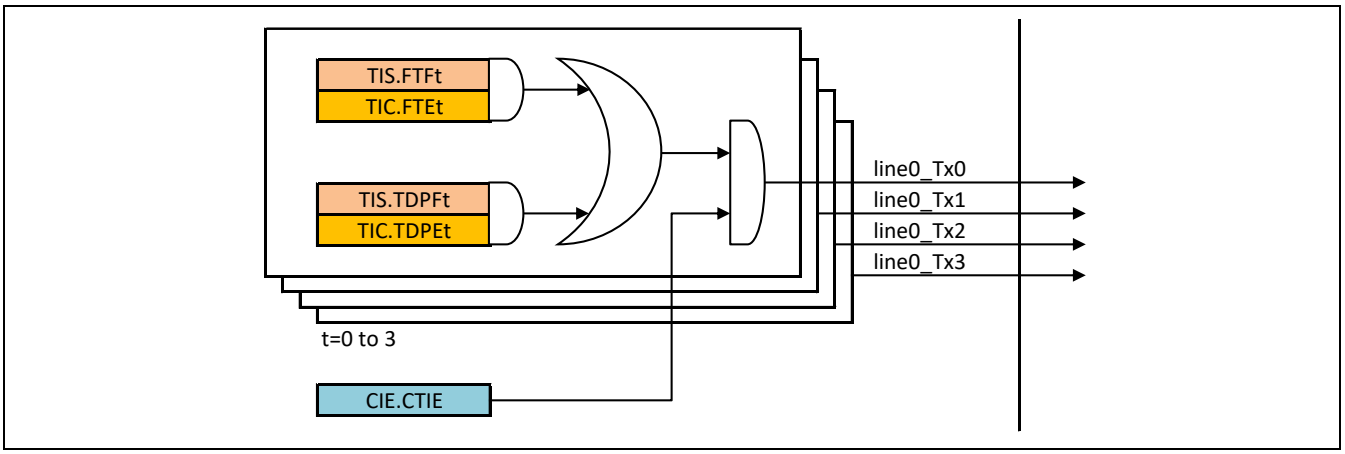

**Figure 100.1.3.11.2 Interrupt group 0, transmission interrupt lines**

**(c) Descriptor and merged interrupts**

There are 2 interrupt lines flagging descriptor interrupts. Line **line0_DiA** has also the capability to generate a merged data interrupt (controlled by **CIE.CL0M**).

Descriptor interrupt 1 is not available as common descriptor interrupt; this descriptor interrupt is split into queue specific descriptor interrupts.

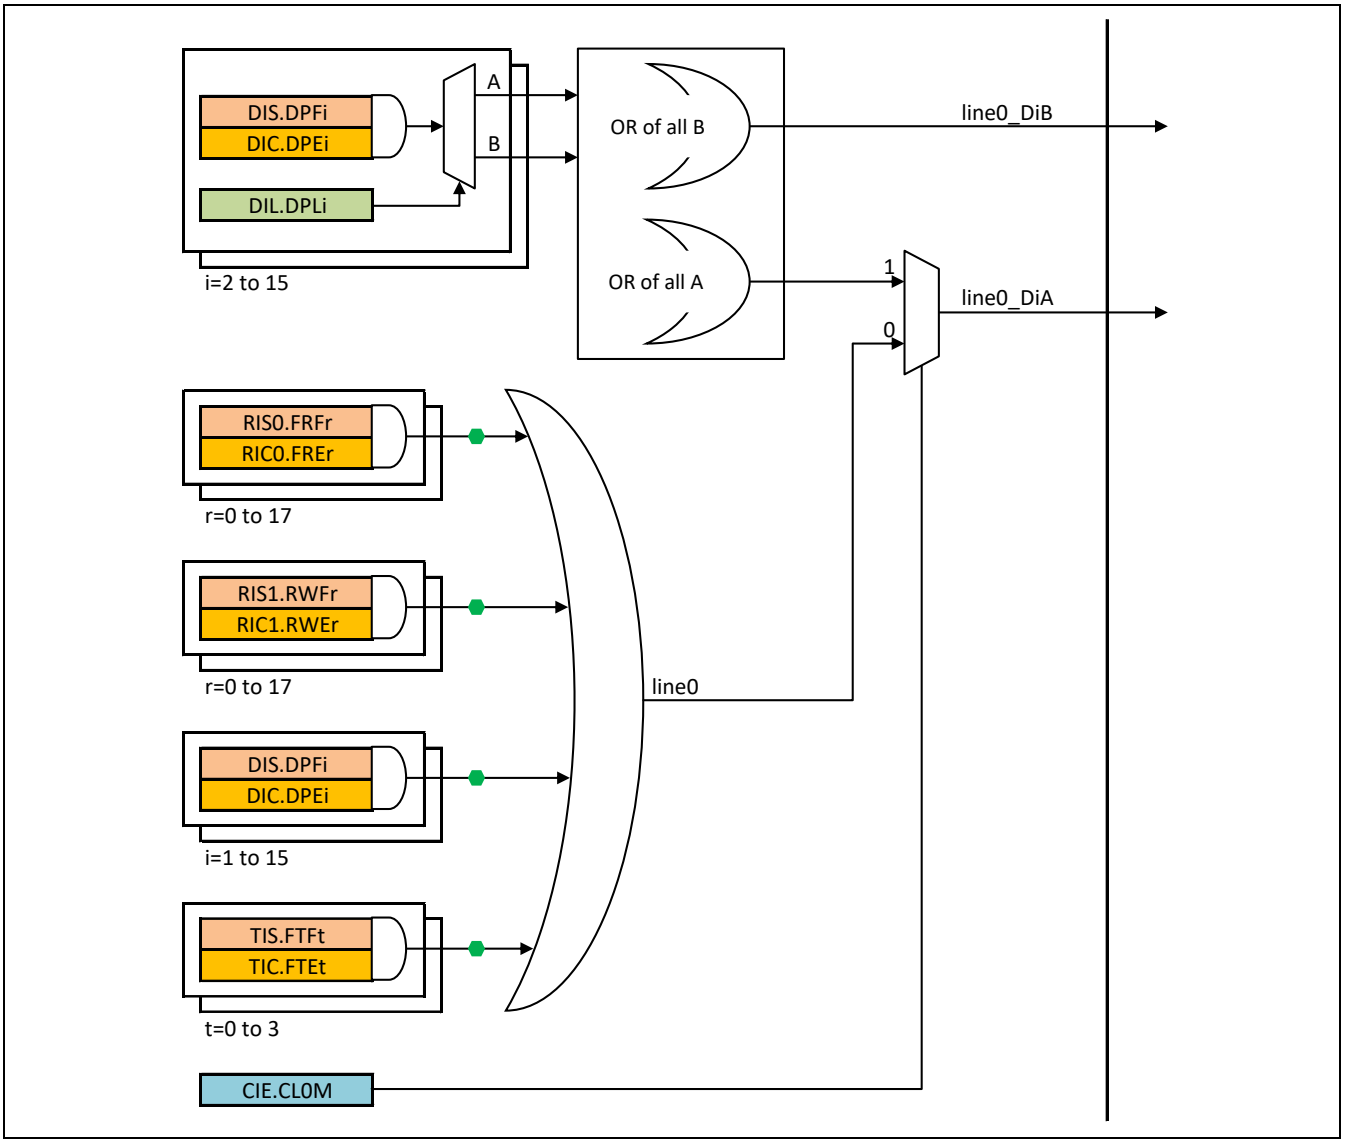

**Figure 100.1.3.11.3 Interrupt group 0, common descriptor and merged interrupt lines**

### (3) Group 1 (Error related interrupts)

This group consists on:

Tx-Buffer full interrupt **EIS.TBFF** (when delaying fetching of transmit frame)
Interrupt for E-MAC Status FIFO overwrite (**EIS.MFFF**)
Interrupt for Timestamp FIFO overrun (**EIS.TFFF**)
Interrupts for CBS limits (**EIS.CULF1**, **EIS.CULF0**, **EIS.CLLF1**, **EIS.CLLF0**)
Interrupt for separation filtering error (**EIS.SEF**)
Interrupt for queue error (error while processing receive or transmit queue) (**EIS.QEF**)

Interrupt for transmission error detected by E-MAC (**EIS.MTEF, EIS.MREF**)
Rx-FIFO full interrupt **RIS2.RFFF** (when Rx-FIFO overflows)
Receive queue full interrupts **RIS2.QFFr** (when no sufficient space is in receive queue)

By reading **EIS**, CPU get an overview of all error interrupts. Additionally **ISS.EM** informs about pending error related interrupt.

Interrupt group 1 consists on these 2 interrupt lines:

Line1_A (Share the interrupt line : Group0.Line0_DiA, Group1.Line1_A, Group2.Line2_A)
Line1_B (Share the interrupt line : Group0.Line0_DiB, Group1.Line1_B, Group2.Line2_B)

For the queue full flag it is configurable by **CIE.RQFM** if these notification are part of the queue specific reception interrupt lines or part of the error interrupt line **line1_A.**

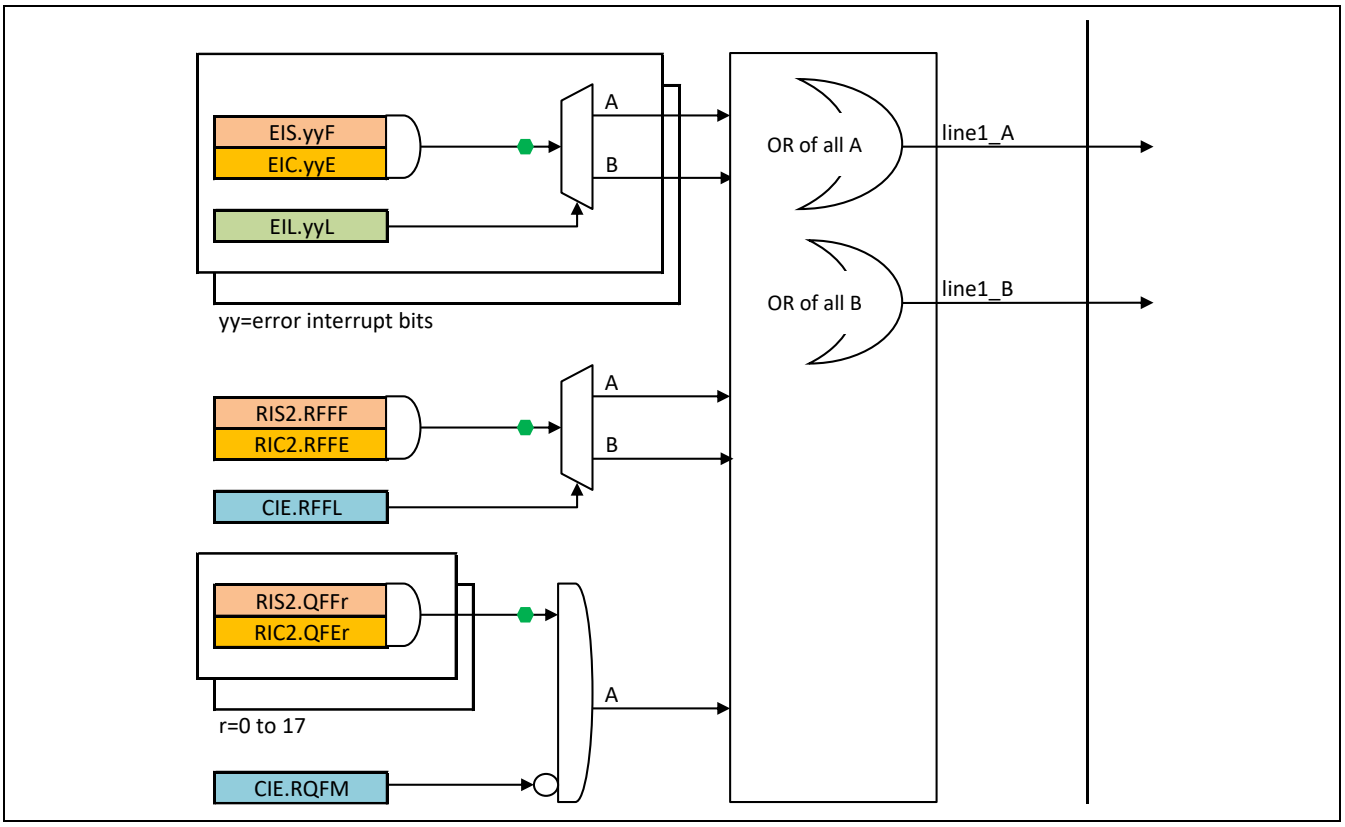

**Figure 100.1.3.11.4 Interrupt group 1, error interrupt lines**

The abbreviation **yy** in figure indicates error interrupts: **TBF**, **MFF**, **TFF**, **CULFc**, **CLLFc**, **SE**, **QE**, **MTE**, and **MRE**.

### (4) Group 2 (Management related interrupts)

Reception

Rx-FIFO Warning interrupt **RIS1.RFWF** (Rx-FIFO has reached configured warning level)

Transmission

E-MAC status FIFO warning interrupt **TIS.MFWF**
E-MAC Status FIFO updated interrupt **TIS.MFUF**
Timestamp FIFO warning interrupt **TIS.TFWF**
Timestamp FIFO updated interrupt **TIS.TFUF**

gPTP

AVTP time captured interrupt **GIS.ATCFi**
AVTP presentation target matched interrupt **GIS.PTMFi**
AVTP presentation time overrun interrupt **GIS.PTOF** (when external trigger before old value is processed)
AVTP presentation time captured interrupt **GIS.PTCF**

By reading **ISS**, CPU get an overview of all management related interrupts (**ISS.RFWM**, **ISS.MFWM**, **ISS.MFUM**, **ISS.TFWM**, **ISS.TFUM**, **ISS.CGIM**).

Interrupt group 2 consists on these 2 interrupt lines:

Line2_A (Share the interrupt line : Group0.Line0_DiA, Group1.Line1_A, Group2.Line2_A)
Line2_B (Share the interrupt line : Group0.Line0_DiB, Group1.Line1_B, Group2.Line2_B)

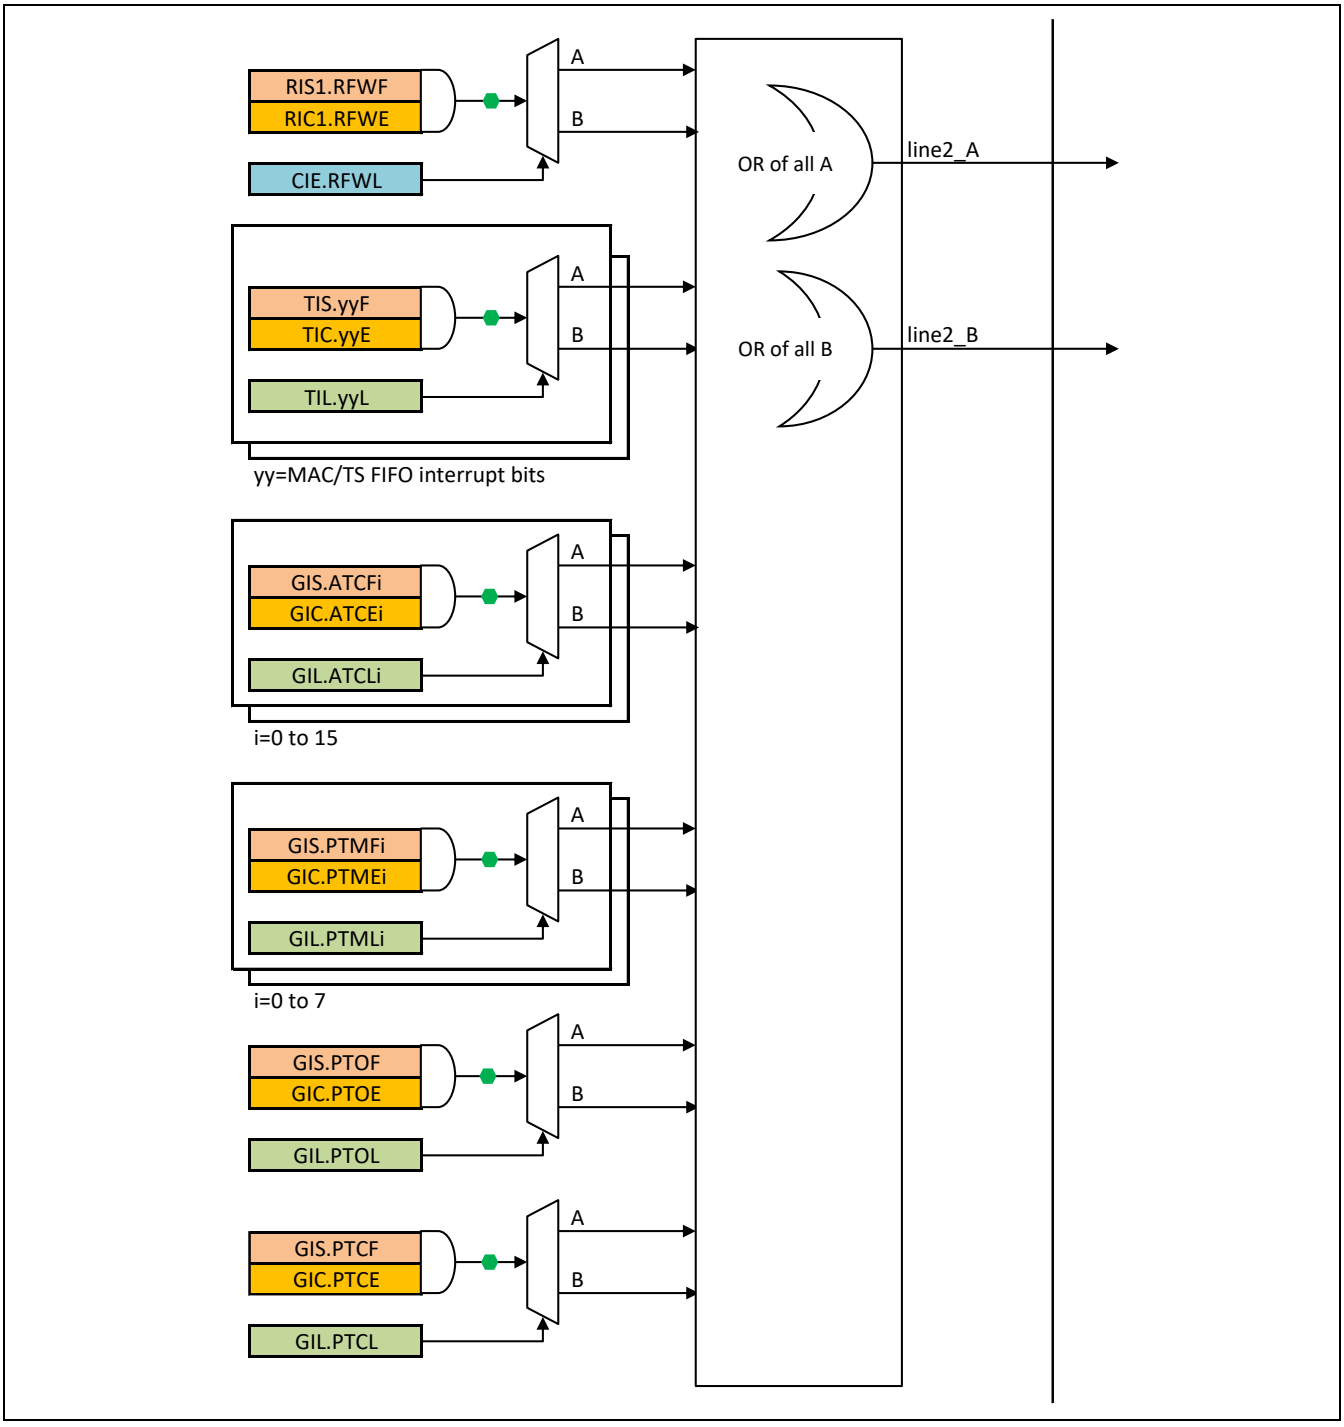

**Figure 100.1.3.11.5 Interrupt group 2, management interrupt lines**

The abbreviation **yy** in figure indicates error interrupts: **MFW**, **MFU**, **TFW**, and **TFU**.

### (5) Line 3 (E-MAC interrupt)

The E-MAC interrupt is conveyed when the E-MAC interrupt source is generated.

The general error interrupt state can be checked by reading the E-MAC interrupt summary bit in the interrupt summary status register (ISS.MS).

### 100.1.3.10 Flows of Operations

#### (1) Flow of E-MAC Initialization

Figure 100.1.3.12.1 shows the flow of E-MAC initialization (for AVB mode and full-duplex operation).

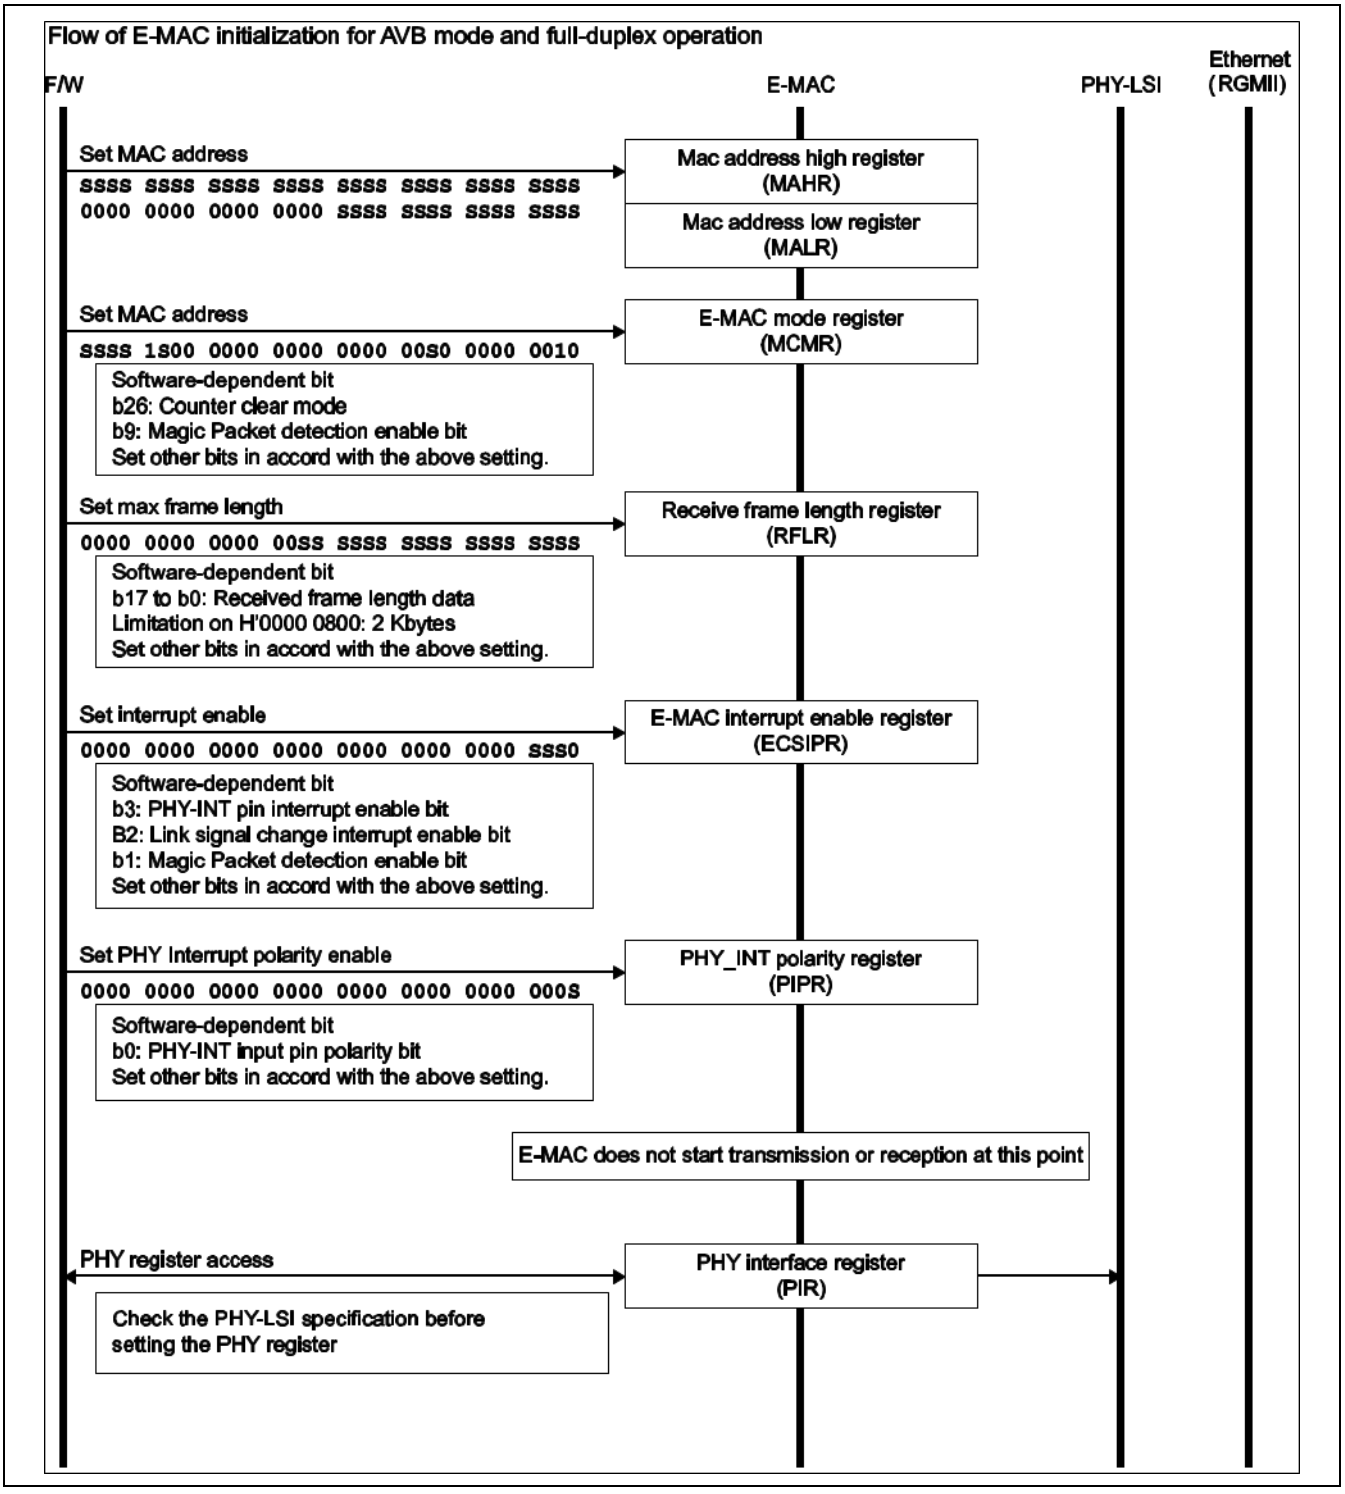

**Figure 100.1.3.12.1 Flow of E-MAC Initialization (for AVB Mode and Full-Duplex Operation)**

### (2) Flow of AVB-DMAC Initialization

Figure 100.1.3.12.2 shows the flow of AVB-DMAC initialization (for AVB mode and full-duplex operation).

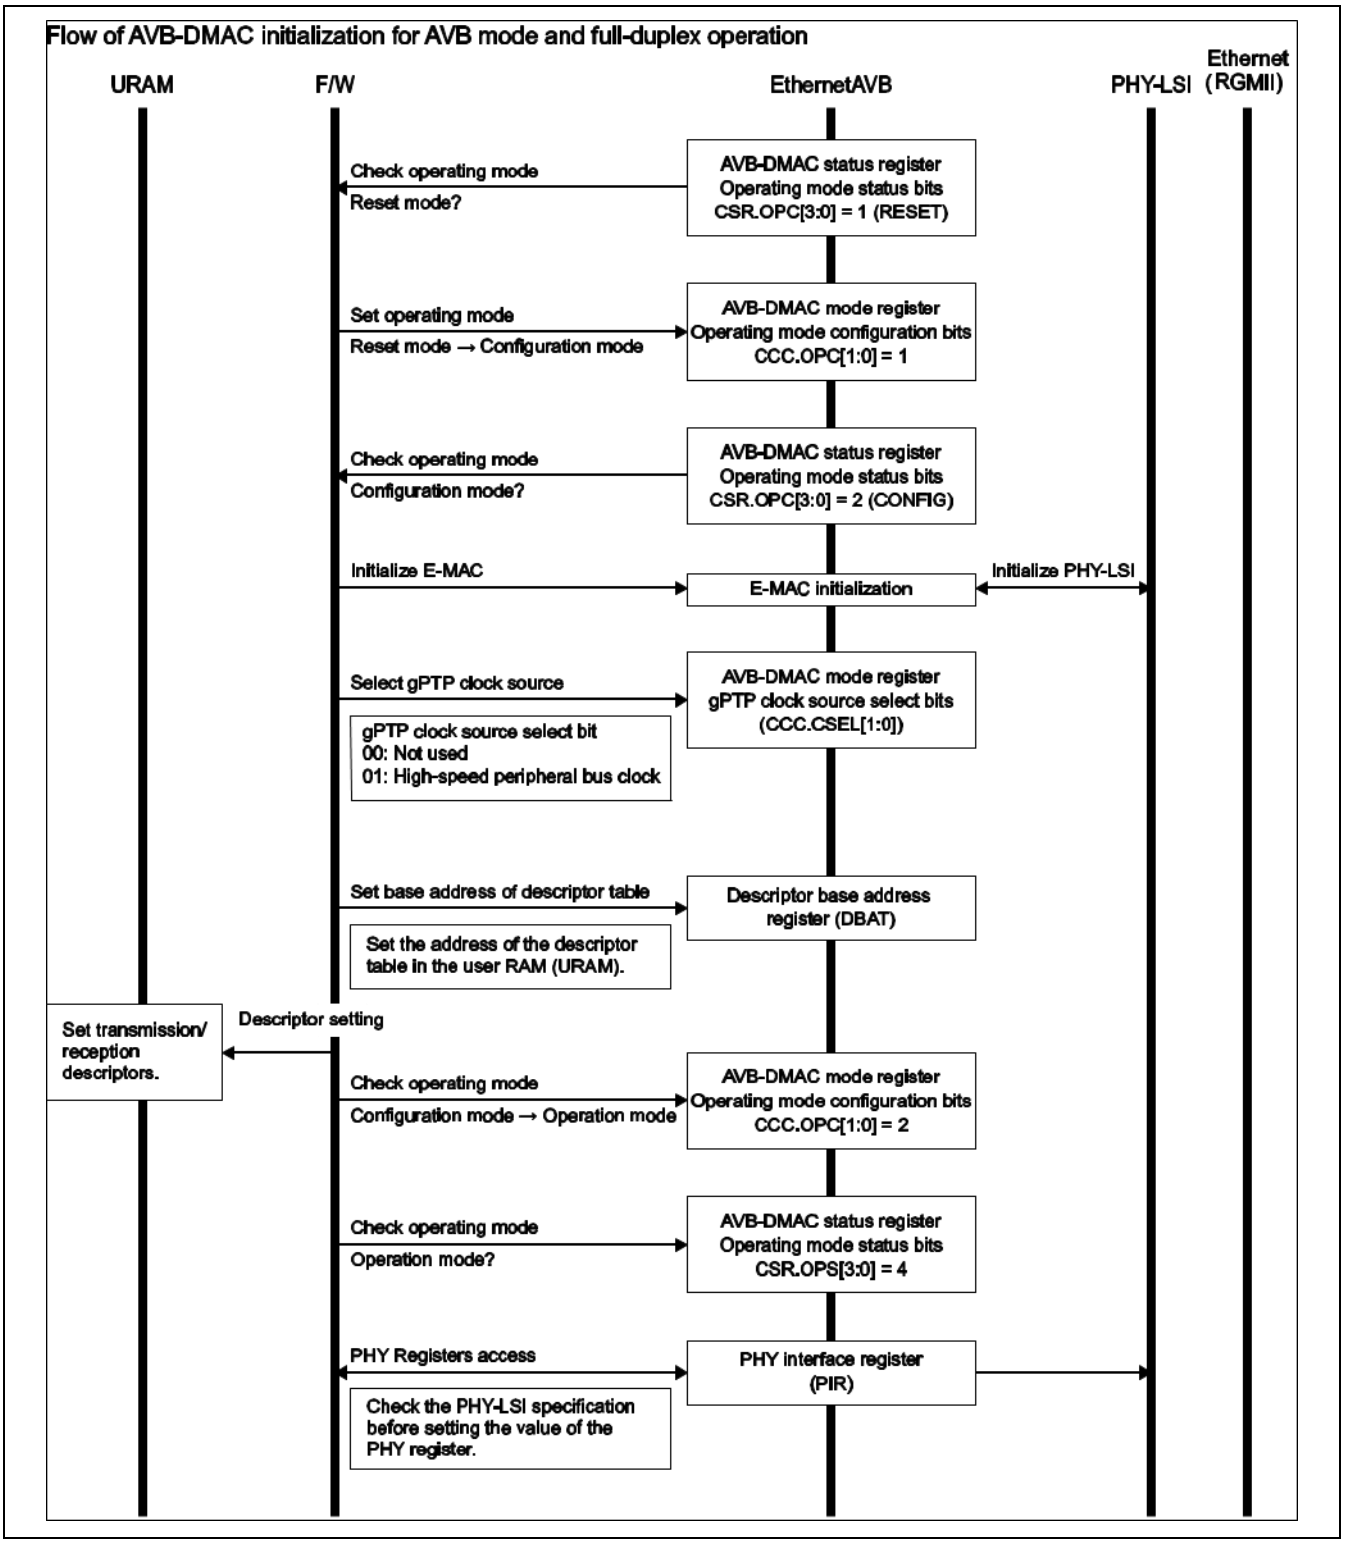

**Figure 100.1.3.12.2 Flow of AVB-DMAC Initialization (for AVB Mode and Full-Duplex Operation)**

### (3) Flow for the AVB-DMAC in Reception

Figure 100.1.3.12.3 shows the flow for the AVB-DMAC in reception (in AVB mode and full-duplex operation).

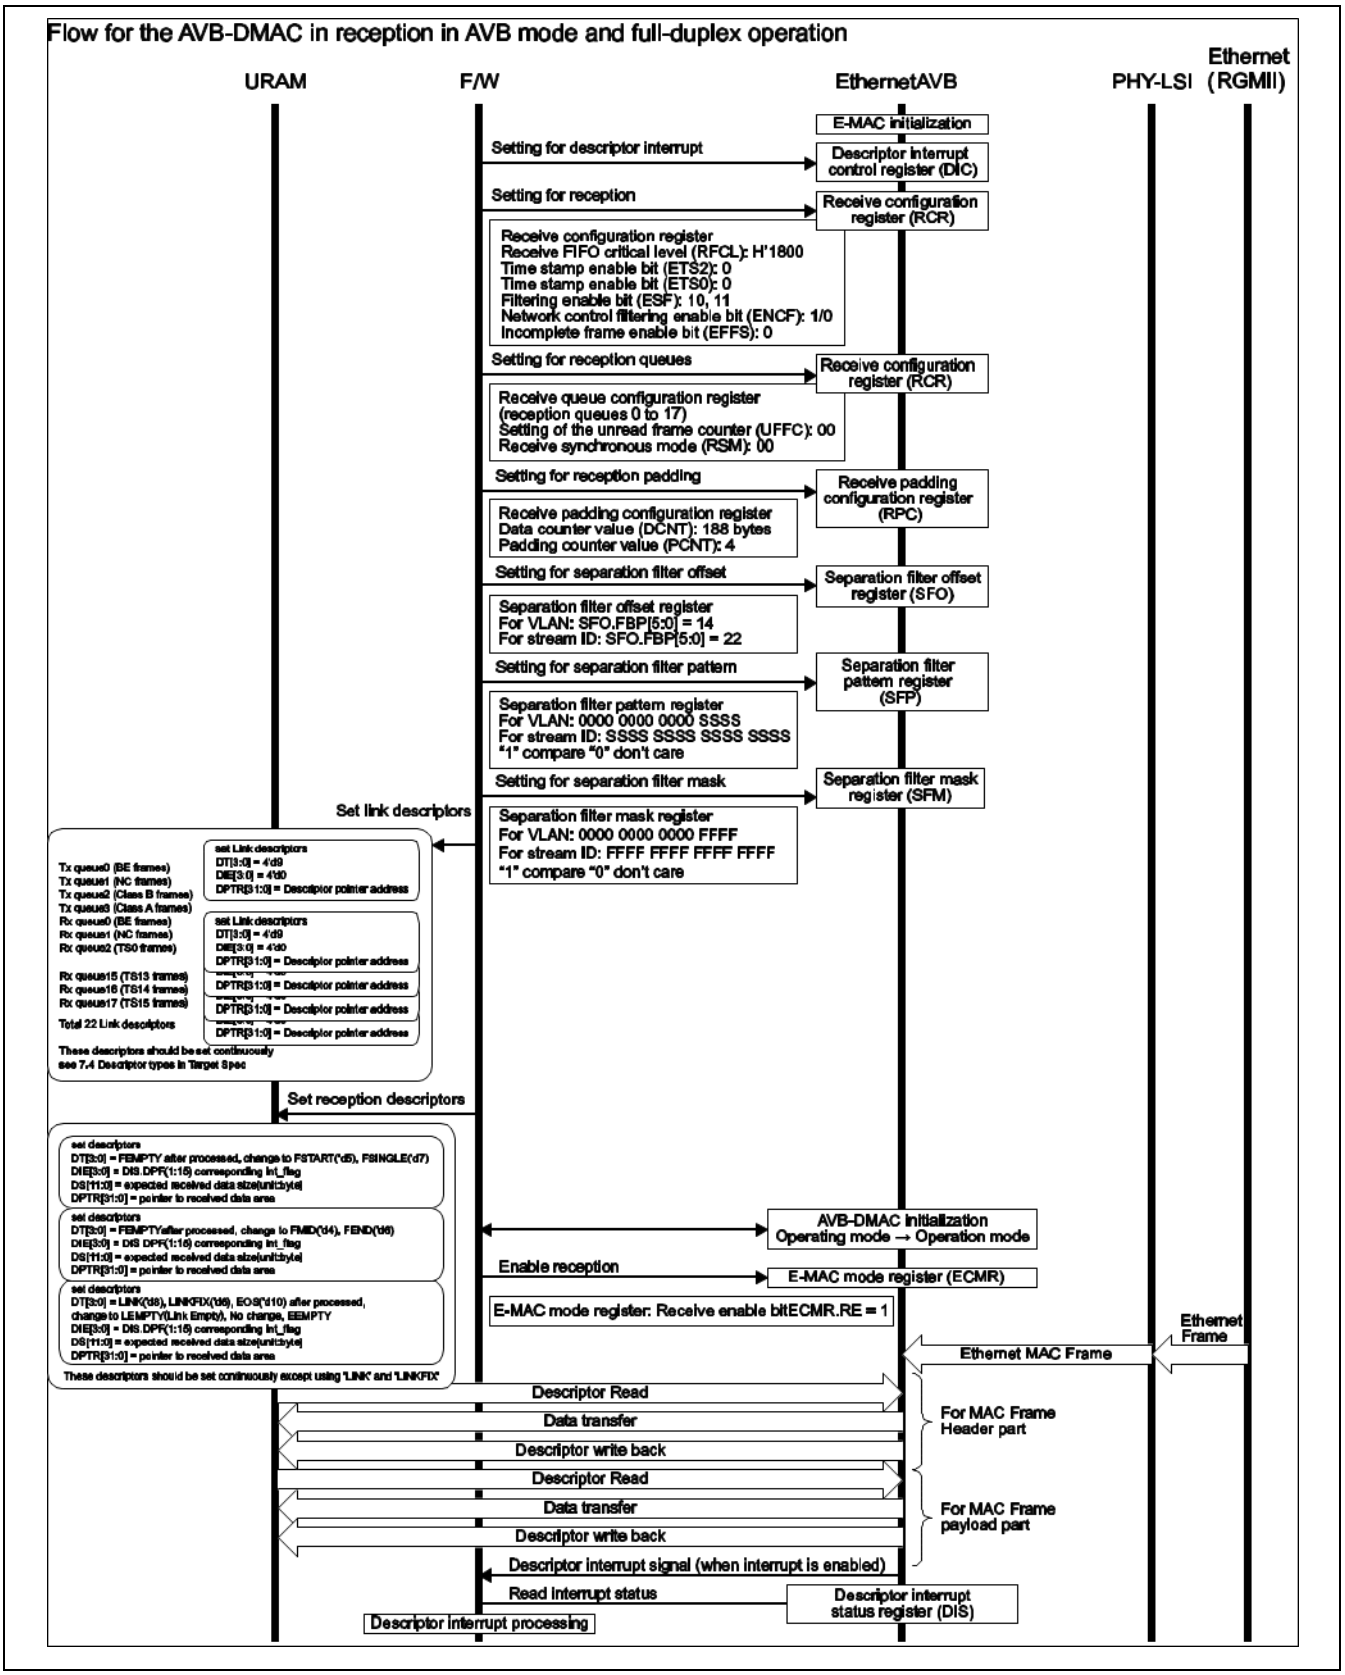

**Figure 100.1.3.12.3 Flow for the AVB-DMAC in Reception (in AVB Mode and Full-Duplex Operation)**

### (4) Flow for the AVB-DMAC in Transmission

Figure 100.1.3.12.4 shows the flow for the AVB-DMAC in transmission (in AVB mode and full-duplex operation).

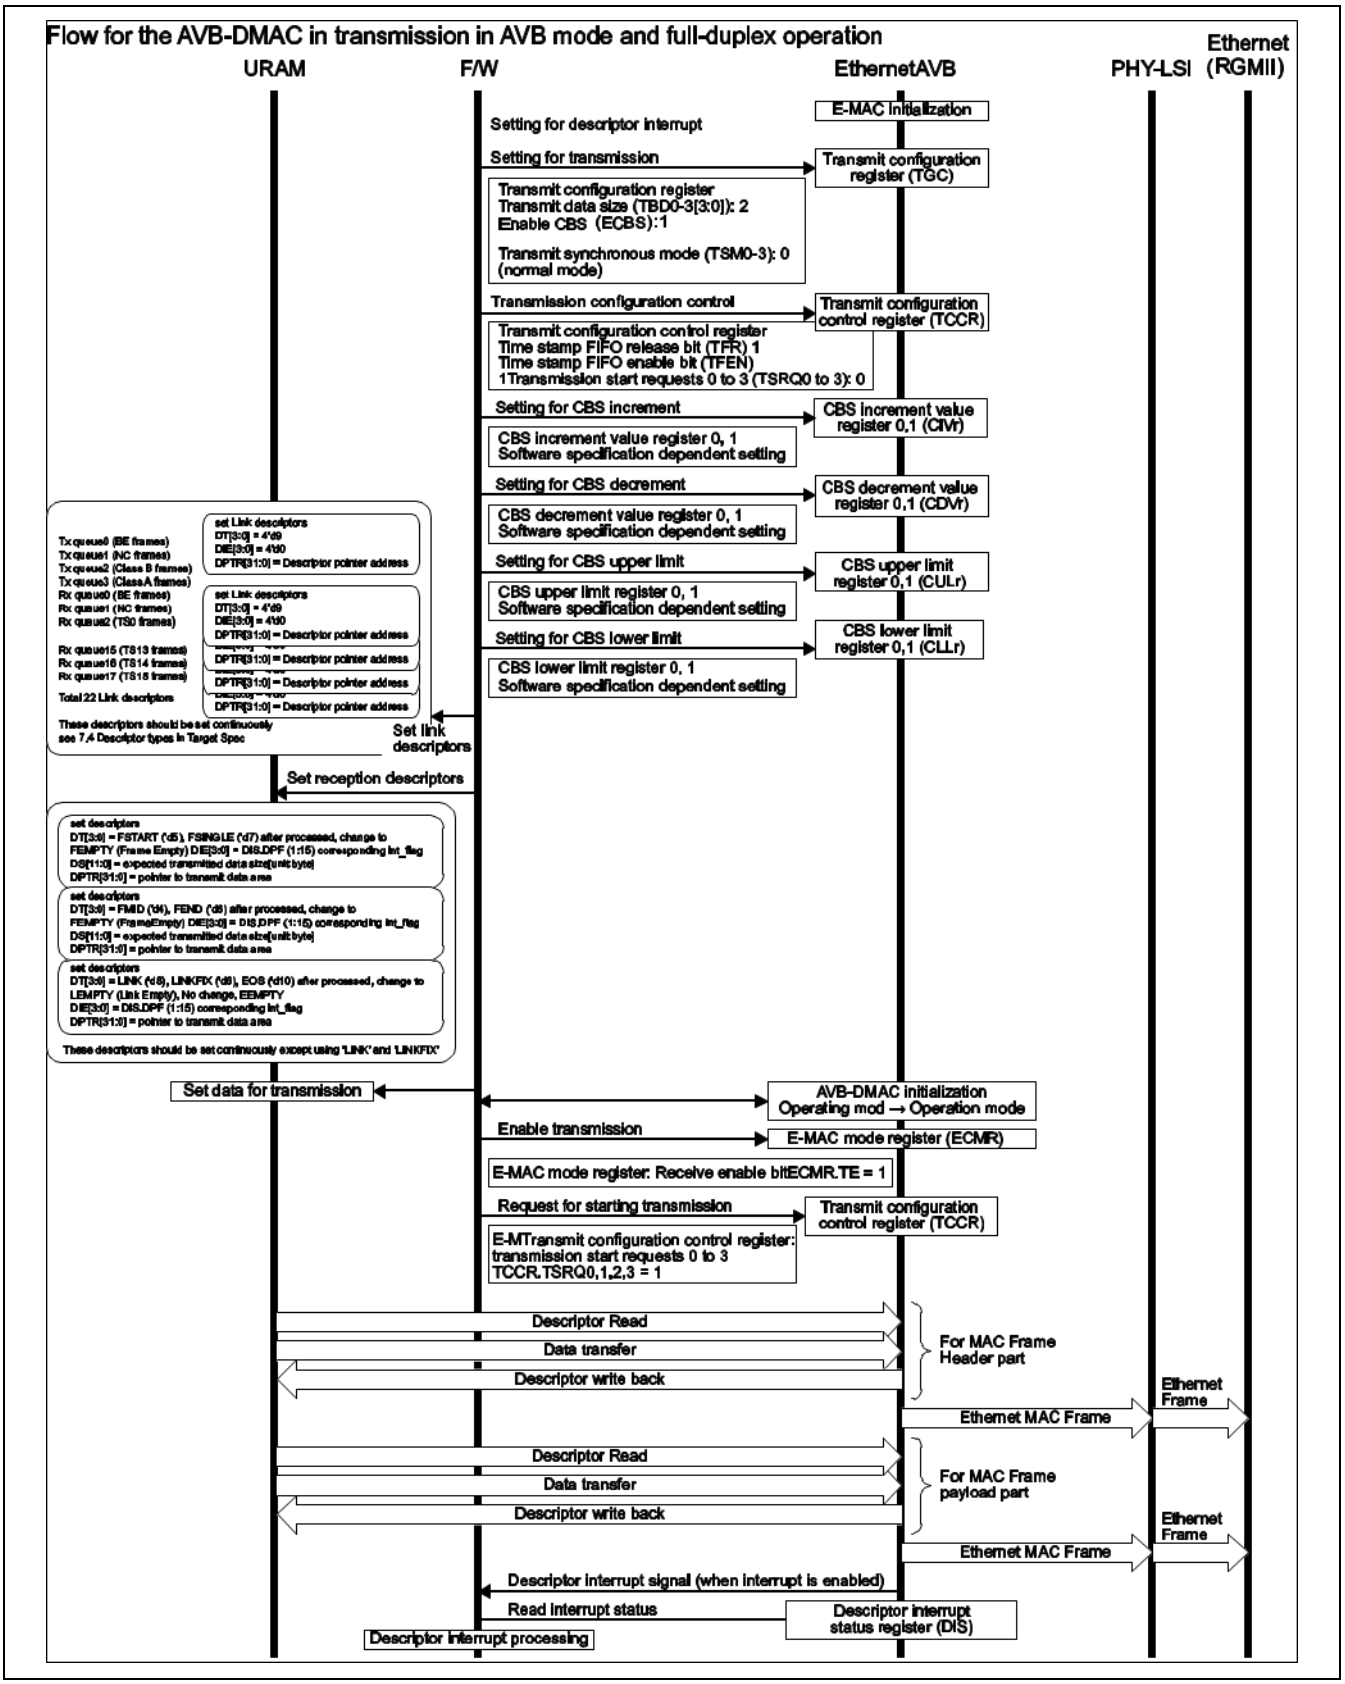

**Figure 100.1.3.12.4 Flow for the AVB-DMAC in Transmission (in AVB Mode and Full-Duplex Operation)**

### (5) Flow for Stopping AVB-DMAC Operation in Reception

Figure 100.1.3.12.5 shows the flow for stopping AVB-DMAC operation in reception (normal, common to all modes).

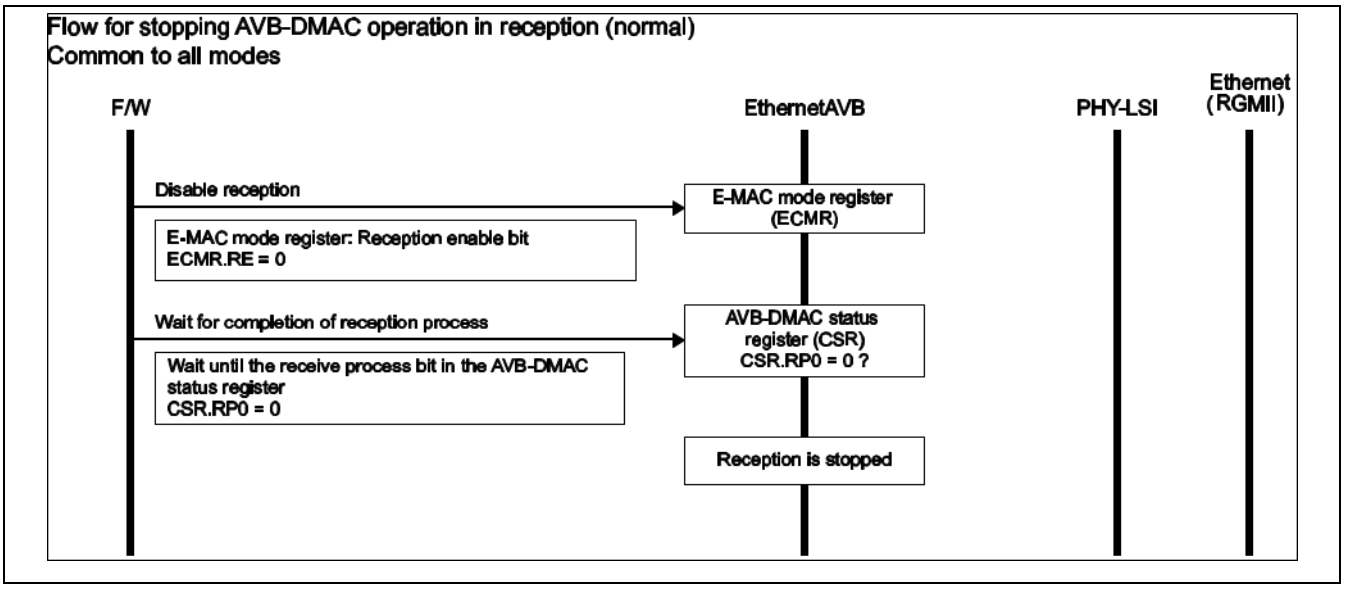

**Figure 100.1.3.12.5 Flow for Stopping AVB-DMAC Operation in Reception (Normal, Common to All Modes)**

### (6) Flow for Stopping AVB-DMAC Operation in Transmission

Figure 100.1.3.12.6 shows the flow for stopping AVB-DMAC operation in transmission (normal, common to all modes).

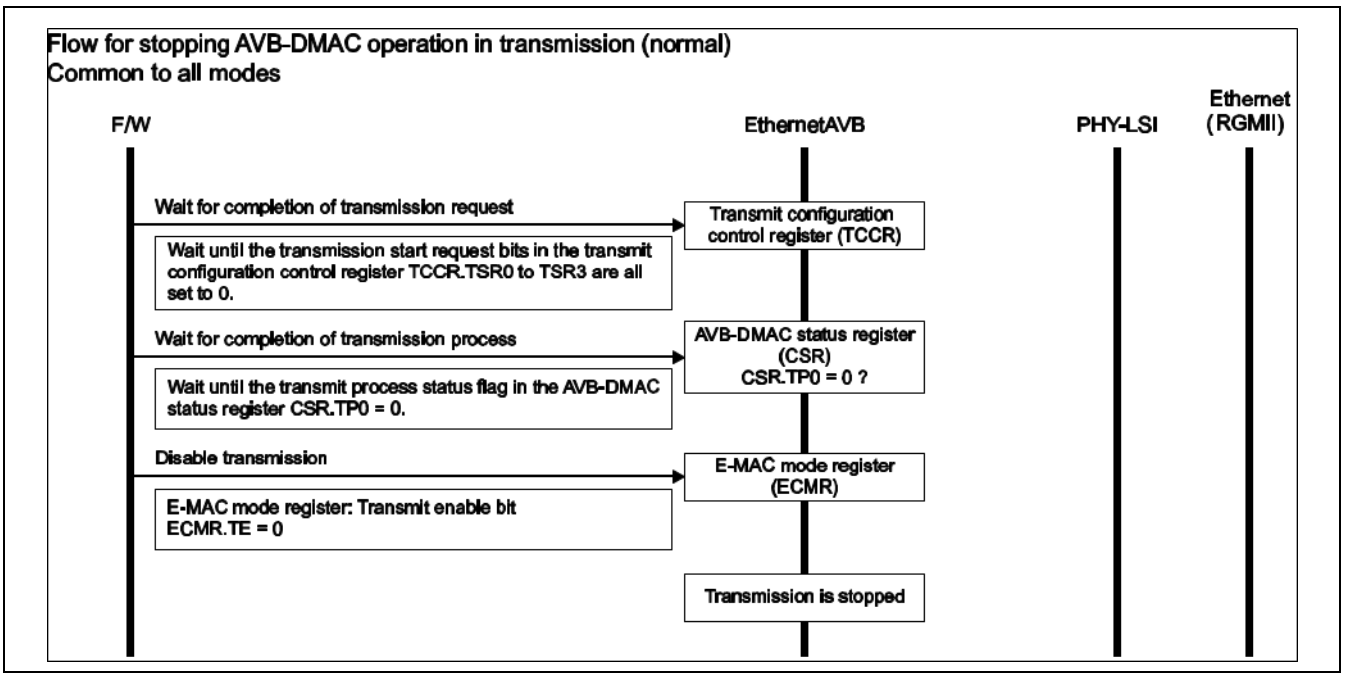

**Figure 100.1.3.12.6 Flow for Stopping AVB-DMAC Operation in Transmission (Normal, Common to All Modes)**

### (7) Flow for Stopping and Resetting the AVB-DMAC

Figure 100.1.3.12.7 shows the flow for stopping and resetting the AVB-DMAC (normal, common to all modes).

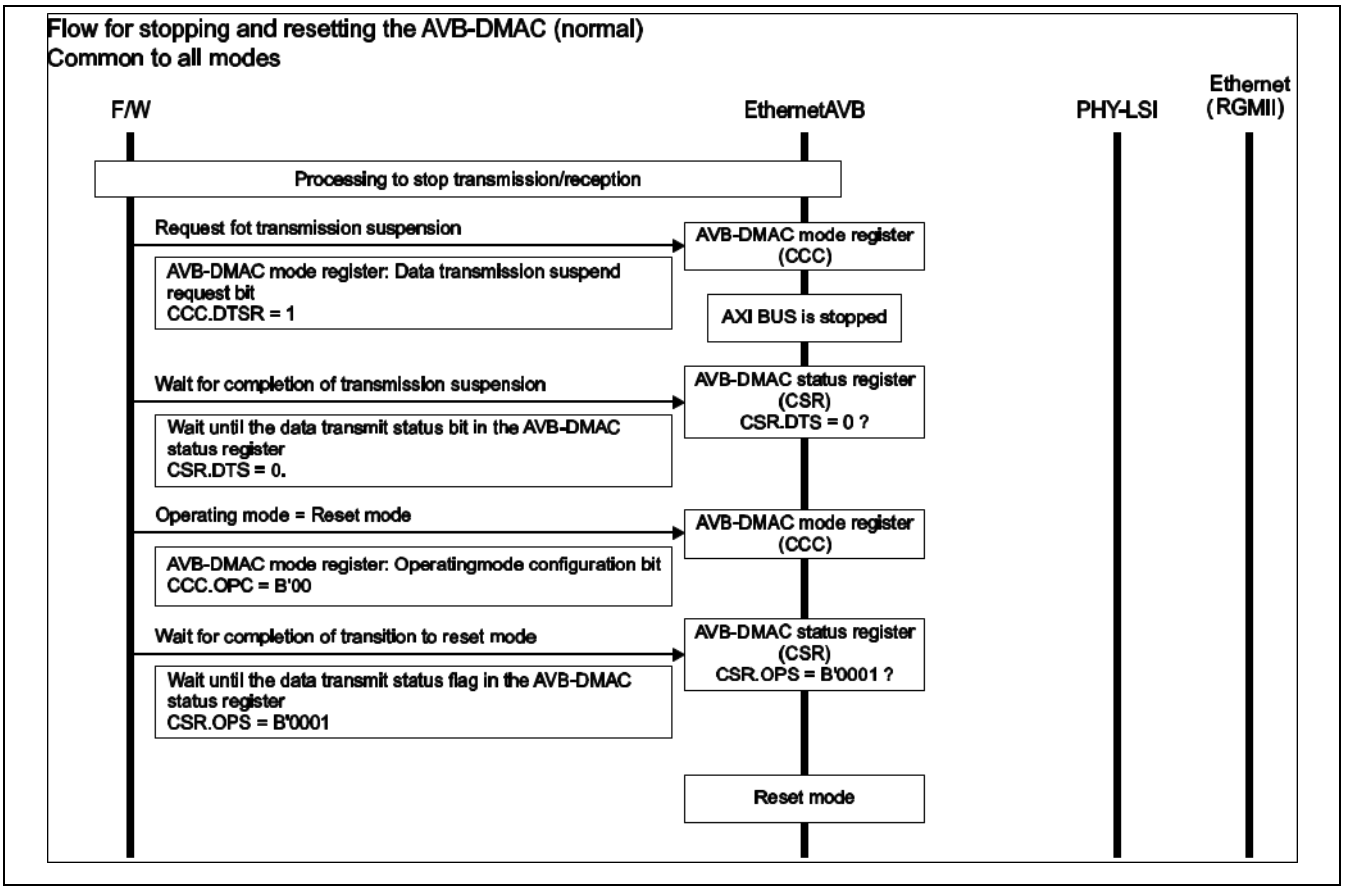

**Figure 100.1.3.12.7 Flow for Stopping and Resetting the AVB-DMAC (Normal, Common to All Modes)**

### (8) Flow for Emergency Stopping the AVB-DMAC

Figure 100.1.3.12.8 shows the flow for emergency stopping the AVB-DMAC (normal, common to all modes).

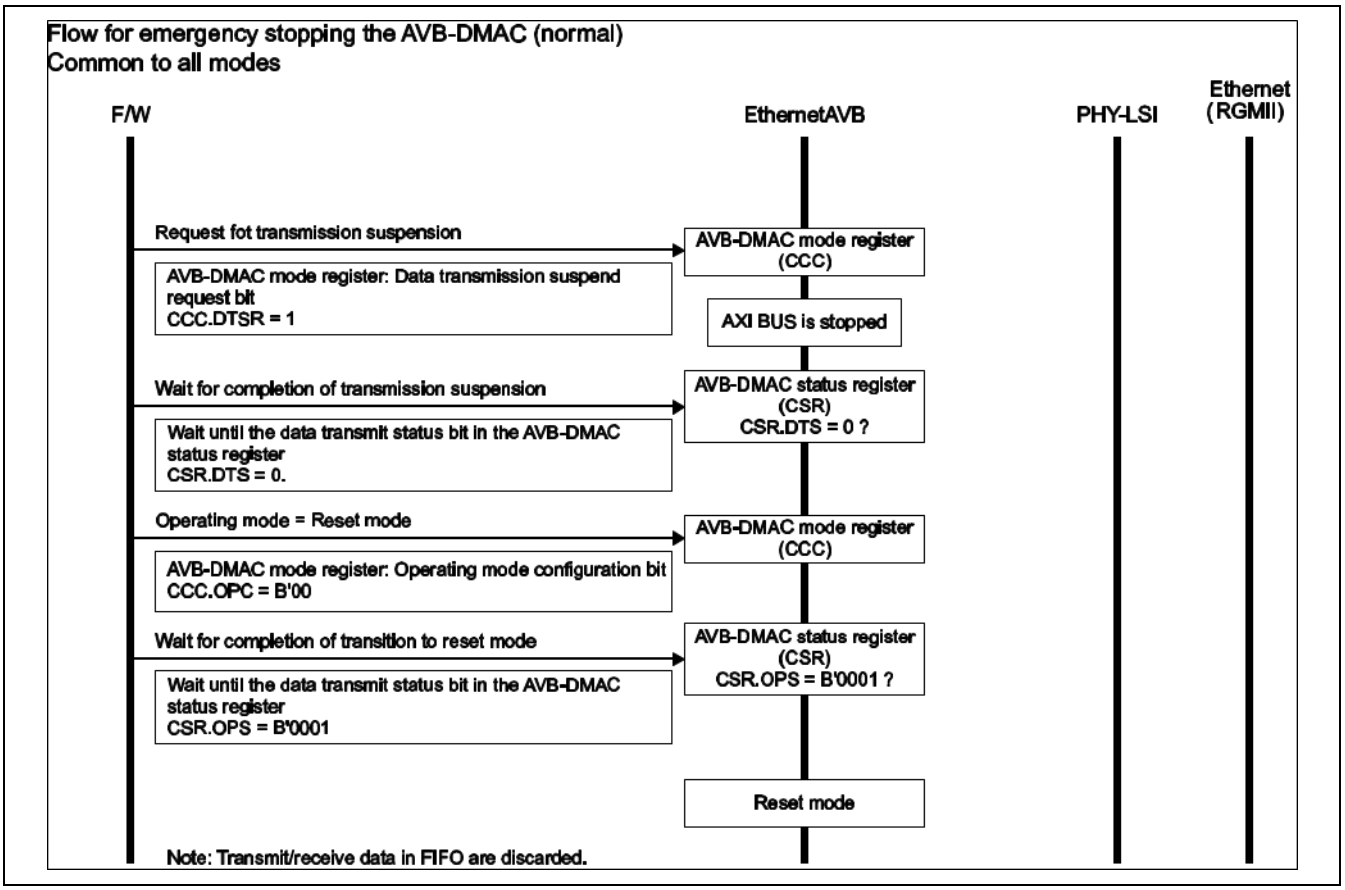

**Figure 100.1.3.12.8 Flow for Emergency Stopping the AVB-DMAC (Normal, Common to All Modes)**

### (9) Flow of gPTP Initialization

Figure 100.1.3.12.9 shows the flow of gPTP initialization (normal, common to all modes).

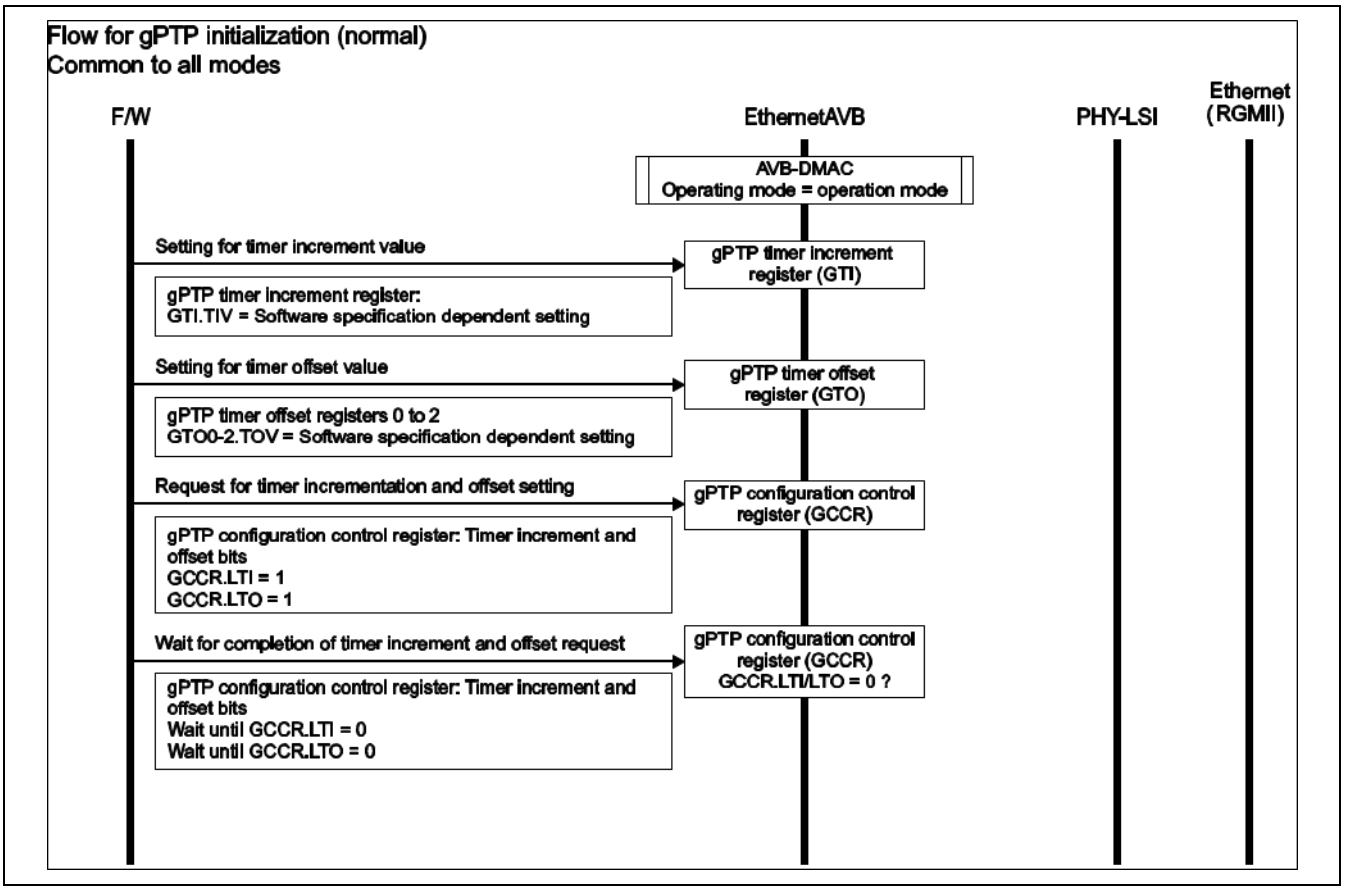

**Figure 100.1.3.12.9 Flow of gPTP Initialization (Normal, Common to All Modes)**

### (10) Flow of gPTP Time Stamping in Transmission

Figure 100.1.3.12.10 shows the flow of gPTP time stamping in transmission (normal, common to all modes).

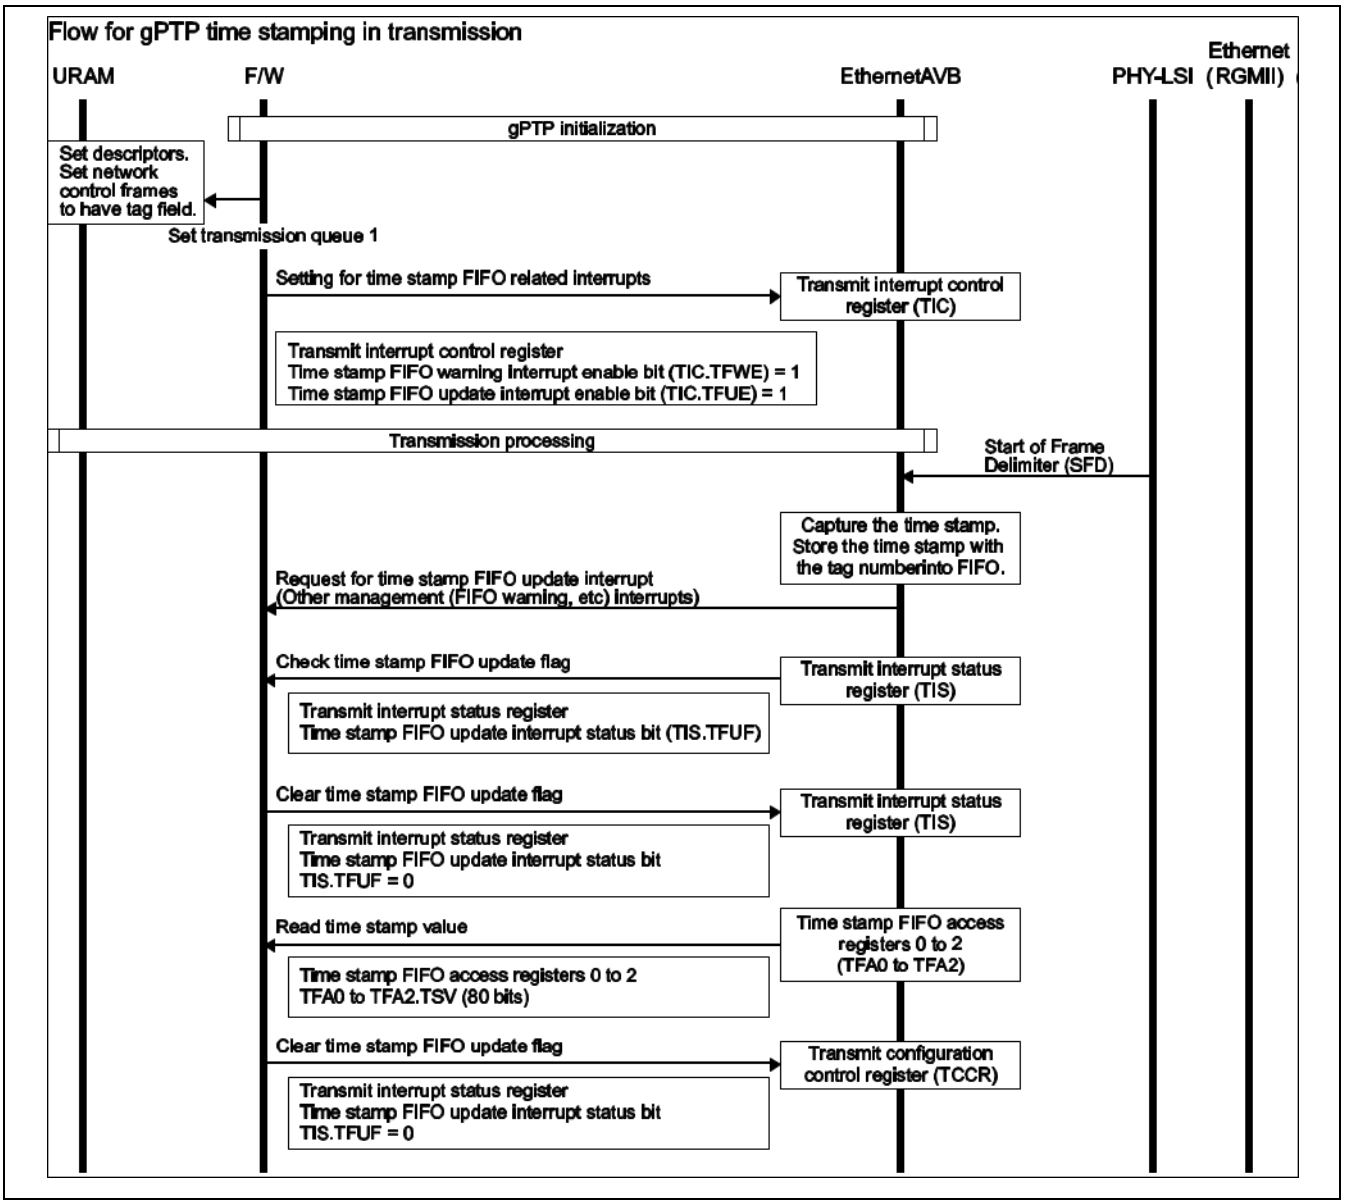

**Figure 100.1.3.12.10 Flow of gPTP Time Stamping in Transmission (Normal, Common to All Modes)**

### (11) Flow of gPTP Time Stamping and Synchronization in Reception

Figure 100.1.3.12.11 shows the flow of gPTP time stamping and synchronization in reception (normal, common to all modes).

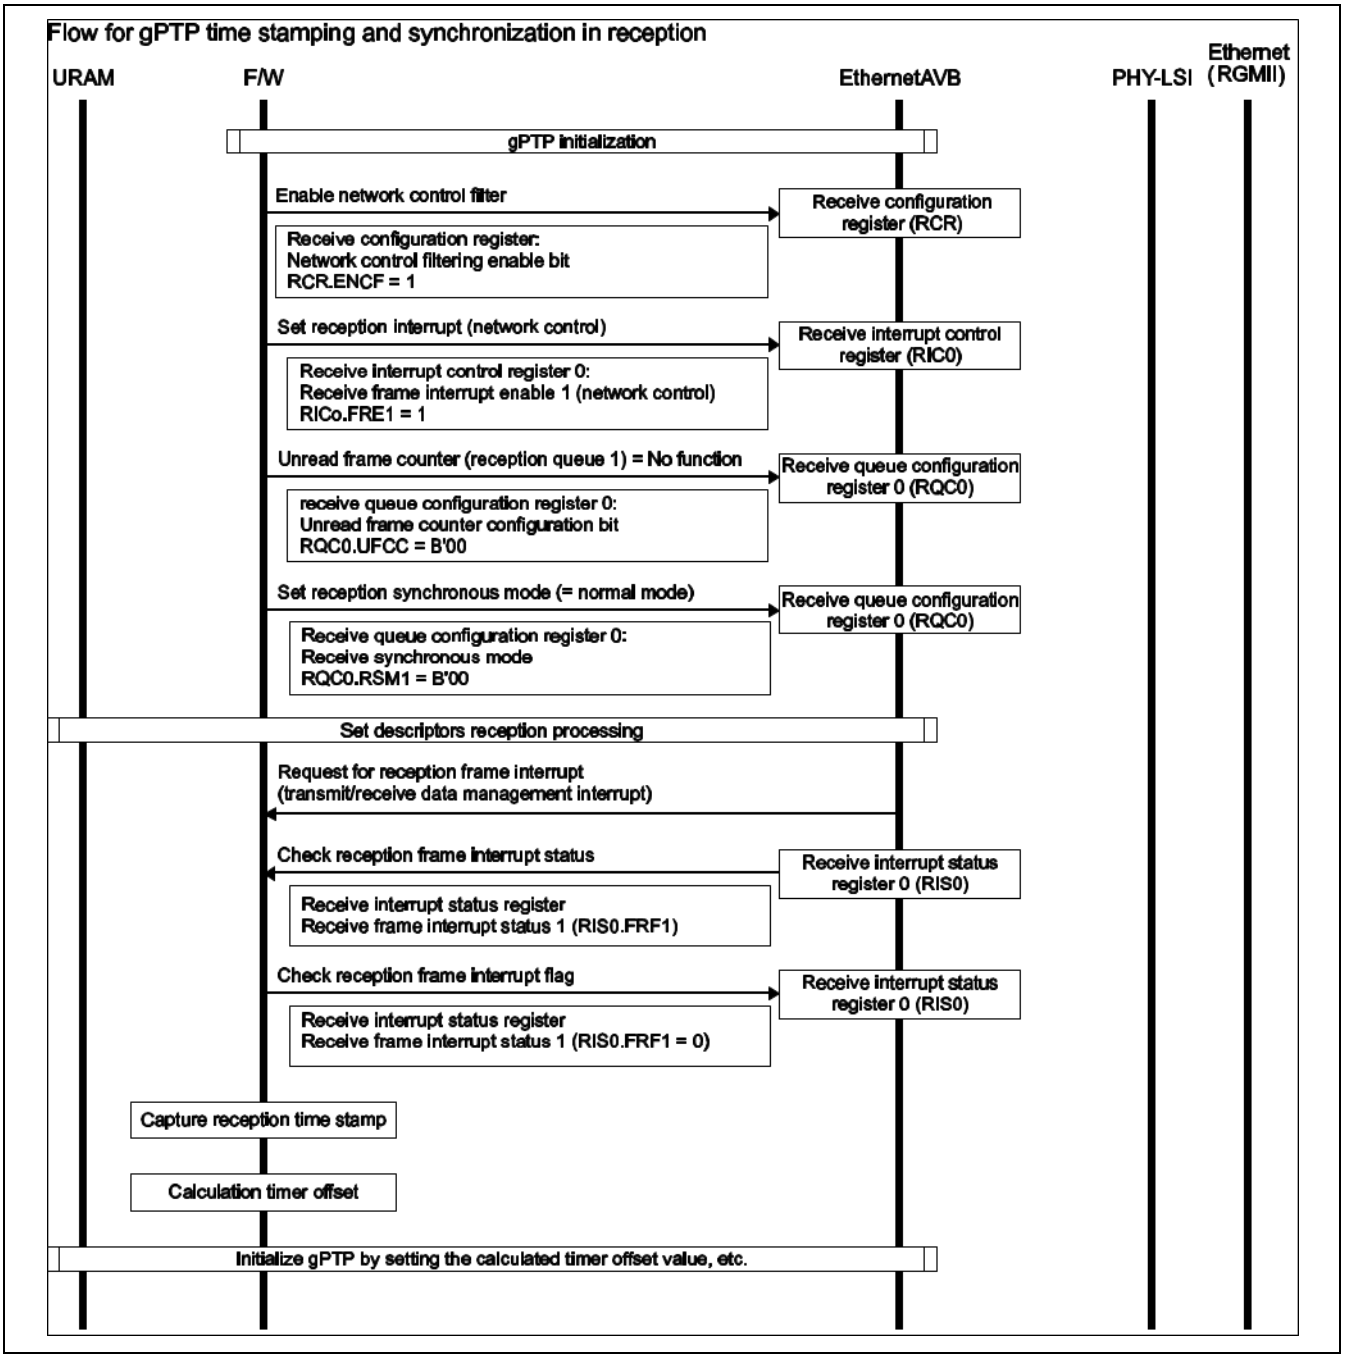

**Figure 100.1.3.12.11 Flow of gPTP Time Stamping and Synchronization in Reception (Normal, Common to All Modes)**

### (12) Flow of Capturing gPTP Presentation Times

Figure 100.1.3.12.12 shows the flow of capturing gPTP presentation times (common to all modes).

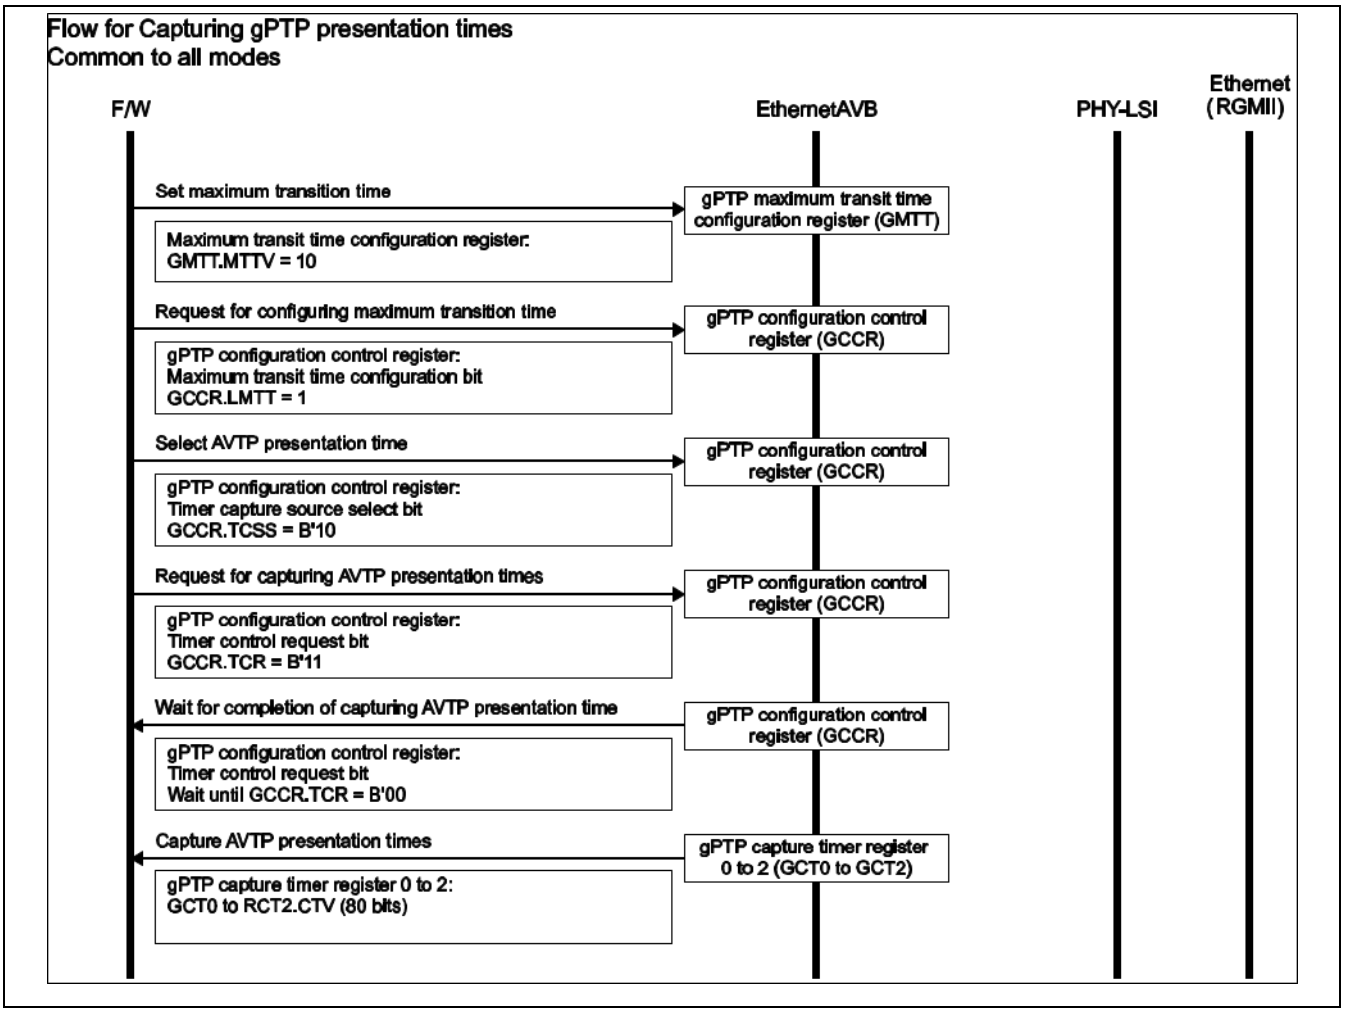

**Figure 100.1.3.12.12 Flow of Capturing gPTP Presentation Times (Common to All Modes)**

### (13) Flow of AVTP Presentation Time Comparison

Figure 100.1.3.12.13 shows the flow of AVTP presentation time comparison (common to all modes).

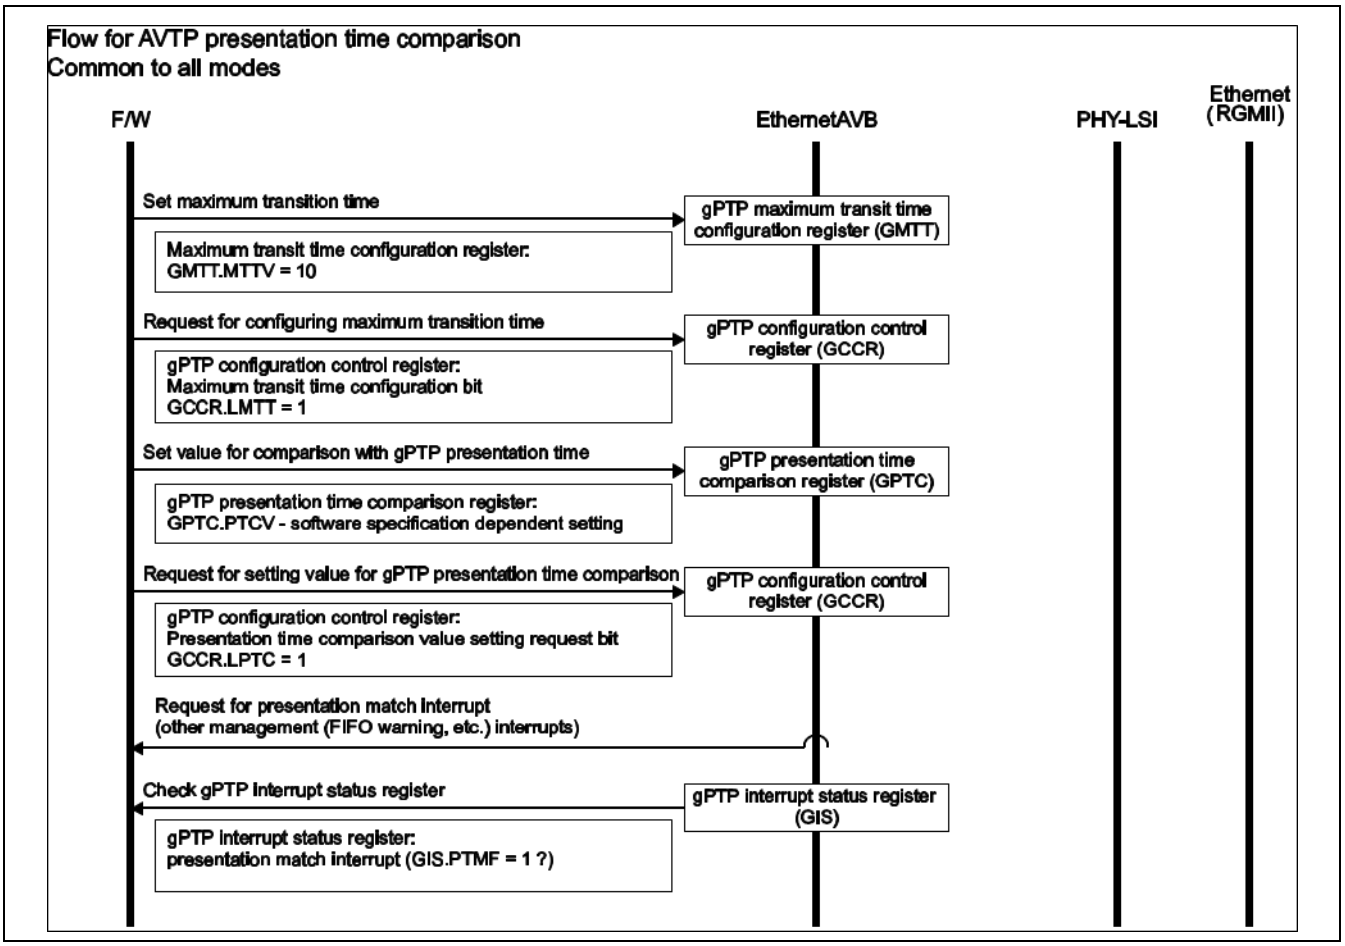

**Figure 100.1.3.12.13 Flow of AVTP Presentation Time Comparison (Common to All Modes)**

### (14) Flow of Loopback Mode Operation

Figure 100.1.3.12.14 shows the flow of loopback mode operation.

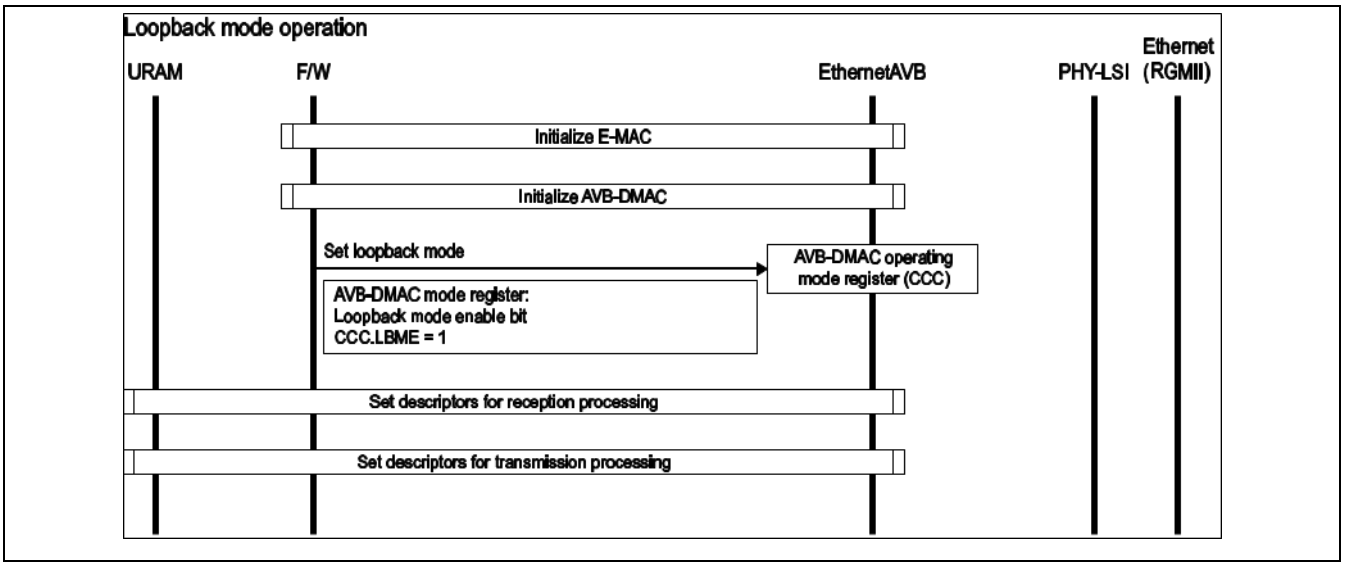

**Figure 100.1.3.12.14 Flow of Loopback Mode Operation**

### 100.1.3.11 Connection to PHY-LSI

#### (1) RGMII Frame Transmission/Reception Timing

Each RGMII frame transmission/reception timing is shown in Figure 100.1.3.13.1 to Figure 100.1.3.13.8.

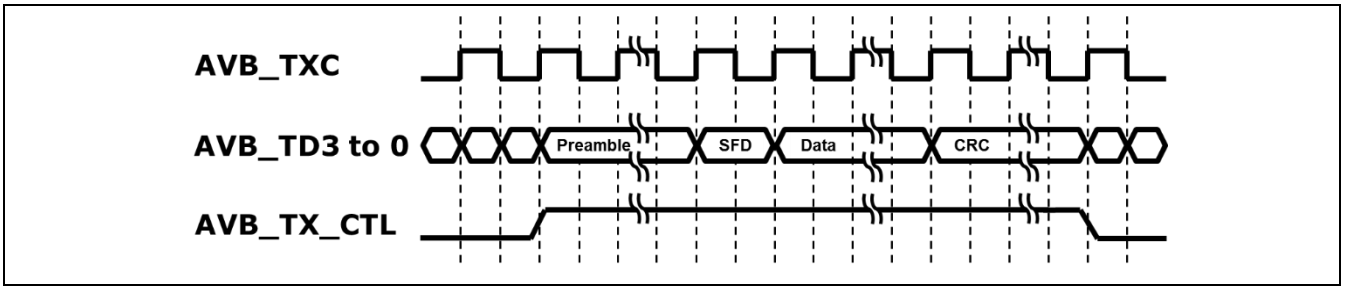

**Figure 100.1.3.13.1 RGMII Frame Transmit Timing (Normal Transmission)**

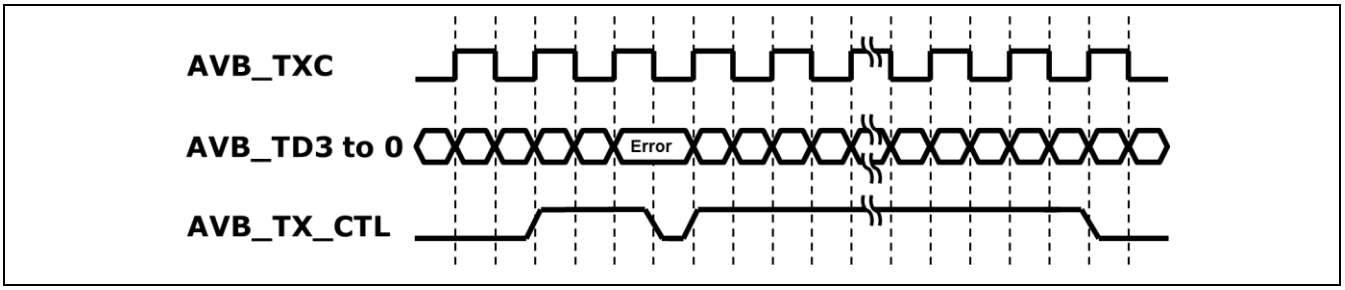

**Figure 100.1.3.13.2 RGMII Frame Transmit Timing (Transmit Error)**

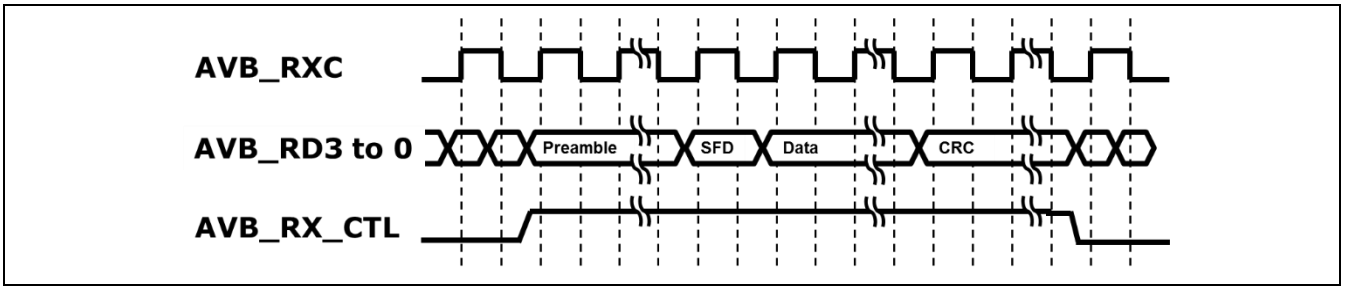

**Figure 100.1.3.13.3 RGMII Frame Receive Timing (Normal Reception)**

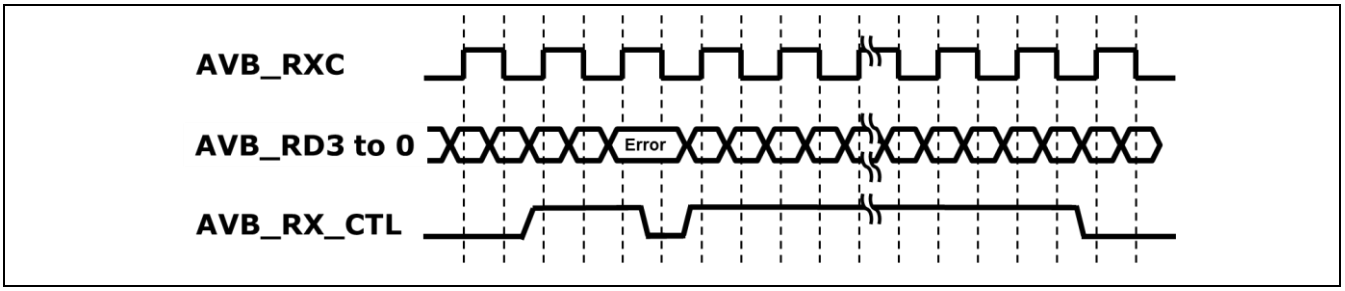

**Figure 100.1.3.13.4 RGMII Frame Receive Timing (Reception Error)**

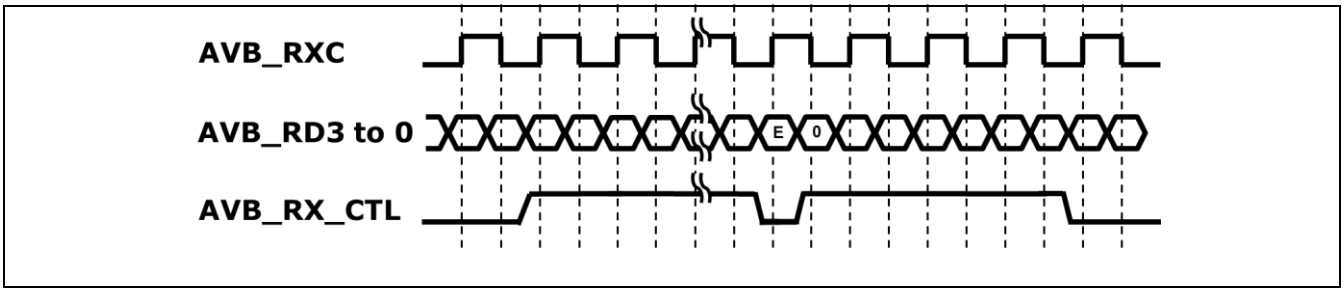

**Figure 100.1.3.13.5 RGMII Frame Receive Timing (False Carrier indication)**

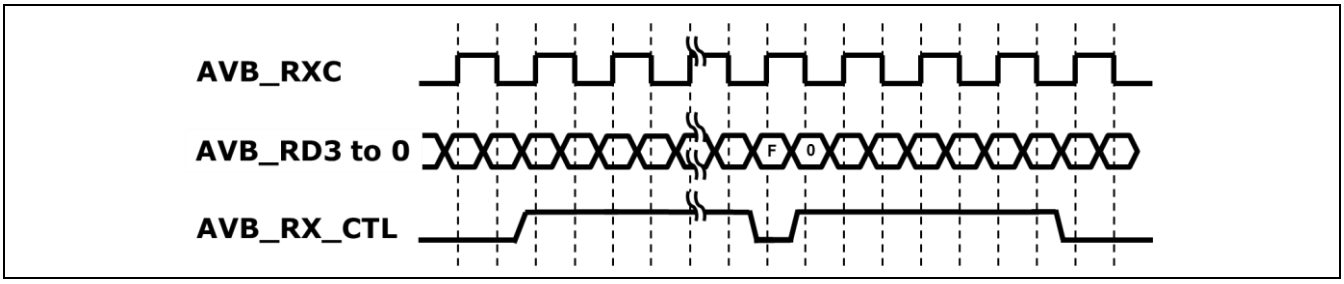

**Figure 100.1.3.13.6 RGMII Fame Receive Timing (Carrier Extend)**

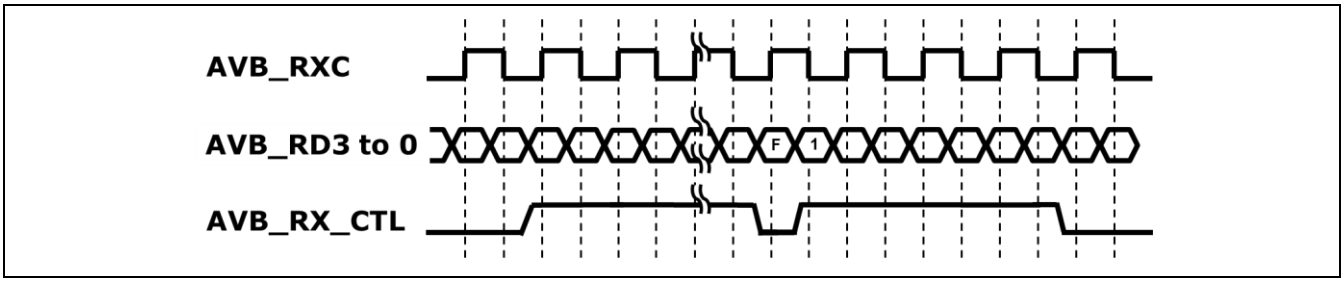

**Figure 100.1.3.13.7 RGMII Frame Receive Timing (Carrier Extend Error)**

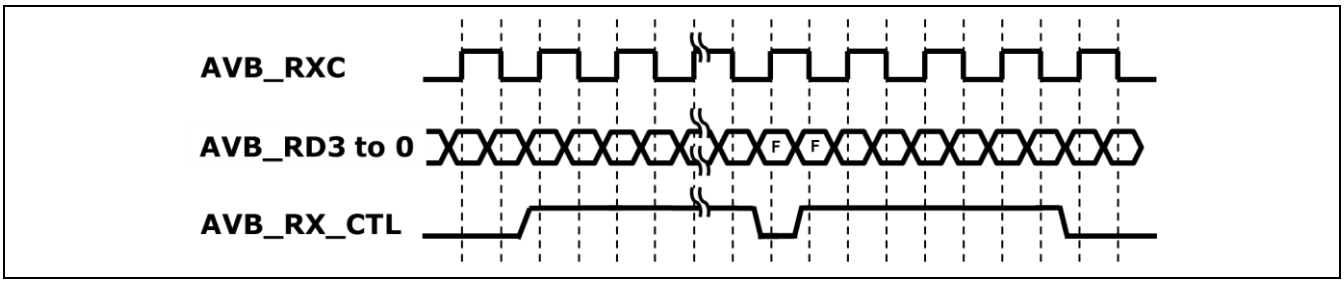

**Figure 100.1.3.13.8 RGMII Fame Receive Timing (Carrier Sense)**

### (2) Accessing MII Management Registers

MII management registers in the PHY-LSI are accessed via PIR in this LSI. PIR is used as a serial interface conforming to the MII frame format specified in IEEE802.3u.

#### (a) MII Management Frame Format

Figure 100.1.3.13.9 shows the format of an MII management frame. To access an MII management register, a management frame is implemented by the program in accordance with the procedures shown in MII Management Register Access Procedure.

| Access Type | MII Management Frame | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| Item | PRE | ST | OP | PHYAD | REGAD | TA | DATA | IDLE |
| Number of bits | 32 | 2 | 2 | 5 | 5 | 2 | 16 | |
| Read | 1..1 | 01 | 10 | 00001 | RRRRR | Z0 | D...D | |
| Write | 1..1 | 01 | 01 | 00001 | RRRRR | 10 | D...D | X |

[Legend]
PRE: 32 consecutive 1 s
ST: Write of B'01 indicating start of frame
OP: Write of code indicating access type
PHYAD: Write of B'00001 if the PHY-LSI address is 1 (sequential write starting with the MSB).
This bit changes depending on the PHY-LSI address.
REGAD: Write of 000q if the register address is 1 (sequential write starting with the MSB).
This bit changes depending on the PHY-LSI register address.
TA: Time for switching data transmission source on MII interface
(a) Write: 10 written
(b) Read: Bus release (notation: Z0) performed
DATA: 16-bit data. Sequential write or read from MSB
(a) Write: 16-bit data write
(b) Read: 16-bit data read
IDLE: Wait time until next MII management format input
(a) Write: Independent bus release (notation: X) performed
(b) Read: Bus already released in TA: control unnecessary

**Figure 100.1.3.13.9 MII Management Frame Format**

#### (b) MII Management Register Access Procedure

The program accesses MII management registers via PIR. Access is implemented by a combination of 1-bit-unit data write, 1-bit-unit data read, bus release, and independent bus release. Figure 100.1.3.13.10 to Figure 100.1.3.13.13 show the MII management register timing. The timing will differ depending on the PHY-LSI type.

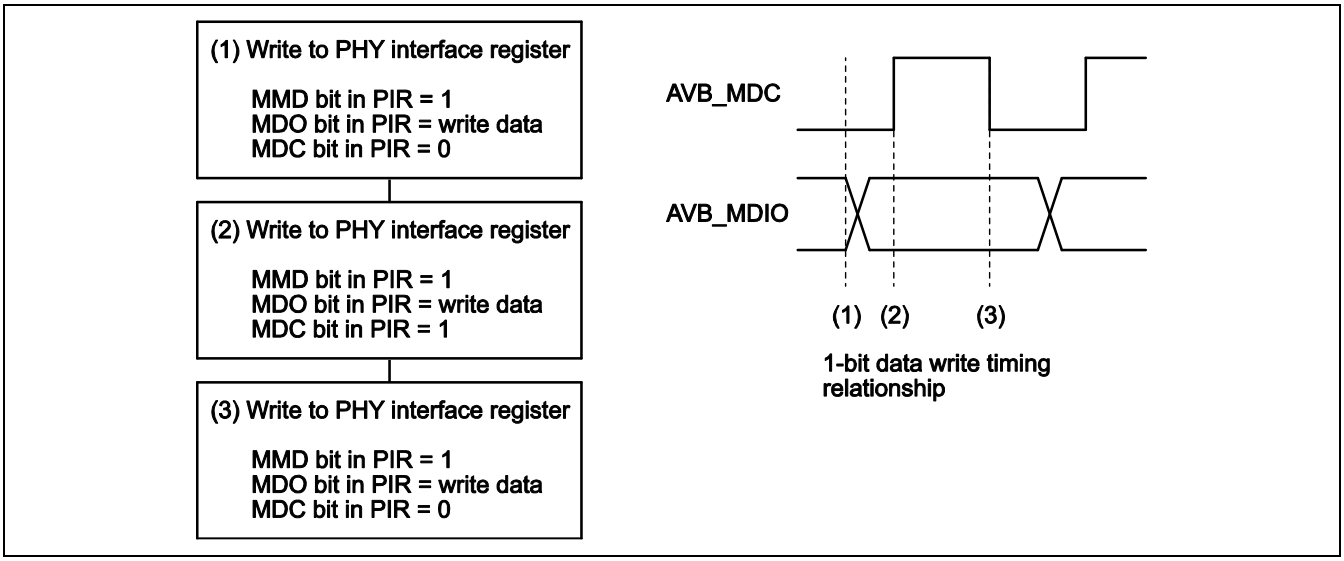

**Figure 100.1.3.13.10 1-Bit Data Write Flowchart**

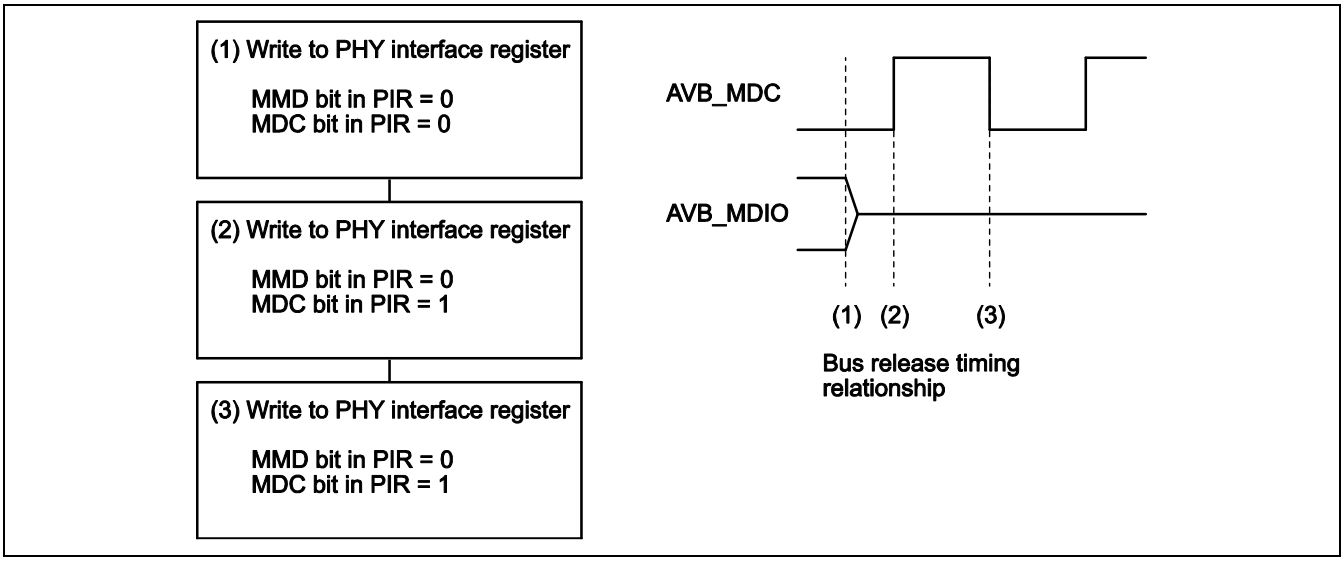

Note: TA in Read in Figure 100.1.3.13.9

**Figure 100.1.3.13.11 Bus Release Flowchart**

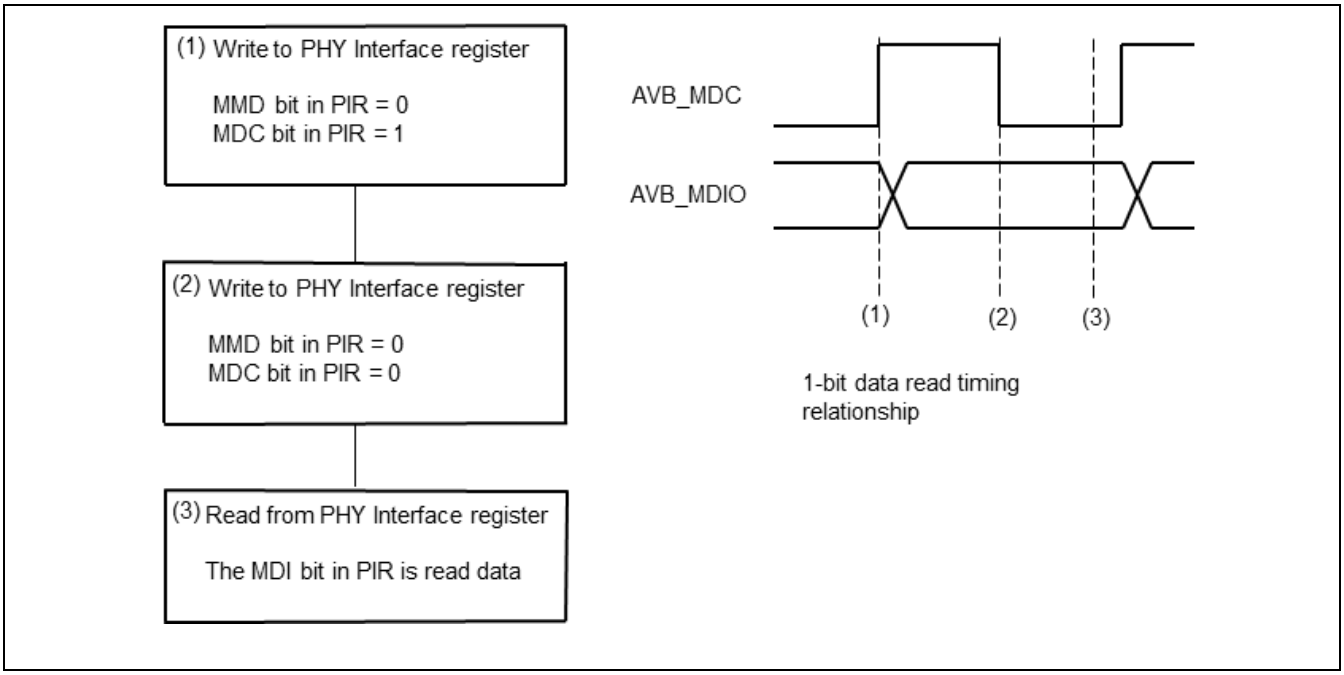

**Figure 100.1.3.13.12 1-Bit Data Read Flowchart**

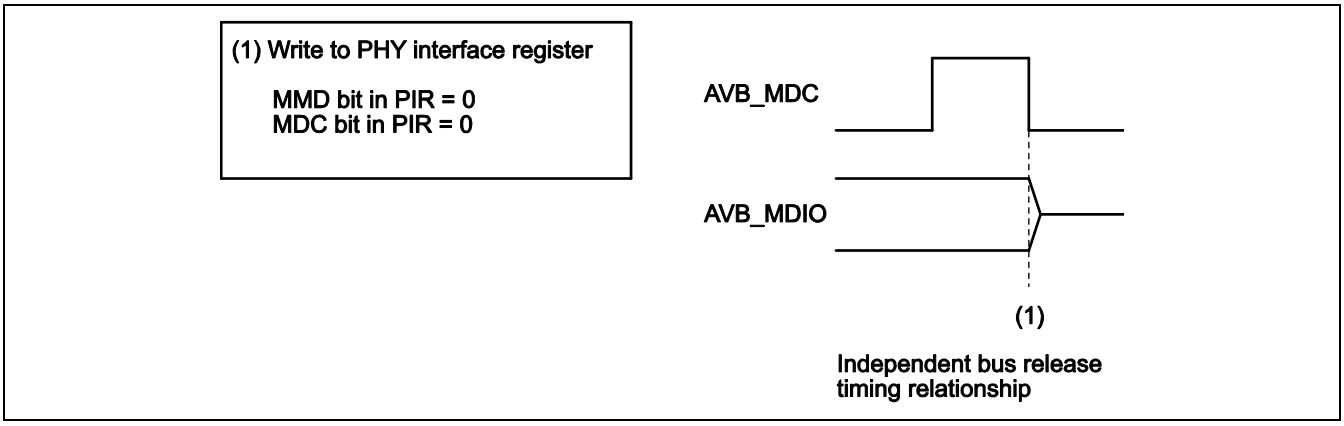

Note: IDLE in Write in Figure 100.1.3.13.9

**Figure 100.1.3.13.13 Independent Bus Release Flowchart**

### 100.1.3.12 Usage Notes

**(a) Reception is Ignored when AVB_RX_CTL indicates an error from PHY is Flagged at 1st Data Byte**

The issue is limited to reception of frames with physical faults. Flagging of occurrence in SFR is missing. When EthernetAVB-IF is configured to store faulty frames in reception queue 0 (BE) by RCR.EFFS there is no storage.

**(b) Unexpected Data are Exported when AVB_RX_CTL indicates an error is Flagged at 8th Data Byte**

The issue is limited to reception of frames with physical faults.

Flagging of occurrence in SFR is invalid. When EthernetAVB-IF is configured to store faulty frames in reception queue 0 (BE) by RCR.EFFS corrupted data is stored and MAC status code is wrong.

**(c) Receive Frame Interrupt and Descriptor Interrupt may be Issued before Completion of Writing Data**

When receive frame interrupt and descriptor interrupt are issued, whether writing data is completed by DESCR.DT in a descriptor can be confirmed.

And CDARq register has the descriptor address which EthernetAVB-IF is processing currently or is going to process at the next time.

The descriptors before one indicated by CDARq register are scope for receive frame interrupt and descriptor interrupt scope.

If there is a descriptor which wait for HW processing (ex. FEMPTY), it's delayed. Confirm the descriptor again after waiting for 1ms.

### 100.1.3.13 Support for UDP/IP

#### (1) Reception Queues Selection

The AVB-DMAC applies its separation filtering mechanism to select the reception queue for storing a received frame. The AVB-DMAC stores all received frames in the URAM.

There are two conditions for the AVB-DMAC to discard a received frame.

- Detection of an error during reception by the E-MAC
  - Whether error frames are discarded or stored in reception queue 0 (best effort) depends on the setting of the error frame enable bit in the receive configuration register (RCR.EFFS). If error frames are to be stored (RCR.EFFS = 1), they are always stored in queue 0 (best effort). In this case, characteristics specific to the queue (e.g. truncation) will vary. If the storage of time stamps for reception queue 0 (best effort) is enabled (the time stamp enable bit in the receive configuration register RCR.ETS0 = 1), time stamps are stored even for error frames.
- Frame fails the separation filter
  - It depends on RCR.ESF if such frame is discarded or stored in receive queue 0 (best effort).

The flowchart in Figure 100.1.3.15.1 shows how the AVB-DMAC selects the reception queue in accord with the frame type, including judgment by the separation filter. Selection of the queue starts when the E-MAC completes frame reception. The result is storage of the frame in the proper queue or the frame being discarded.

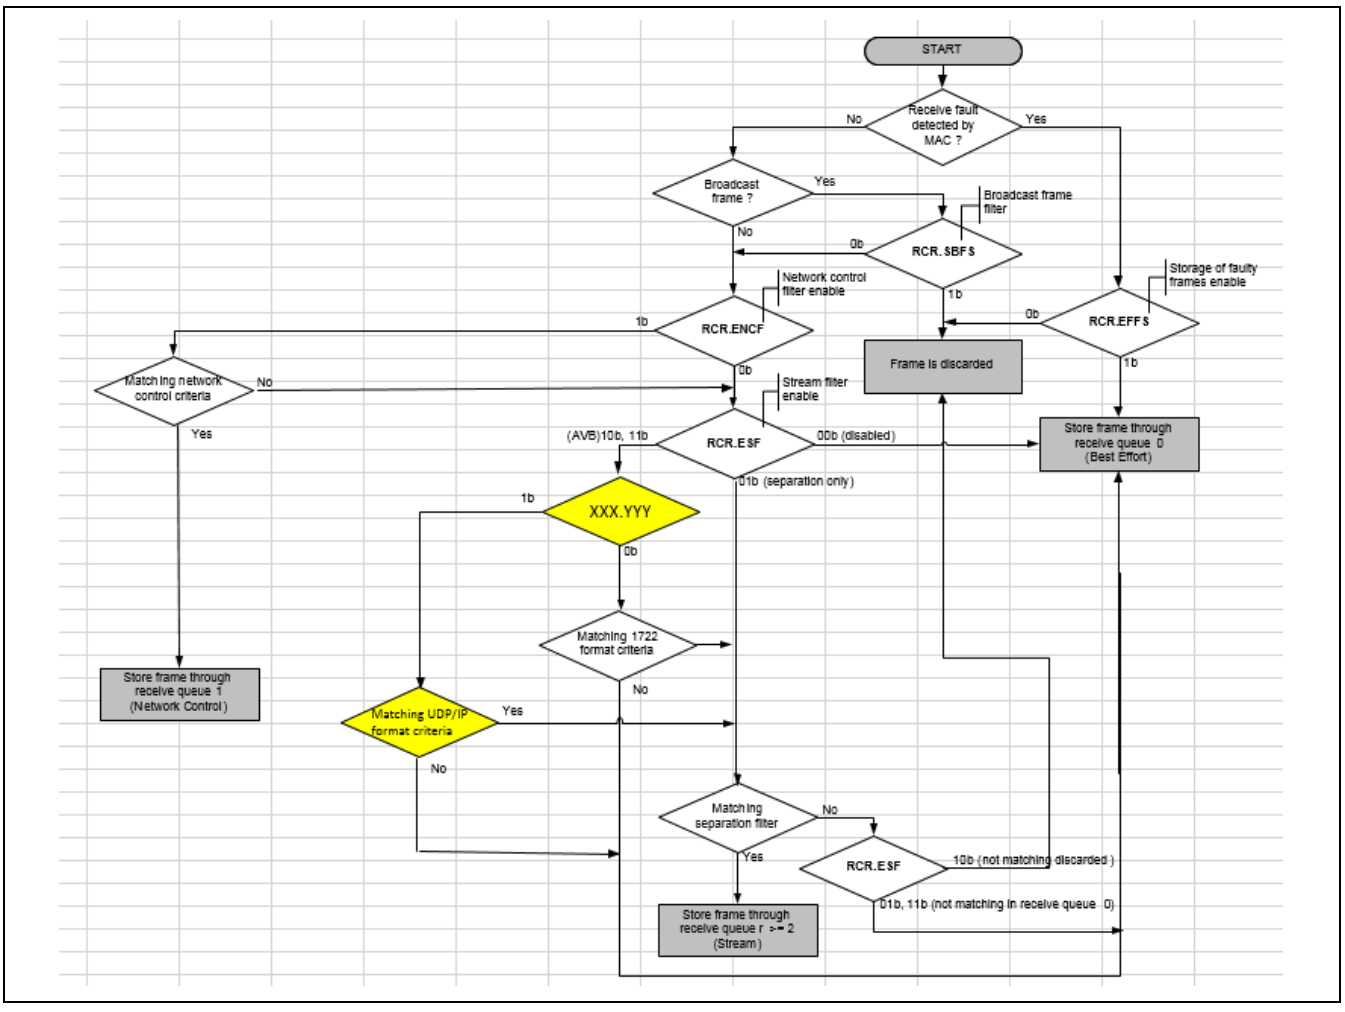

**Figure 100.1.3.15.1 Mechanism of Reception Queue Selection**

Notes on the meanings of entries in the flowchart

- "Condition for determining network control frames"
  The Ethernet destination address (DA) is 01:80:C2:00:00:0E.
  The Ethernet type (ET) is 88:F7.
- "Condition for determining IEEE 1722 frames"
  The Ethernet destination address (DA) is within the range from 91:E0:F0:00:00:00 to 91:E0:F0:00:FE:FF.
  The VLAN tagged TPID (tag protocol identifier) field (VL) is 81:00.
  The Ethernet type (ET) is 22:F0.
- "Condition for separation filter determination"
  See section 100.1.3.4(1)(a) Separation Filtering.

Figure 100.1.3.15.2 shows the allocation of bits related to the network and stream types in Ethernet frames. The preambles of Ethernet frames are not taken into account.

| Data bytes | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Network type | DA1 | DA2 | DA3 | DA4 | DA5 | DA6 | SA1 | SA2 | SA3 | SA4 | SA5 | SA6 | ET1 | ET2 | ... | ... | ... | ... | ... | ... |
| Stream type | DA1 | DA2 | DA3 | DA4 | DA5 | DA6 | SA1 | SA2 | SA3 | SA4 | SA5 | SA6 | VL1 | VL2 | - | - | ET1 | ET2 | ... | ... |

**Figure 100.1.3.15.2 Data Bytes of Ethernet Frames Used in Classification**

**(a) Separation Filtering**

Separation filtering involves the checking of up to 64 bits (eight successive bytes) in received Ethernet frames. The setting for the first byte (i.e. the setting of the separation filter offset configuration register (SFO.FBP)), selects the part of frames to be used in separation filtering. There is also a common filter mask (set in the separation filter mask configuration register (SFMi.CFM)) that can be freely set to reduce the number of bytes used in separation filtering or to mask particular bits.

**Examples**

To use one byte in separation, set separation filter mask configuration register 0 (SFM0.CFM) to H'0000 00FF and separation filter mask configuration register 1 (SFM1.CFM) to H'0000 0000.

To use seven bytes in separation, set separation filter mask configuration register 0 (SFM0.CFM) to H'FFFF FFFF and separation filter mask configuration register 1 (SFM1.CFM) to H'00FF FFFF.

Note: If bits at some positions are set to 0 in the separation mask, in order to match with the pattern, the bits at the corresponding positions of the pattern must also be set to 0. Only those bits in which the separation filter pattern configuration register (SFPi.FPs) setting is equal to the separation filter mask configuration register (SFMi.CFM) are sorted by matching with received data.

Figure 100.1.3.15.3 shows separation filtering. The selected data from a received frame (Rx_Frame[63:0]) are masked by the common filter mask. As a result, the selected frame data can be obtained. This value is compared with all filter patterns. The separation filter circuit in the AVB-DMAC selects the filter pattern that matches the queue having the lowest index s or selects a flag to indicate that there is no matching separation pattern.

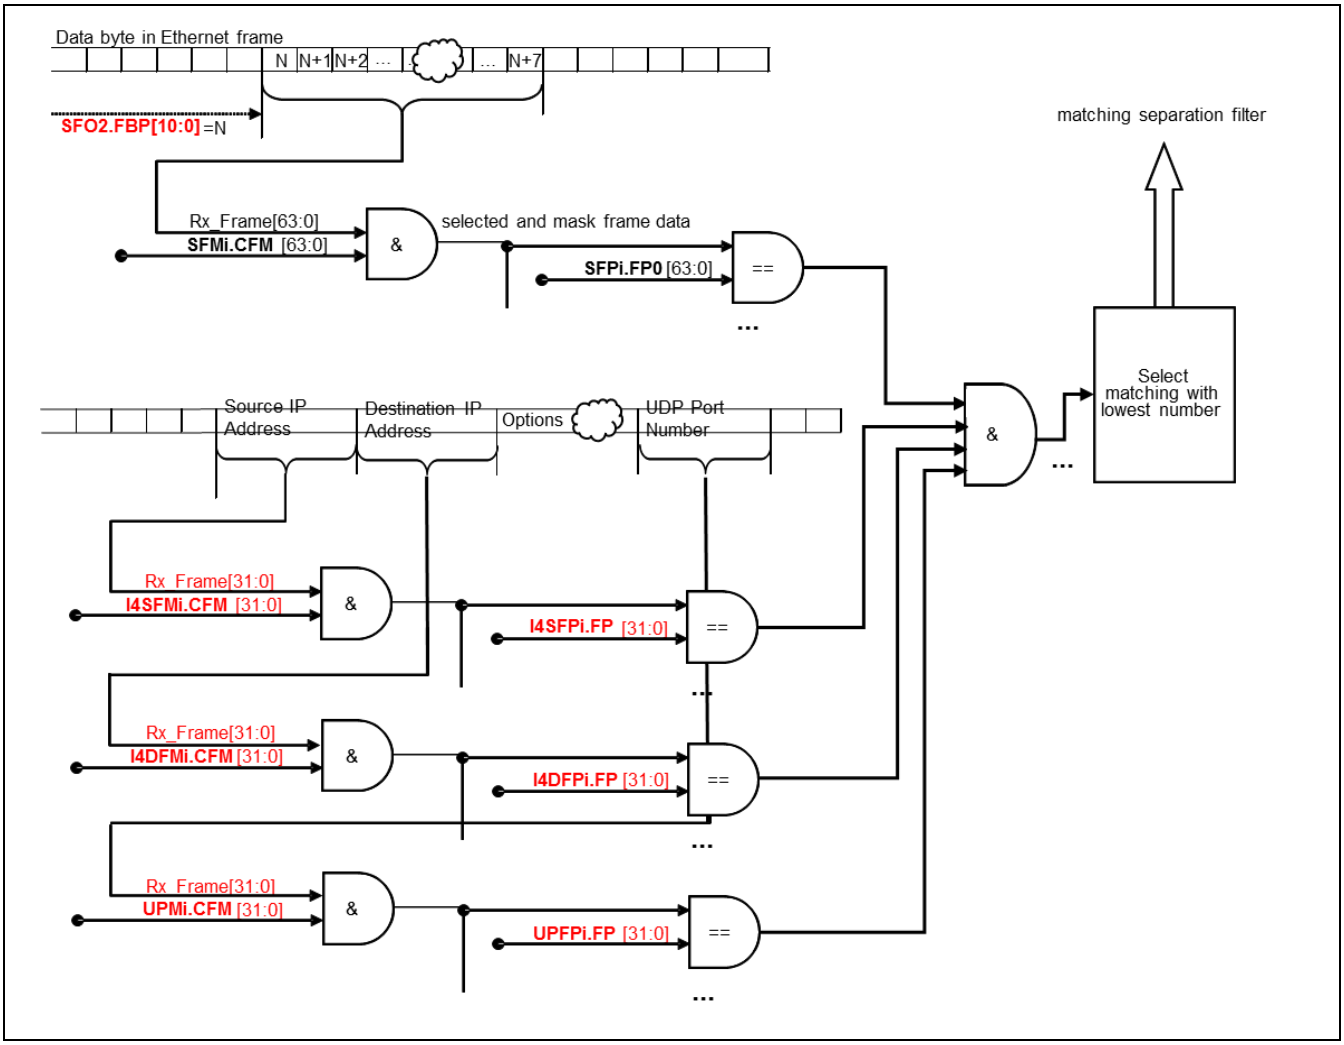

**Figure 100.1.3.15.3 Separation Filtering**

### (b) Separating Streams

The AVB-DMAC applies separation filtering to sort frames received in streams. An AVB network has a concept of “Talker” and “Listener”. A Talker is an end station that generates one or more streams. A Listener is an end station that has the role of being a sink for at least one stream. The various A/V streams are identified by 8-byte stream IDs.

The number of end stations within an AVB network and their roles differ with the application.

The stream ID is a general pattern of the AVB network for identifying one stream. Figure 100.1.3.4.5 shows the bit allocation of bits in IEEE1722 Ethernet frames and stream ID fields.

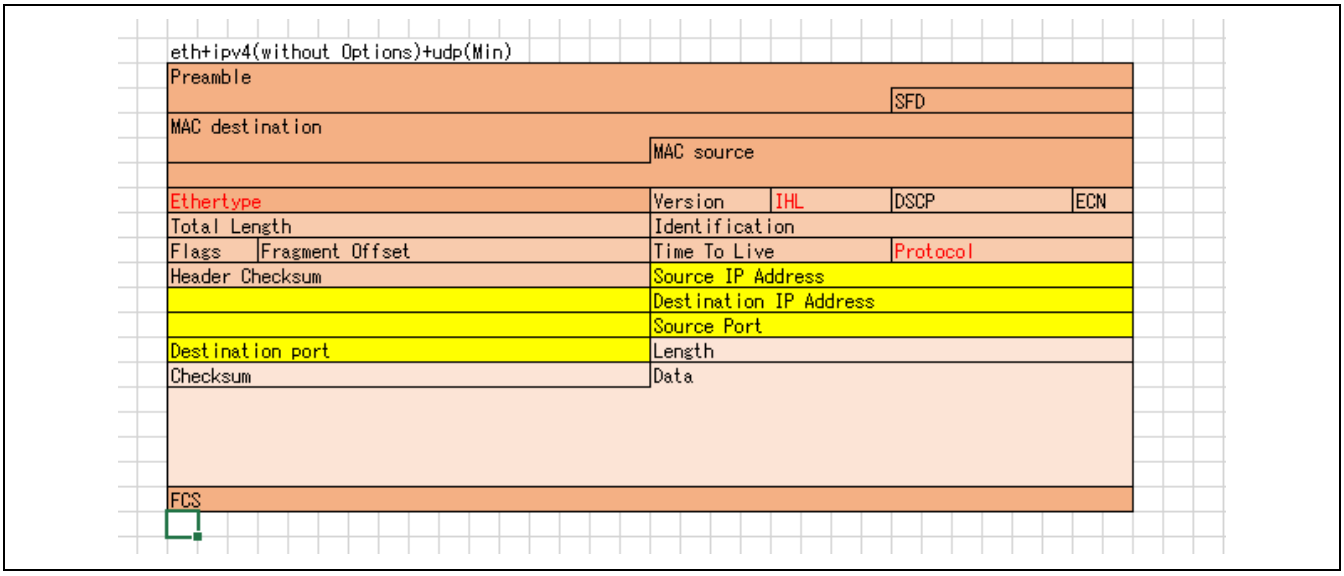

**Figure 100.1.3.15.4 With UDP/IPv4 Frame Layout**

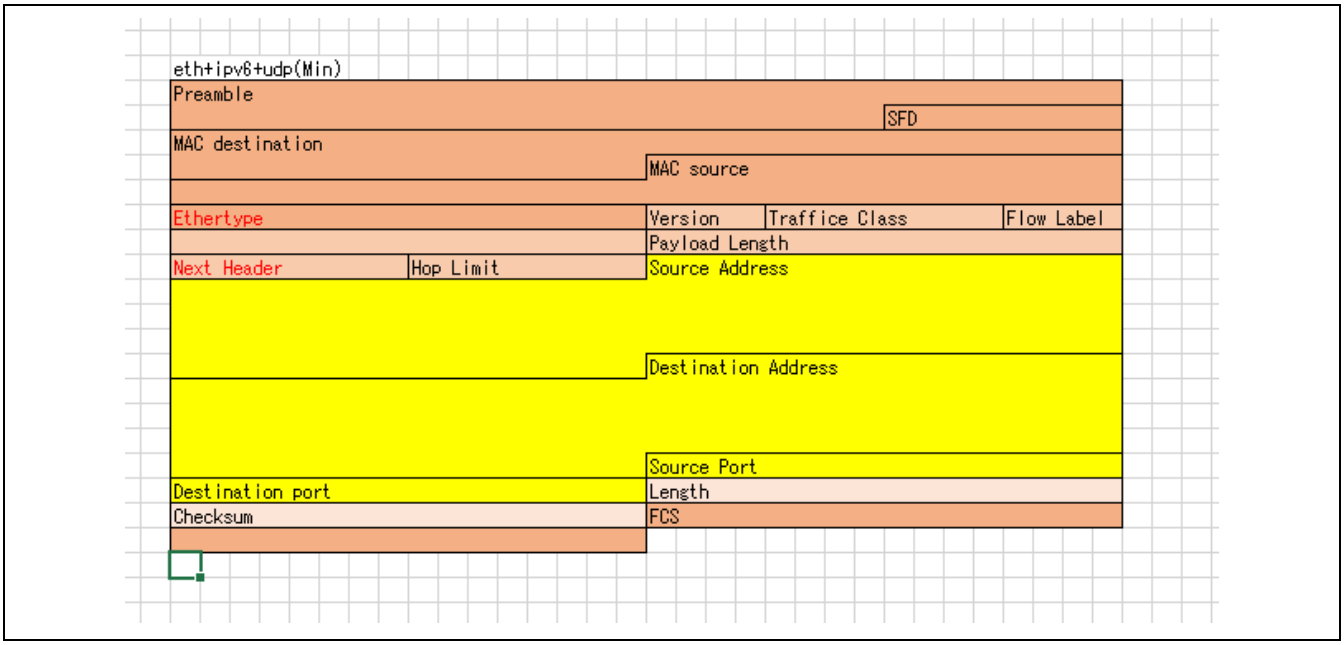

**Figure 100.1.3.15.5 With UDP/IPv6 Frame Layout**

The IEEE 1722 standard stipulates that the stream ID field starts from the 23rd byte (not counting the preamble). Accordingly, set the separation filter offset (SFO.FBP) to 22 in operations on IEEE 1722 streams. Set the separation filter mask (SFMi) and separation filter pattern (SFPi) in accord with the specification of the product in which the chip is being used.

Example: In the example of a stream ID shown in Figure 100.1.3.4.5, the current application divides the field into the talker source address and the unique stream ID. The unique ID is used to differentiate between multiple streams from the same talker. Based on this, there are two settings for separation filter masking:

- To divide various streams into individual queues, set SFM0.CFM to H'FFFF FFFF and SFM1.CFM to H'FFFF FFFF.
- To divide streams from various talkers into individual queues, set SFM0.CFM to H'FFFF FFFF and SFM1.CFM to H'0000 FFFF. This excludes the unique ID from the filter condition.

**(c) Reconfiguration of separation filter during OPERATION**

In CONFIG mode the initial separation filter configuration is defined. To prevent inconsistent filter results during OPERATION direct parameter change is not possible; instead update mechanism by **SFVi.LV** and **SFL.LC** should be used.

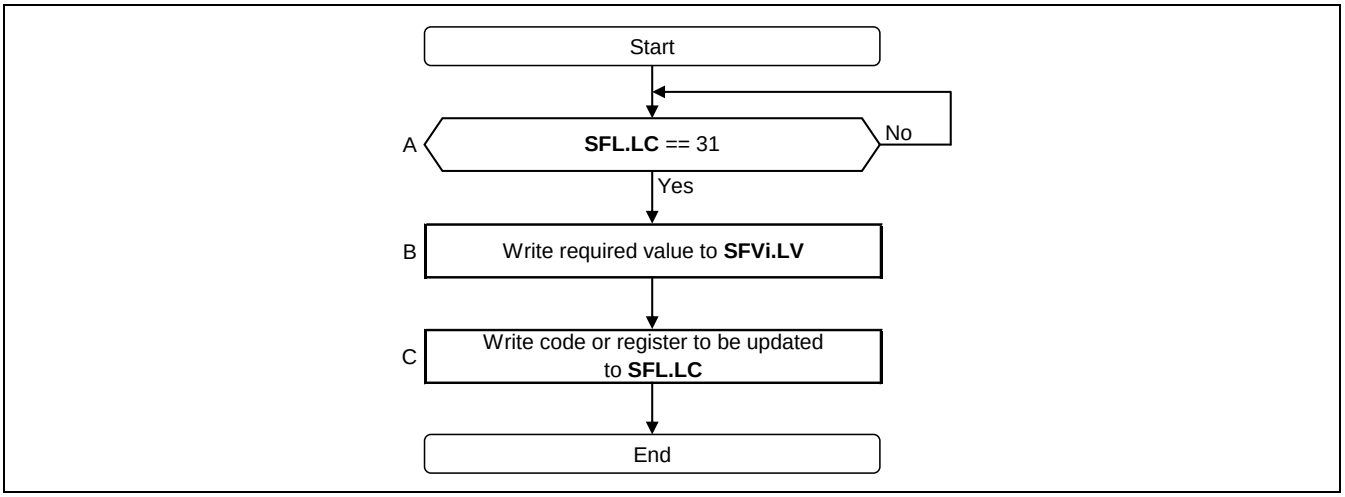

**Figure 100.1.3.15.6 SW flow to update separation filter during OPERATION**

When reconfigure separation filter, EthernetAVB-IF guarantees consistent classification for one received frame. If reconfiguration requires a sequence of parameter changes, CPU has to order reconfiguration based on application demand.
EthernetAVB-IF updates filter configurations when no frame reception is handled. In worse case the update is delayed by one frame reception. Exact duration depends on PHY speed and frame size. By reading **SFL.LC** CPU can observe when a previous update has been processed.
Note: Frame classification happens during frame reception and storage into internal Rx-FIFO. There may be frames with old classification pending in Rx-FIFO or under storage to URAM when filter reconfiguration is accepted.

**(d) Disable Manual Offset Mode**

Enable Manual Offset Mode

0: Manual Offset Mode disabled
1: Manual Offset Mode enabled

When this bit is 0, These bits set the position in Ethernet frames of the first byte of the bytes(see section (a) Disable Manual Offset Mode) to be used by the separation filter. A fixed value by rx_data[31:16] is selected as shown in the table below.

| mir_macrx_data[31:16] | IPv4 Source Address Filter Offset | IPv4 Destination Address Filter Offset | IPv6 Source Address Filter Offset | IPv6 Destination Address Filter Offset | UDP Port Number Filter Offset |
|---|---|---|---|---|---|
| 16'h8100 (802.1) | (ipv4_ihl << 2) + 10'd10 | (ipv4_ihl << 2) + 10'd14 | 10'd26 | 10'd42 | 10'd58 |
| 16'h0800 (ipv4) | (ipv4_ihl << 2) + 10'd6 | (ipv4_ihl << 2) + 10'd10 | 10'd22 | 10'd38 | (ipv4_ihl << 2) + 10'd14 |
| others | (ipv4_ihl << 2) + 10'd6 | (ipv4_ihl << 2) + 10'd10 | 10'd22 | 10'd38 | 10'd54 |

When this bit is 1, These bits set the position in Ethernet frames of the first byte of the bytes**(I4SFO.FBP, I4DFO.FBP, I6SFO.FBP, I6DFO.FBP and UPFO.FBP)** to be used by the separation filter.

| IPv4 Source Address Filter Offset | IPv4 Destination Address Filter Offset | IPv6 Source Address Filter Offset | IPv6 Destination Address Filter Offset | UDP Port Number Filter Offset |
|---|---|---|---|---|
| I4SFO.FBP Register | I4DFO.FBP Register | I6SFO.FBP Register | I6DFO.FBP Register | UPFO.FBP Register |

| PS | Refer Table 100.16. |
| EI | Refer Table 100.16. |
| TI | Refer Table 100.16. |

## 100.1.4 Usage Notes

### 100.1.4.1 Checksum Calculation of Ethernet Frames

This LSI is capable of calculating the checksum data of the received frames. Only the data fields of the Ethernet frames are subject to checksum calculation. Specifically, a data field follows the length/type field and is followed by the CRC field. Figure 100.1.4.1.1 shows schematics indicating which parts of the Ethernet frames are calculated. Calculation involves 16-bit addition only; it does not involve bit inversion. Note that when the checksum data is valid, the CRC data (4 bytes) is not transferred as a receive frame, and the checksum data (sum data) is added automatically. Figure 100.1.4.1.2 shows schematics of Ethernet frames to which the checksum data has been added.

Note: Also for the frames with VLANtag inserted, the 15th byte from the top and the following bytes before the CRC field are subject to calculation.

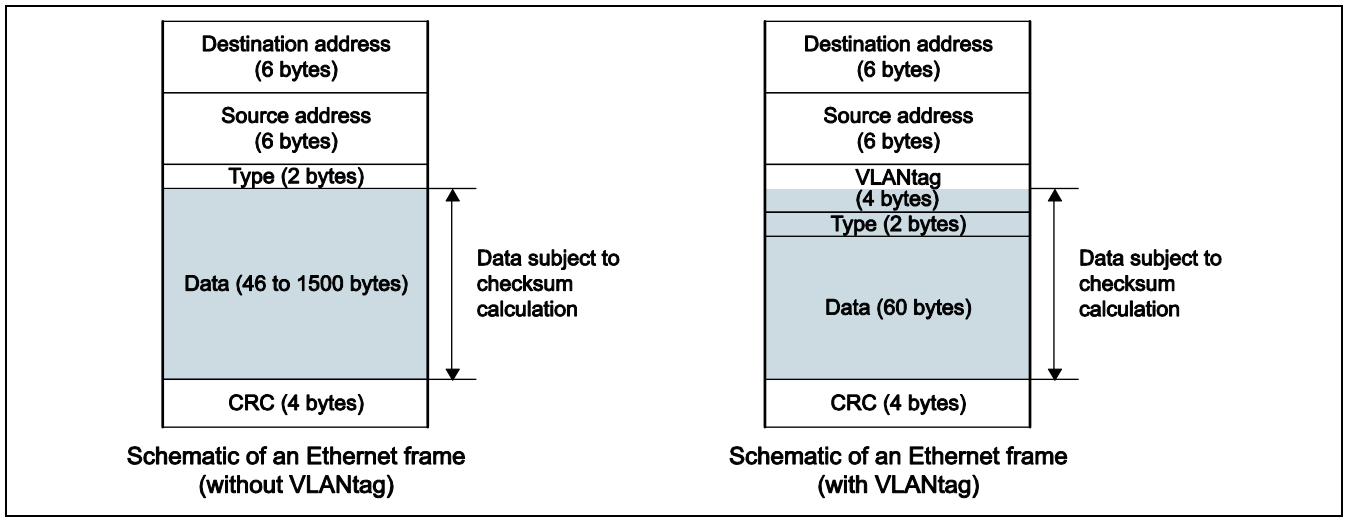

**Figure 100.1.4.1.1 Data Subject to Checksum Calculation**

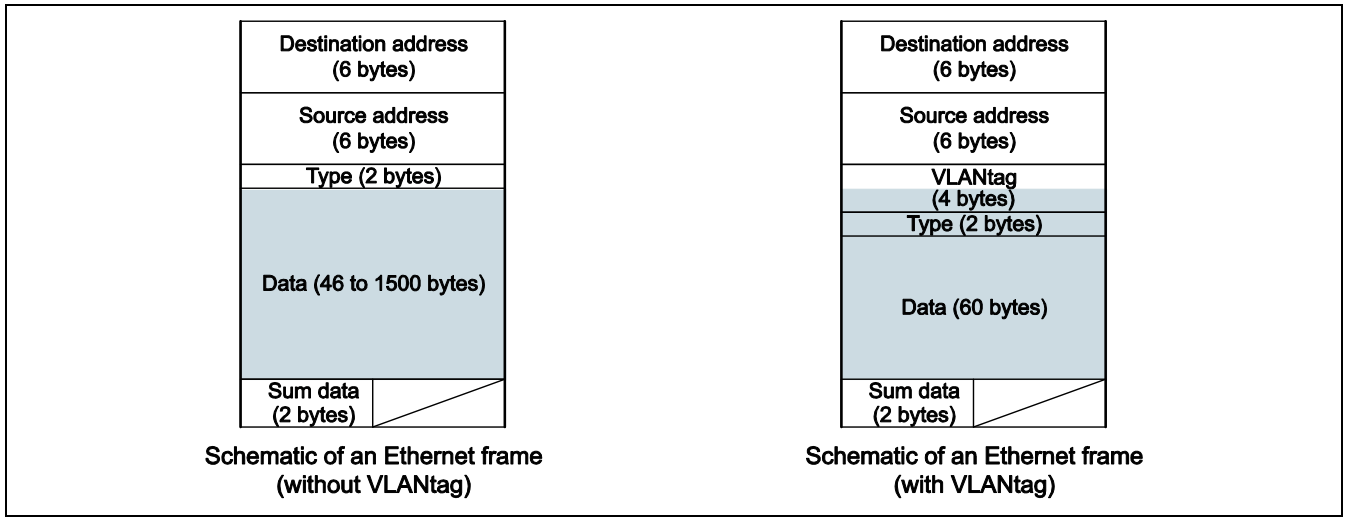

**Figure 100.1.4.1.2 Data after Checksum Data Addition**

### 100.1.4.2 Data Transfer Function Stops after Read Access Error

If EthernetAVB-IF gets an access error when reading from work RAM, it may happen that no further work RAM accesses are issued. So transfer of receive/transmit frames is halted. By using the data transfer suspend function SW can observe if data transfer function is available or not.

Perform one of given SW flows which are triggered by this start condition: when AXI read access error has been flagged by EIS.QEF is 1, and ESR.ET is B'0000 or B'0100; additionally when ESR.EIL is 1 (this is an indication that an work RAM read error may be lost).

There are two possible SW flows given. Figure 100.1.4.2.1 applies always the SW reset, independently if this is required or not. Figure 100.1.4.2.2 checks in addition if SW reset is required; checking CSR.DTS after wait gives an indication that issue has been occurred.

Note that the wait after write of CCC.DTSR is mandatory to prevent cases where issue has not been occurred.

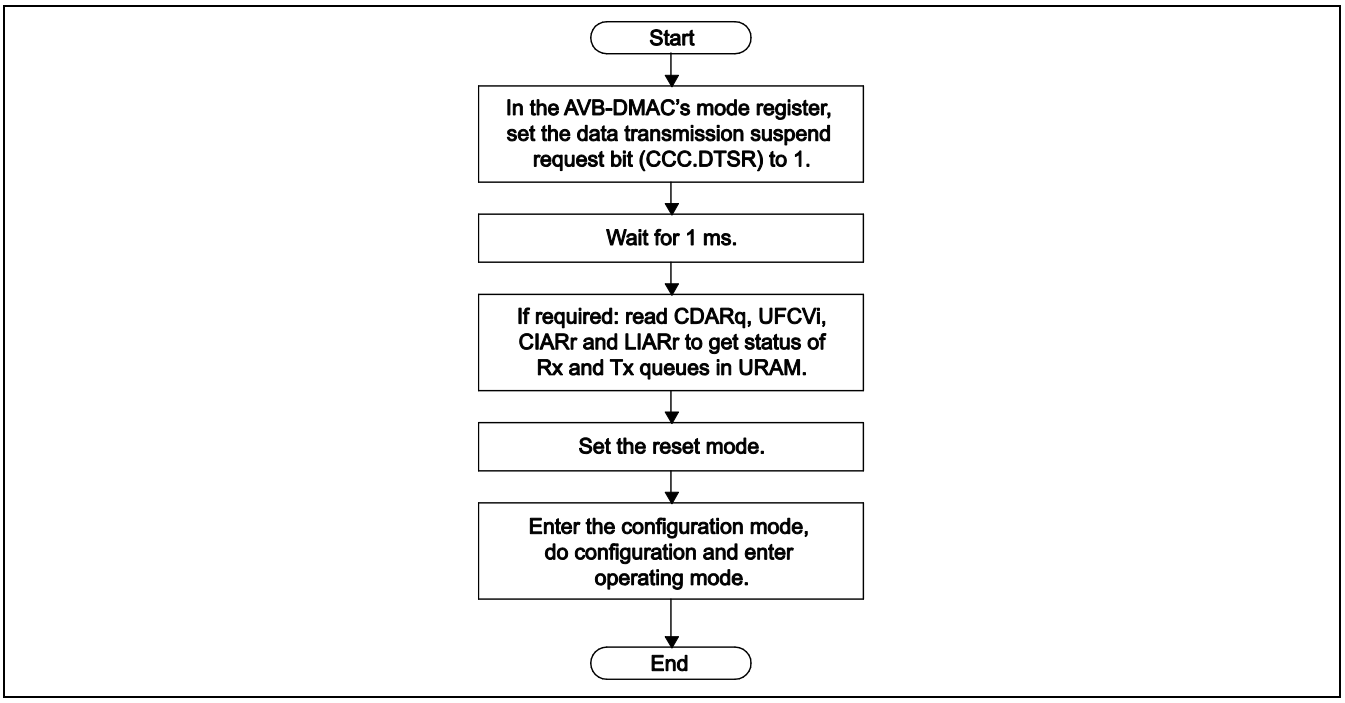

**Figure 100.1.4.2.1 Data Transfer Function Stop Flow1 after Read Access Error**

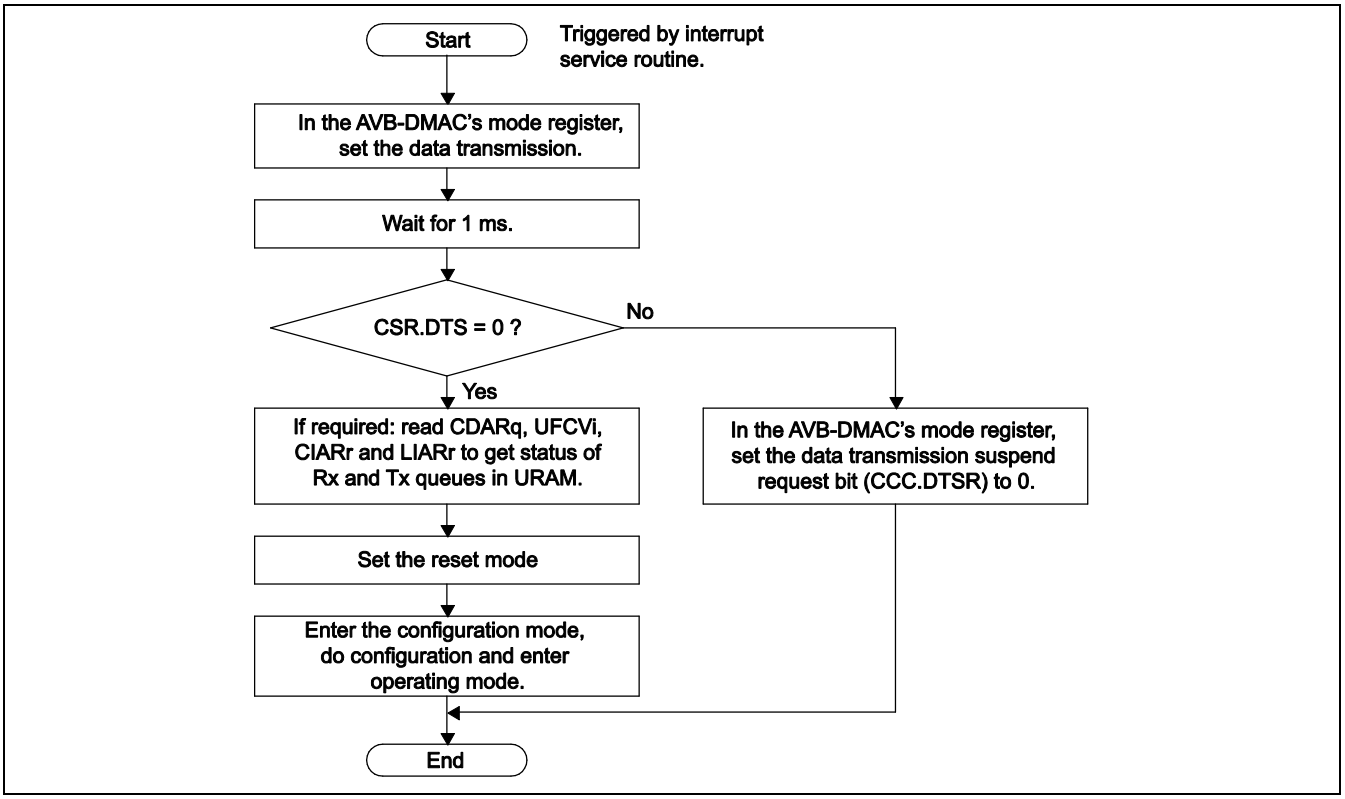

**Figure 100.1.4.2.2 Data Transfer Function Stop Flow2 after Read Access Error**

### 100.1.4.3 Power Down Request

If EthernetAVB-IF gets a power down request while writing to work RAM, it may happen that the request is not accepted even if the transfer is completed. Due to this the external power down module cannot complete the power down sequence.

A power down request is acceptable only when EthernetAVB-IF is in RESET state.

### 100.1.4.4 MII Interface

#### (1) Specifications of the MII in Outline

The media independent interface (MII) is a specification for use in connection between the MAC and PHY layers of an Ethernet communications interface. The MII is originally defined in IEEE802.3 as a standard interface to connect a Ethernet media access control (MAC) block to a PHY chip at 100Mbps.
MII supports 3.3V CMOS interface voltage for all IO pins and 25MHz reference clock for 100Mbps communication.

**(a)** Signal Line Specification in the MII

The MII uses fourteen signals to connect the MAC and PHY layers. With an MII, the contents of the data and control signals for transmission and reception change on rise edges of the respective clock signals.

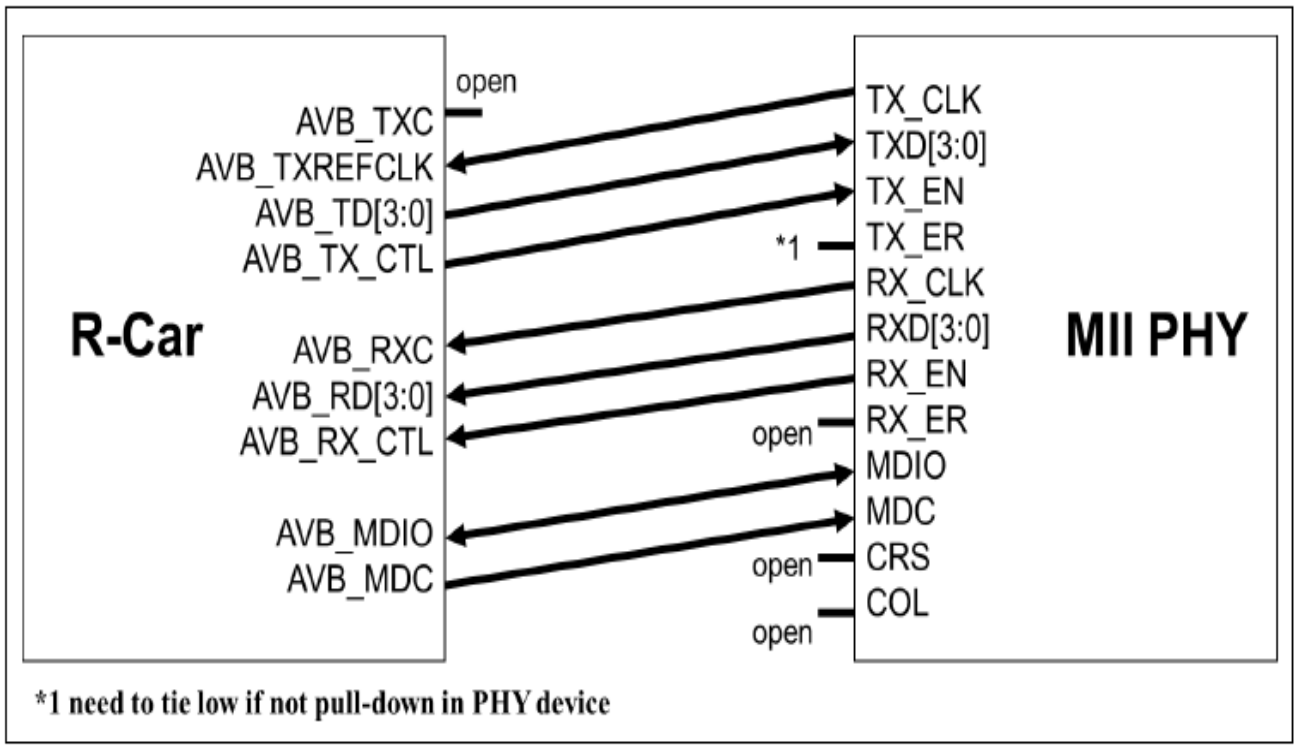
Definitions of Signals Used in an MII is shown below:

| MII Signal | Source | Sink | Description |
|---|---|---|---|
| TXC | PHY | MAC | Reference clock for use in transmission. It runs at 25MHz. |
| TD[3:0] | MAC | PHY | Data being transmitted. The meanings of the signals differ with the edge of the TXC signal. |
| TX_EN | MAC | PHY | Control signal for transmission. The meaning of the signal differs with the edge of the TXC signal. |
| RXC | PHY | MAC | Reference clock for use in reception. It runs at 25MHz. |
| RD[3:0] | PHY | MAC | Data being received. The meanings of the signals differ with the edge of the RXC signal. |
| RX_EN | PHY | MAC | Control signal for reception. The meaning of the signal differs with the edge of the RXC signal. |
| MDIO | MAC or PHY | MAC or PHY | IO signal for control over the PHY layer. |
| MDC | MAC | PHY | Clock signal for control over the PHY layer. |
| TX_ER | MAC | PHY | Transmit enable |
| RX_ER | PHY | MAC | Receive error |
| CLS | PHY | MAC | Carrier sense |
| COL | PHY | MAC | Collision detect |

**(b) External Devices**

We assume that two types of device, PHY devices and switches, may be externally connected to the MII of an R-Car device. Note that the MII connections to both types of device are handled in the same way.

• PHY device
This type of device is used for systems with a single port directly connected to an Ethernet cable.



### (2) Specifications for the MII in R-Car Series Devices

#### (a) Specifications for the MII in R-Car Series Devices

The correspondence between pins of R-Car devices and MII signals is given in below table. MII Signal “TXC” should be connected to “AVB_TXCREFCLK” in R-Car. “AVB_TXC” is not used in MII connection mode.

| MII Signal | R-Car Signal | Source | Sink |
|---|---|---|---|
| TX_CLK | AVB_TXCREFCLK | PHY | MAC |
| TXD[3:0] | AVB_TD[3:0] | MAC | PHY |
| TX_EN | AVB_TX_CTL | MAC | PHY |
| TX_ER | — | MAC | PHY |
| RX_CLK | AVB_RXC | PHY | MAC |
| RXD[3:0] | AVB_RD[3:0] | PHY | MAC |
| RX_DV | AVB_RX_CTL | PHY | MAC |
| RX_ER | — | PHY | MAC |
| MDIO | AVB_MDIO | MAC or PHY | MAC or PHY |
| MDC | AVB_MDC | MAC | PHY |
| CRS | — | PHY | MAC |
| COL | — | PHY | MAC |

#### (b) Clock setting

RGMII mode and MII mode can be switched by AVB-DMAC Product Specific Register (APSR)：H'E68n 008C (n=0-2).

Bit24 of APSR should be set “1” to change RGMII mode(default) to MII mode. The value should be fixed before starting communication.

**(c) Data rate setting**

Because MII is limited at 100Mbps, it should be set 100Mbps. Bit0 of E-MAC Mode Register 2 should be set “0” to change 1000Mbps to 100Mbps. The value should be fixed before starting communication.

### (3) Timing Specification: MII Timing

Timing specification between R-Car and PHY with MII communication is showed in below table. R-Car is not fully compliant with MII standard pin. Therefore, TX_ER, RX_ER, CLS and COL is not supported and undefined in timing specification.

Conditions: VDDQ18_25_AVB = 1.8/2.5V Tj= -40 to +125℃ GND = VSS = 0 V, CL = 30 pF

| Item | Symbol | Min. | Typ. | Max. | Unit | Figures |
|---|---|---|---|---|---|---|
| AVB_TXCREFCLK input frequency | fTx | — | 25 ±100ppm | — | MHz | — |
| AVB_TX_CTL output delay | tTEND | 0 | — | 25 | ns | Figure 100.1.4.4.1 |
| AVB_TD[3:0] output delay | tETDD | 0 | — | 25 | ns | |

# 100.2 gPTP

## 100.2.1 Overview

The gPTP module is described in the gPTP specification. Refer to "100_2_uciapgptp020(gPTP)_IPSpec_v1.01.pdf".

# 100.3 RGMII

## 100.3.1 Overview

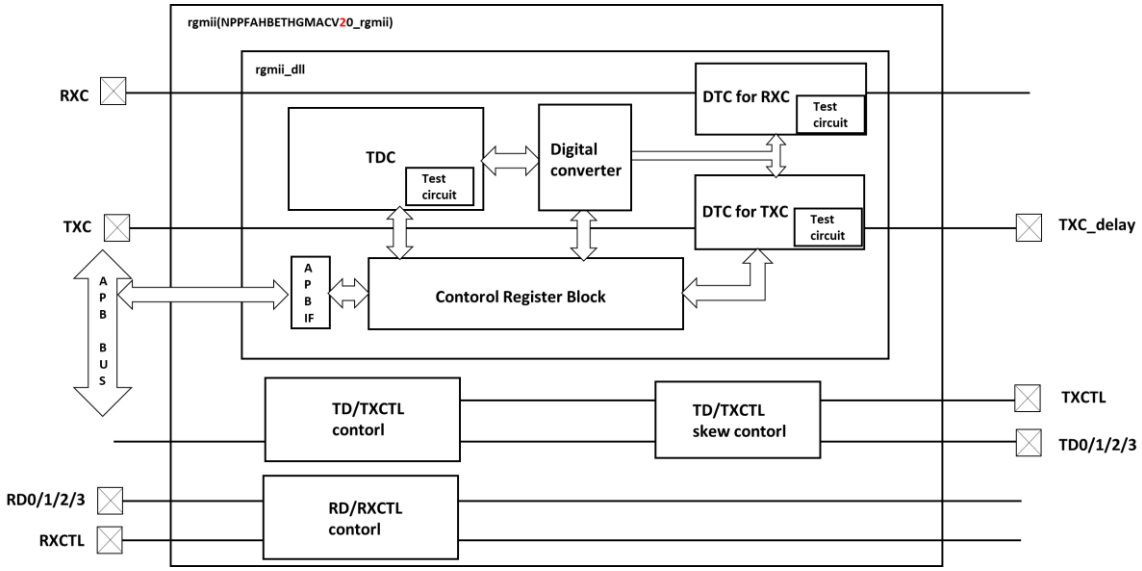
RGMII Interface logic.

Ethernet network using a 10 Mbps, 100 Mbps, or 1 Gbps full-duplex link via RGMII. Depending on the connected PHY.

AC spec covers RGMII Specification V2.0 and OPEN Alliance RGMII EPL v2.2

- Parallel loopback mode for AC measure and sort.
- Internal delay is adjusted with delay calibration circuit.
- Offset adjustment function for software workaround.
- Delay can be changed by software.

### 100.3.1.1 Block diagram



### 100.3.1.2 Register Configuration

| **Ch** | **Base Address** |
|---|---|
| AVB0 (EthernetAVB-IF 0) | H'E680 1000 |
| AVB1 (EthernetAVB-IF 1) | H'E681 1000 |
| AVB2 (EthernetAVB-IF 2) | H'E682 1000 |

| Name | Abbreviation | R/W | Offset Address | Initial Value | Access Size |
|---|---|---|---|---|---|
| TDC enable register | TDCEN | R/W | H'0004 | H'0000 0000 | 32 |
| Offset value setting register | OFFSET | R/W | H'0008 | H'0000 0000 | 32 |
| Select output register | SEL_OUT | R/W | H'002C | H'0000 0020 | 32 |
| DTCDEC(TX) manual mode register | DTCDEC_TX_MANUAL_MODE | R/W | H'0040 | H'0000 0000 | 32 |
| DTCDEC(TX) config register | DTCDEC_TX_CONFIG | R/W | H'0044 | H'0010 4010 | 32 |
| DTCDEC(RX) manual mode register | DTCDEC_RX_MANUAL_MODE | R/W | H'0080 | H'0000 0000 | 32 |
| DTCDEC(RX) config register | DTCDEC_RX_CONFIG | R/W | H'0084 | H'0010 4010 | 32 |
| dTDC monitor register | DTDC | R/W | H'00A0 | H'0000 0000 | 32 |

## 100.3.2 Register Description

The registers of the RGMII are assigned to and located in the address space of the internal bus.

[Legend for Register Descriptions]

Initial value: Register value after a reset.

—: Undefined value

R/W: Readable/writable. The written value can be read.

R/WC0: Readable/writable. Writing 0 initializes the bit. Writing 1 is ignored.

R/WC1: Readable/writable. Writing 1 initializes the bit. Writing 0 is ignored.

R: Read-only. The write value should always be initial value.

−/WB: Write-only. The read value is undefined.

### 100.3.2.1 TDCEN Register (TDCEN)

TDCEN is a 32-bit register that controls the enable/disable of the TDC circuit.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | tdcen |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 31 to 1 | — | 0 | R | Reserved<br>These bits are always read as initial value. The write value should always be initial value. |
| 0 | tdcen | 0 | R/W | TDC circuit enable bit<br>0 : TDC circuit disable<br>1 : TDC circuit enable |

### 100.3.2.2 OFFSET Register (OFFSET)

OFFSET is a 32-bit register to specify the Offset value for TDC circuit.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | offset [7:0] | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 31 to 8 | — | 0 | R | Reserved<br>These bits are always read as initial value. The write value should always be initial value. |
| 7 to 0 | offset [7:0] | H'00 | R/W | TDC offset delay value setting<br>H'00 : Shortest offset delay<br>…<br>H'FF : Longest offset delay |

### 100.3.2.3 DTCDEC_TX_MANUAL_MODE Register (DTCDEC_TX_MANUAL_MODE)

DTCDEC_TX_MANUAL_MODE is a 32-bit register to specify delay value of DTC for TXC manually.

If Manual mode is selected, delay converter result is ignored.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | tx_manual_sel_mode | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | tx_manual_tap_num [6:0] | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 31 | tx_manual_sel_mode | 0 | R/W | TXC DTC tap selection mode<br>0 : Auto mode<br>1 : Manual mode |
| 30 to 7 | — | 0 | R | Reserved<br>These bits are always read as initial value. The write value should always be initial value. |
| 6 to 0 | tx_manual_tap_num [6:0] | H’00 | R/W | DTC offset delay value setting for TXC.<br>If TX_MAN_SEL=1, this value is used for DTC delay value.<br>H’00 : Shortest offset delay<br>…<br>H’7F : Longest offset delay |

### 100.3.2.4 DTCDEC_TX_CONFIG Register (DTCDEC_TX_CONFIG)

DTCDEC_TX_CONFIG is a 32-bit register to specify the calculation value for delay decoder circuit.

If “Auto mode” of DTCDEC_TX_MANUAL_MODE is selected, this result is used for DTC delay value.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | tx_offset2 [4:0] | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R/W | R/W | R/W | R/W | R/W |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | tx_mult [7:0] | | | | | | | | tx_offset1 [7:0] | | | | | | | |
| Initial value: | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 30 to 21 | — | 0 | R | Reserved<br>These bits are always read as initial value. The write value should always be initial value. |
| 20 to 16 | tx_offset2 [4:0] | H’10 | R/W | Delay decoder offset2 value<br>H’00 : Shortest offset delay<br>…<br>H’1F : Longest offset delay |
| 15 to 8 | tx_mult [7:0] | H’40 | R/W | Delay decoder dividing value of TDC result<br>Set target delay value point of delay decorder.<br>Initial value is 64/256 = 1/4 period.<br>dDTC= (dTDC+offset1[7:0]-128)×TX_MULT[7:0]/256+offset2[4:0]-16<br>dDTC : DTC delay value.<br>dTDC : The result of TDC to measure 1 period. |
| 7 to 0 | tx_offset1 [7:0] | H’10 | R/W | Delay decoder offset1 value<br>H’00 : Shortest offset delay<br>…<br>H’FF : Longest offset delay |

Note : Recommended setting of DTCDEC_TX_CONFIG

| | | DTCDEC_TX_CONFIG |
|---|---|---|
| 1.8V | AVB0 | H’014880 |
| | AVB1 | H’0F4840 |
| | AVB2 | H’104840 |
| 2.5V | AVB0 | H’034880 |
| | AVB1 | H’114840 |
| | AVB2 | H’004880 |

### 100.3.2.5 DTCDEC_RX_MANUAL_MODE Register (DTCDEC_RX_MANUAL_MODE)

DTCDEC_RX_MANUAL_MODE is a 32-bit register to specify delay value of DTC for RXC manually.

If Manual mode is selected, delay converter result is ignored.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | rx_manual_sel_mode | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

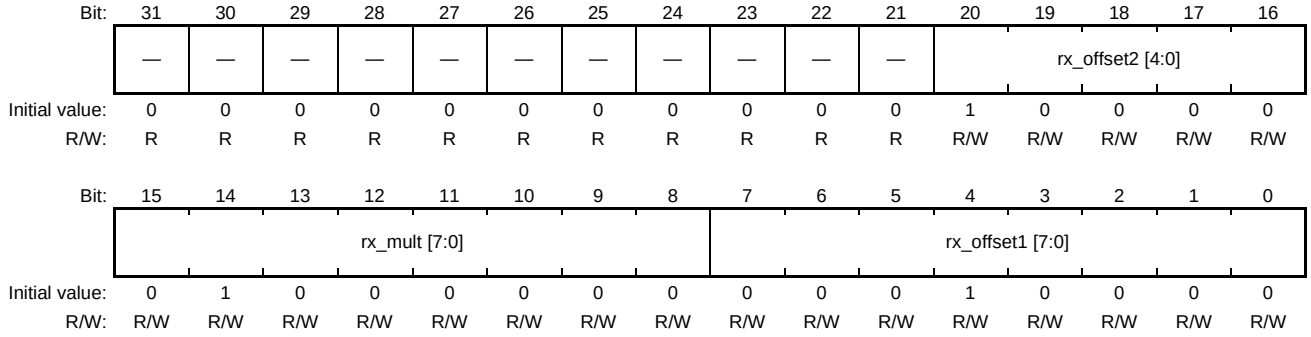
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | rx_manual_tap_num [6:0] | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 31 | rx_manual_sel_mode | 0 | R/W | RXC DTC tap selection mode<br>0 : Auto mode<br>1 : Manual mode |
| 30 to 7 | — | 0 | R | Reserved<br>These bits are always read as initial value. The write value should always be initial value. |
| 6 to 0 | rx_manual_tap_num [6:0] | H'00 | R/W | DTC offset delay value setting for RXC.<br>If RX_MAN_SEL=1, this value is used for DTC delay value.<br>H'00 : Shortest offset delay<br>…<br>H'7F : Longest offset delay |

### 100.3.2.6 DTCDEC_RX_CONFIG Register (DTCDEC_RX_CONFIG)

DTCDEC_RX_CONFIG is a 32-bit register to specify the calculation value for delay decoder circuit.

If “Auto mode” of DTCDEC_RX_MANUAL_MODE is selected, this result is used for DTC delay value.



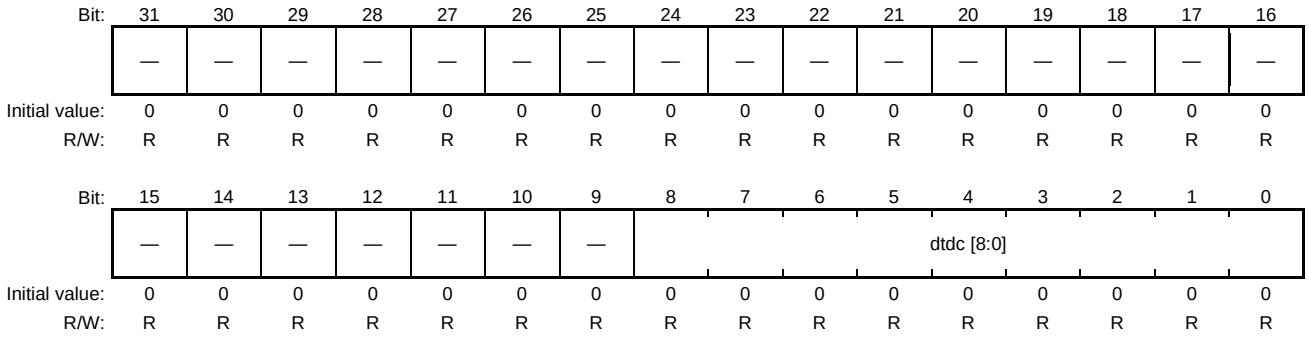
| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 30 to 21 | — | 0 | R | Reserved<br>These bits are always read as initial value. The write value should always be initial value. |
| 20 to 16 | rx_offset2 [4:0] | H’10 | R/W | Delay decoder offset2 value<br>H’00 : Shortest offset delay<br>…<br>H’1F : Longest offset delay |
| 15 to 8 | rx_mult [7:0] | H’40 | R/W | Delay decoder dividing value of TDC result<br>Set target delay value point of delay decorder.<br>Initial value is 64/256 = 1/4 period.<br>dDTC= (dTDC+offset1[7:0]-128)×RX_MULT[7:0]/256+offset2[4:0]-16<br>dDTC : DTC delay value.<br>dTDC : The result of TDC to measure 1 period. |
| 7 to 0 | rx_offset1 [7:0] | H’10 | R/W | Delay decoder offset1 value<br>H’00 : Shortest offset delay<br>…<br>H’FF : Longest offset delay |

Note : Recommended setting of DTCDEC_RX_CONFIG

| | | DTCDEC_RX_CONFIG |
|---|---|---|
| 1.8V | AVB0 | H’114840 |
| | AVB1 | H’014880 |
| | AVB2 | H’0C4840 |
| 2.5V | AVB0 | H’014880 |
| | AVB1 | H’044880 |
| | AVB2 | H’0F4840 |

### 100.3.2.7 DTDC Register (DTDC)

DTDC is a 32-bit register to monitor the measurement result of TDC circuit.



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 31 to 9 | — | 0 | R | Reserved<br>These bits are always read as initial value. The write value should always be initial value. |
| 8 to 0 | dtdc [8:0] | H'000 | R | TDC measurement result of 1 period.<br>H'000 : Shortest TDC delay is selected<br>…<br>H'1FF : Longest TDC delay is selected |

### 100.3.2.8 Select output signal register (SEL_OUT)

SEL_OUT is a 32-bit register that controls the signal of the test function.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

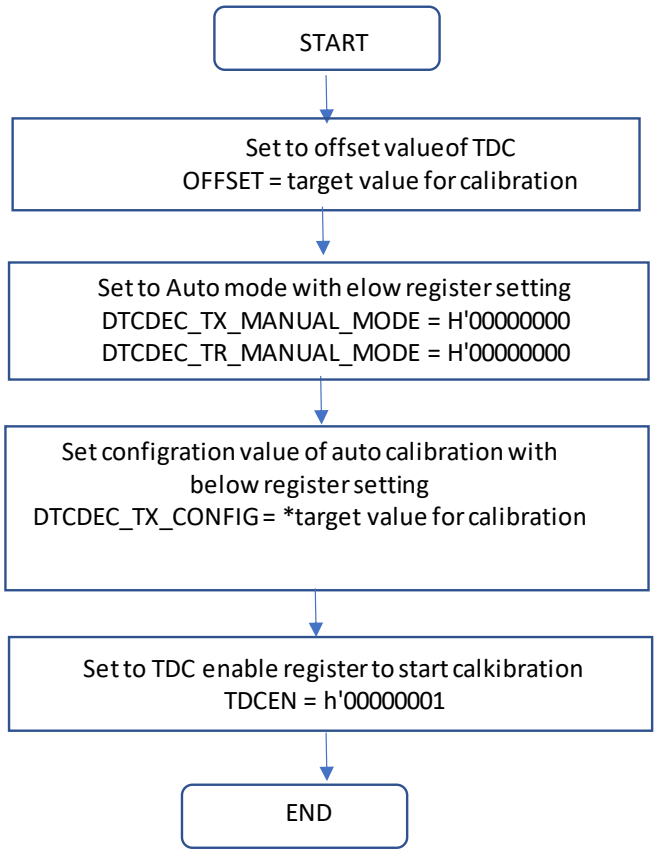
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | — | PLL mode | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R/W | R | R | R |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 31 to 6 | — | 0 | R | Reserved<br>These bits are always read as initial value. The write value should always be initial value. |
| 5 | — | 1 | R | Reserved<br>These bits are always read as initial value. The write value should always be initial value. |
| 4 | — | 0 | R | Reserved<br>These bits are always read as initial value. The write value should always be initial value. |
| 3 | PLL mode | 0 | R/W | REFCLK selection<br>0 : TXC clock = Normal mode<br>1 : TXC clock = PLL mode |
| 2 to 0 | — | 0 | R | Reserved<br>These bits are always read as initial value. The write value should always be initial value. |

## 100.3.3 Operation

### 100.3.3.1 Initialize sequence with Auto calibration

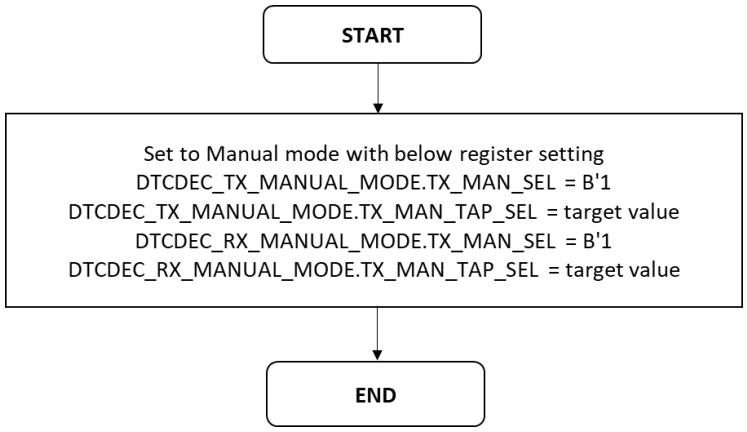
Refer following figure to initialize and activate sequence of this auto calibration function.



* TX/RX_OFFSET1 value shoukd be set ti same vlue with OFFSET register

### 100.3.3.2 Initialize sequence without Auto calibration

Refer following figure to initialize and activate sequence without auto calibration function.



### 100.3.3.3 PLL mode

[Block diagram of delay block with PLL mode circuit]
PLL mode use PLL7 for TXC clock.

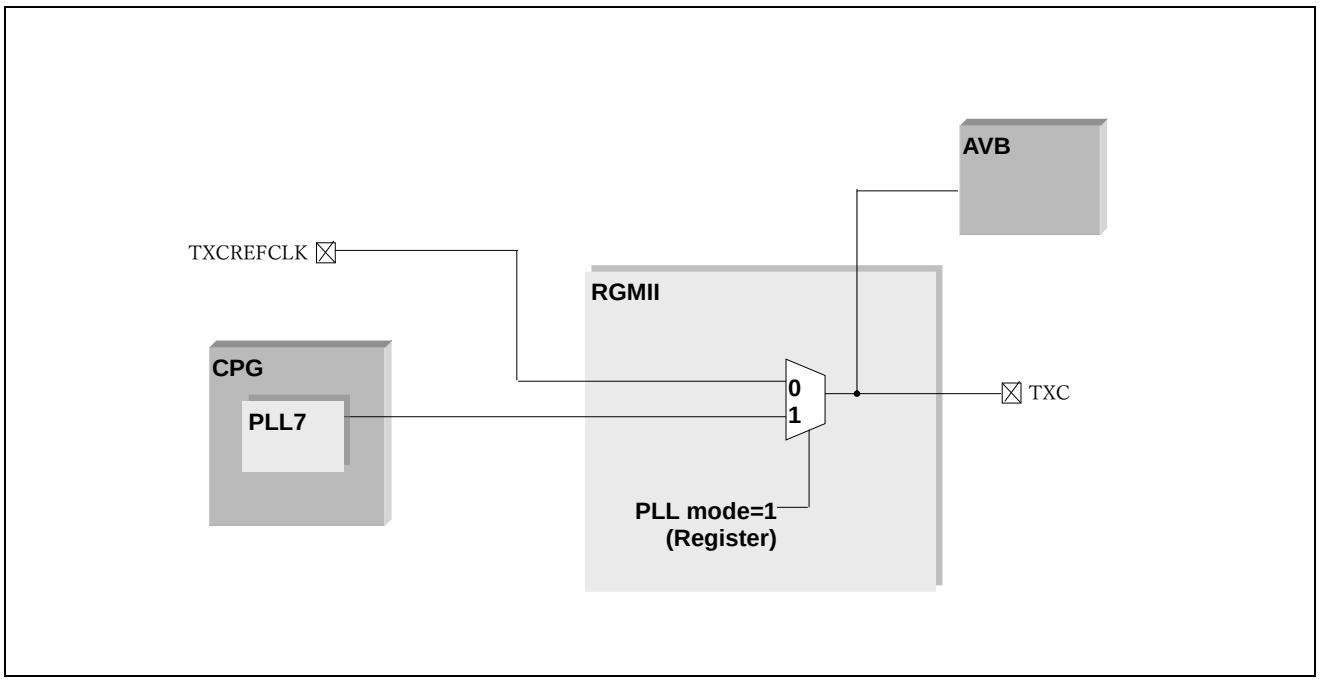


Figure 100.1 Block diagram of PLL mode

[Initialization procedure of PLL mode]
Enable PLL7 and set RGMII PLL mode=1 before RGMII initialization.

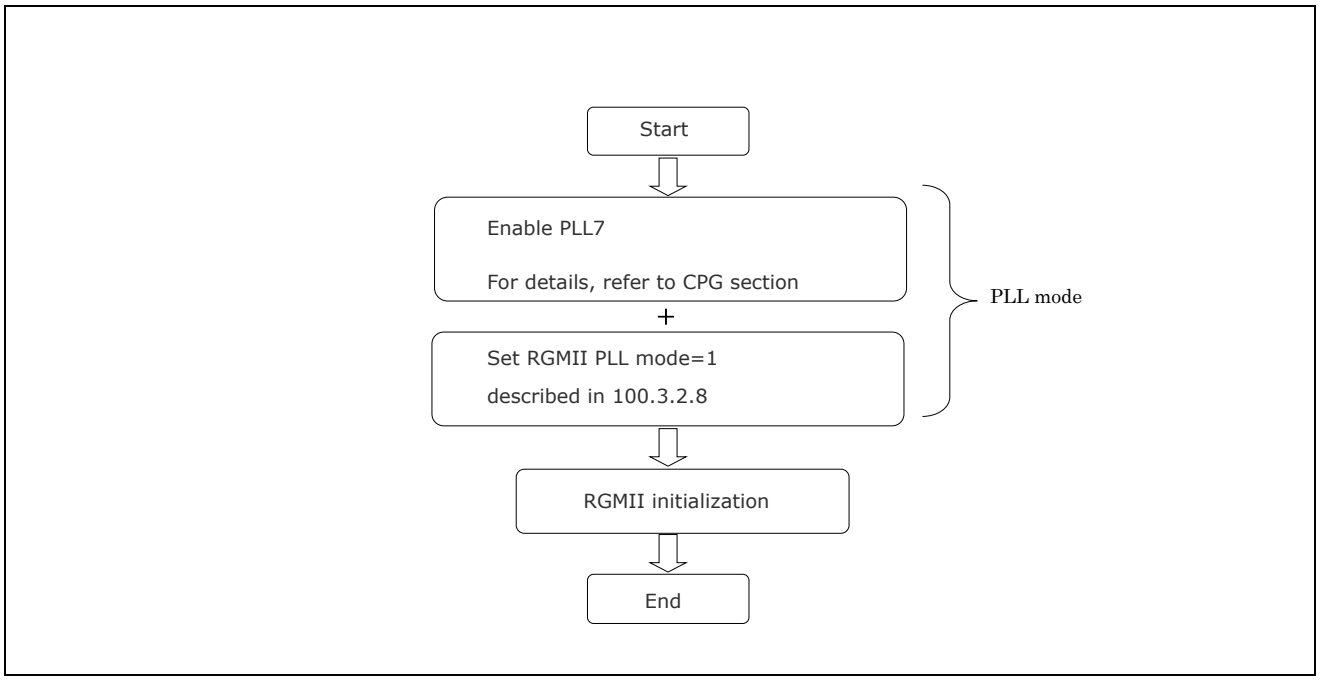

Figure 100.2 Initialization procedure of PLL mode

### 100.3.4 Usage Notes

When using RGMII interface, need to supply clock for EtherAVB module.

### 100.3.5 Safety Mechanisms

No description on this section.

# 102. CAN-FD

This section contains a generic description of the CANFD interface (RS-CANFD).
The first part of this section describes all specific properties, such as the number of units, register base addresses, etc. The remainder of the section describes the functions and registers of RS-CANFD.

## 102.1 Overview

### 102.1.1 Functional Overview

**Table 102.1 RS-CANFD Module Specifications**

| Item | Specification |
|---|---|
| Communication | CAN functionality conform to CAN-FD ISO 11898-1 (2015) |
| Protocol engine Version | RS-CANFD_PE V3.0 |
| Gateway Function | CAN 2.0 <> CAN 2.0<br>CAN 2.0 <> CAN-FD Gateway (Only 8 Byte Payload)<br>CAN-FD <> CAN-FD |
| Data transfer rate | up to 1Mbps for arbitration phase and up to 8Mbps for data phase , individually for each CAN channel |
| Proposed min. operation frequency<br>peripheral clock/APB clock | 133.33MHz |
| Data Link Layer clock (DLLC) | 40MHz(Max) |
| Input/Output pins | TX/RX |
| CAN channels | 4 |
| Selectable ID type | 11-bit Standard ID |
| | 11-bit Standard ID + 18-bit Extended ID |
| Selectable Frame Type | Data Frame (RTR = 0) (CAN and CAN-FD frames) |
| | Remote Frame (RTR = 1) (only CAN frames) |
| Variable Data Byte Count for Data Frames | DLC range: 0 to F |
| Message Buffer | 32 transmit message buffers per channel **1<br>4 transmission queue per channel<br>Automatic message transfer into transmission queues supported |
| | 64 shared buffers for RXMB and FIFO buffers per channel **1<br>- RXMB:<br>- Up to 16*(n+1) reception message buffers, shared among all the CAN channels<br>- FIFO buffers:<br>- 8 Reception FIFO Buffers<br>- Up to 3*(n+1) FIFOs individually configurable as<br>Reception FIFO / Transmission FIFO / CAN to CAN Gateway FIFO |
| Automatic delay interval timer for transmission | The delay timer can be applied to:<br>-Transmission FIFO<br>-CAN to CAN Gateway FIFO |
| Enhanced reception filtering | support of 11bit and 29bit CAN identifier |
| | programmable 29 bit CAN identifier acceptance filter mask for each entry |
| | programmable GW routing capability for each channel (up to 8 routing destinations) |

| | |
|---|---|
| | **RTR and IDE masking** |
| | **DLC filter** |
| | **Message buffer payload overload protection** |
| | **Payload filter** |
| | **Updating AFL entry during communication** |
| **General SW Support** | **Automatic label information added to receive message (for upper SW layer support)** |
| **Timer** | **TX and RX Time Stamp function** |
| **Power down function** | **Module start stop function for each CAN node (Channel & Global Sleep Mode)** |
| **RAM** | **RAM ECC protected** |
| **Bus traffic measurement** | **CAN bus traffic measurement of each Channel is possible** |
| **FFI mode** | **This product cannot use FFI mode.** |

### 102.1.2 Features of RS-CANFD

RS-CANFD has two interface modes (classical CAN mode and CAN FD mode), and uses different registers in each mode. The different register names RSCFD{unit}XXX and RSCFD{unit}CFDXXX are used in the different interface modes (XXX can be any character). In this document, the registers common to the two modes are indicated as RSCFD{unit}CFDXXX.

#### 102.1.2.1 Number of Units and Channels

This microcontroller has the following number of RS-CANFD units.

**Number of Units and Channels**

| Product Name | R-Car V4M |
|---|---|
| Number of Units | 1 |
| Number of Channels | 4 |
| Number of Channel per Unit | 4 |
| Transmission Message Buffers per Channel | 32 |
| Shared Buffers for per Channel | 64 |
| Total Message Buffer | 384 |

**Table 102.1 Index**

| Index | Description |
|---|---|
| unit | Throughout this section, the individual RS-CANFD units are generically indicated by the index “unit”.<br>For example, RSCFD[unit]CFDGCTR is the global control register of the RSCFDunit unit. |
| n | Throughout this section, the individual channels of RS-CANFD units are generically indicated by the index “n”.<br>For example, RSCFD[unit]CFDCnSTS is the channel n status register. |
| m | The individual channels of RSCFD unit is generically indicated by the index “m”.<br>For example, CANFDm_RX is receive data input. |
| d | The individual common FIFO buffers are generically indicated by the index “d”.<br>For example, RSCFD[unit]CFDCFCCd is the common FIFO buffer configuration/control register. |
| a | The individual receive FIFO buffers are generically identified by the index “a”.<br>For example, RSCFD[unit]CFDRFSTSa is the receive FIFO buffer status register. |
| p | Data field registers of common FIFO buffers and receive FIFO buffers are identified by “p”.<br>For example, RSCFD[unit]CFDCFDFp is the common FIFO access data field register. |
| i | The individual transmit control buffers are generically indicated by the index “i”.<br>For example, RSCFD[unit]CFDTMCi is transmit message buffer control register. |
| j | The individual transmit status buffers are generically indicated by the index “j”.<br>For example, RSCFD[unit]CFDTMSTSj is transmit message buffer status register. |
| k | The individual RAM tests for CAN are generically indicated by the index “k”.<br>For example, RSCFD[unit]CFDRPGACCk is the RAM test page access register. |
| f | The transmit message buffer transmission are generically indicated by index “f”.<br>For example, RSCFD[unit]CFDTMTRSTSf is the transmit message buffer transmission request status register. |
| w | A global register which setting for channels indicated by the index "w".<br>For example, RSCFD[unit]CFDGAFLCFGw is global Acceptance Filter List configuration register. |
| v | A global register which setting for 04 channels indicated by the index “v”.<br>For example, RSCFD[unit]CFDGTINTSTSv is the global transmit interrupt status register. |
| t | The receive message buffer new data are generically indicated by index “t”.<br>For example, RSCFD[unit]CFDRMNDt is a receive message buffer new data register. |

Note 1. The functions and descriptions of registers in this section are for the RS-CANFDs that has 4 channels (m = 0 to 3). When referring to information with indices, regard the index values as the ones corresponding to the target product.

Note 2. In some figure or table, this section use acronyms: CH, Ch, Ch instead of "channel".

**Table 102.2 Indices for Individual Products**

| Index Correspondence of Each Product | R-CarV4M |
|---|---|
| unit | 0 |
| n | 0 to 3 |
| m | 0 to 3 |
| d | 0 to 11 |
| a | 0 to 7 |
| p | 0 to 15 |
| i | 0 to 127 |
| j | 0 to 127 |
| k | 0 to 63 |
| f | 0 to 7 |
| w | 0 to 1 for RSCFD[unit]CFDGAFLCFGw<br>0 for RSCFD[unit]CFDGPFLCFGw |
| v | 0 |
| t | 0 to 1 |

### 102.1.3 Interface Mode

RS-CANFD has the following two interface modes.

- Classical CAN mode: Only classical CAN frames are handled.
- CAN FD mode: both the classical CAN frames and CAN FD frames are handled.

Two modes use different register maps with the same base address, and the register maps are switched by switching the modes.

Interface modes can be switched using the CLOE bit in the RSCFD{unit}CFDCnFDCFG register.

### 102.1.4 Block Diagram

The block diagram which shows connection with a peripheral module is shown.

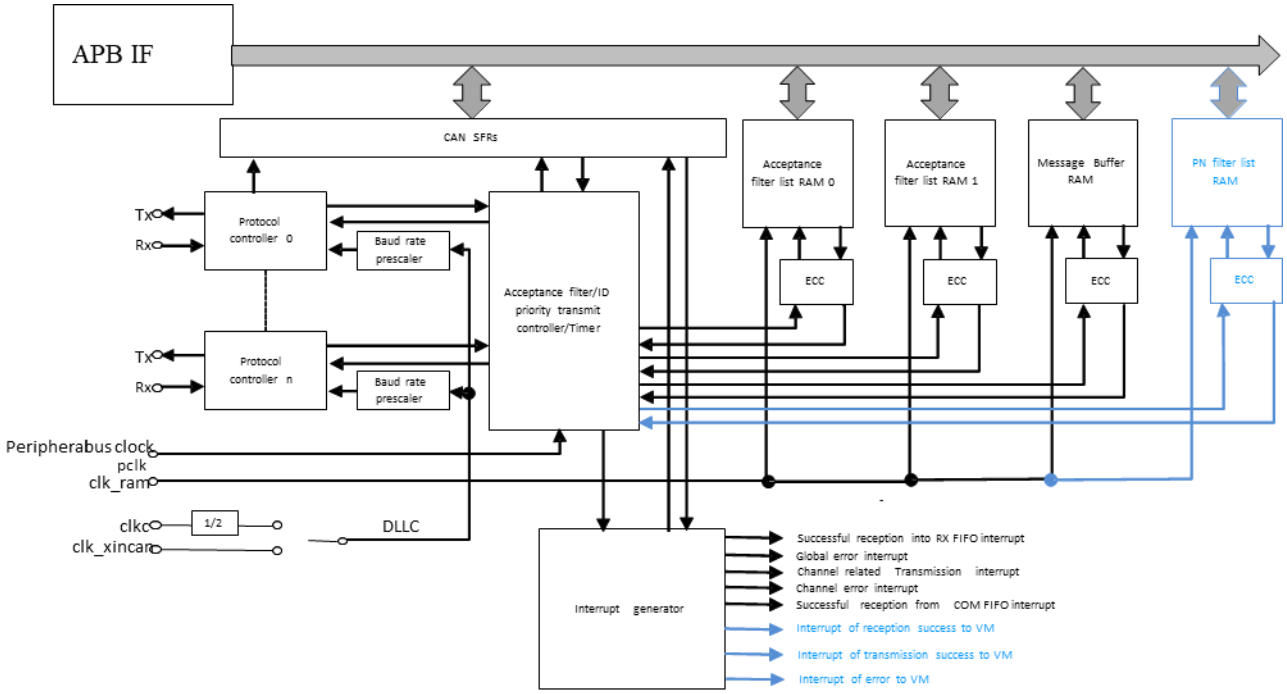

**Figure 102.1 RS-CANFD Module Block Diagram (in classical CAN mode)**

CANFDϕ must be set as follows.

R-Car V4M: 80(MHz)

Peripheral bus clock (pclk): SASYNCPERD2ϕ

clkc: CANFDϕ

clk_xincan: CAN_CLK

clk_ram: SASYNCPERD1ϕ

### 102.1.5 External Pins

Table 102.3 shows the CAN module pin.

Pin switching is required for pins which are multiplexed with other Function. For details, see section 7, Pin Function Controller (PFC).

**Table 102.3 Pin Configuration**

| Name | Abbreviation | I/O | Function |
|---|---|---|---|
| CANFDm_RX | — | Input | Pins for receiving data |
| CANFDm_TX | — | Output | Pins for transmitting data |
| CAN_CLK | — | Input | Input pin used for external clock input. |

### 102.1.6 Connected module

**Table 102.4 Connected module**

| Module name | Connected module name | function of the related module |
|---|---|---|
| CANFD | AXI | Register access of CPU |
| | CPG | Clock output |
| | PFC | Selection of external pins |
| | Module Standby | Clock stop control |
| | Software Reset | Soft reset execution |
| | INTC | Interruption |
| | SYS-DMAC | DMA transmission |
| | CRC | CRC module |
| | MFIS | MFIS module |

#### 102.1.6.1 Register Base Address

RSCFD{unit} base addresses are listed in the following table.

RSCFD{unit} register addresses are given as offsets from the base addresses in general.

**Table 102.5 Register Base Address**

| Base Address Name | Base Address |
|---|---|
| <RSCFD0_base> | H'E666 0000 |

### 102.1.7 Register Configuration

This section describes all registers of RS-CANFD

#### 102.1.7.1 List of Registers

RSCFD registers are listed in the table below.

For details about Register Base Addresses.

| Register Name | Symbol RSCFD0+{registers of RS-CANFD} | R/W (*1) | Address | Access Size |
|---|---|---|---|---|
| Channel n Nominal Bitrate Configuration Register | RSCFD0CFDCnNCFG | - | <RSCFD0_base> + 0000h + n*0010h | 8, 16, 32 |
| Channel n Control Registers | RSCFD0CFDCnCTR | - | <RSCFD0_base> + 0004h + n*0010h | 8, 16, 32 |
| Channel n Status Registers | RSCFD0CFDCnSTS | - | <RSCFD0_base> + 0008h + n*0010h | 8, 16, 32 |
| Channel n Error Flag Registers | RSCFD0CFDCnERFL | - | <RSCFD0_base> + 000Ch + n*0010h | 8, 16, 32 |
| Global IP Version Register | RSCFD0CFDGIPV | - | <RSCFD0_base> + 0080h | 8, 16, 32 |
| Global Configuration Register | RSCFD0CFDGCFG | - | <RSCFD0_base> + 0084h | 8, 16, 32 |
| Global Control Register | RSCFD0CFDGCTR | - | <RSCFD0_base> + 0088h | 8, 16, 32 |
| Global Status Register | RSCFD0CFDGSTS | - | <RSCFD0_base> + 008Ch | 8, 16, 32 |
| Global Error Flag Register | RSCFD0CFDGERFL | - | <RSCFD0_base> + 0090h | 8, 16, 32 |
| Global Timestamp Counter Register | RSCFD0CFDGTSC | - | <RSCFD0_base> + 0094h | 16, 32 |
| Global Acceptance Filter List Entry Control Register | RSCFD0CFDGAFLECTR | - | <RSCFD0_base> + 0098h | 8, 16, 32 |
| Global Acceptance Filter List Configuration Register w | RSCFD0CFDGAFLCFGw | - | <RSCFD0_base> + 009Ch + w*0004h | 8, 16, 32 |
| RX Message Buffer Number Register | RSCFD0CFDRMNB | - | <RSCFD0_base> + 00Ach | 8, 16, 32 |
| RX Message Buffer New Data Register t | RSCFD0CFDRMNDt | - | <RSCFD0_base> + 00B0h + t*0004h | 8, 16, 32 |
| RX FIFO Configuration / Control Registers a | RSCFD0CFDRFCCa | - | <RSCFD0_base> + 00C0h + a*0004h | 8, 16, 32 |
| RX FIFO Status Registers a | RSCFD0CFDRFSTSa | - | <RSCFD0_base> + 00E0h + a*0004h | 8, 16, 32 |
| RX FIFO Pointer Control Registers a | RSCFD0CFDRFPCTRa | - | <RSCFD0_base> + 0100h + a*0004h | 8, 16, 32 |
| Common FIFO Configuration / Control Registers d | RSCFD0CFDCFCCd | - | <RSCFD0_base> + 0120h + d*0004h | 8, 16, 32 |
| Common FIFO Configuration / Control Enhancement Registers d | RSCFD0CFDCFCCEd | - | <RSCFD0_base> + 0180h + d*0004h | 8, 16, 32 |
| Common FIFO Status Registers d | RSCFD0CFDCFSTSd | - | <RSCFD0_base> + 01E0h + d*0004h | 8, 16, 32 |
| Common FIFO Pointer Control Registers d | RSCFD0CFDCFPCTRd | - | <RSCFD0_base> + 0240h + d*0004h | 8, 16, 32 |
| FIFO Empty Status Register | RSCFD0CFDFESTS | - | <RSCFD0_base> + 02A0h | 8, 16, 32 |
| FIFO Full Status Register | RSCFD0CFDFFSTS | - | <RSCFD0_base> + 02A4h | 8, 16, 32 |
| FIFO Message Lost Status Register | RSCFD0CFDFMSTS | - | <RSCFD0_base> + 02A8h | 8, 16, 32 |

| | | | | |
|---|---|---|---|---|
| RX FIFO Interrupt Flag Status Register | RSCFD0CFDRFISTS | - | <RSCFD0_base> + 02Ach | 8, 16, 32 |
| Common FIFO RX Interrupt Flag Status Register | RSCFD0CFDCFRISTS | - | <RSCFD0_base> + 02B0h | 8, 16, 32 |
| Common FIFO TX Interrupt Flag Status Register | RSCFD0CFDCFTISTS | - | <RSCFD0_base> + 02B4h | 8, 16, 32 |
| Common FIFO One Frame RX Interrupt Flag Status Register | RSCFD0CFDCFOFRISTS | - | <RSCFD0_base> + 02B8h | 8, 16, 32 |
| Common FIFO One Frame TX Interrupt Flag Status Register | RSCFD0CFDCFOFTISTS | - | <RSCFD0_base> + 02BCh | 8, 16, 32 |
| Common FIFO Message Over Write Status Register | RSCFD0CFDCFMOWSTS | - | <RSCFD0_base> + 02C0h | 8, 16, 32 |
| FIFO FDC Full Status Register | RSCFD0CFDFFFSTS | - | <RSCFD0_base> + 02C4h | 8, 16, 32 |
| TX Message Buffer Control Registers i | RSCFD0CFDTMCi | - | <RSCFD0_base> + 02D0h + i*0001h | 8 |
| TX Message Buffer Status Registers j | RSCFD0CFDTMSTSj | - | <RSCFD0_base> + 07D0h + j*0001h | 8 |
| TX Message Buffer Transmission Request Status Register f | RSCFD0CFDTMTRSTSf | - | <RSCFD0_base> + 0CD0h + f*0004h | 8, 16, 32 |
| TX Message Buffer Transmission Abort Request Status Register f | RSCFD0CFDTMTARSTSf | - | <RSCFD0_base> + 0D70h + f*0004h | 8, 16, 32 |
| TX Message Buffer Transmission Completion Status Register f | RSCFD0CFDTMTCSTSf | - | <RSCFD0_base> + 0E10h + f*0004h | 8, 16, 32 |
| TX Message Buffer Transmission Abort Status Register f | RSCFD0CFDTMTASTSf | - | <RSCFD0_base> + 0EB0h + f*0004h | 8, 16, 32 |
| TX Message Buffer Interrupt Enable Configuration Register f | RSCFD0CFDTMIECf | - | <RSCFD0_base> + 0F50h + f*0004h | 8, 16, 32 |
| TX Queue Configuration / Control Registers 0 [n] | RSCFD0CFDTXQCC0[n] | - | <RSCFD0_base> + 1000h + n*0004h | 8, 16, 32 |
| TX Queue Status Registers 0 [n] | RSCFD0CFDTXQSTS0[n] | - | <RSCFD0_base> + 1020h + n*0004h | 8, 16, 32 |
| TX Queue Pointer Control Registers 0 [n] | RSCFD0CFDTXQPCTR0[n] | - | <RSCFD0_base> + 1040h + n*0004h | 8, 16, 32 |
| TX Queue Configuration / Control Registers 1 [n] | RSCFD0CFDTXQCC1[n] | - | <RSCFD0_base> + 1060h + n*0004h | 8, 16, 32 |
| TX Queue Status Registers 1 [n] | RSCFD0CFDTXQSTS1[n] | - | <RSCFD0_base> + 1080h + n*0004h | 8, 16, 32 |
| TX Queue Pointer Control Registers 1 [n] | RSCFD0CFDTXQPCTR1[n] | - | <RSCFD0_base> + 10A0h + n*0004h | 8, 16, 32 |
| TX Queue Configuration / Control Registers 2 [n] | RSCFD0CFDTXQCC2[n] | - | <RSCFD0_base> + 10C0h + n*0004h | 8, 16, 32 |
| TX Queue Status Registers 2 [n] | RSCFD0CFDTXQSTS2[n] | - | <RSCFD0_base> + 10E0h + n*0004h | 8, 16, 32 |
| TX Queue Pointer Control Registers 2 [n] | RSCFD0CFDTXQPCTR2[n] | - | <RSCFD0_base> + 1100h + n*0004h | 8, 16, 32 |
| TX Queue Configuration / Control Registers 3 [n] | RSCFD0CFDTXQCC3[n] | - | <RSCFD0_base> + 1120h + n*0004h | 8, 16, 32 |
| TX Queue Status Registers 3 [n] | RSCFD0CFDTXQSTS3[n] | - | <RSCFD0_base> + 1140h + n*0004h | 8, 16, 32 |
| TX Queue Pointer Control Registers 3 [n] | RSCFD0CFDTXQPCTR3[n] | - | <RSCFD0_base> + 1160h + n*0004h | 8, 16, 32 |
| TX Queue Empty Status Register | RSCFD0CFDTXQESTS | - | <RSCFD0_base> + 1180h | 8, 16, 32 |
| TX Queue Full Interrupt Status Register | RSCFD0CFDTXQFISTS | - | <RSCFD0_base> + 1184h | 8, 16, 32 |
| TX Queue Message Lost Status Register | RSCFD0CFDTXQMSTS | - | <RSCFD0_base> + 1188h | 8, 16, 32 |
| TX Queue Message Overwrite Status Register | RSCFD0CFDTXQOWSTS | - | <RSCFD0_base> + 118Ch | 8, 16, 32 |
| TX Queue Interrupt Status Register | RSCFD0CFDTXQISTS | - | <RSCFD0_base> + 1190h | 8, 16, 32 |
| TX Queue One Frame TX Interrupt Status Register | RSCFD0CFDTXQOFTISTS | - | <RSCFD0_base> + 1194h | 8, 16, 32 |
| TX Queue One Frame RX Interrupt Status Register | RSCFD0CFDTXQOFRISTS | - | <RSCFD0_base> + 1198h | 8, 16, 32 |
| TX Queue Full Status Register | RSCFD0CFDTXQFSTS | - | <RSCFD0_base> + 119Ch | 8, 16, 32 |
| TX History List Configuration / Control Register n | RSCFD0CFDTHLCCn | - | <RSCFD0_base> + 1200h + n*0004h | 8, 16, 32 |
| TX History List Status Register n | RSCFD0CFDTHLSTSn | - | <RSCFD0_base> + 1220h + n*0004h | 8, 16, 32 |
| TX History List Pointer Control Registers n | RSCFD0CFDTHLPCTRn | - | <RSCFD0_base> + 1240h + n*0004h | 8, 16, 32 |
| Global TX Interrupt Status Register v | RSCFD0CFDGTINTSTSv | - | <RSCFD0_base> + 1300h + v*4 | 8, 16, 32 |
| Global Test Configuration Register | RSCFD0CFDGTSTCFG | - | <RSCFD0_base> + 1308h | 8, 16, 32 |
| Global Test Control Register | RSCFD0CFDGTSTCTR | - | <RSCFD0_base> + 130Ch | 8, 16, 32 |
| Global FD Configuration register | RSCFD0CFDGFDCFG | - | <RSCFD0_base> + 1314h | 8, 16, 32 |
| Global FD CRC Configuration register | RSCFD0CFDGCRCCFG | - | <RSCFD0_base> + 1318h | 8, 16, 32 |
| Global Lock Key Register | RSCFD0CFDGLOCKK | - | <RSCFD0_base> + 131Ch | 16, 32 |

| | | | | |
|---|---|---|---|---|
| Global AFL Ignore Entry Register | RSCFD0CFDGAFLIGNENT | - | <RSCFD0_base> + 1324h | 8, 16, 32 |
| Global AFL Ignore Control Register | RSCFD0CFDGAFLIGNCTR | - | <RSCFD0_base> + 1328h | 16, 32 |

## 102.5 Safety Mechanisms

### 102.5.1 ECC for CAN-FD (IP uciapecc7w10)

#### 102.5.1.1 Overview

ECC IP – Function block diagram:

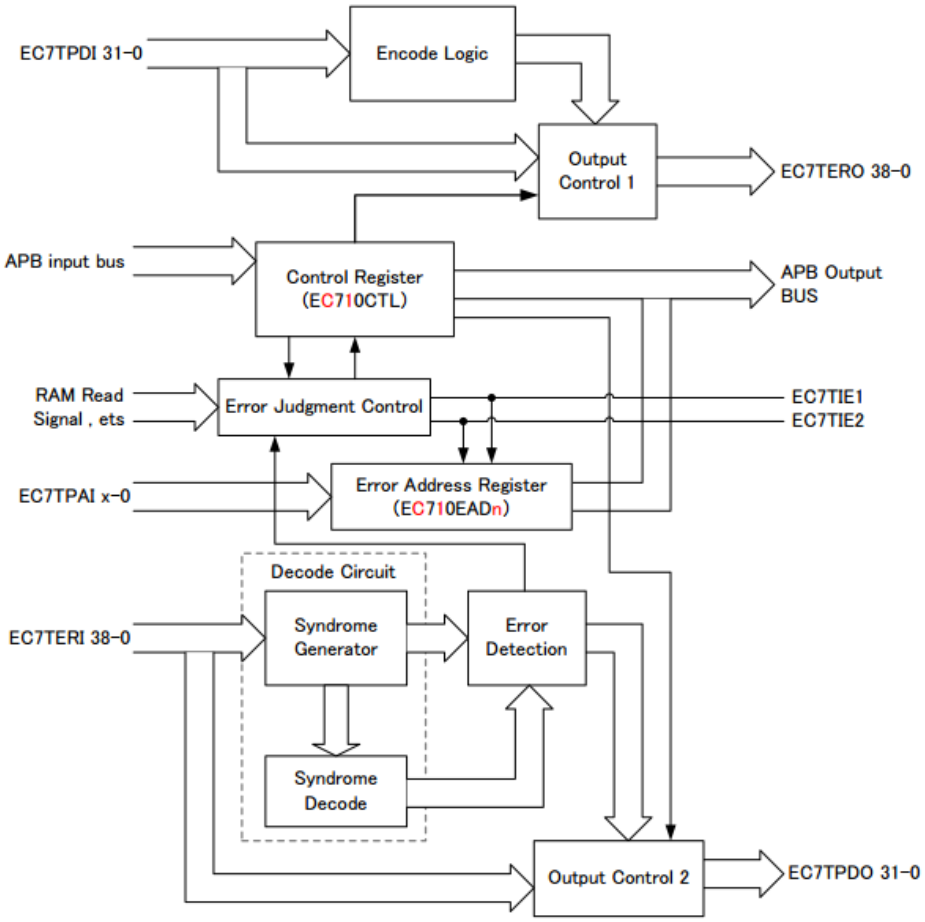

**Figure 102.2 ECC Block diagram**

EDC protection is applied to internal buffer (Acceptance filter list RAM, Message Buffer RAM) of CAN-FD.

#### 102.5.1.1.1 Error Detection and Correction

-Seven-bit ECC data is appended to the 32-bit RAM data.

-This ECC module provides 2-bit ECC error detection and 1-bit ECC error detection and correction.

*Note: This module is not capable of reliably detecting errors in three or more bits. If errors occur in three or more bits, the module may detect the errors as 1- or 2-bit ECC errors or not detect any errors. Depending on the settings, this may lead to the correction of a bit that was not actually inverted.

#### 102.5.1.1.2 Enabling or Disabling ECC Error Detection and Correction

-ECC error detection can be either enabled or disabled.

-One-bit ECC error correction can be either enabled or disabled.

-If all the bits of RAM output data are stuck to 0 or 1, it is detected as a 2-bit ECC error.

#### 102.5.1.1.3 Error Notification

-The ECM is notified when 2-bit ECC errors are detected (this can be enabled or disabled).

-The ECM is notified when 1-bit ECC errors are detected (this can be enabled or disabled).

-Once the ECM has been notified of an error, even if another ECC error is detected, the ECM is not notified until the error status bit corresponding to the initial error is cleared.

#### 102.5.1.1.4 Error Status

-Detection of 2-bit and 1-bit ECC errors can be monitored.

-Special registers are provided to clear error status.

#### 102.5.1.1.5 Address Capture

-Only one address at which an ECC error has occurred can be captured.

-When a 2-bit or 1-bit ECC error is detected, the error-causing address is captured. It is used to capture only when the first error is detected after the flag is cleared.

#### 102.5.1.1.6 Testing Function (Error Insertion)

-By setting the test mode, register values can be used as the data to be output to the RAM. When a peripheral module writes to the RAM, the ECEDB[31:0] register value can be written to the RAM data section, and the ECERDB[6:0] register value can be written to the ECC redundant bit section.

-By setting the test mode, the ECC redundant bit section can be latched when RAM data is read, and the value can be confirmed.

-By setting the test mode, the ECC redundant bit (encoding circuit) and syndrome code (decoding circuit), which are generated from the input data, can be confirmed.

### 102.5.1.2 Hardware Description

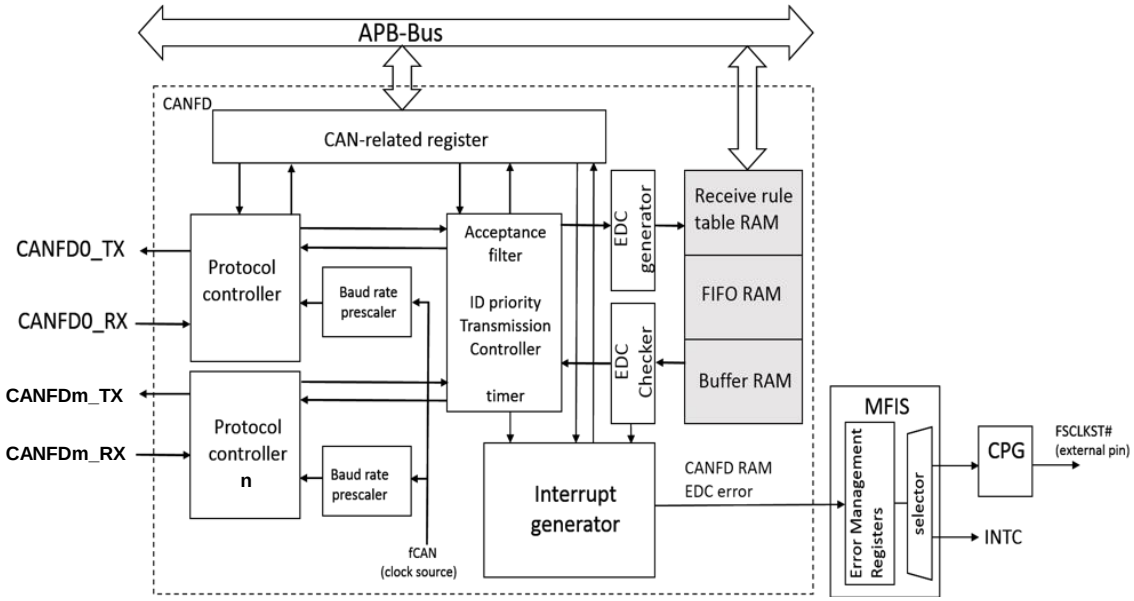

**Figure 102.3 EDC protection for CAN-FD**

**Table 102.6 Register Configuration**

| Register Name | Abbreviation | R/W | Address | Initial Value | Size |
|---|---|---|---|---|---|
| ECC control register | EC710CTL | R/W | H'E66C_8000 | H'0000 0000 | 32 |
| ECC test mode control register | EC710TMC | R/W | H'E66C_8004 | H'0000 0000 | 32 |
| ECC redundant bit data control test register | EC710TRC | R | H'E66C_8008 | H'0000 0000 | 32 |
| ECC encoder and decoder data test register | EC710TED | R/W | H'E66C_800C | H'0000 0000 | 32 |
| ECC error address register | EC710EAD | R | H'E66C_8010 | H'0000 0000 | 32 |

#### 102.5.1.2.1 Register Description

**(a) EC710CTL — ECC control register**

E710CTL controls the status and modes of the ECC module.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| R/W: | R/W | R/W | R | R | R | R/W | R/W | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 31 to 16 | - | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 15 to 14 | EMCA[1:0] | All 0 | R/W | These 2bits are the write trigger reserve bits to bit6. These read value are always B’0. When the value of these bits is 2’b01, then it is possible to write access to bit6 “ECERVF”. If these bits are not 2’b01, the write access to bit6 is ignored and the value is not written.<br>These bits reserve the write trigger to bit 7. |
| 13 to 11 | - | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 10 | ECER2C | 0 | R/W | 2-Bit ECC Error Detection Flag Clear<br>Clears the bit 2 “ECER2F” status flag.<br>The read value is always B’0, and writing B’0 to ECER2C does not change the state.<br>If writing B’1 to ECER2C conflicts with the condition for setting bit 2, the former takes priority.<br>Writing B’1 to ECER2C while “ECER2F” is set clears “ECER2F” |
| 9 | ECER1C | 0 | R/W | 1-Bit ECC Error Detection Flag Clear<br>Clears the bit 1 “ECER1F” status flag.<br>The read value is always B’0, and writing B’0 to ECER1C does not change the state.<br>If writing B’1 to ECER1C conflicts with the condition for setting bit 1, the former takes priority.<br>Writing B’1 to ECER1C while “ECER1F” is set clears “ECER1F”.<br>Flag clear bit of accumulating ECC error detection and correctio |
| 8 | - | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 7 | ECTHM | 0 | R/W | ECC Function Disable Select<br>Selects the ECC decoding operation. Write access to ECTHM is enabled when the value of bits 15 and 14 is 2'b01. Therefore, only the 16-bit manipulation instruction is valid.<br>Setting ECTHM to B'1 disables error detection and bit correction. Here, if the data to be output to the peripheral module contains an error, the data is output without bit correction. Setting ECTHM to B'1 has no effect on the encoder side.<br>0: Enables ECC detection and correction.<br>1: Disables ECC detection and correction. |
| 6 | ECERVF | 0 | R/W | Flag bit to enable ECC error judgment<br>Setting this bit to B'1 enables to judge error. The correction of output data and the interrupt output depend on setting of bit 5 "EC1ECP", bit 4 "EC2EDIC" and bit 3 "EC1EDIC".<br>But the write access to this bit is valid when the value of upper bit15 and bit14 is 2'b01.<br>So only the 16bits operation command is valid in the case of the write access to this bit. |
| 5 | EC1ECP | 0 | R/W | Permission bit of ECC 1bit error correction<br>This bit sets enable or disable to correct the 1bit error when ECC error detection and correction is valid.<br>By setting B'1 to this bit, the non-corrected data is outputted if 1bit error is detected.<br>0: At 1bit error detection, the error correction is executed.<br>1: At 1bit error detection, the error correction is not executed. |
| 4 | EC2EDIC | 0 | R/W | Control bit of interrupt at ECC 2bits error detection<br>This bit controls the interrupt output at detecting 2bits error.<br>By setting B'1 to this bit, the 2bits error interrupt "EC7TIE2" is outputted when 2bits error detected.<br>0: When a 2-bit error is detected, the ECM is not notified of the error.<br>1: When a 2-bit error is detected, the ECM is notified of the error. |
| 3 | EC1EDIC | 0 | R/W | Control bit of interrupt at ECC 1bit error detection<br>This bit controls the interrupt output at detecting 1bit error.<br>By setting "1" to this bit, the 1bit error interrupt "EC7TIE1" is outputted when 1bit error detected.<br>0: Interrupt is not occurred at detecting 1bit error. (initial value)<br>1: EC7TIE1 is outputted at detecting 1bit error. |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 2 | ECER2F | 0 | R/W | 2-Bit ECC Error Detection Flag<br>Indicates that errors have been detected at two bits in bits 0 to 38 of the data read from the RAM during RAM read access while error detection is enabled. When the 2bits error interrupt output is enabled, 2bits error interrupt signal “E7TIE2” is outputted by setting this flag.<br>This bit is a read only flag, so writing “1” or “0” does not influence on inner condition.<br>When 2bits error is detected again under the condition that this bit is set, the interrupt signal is not occurred.<br>0: 2-bit error is not generated<br>1: 2-bit error is generated<br>Clearing conditions<br>(1) Reset is applied.<br>(2) 1 is written to ECER2C.<br>(3) ECC detection and correction being disabled (ECTHM = 1). |
| 1 | ECER1F | 0 | R/W | 1-Bit ECC Error Detection And Correction Flag<br>Indicates that an error has been detected at one bit in bits 0 to 38 of the data read from the RAM during RAM read access while error detection is enabled. When the 1bit error interrupt output is enabled, 1bit error interrupt signal “E7TIE1” is outputted by setting this flag.<br>This bit is a read only flag, so writing “1” or “0” does not influence on inner condition.<br>When 1bit error is detected again under the condition that this bit is set, the interrupt signal is not occurred.<br>0: 1-bit error is not generated<br>1: 1-bit error is generated<br>Clearing conditions<br>(1) Reset is applied.<br>(2) 1 is written to ECER1C.<br>(3) ECC detection and correction being disabled (ECTHM = 1). |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 0 | ECEMF | X | R | ECC Error Message Flag<br>Indicates that the current read data bus contains an error.<br>ECEMF is updated every time RAM data is output. Since the RAM value after reset is undefined, the initial value of this module is determined to be an error, and thus ECEMF may be set. Therefore, the ECEMF value after reset is undefined.<br>0: The current read data bus contains no bit errors.<br>1: The current RAM output data contains bit errors.<br>ECEMF remains set as long as RAM data containing a bit error is output with error detection being enabled.<br>Clearing conditions<br>(1) ECC detection and correction being disabled (ECTHM = B'1).<br>(2) Decoding circuit input data contains no 1-bit errors. |

**(b) E710TMC — ECC Test Mode Control Register**

E710TMC is a register to switch the mode to test mode and controls the mode.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | - | - | - | - | - | - | - | - | - | - | - | - | - | - | - | - |

| | ETMA[1:0] | | - | - | - | - | - | - | ECTMCE | - | - | ECTRRS | ECREOS | ECENS | ECDCS | ECREIS |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R | R | R | R | R | R | R/W | R | R | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 31 to 16 | - | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 15 to 14 | ETMA[1:0] | All 0 | R/W | Access Control 1 and 0 to ECC Test Mode Control Enable Bit<br>These bits reserve the write trigger to bit 7. The read value is always 0. |
| 13 to 8 | - | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 7 | ECTMCE | 0 | R/W | ECC Test Mode Control Enable<br>ECTMCE enables or disables access to the test registers and test control bits.<br>Write access to ETCMCE is enabled when the value of bits 15 and 14 is B'10.<br>0: Disables access to the test registers and test control bits.<br>1: Enables access to the test registers and test control bits. |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 6 to 5 | - | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 4 | ECTRRS | 0 | R/W | ECC RAM Read Test Mode Control Enable<br>ECTRRS enables the read status of RAM to be generated by reading the E710TED register, and also allows the RAM output data to be read out when the E710TRC.ECERDB[7:0] bits and the E710TED register are read.<br>Write access to ECTRRS is enabled only when ECTMCE is 1 (can be set simultaneously).<br>ECTRRS is cleared by writing 0 to ECTMCE (can be cleared synchronously).<br>0: Disables generation of RAM read status for testing when E710TED is read.<br>1: Enables generation of RAM read status for testing when E710TED is read.<br>When E710TRC.ECERDB[7:0] and E710TED are read, the values of the RAM output data pin are read out. |
| 3 | ECREOS | 0 | R/W | ECC Redundant Bit Output Data Select<br>ECREOS selects either the ECC encoder output data or the ECERDB register value to be output as the ECC redundant bit output.<br>Write access to ECREOS is enabled only when ECTMCE is 1 (can be set simultaneously).<br>ECREOS is cleared by writing 0 to ECTMCE (can be cleared synchronously).<br>0: Allows encoding result to be output as the ECC redundant bit output.<br>1: Allows the E710TRC.ECERDB[6:0] value to be output as the ECC redundant bit output. |
| 2 | ECENS | 0 | R/W | ECC Encoder Input Select<br>ECENS selects either the data value from the peripheral module or the test register value (E710TED.ECEDB[31:0]) as the input signal to be encoded.<br>Write access to ECENS is enabled only when ECTMCE is 1 (can be set simultaneously).<br>ECENS is cleared by writing 0 to ECTMCE (can be cleared synchronously).<br>0: Allows the RAM write data from the peripheral module to be input as the ECC encoder input data.<br>1: Allows the E710TED.ECEDB[31:0] value to be input as the ECC encoder input data. |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 1 | ECDCS | 0 | R/W | ECC Decoder Input Select<br>ECDCS selects either the lower 32-bit data value from the RAM or the test register value (E710TED.ECEDB[31:0]) as the lower 32-bit data of the input signal to be decoded.<br>Write access to ECDCS is enabled only when ECTMCE is 1 (can be set simultaneously).<br>ECDCS is cleared by writing 0 to ECTMCE (can be cleared synchronously).<br>0: Allows the lower 32-bit RAM output data to be input to the data area (32 lower-order bits) to the decoder.<br>1: Allows the E710TED.ECEDB[31:0] value to be input to the data area to the decoder. |
| 0 | ECREIS | 0 | R/W | ECC Redundant Bit Input Data Select<br>ECREIS selects either the upper 7-bit data value from the RAM (redundant bit area) or the test register value (E710TRC.ECERDB[6:0]) as the upper 7-bit data of the input signal to be decoded.<br>Write access to ECREIS is enabled only when ECTMCE is 1 (can be set simultaneously).<br>ECREIS is cleared by writing 0 to ECTMCE (can be cleared synchronously).<br>0: Allows the upper 7-bit RAM output data to be input to the ECC redundant bit area to the decoder.<br>1: Allows the E710TRC.ECERDB[6:0] value to be input to the ECC redundant bit area to the decoder. |

**(c) E710TRC — ECC Redundant Bit Data Control Test Register**

E710TRC is a 32-bit test register consisting of four fields (ECSYND, ECHORD, ECECRD, and ECRODM) corresponding to the ECC redundant bit area. Each field can be accessed as the 8-bit register with the same name.

When ECTMCE = 0, E710TRC is always read as 0.

When ECTMCE = 1, E710TRC can be read using the 32-bit manipulation instruction.

Note: Changing ECTMCE from 1 to 0 resets E710TED synchronously

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|

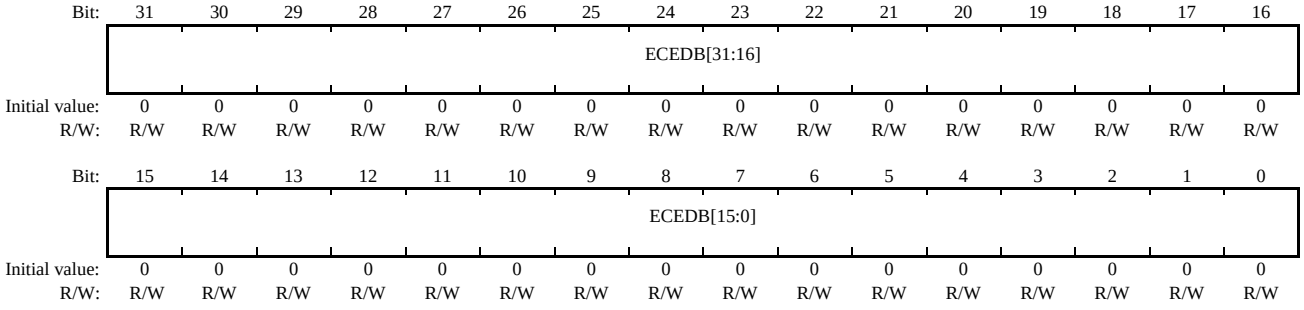
**(d) E710TED — ECC Encoder and Decoder Data Test Register**

E710TED is a 32-bit data test register for ECC encoding and decoding.

When ECTMCE = 1, E710TED can be read and written to using the 32-bit manipulation instruction.

When ECTMCE = 0, E710TED is always read as 0.

In test mode, the E710TED value can be used as the input data to the encoding circuit and decoding circuit.



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 31 to 0 | ECEDB | All 0 | R/W | ECC Encoder and Decoder Data Test Register<br>When E710TMC:ECENS = B'1, the ECEDB value is input to the encoding circuit and supplied to the RAM.<br>When E710TMC:ECDCS = B'1, the ECEDB value is input as the 31th to 0th bits of the input data to the decoding circuit.<br>When E710TMC:ECTRRS = B'1, reading ECEDB returns the RAM output data instead of the data written to ECEDB.<br>Note: Changing ECTMCE from B'1 to B'0 resets E710TED synchronously. |

**(e) E710EAD — ECC Error Address Register**

E710EAD is a read-only register to hold the address at which an ECC error has occurred.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

However, if a 1-bit error is followed by a 2-bit error, the address of the latter is stored.<br>Only one address can be held in E710EAD. |

#### 102.5.1.2.2 Notification to ECM

Detection of errors in two bits can be set for this module and the ECM is notified of detected errors.

- 1-bit Error Notification

  While EC1EDIC is set to B'1, when an error is detected in one bit from among bits 0 to 38 of data read from RAM, the ECM is notified of the 1-bit error. When ECER1F or ECER2F is already set, however, the ECM will not be notified of the error.
- 2-bit Error Notification

While EC2EDIC is set to B'1, when an error is detected in two bits from among bits 0 to 38 of data read from RAM, the ECM is notified of the 2-bit error. When ECER2F is already set, however, the ECM will not be notified of the error.

#### 102.5.1.2.3 Test Function

(1) Writing to RAM Data

Write data to the peripheral RAM. However, the ECC corresponding to the written data will be written to the ECC bits simultaneously. In order to write a specified value to the ECC bits, use the ECC test mode described in (3) below.

(2) Reading RAM Data

(a) Set the ECTHM bit in the ECC control register to 1 to disable ECC error detection and correction.

(b) Read the peripheral RAM. Since neither error detection nor correction proceeds when the peripheral RAM is read, the RAM data is read unchanged.

How to exit this test mode:

(a) Set the ECTHM bit in the ECC control register to 0 to enable ECC error detection and correction.

(3) Writing to the ECC Bits

(a) Set the ECTMCE bit in the ECC test mode control register to 1 to set ECC test mode.

(b) Write the value for writing to the ECC bits to the E710TRC.ECERDB[6:0] bits.

(c) Set the ECREOS bit in the ECC test mode control register to 1 to select writing of the value of the E710TRC.ECERDB[6:0] bits to the ECC bits.

(d) When data are written to the peripheral RAM, the value in the E710TRC.ECERDB[6:0] bits will be written to the ECC bits.

How to exit this test mode:

(a) Set the ECTMCE bit in the ECC test mode control register to 0 to set normal mode.

(4) Reading the ECC Bits

(a) Set the ECTMCE bit in the ECC test mode control register to 1 to set ECC test mode.

(b) When data in the peripheral RAM is read, the ECC bits are stored in the E710TRC.ECHORD[6:0] bits.

How to exit this test mode:

(a) Set the ECTMCE bit in the ECC test mode control register to 0 to set normal mode.

### 102.5.1.3 Error detection operation

#### 102.5.1.3.1 Setting initial value

In this IP (ECC IP), it is possible to select whether the error in the initial value after reset is judged or not with the value of IP terminal “EC7TERVE”.

Followings show operation table with terminal condition and bit setting

| EC7TERVE terminal | ECTHM bit | ECERVF bit | Operation | |
|---|---|---|---|---|
| | | | Error judgment operation | ECERVF bit access |
| 0 | 0 | 0 | Error judgment is permitted. (reset value) | Writing access is invalid |
| | 0 | 1 | Error judgment is permitted. (reset value) | Writing access is invalid |
| | 1 | 0 | Error judgment is prohibited (through mode) | Writing access is invalid |
| | 1 | 1 | Error judgment is prohibited (through mode) | Writing access is invalid |
| 1 | 0 | 0 | Error judgment is prohibited (reset value) | Writing access is valid |
| | 0 | 1 | Error judgment is permitted. | Writing access is valid |
| | 1 | 0 | Error judgment is prohibited (through mode) | Writing access is valid |
| | 1 | 1 | Error judgment is prohibited (through mode) | Writing access is valid |

Example to use at EC7TERVE=1

If the peripheral IP using RAM needs the read access to RAM before completing the RAM initial setting after releasing reset (IP’s RAM access way is read-modify-write type, etc.), the error judgment is prohibited during the initial setting and permitted (ECERVF=1) after completing the RAM initial setting with software. (If some treatment is done to peripheral IP, these operations are not needed.)

#### 102.5.1.3.2 1bit error judgment

If the total number of “1” is odd in the syndrome code (7bits) generated from readout data (including ECC bit) “EC7TERO38-0”, then it is judged as 1bit error. (When 1bit error is occurred in data bit 31-0 and ECC bit 6-0, the total number of “1” set in syndrome code is necessarily odd. When there are plural errors, total number of “1” in syndrome code is odd. But this IP does not guarantee the function like it.)

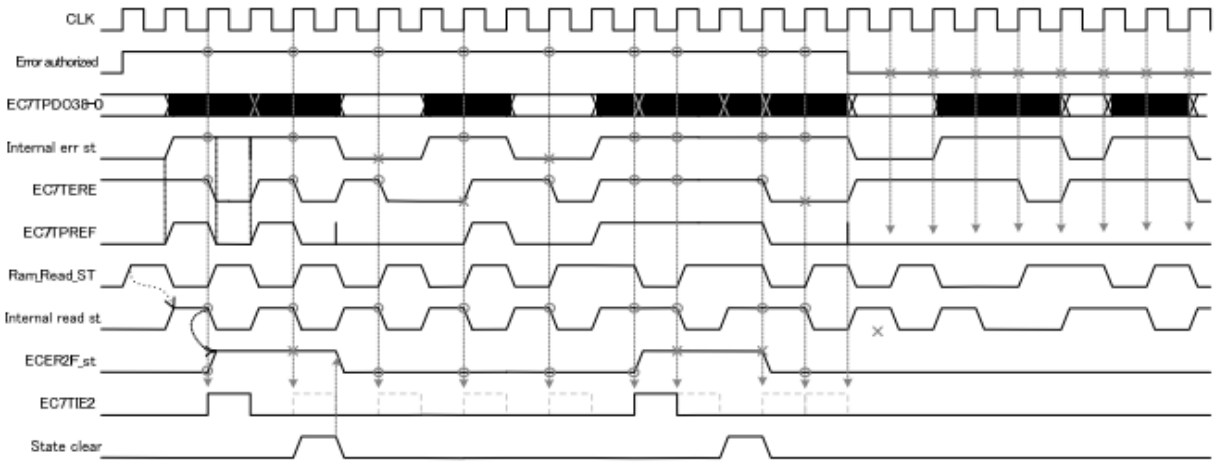
#### 102.5.1.3.3 2bit error judgment

If the syndrome code (7bits) generated from readout data (including ECC bit) “EC7TERO38－0” is not 7’h00 and the error bit placement detecting code (p38-0) (p38-32 are ECC bit parts (7bits redundant bit parts)) is 39’h0000000000, then it is judged 2bits error.

When “Synd[6:0] is not 7’h00” and “p[38:0] is 39’h0000000000”, then it is 2bits error.

Primly the 2bits error is judged when the total number of “1” set in syndrome code (7bits). But this IP judges with the syndrome code and the error bit placement detecting code to not detect the false error in the case that all data (including ECC bit part) are fixed to “0” or “1”. (So if there is more than 3bits error, the possibility is up to judge as 2bits error.)

#### 102.5.1.3.4 Timing chart error judgment (Close to user)



When the condition is not the error judgment enable (Error authorized =1 on above timing chart) and EC7TERE (error judgment enable signal) is not “High”, the 2bits error detect flag (ECER2F) and interrupt (EC7TIE2) are not occurred. (ECER1F: Flag bit of ECC 1bits error detection and correction and 1bit error interrupt is also. And ECEMF (ECC error detecting flag) is not outputted when the error judgment is enable and EC7TERE is not active.

#### 102.5.1.3.5 Error address capture overflow detection

When this IP has error address register (P_ERR_STAG=1-8), the overflow flag (ECOVFF) is set and the overflow interruption is outputted by detecting new error address under the condition that the register is full.
If all error address register is full of 1bit error address and 2bits error is detected, overflow flag (ECOVFF) and 2bits error detection flag (ECER2F) are set at the same time. And when 2bits error interruption output is permitted, so it occurs, too.

# 103. FlexRay

## 103.1 Overview

The FlexRay IP-module performs communication according to the FlexRay protocol specification v2.1. With maximum specified sample clock the bitrate is 10 MBit/s. Additional bus driver (BD) hardware is required for connection to the physical layer.

### 103.1.1 Features

For communication on a FlexRay network, individual message buffers with up to 254 data bytes are configurable. The message storage is a Message RAM that holds up to 128 message buffers. All functions concerning the handling of messages are implemented in the Message Handler. Those functions are the acceptance filtering, the transfer of messages between the two FlexRay Channel Protocol Controllers and the Message RAM, maintaining the transmission schedule as well as providing message status information.
The register set of the FlexRay IP-module can be accessed directly by an external Host via the module's Host interface. These registers are used to control/configure/monitor the FlexRay Channel Protocol Controllers, Message Handler, Global Time Unit, System Universal Control, Frame and Symbol Processing, Network Management, Interrupt Control, to access the Message RAM via Input / Output Buffer; and to control the data transfer between the Message RAM and the user RAM(URAM).

In this section, User RAM means to the local RAM (and external memory for the SoC if possible in your product).

The FlexRay IP-module supports the following features:

| Item | Specification |
|---|---|
| Communication | Comply with FlexRay protocol specification v2.1 |
| Data transfer rate | up to 10 Mbit/s on each channel |
| FlexRay channels | 2 (channel A and B) |
| Message buffer | Up to 128 message buffers configurable<br>Configuration of message buffers with different payload lengths possible<br>Each message buffer can be configured as receive buffer, as transmit buffer or as part of the receive FIFO<br>Filtering for slot counter, cycle counter, and channel |
| Message RAM | 8 Kbyte of Message RAM for storage of e.g.<br>128 message buffers with max. 48 byte data section<br>up to 30 message buffers with 254 byte data section |
| FIFO | One configurable receive FIFO |
| Message buffer access | by Host CPU via Input and Output Buffer<br>Input Buffer: Holds message to be transferred to the Message RAM<br>Output Buffer: Holds message read from the Message RAM |
| | by data transfer function<br>Input transfer: Message buffer content is transferred from URAM to Message RAM on CPU request<br>Output transfer: Message buffer content is transferred from Message RAM to URAM automatically |
| Network management | Automatic HW support |
| Interrupts | Maskable module interrupts |
| Timer | 2 absolute timers<br>1 relative timer |

### 103.1.2 Block Diagram

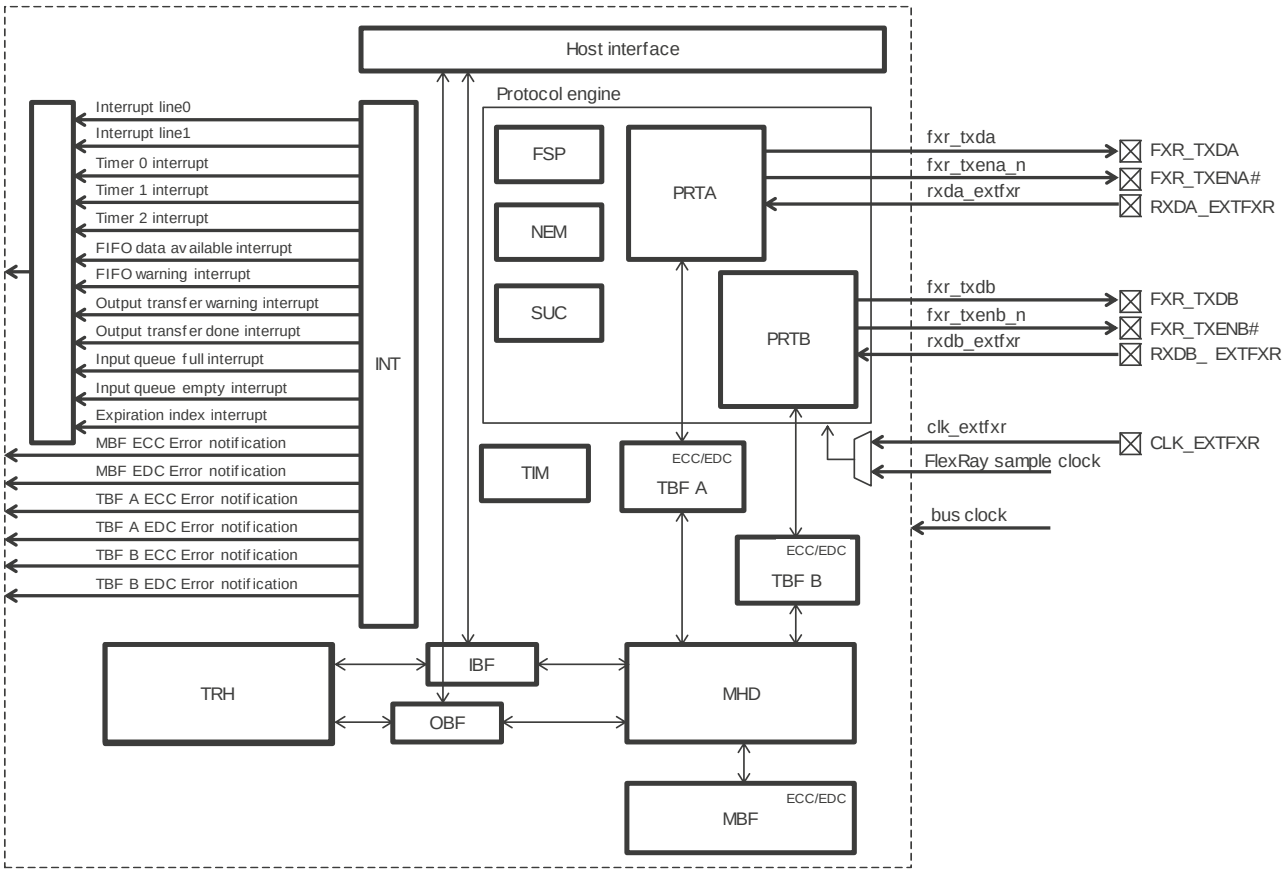


**Figure 103.1 FlexRay Block Diagram**

**Input Buffer (IBF)**
For write access to the message buffers configured in the Message RAM, the Host can write the header and data section for a specific message buffer to the Input Buffer. The Message Handler then transfers the data from the Input Buffer to the selected message buffer in the Message RAM.

**Output Buffer (OBF)**
For read access to a message buffer configured in the Message RAM the Message Handler transfers the selected message buffer to the Output Buffer. After the transfer has completed, the Host can read the header and data section of the transferred message buffer from the Output Buffer.

**Message Handler (MHD)**
The FlexRay Message Handler controls data transfers between the following components:

Input / Output Buffer and Message RAM

Transient Buffer RAMs of the two FlexRay Protocol Controllers and Message RAM

**Message RAM (MRAM, MBF)**
The Message RAM (MBF) consists of a single-ported RAM that stores up to 128 FlexRay message buffers together with the related configuration data (header and data partition).

**Transient Buffer RAM (TBF A/B)**
Stores the data section of two complete messages.

**FlexRay Channel Protocol Controllers (PRT A/B)**
The FlexRay Channel Protocol Controllers consist of shift register and FlexRay protocol FSM. They are connected to the Transient Buffer RAMs for intermediate message storage and to the physical layer via bus driver BD.

They perform the following functionality:
Control and check of bit timing
Reception / transmission of FlexRay frames and symbols
Check of header CRC
Generation / check of frame CRC
Interfacing to bus driver

**System Universal Control (SUC)**
The System Universal Control controls the following functions:
Configuration
Wakeup
Startup
Normal Operation
Passive Operation

**Frame and Symbol Processing (FSP)**
The Frame and Symbol Processing controls the following functions:
Checks the correct timing of frames and symbols
Tests the syntactical and semantical correctness of received frames
Sets the slot status flags

**Network Management (NEM)**
Handles the network management vector.

**Interrupt Control (INT)**
The Interrupt Controller performs the following functions:
Provides error and status interrupt flags
Enable / disable interrupt sources
Assignment of interrupt sources to one of the two general module interrupt lines
Enable / disable module interrupt lines

**Timer (TIM)**
The Timer module includes the following macrotick timer:
Two absolute timer
One relative timer
One stop watch timer

**Transfer Handler (TRH)**
Handles the data transfer between URAM and FlexRay module.
The Transfer Handler supports the following transfer types:
Transfer of buffer configuration data from the URAM to the Message RAM
Transfer of payload data for transmit buffer from the URAM to the Message RAM

Transfer of buffer configuration data and payload data for transmit buffer from the URAM to the Message RAM
Automatic transfer of payload data from receive buffer to the URAM upon frame reception
Automatic transfer of payload data, buffer configuration data and message buffer status data from receive buffer to the URAM upon frame reception
Automatic transfer of buffer configuration data and message buffer status data from dedicated transmit and receive buffer to the URAM upon slot status update
Manual transfer of payload data, buffer configuration data and message buffer status data from dedicated transmit and receive buffer to the URAM

### 103.1.3 External Pins

**Table 103.1 Pin Configuration**

| Name | Abbreviation | I/O | Function |
|---|---|---|---|
| RXDA_EXTFXR | — | I | FlexRay receive data channel A |
| RXDB_EXTFXR | — | I | FlexRay receive data channel B |
| FXR_TXDA | — | O | FlexRay transmit data channel A |
| FXR_TXDB | — | O | FlexRay transmit data channel B |
| FXR_TXENA# | — | O | FlexRay transmit enable channel A |
| FXR_TXENB# | — | O | FlexRay transmit enable channel B |
| CLK_EXTFXR | — | I | Conformance test clock |

#### 103.1.3.1 RXDA_EXTFXR

FlexRay receive data channel A

If FlexRay communication is not used in systems, please input fixed value 1’b1 to this port.

#### 103.1.3.2 RXDB_EXTFXR

FlexRay receive data channel B

If FlexRay communication is not used in systems, please input fixed value 1’b1 to this port.

#### 103.1.3.3 FXR_TXDA

FlexRay transmit data signal channel A

Initial value is 1’b1. If FlexRay communication is not used in systems, please left fxr_txda open.

#### 103.1.3.4 FXR_TXDB

FlexRay transmit data signal channel B

Initial value is 1’b1. If FlexRay communication is not used in systems, please left fxr_txda open.

#### 103.1.3.5 FXR_TXENA#

FlexRay transmit enable signal channel A

When HIGH, channel A transmission is inactive. When LOW, channel A transmission is active.

#### 103.1.3.6 FXR_TXENB#

FlexRay transmit enable signal channel B

When HIGH, channel B transmission is inactive. When LOW, channel B transmission is active.

#### 103.1.3.7 CLK_EXTFXR

Conformance test clock

### 103.1.4 Register Configuration

The FlexRay module allocates an address space as shown in Table 103.2

Within this specification the "Values after reset" refers to the microcontroller's HW RESET. For registers in the address range h'0010 to h'0FFF the "Value after reset" are also applicable when the SW RESET (using **FROC.OE**) is applied.

The addresses given in this specification are relative addresses. The address offset ERAY needs to be added to all given addresses.

Offset Address : ERAY = h'E6B0

AccessSize : AS = 32/16/8

**Table 103.2 Register Configuration**

| Name | Abbreviation | R/W | Address | Initial value | Access Size |
|---|---|---|---|---|---|
| FlexRay Operation Control register | FROC | R/W | <ERAY>+H'0004 | H'0000 0000 | 32,16,8 |

### 103.1.5 Connected Module

**Table 103.3 Connected Modules**

| Module Name | Connected Module Name | Connected Module Function |
|---|---|---|
| FlexRay | CPG | Clock output |
| | RST | Reset output |
| | INTC and ECM | Interrupt input |
| | PAD logic | I/O terminal connection |
| | | Bus connection<br>(register access and data transfer) |

## 103.2 Register Description

[Initial value Symbol Description]

- : Undefined value

[R/W Symbol Description]

R/W : read and write allowed. You can read the writing value.

R/WC0 : read and write allowed. 0 is written, the bit is initialized, but one of the writing will be ignored.

R : Read only variable. Please value is always set to 0 to write.

-/WB : write only variable. Read value is undefined.

### 103.2.1 Register Operation register

#### 103.2.1.1 FROC [h'0004]

FlexRay Operation Control register

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | - | - | - | - | - | - | - | - | - | - | - | - | - | T2IE | T1IE | T0IE |

|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | - | - | - | - | - | - | - | - | OEP | - | - | - | - | - | BEC | OE |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R/W | R | R | R | R | R | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:19] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [18] | T2IE | 0 | R/W | Timer 2 interrupt enable. 0: Disabled , 1: Enabled |
| [17] | T1IE | 0 | R/W | Timer 1 interrupt enable. 0: Disabled , 1: Enabled |
| [16] | T0IE | 0 | R/W | Timer 0 interrupt enable. 0: Disabled , 1: Enabled |
| [15:8] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [7] | OEP | 0 | R/W | Operation Enable bit Protection.<br>0: OE is unprotected , 1: OE is protected |
| [6:2] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [1] | BEC | 0 | R/W | Byte Endian Control. 0: Little endian , 1: Big endian |
| [0] | OE | 0 | R/W | Operation Enable.<br>0: Operation disabled, SW reset , 1: Operation Enabled |

### (1) FROC.T2IE

Timer 2 interrupt enable

This bit controls the timer 2 interrupt.

0: Disabled
No interrupt will be requested and the timer 2 interrupt line will be released if pending.

1: Enabled
Timer 2 interrupt will be asserted when **FROS.T2IS** is '1'.

### (2) FROC.T1IE

Timer 1 interrupt enable

The user should only set this bit to '1' when timer 1 interrupt is not enabled in the FlexRay Status interrupt enable register (**FRSIES.TI1E** should be '0').

This bit controls the timer 1 interrupt.

0: Disabled
No interrupt will be requested and the timer 1 interrupt line will be released if pending.

1: Enabled
Timer 1 interrupt will be asserted when **FROS.T1IS** is '1'.

### (3) FROC.T0IE

Timer 0 interrupt enable

The user should only set this bit to '1' when timer 0 interrupt is not enabled in the FlexRay Status interrupt enable register (**FRSIES.TI0E** should be '0').

This bit controls the timer 0 interrupt.

0: Disabled

No interrupt will be requested and the timer 0 interrupt line will be released if pending.

1: Enabled
Timer 0 interrupt will be asserted when **FROS.T0IS** is '1'.

### (4) FROC.OEP

Operation Enable bit Protection

This bit protects against unintended write access to the **FROC.OE** bit.

0: **OE** is unprotected
Write access to the **OE** bit is enabled

1: **OE** is protected
Write access to the **OE** bit is disabled

### (5) FROC.BEC

Byte Endian Control

The user should only change this bit when **FROS.OS** is '1'.

This bit controls the byte order on reading and writing the FlexRay Network Management Vector register (**FRNMVn**), FlexRay Write Data Section (**FRWRDSn**) and FlexRay Read Data Section (**FRRDDSn**). This bit also controls the byte order when reading or writing FlexRay payload data using the data transfer function.

For details about the byte alignment please refer to section 103.3.17.

**0**: Little endian
Byte alignment in **FRNMVn**, **FRWRDSn** and **FRRDDSn** is in little endian style.

**1**: Big endian
Byte alignment in **FRNMVn**, **FRWRDSn** and **FRRDDSn** is in big endian style.

### (6) FROC.OE

Operation Enable

The user can only write to this bit when **FROC.OEP** is '0'.

The user should only write this bit with '0' when **FROS.OS** is '1'.

The user should only write this bit with '1' when **FROS.OS** is '0' and the FlexRay sample clock is enabled.

This bit controls the operation state and serves the software reset of the FlexRay module. The operation status bit (**FROS.OS**) indicates whether the FlexRay module is in reset state or not.

0: Operation disabled, SW reset
Forcibly moves the FlexRay module to its reset state, whatever the state of the FlexRay module is.

1: Operation Enabled
Reset state of the FlexRay module is released.

### 103.2.1.2 FROS [h'000C]

FlexRay operation status register

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | - | - | - | - | - | - | - | - | - | - | - | - | - | T2IS | T1IS | T0IS |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R/W | R/W | R/W |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | - | - | - | - | - | - | - | - | - | - | - | - | - | - | - | OS |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:19] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [18] | T2IS | 0 | R/W | Timer 2 Interrupt Status.<br>0: Timer 2 has not matched the conditions configured in the FRT2C register.<br>1: Timer 2 matched the conditions configured in the FRT2C register. |
| [17] | T1IS | 0 | R/W | Timer 1 Interrupt Status.<br>0: Timer 1 has not matched the conditions configured in the FRT1C register.<br>1: Timer 1 matched the conditions configured in the FRT1C register. |
| [16] | T0IS | 0 | R/W | Timer 0 Interrupt Status.<br>0: Timer 0 has not matched the conditions configured in the FRT0C register.<br>1: Timer 0 matched the conditions configured in the FRT0C register. |
| [15:1] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [0] | OS | 0 | R | Operation Status.<br>0: Operation disabled, reset state , 1: Operation enabled |

#### (1) FROS.T2IS

Timer 2 Interrupt Status

Writing '0' has no effect on the bit value.

This bit represents that the expiration criteria configured in **FRT2C** register has matched the FlexRay local time.

If enabled in **FROC.T2IE** the timer 2 interrupt is generated when **FROS.T2IS** is '1'.

[Clearing condition]
This bit is cleared by writing '1' to **FROS.T2IS**.
This bit is cleared when **FROS.OS** changes from '1' to '0'.

[Setting condition]
This bit is set when the expiration criteria configured in **FRT2C** matches the FlexRay local time.

### (2) FROS.T1IS

Timer 1 Interrupt Status

Writing '0' has no effect on the bit value.

This bit represents that the expiration criteria configured in **FRT1C** register has matched the FlexRay local time.

If enabled in **FROC.T1IE** the timer 1 interrupt is generated when **FROS.T1IS** is '1'.

[Clearing condition]
This bit is cleared by writing '1' to **FROS.T1IS**.
This bit is cleared when **FROS.OS** changes from '1' to '0'.

[Setting condition]
This bit is set when the expiration criteria configured in **FRT1C** matches the FlexRay local time.

### (3) FROS.T0IS

Timer 0 Interrupt Status

Writing '0' has no effect on the bit value.

This bit represents that the expiration criteria configured in **FRT0C** register has matched the FlexRay local time.

If enabled in **FROC.T0IE** the timer 0 interrupt is generated when **FROS.T0IS** is '1'.

[Clearing condition]
This bit is cleared by writing '1' to **FROS.T0IS**.
This bit is cleared when **FROS.OS** changes from '1' to '0'.

[Setting condition]
This bit is set when the expiration criteria configured in **FRT0C** matches the FlexRay local time.

### (4) FROS.OS

Operation Status

This bit represents if the FlexRay module is in the reset or the operation state.

When **FROS.OS** is '0' the FlexRay module gets initialized and registers mapped to the address area ERAY+h'0010 to ERAY+h'0FFF cannot be accessed; read access from these registers will return undefined data.

When **FROS.OS** is '1' it is possible to access to the address area ERAY+h'0010 to ERAY+h'0FFF and to perform FlexRay communication.

When **FROS.OS** changes from '0' to '1' all registers in the address range ERAY+h'0010 to ERAY+h'0FFF are set to the "Values after reset".

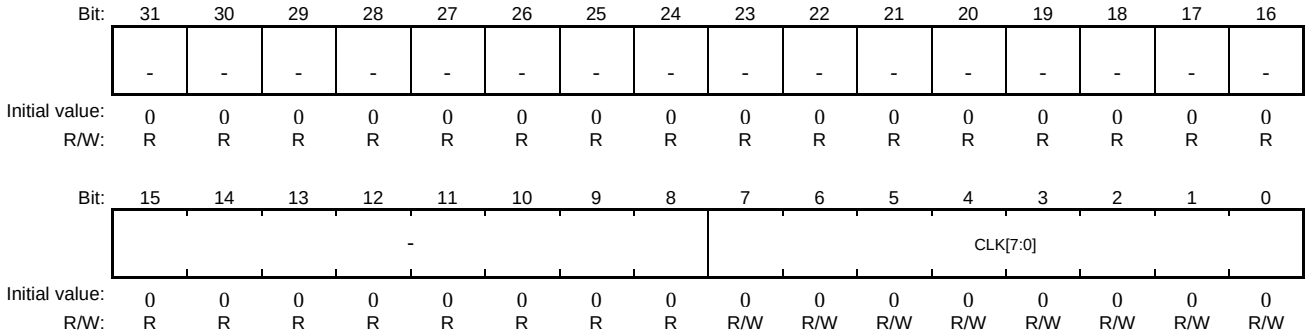
[Clearing condition]
When **FROC.OE** is set to ‘0’. It takes up to two peripheral bus clock cycles until **FROS.OS** is set to '0'.

[Setting condition]
When **FROC.OE** is set to ‘1’ it takes up to four peripheral clock cycles of the clock with the lower frequency out of the FlexRay sample clock and peripheral bus clock until **FROS.OS** is set to ‘1’.

### 103.2.2 Special Registers

#### 103.2.2.1 FRLCK [h'001C]

FlexRay Lock Register



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:16] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [15:8] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [7:0] | CLK | 0 | R/W | Configuration Lock Key |

**(1) FRLCK.CLK**

Configuration Lock Key

The Lock Register is write-only. Reading the register will return 0x0000 0000.

To leave CONFIG state by writing **FRSUCC1.CMD** (command READY), the write operation has to be directly preceded by two write accesses to the Configuration Lock Key (unlock sequence). If the write sequence below is interrupted by other write accesses between the second write to the Configuration Lock Key and the write access to the **FRSUCC1** register, the CC remains in CONFIG state and the sequence has to be repeated.

First write: **FRLCK.CLK** = "1100 1110" (0xCE)
Second write: **FRLCK.CLK** = "0011 0001" (0x31)
Third write: **FRSUCC1.CMD**

**Note:** In case that the Host uses 8/16-bit accesses to write the listed bit fields, the programmer has to ensure that no "dummy accesses" e.g. to the remaining register bytes / words are inserted by the compiler.

### 103.2.3 Interrupt Registers

#### 103.2.3.1 FREIR [h'0020]

FlexRay Error Interrupt Register

The flags are set when the CC detects one of the listed error conditions. The flags remain set until the Host clears them.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|

| [0] | PEMC | 0 | R/W | POC Error Mode Changed<br>0 = Error mode has not changed<br>1 = Error mode has changed |

(1) **FREIR.TABB**

Transmission Across Boundary Channel B

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

The flag signals to the Host that a transmission across a slot boundary occurred for channel B.

(2) **FREIR.LTVB**

Latest Transmit Violation Channel B

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

The flag signals a latest transmit violation on channel B to the Host.

(3) **FREIR.EDB**

Error Detected on Channel B

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This bit is set whenever one of the flags **FRACS.SEDB**, **FRACS.CEDB**, **FRACS.CIB**, **FRACS.SBVB** changes from ’0’ to ’1’.

(4) **FREIR.TABA**

Transmission Across Boundary Channel A

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

The flag signals to the Host that a transmission across a slot boundary occurred for channel A.

(5) **FREIR.LTVA**

Latest Transmit Violation Channel A

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

The flag signals a latest transmit violation on channel A to the Host.

(6) **FREIR.EDA**

Error Detected on Channel A

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This bit is set whenever one of the flags **FRACS.SEDA**, **FRACS.CEDA**, **FRACS.CIA**, **FRACS.SBVA** changes from ’0’ to ’1’.

(7) **FREIR.MHF**

Message Handler Constraints Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

The flag signals a Message Handler constraints violation condition. It is set whenever one of the flags **FRMHDF.SNUA**, **FRMHDF.SNUB**, **FRMHDF.FNFA**, **FRMHDF.FNFB**, **FRMHDF.TBFA**, **FRMHDF.TBFB**, **FRMHDF.WAHP** changes from ’0’ to ’1’.

(8) **FREIR.IOBA**

Illegal Output buffer Access

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set by the CC when the Host requests the transfer of a message buffer from the Message RAM to the Output Buffer while **FROBCR.OBSYS** is set to ’1’.

(9) **FREIR.IIBA**

Illegal Input Buffer Access

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set by the CC when the Host wants to modify a message buffer via Input Buffer and one of the following conditions applies:

1) The CC is not in CONFIG or DEFAULT_CONFIG state and the Host writes to the Input Buffer Command Request register to modify the
Header section of message buffer 0, 1 if configured for transmission in key slot
Header section of static message buffers with buffer number < **FRMRC.FDB** while **FRMRC.SEC** = "01"
Header section of any static or dynamic message buffer while **FRMRC.SEC** = "1x"
Header and / or data section of any message buffer belonging to the receive FIFO
2) The Host writes to any register of the Input Buffer while **FRIBCR.IBSYH** is set to ’1’.

(10) **FREIR.EFA**

Empty FIFO Access

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set by the CC when the Host requests the transfer of a message from the receive FIFO via Output Buffer while the receive FIFO is empty.

(11) **FREIR.RFO**

Receive FIFO Overrun

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

The flag is set by the CC when a receive FIFO overrun is detected. When a receive FIFO overrun occurs, the oldest message is overwritten with the actual received message. The actual state of the FIFO is monitored in register **FRFSR**.

(12) **FREIR.AERR**

Access Error

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

The flag signals an access error to the Host.

It is set when of the flags **FRMHDS.AMR**, **FRMHDS.ATBF1** or **FRMHDS.ATBF2** changes from ’0’ to ’1’.

(13) **FREIR.CCL**

CHI Command Locked

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

The flag signals that the write access to the CHI command vector **FRSUCC1.CMD** was not successful because the execution of the previous CHI command has not yet completed. In this case bit **FREIR.CNA** is also set to ’1’.

(14) **FREIR.CCF**

Clock Correction Failure

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set at the end of the cycle whenever one of the following errors occurred:

Missing offset and / or rate correction

Clock correction limit reached

The clock correction status is monitored in registers **FRCCEV** and **FRSFS**. A failure may occur during startup, therefore bit **FREIR.CCF** should be cleared by the Host after the CC entered NORMAL_ACTIVE state.

(15) **FREIR.SFO**

Sync Frame Overflow

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

Set when either the number of sync frames received during the last communication cycle or the total number of different sync frame IDs received during the last double cycle exceeds the maximum number of sync frames as defined by **FRGTUC2.SNM**.

(16) **FREIR.SFBM**

Sync Frames Below Minimum

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set at the end of a cycle if the number of sync frames received during the last communication cycle was below the limit required for rate or offset correction term calculation (i.e. missing offset and / or missing rate correction). The clock correction status is monitored in **FRCCEV** and **FRSFS**.

The required limit may be dropped during startup. Therefore **FREIR.SFBM** should be cleared by the Host after the CC entered NORMAL_ACTIVE state.

(17) **FREIR .CNA**

Command Not Accepted

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

The flag signals that the write access to the CHI command vector **FRSUCC1.CMD** was not successful because the requested command was not valid in the actual POC state, or because the CHI command was locked (**FREIR.CCL** = ’1’).

(18) **FREIR .PEMC**

POC Error Mode Changed

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set whenever the error mode signaled by **FRCCEV.ERRM** has changed.

### 103.2.3.2 FRSIR [h'0024]

FlexRay Status Interrupt Register

The flags are set when the CC detects one of the listed events. The flags remain set until the Host clears them.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

(1) **FRSIR.MTSB**

MTS Received on Channel B (vSS!ValidMTSB)

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

Media Access Test symbol received on channel B during the preceding symbol window.

Updated by the CC for each channel at the end of the symbol window.

(2) **FRSIR.WUPB**

Wakeup Pattern Channel B

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set by the CC when a wakeup pattern was received on channel B.
Only set when the CC is in one of these states:
WAKEUP
READY
STARTUP

(3) **FRSIR.MTSA**

MTS Received on Channel A (vSS!ValidMTSA)

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

Media Access Test symbol received on channel A during the preceding symbol window.

Updated by the CC for each channel at the end of the symbol window.

(4) **FRSIR.WUPA**

Wakeup Pattern Channel A

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set by the CC when a wakeup pattern was received on channel A.
Only set when the CC is in one of these states:
WAKEUP
READY
STARTUP

(5) **FRSIR.SDS**

Start of Dynamic Segment

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set by the CC when the dynamic segment starts.

(6) **FRSIR.MBSI**

Message Buffer Status Interrupt

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set by the CC when the message buffer status **FRMBS** has changed and if bit **MBI** of that message buffer is set (see received valid data frames only. Table 103.3).

(7) **FRSIR.SUCS**

Startup Completed Successfully

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set whenever a startup completed successfully and the CC entered NORMAL_ACTIVE state.

(8) **FRSIR.SWE**

Stop Watch Event

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set after a stop watch activation when the actual cycle counter and macrotick value are stored in the Stop Watch register (see section 103.2.4.4).

(9) **FRSIR.TOBC**

Transfer Output Buffer Completed

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set whenever a transfer from the Message RAM to the Output Buffer has completed and **FROBCR.OBSYS** has been reset by the Message Handler.

(10) **FRSIR.TIBC**

Transfer Input Buffer Completed

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set whenever a transfer from Input Buffer to the Message RAM has completed and **FRIBCR.IBSYS** has been reset by the Message Handler.

(11) **FRSIR.TI1**

Timer Interrupt 1

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set whenever timer 1 matches the conditions configured in register **FRT1C**.

A FlexRay timer interrupt 1 is generated if enabled in **FROC.T1IE**.

(12) **FRSIR.TI0**

Timer Interrupt 0

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set whenever timer 0 matches the conditions configured in register **FRT0C**.

A FlexRay timer interrupt 0 is generated if enabled in **FROC.T0IE**.

(13) **FRSIR.NMVC**

Network Management Vector Changed

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This interrupt flag signals a change in the Network Management Vector visible to the Host.

(14) **FRSIR.RFCL**

Receive FIFO Critical Level

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set when the receive FIFO fill level **FRFSR.RFFL** is equal or greater than the critical level as configured by **FRFCL.CL**.

(15) **FRSIR.RFNE**

Receive FIFO Not Empty

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set by the CC when a received valid frame was stored into the empty receive FIFO. The actual state of the receive FIFO is monitored in register **FRFSR**.

(16) **FRSIR.RXI**

Receive Interrupt

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set by the CC whenever the set condition of a message buffers **ND** flag is fulfilled (see section 103.2.8.6), and if bit **MBI** of that message buffer is set to ’1’ (see received valid data frames only. Table 103.3)

(17) **FRSIR.TXI**

Transmit Interrupt

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set by the CC at the end of frame transmission if bit **MBI** in the respective message buffer is set to ’1’ (see received valid data frames only. Table 103.3).

(18) **FRSIR.CYCS**

Cycle Start Interrupt

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set by the CC when a communication cycle starts.

(19) **FRSIR.CAS**

Collision Avoidance Symbol

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set by the CC during STARTUP state when a CAS or a potential CAS was received.

(20) **FRSIR.WST**

Wakeup Status

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set when **FRCCSV.WSV** changes to a value other than UNDEFINED.

### 103.2.3.3 FREILS [h'0028]

FlexRay Error Interrupt Line Select

The FlexRay Error Interrupt Line Select register assigns an interrupt generated by a specific error interrupt flag from register **FREIR** to one of the FlexRay IP interrupt lines (FlexRay interrupt 0, FlexRay interrupt 1).

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

### 103.2.3.5 FREIES [h'0030]

FlexRay Error Interrupt Enable Set

The settings in the FlexRay Error Interrupt Enable Set and FlexRay Error Interrupt Enable Reset registers determine which status changes in the FlexRay Error Interrupt Register will result in an interrupt.

The enable bits are set by writing to **FREIES** and reset by writing to **FREIER**. Reading from both addresses will result in the same value.

Writing '0' has no effect on the bit value.

Writing a '1' sets the interrupt enable bit.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

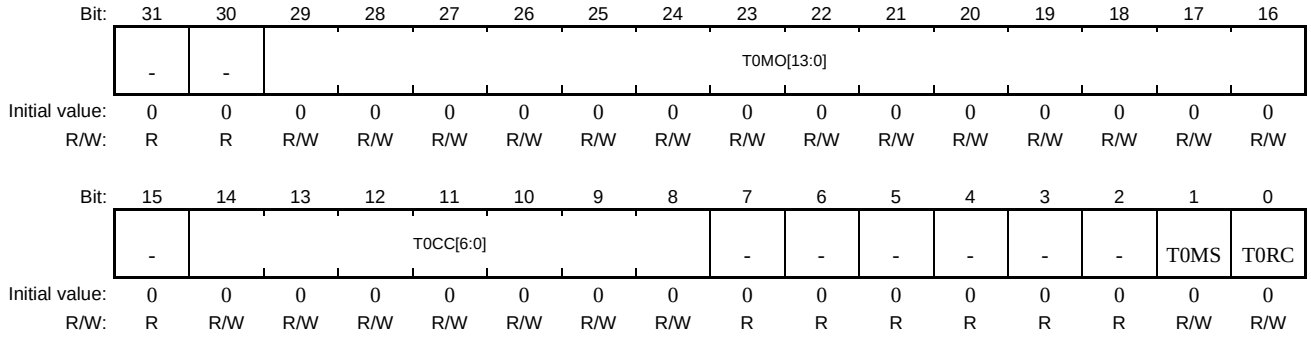
## 103.2.4 FlexRay Timer

### 103.2.4.1 FRT0C [h'0044]

FlexRay Timer 0 Configuration

Absolute timer.
Specifies in terms of cycle count and macrotick the point in time when the FlexRay timer 0 interrupt occurs.
When the FlexRay timer 0 elapses, **FRSIR.TI0** and **FROS.T0IS** are set to '1' and, if enabled in **FROC.T0IE** the FlexRay timer interrupt 0 is asserted.

**Note:** The configuration of timer 0 is compared against the macrotick counter value, there is no separate counter for timer 0.



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:30] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [29:16] | T0MO | 0 | R/W | Timer 0 Macrotick Offset |
| [15] | - | 0 | R | Reserved<br>This bit is always read as 0. The write value should be always 0 |
| [14:8] | T0CC | 0 | R/W | Timer 0 Cycle Code |
| [7:2] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [1] | T0MS | 0 | R/W | Timer 0 Mode Select<br>0 = Single-shot mode<br>1 = Continuous mode |
| [0] | T0RC | 0 | R/W | Timer 0 Run Control<br>0 = Timer 0 halted<br>1 = Timer 0 running |

(1) **FRT0C.T0MO**

Timer 0 Macrotick Offset

Before reconfiguration of the timer, the timer has to be halted first by writing bit **FRT0C.T0RC** to ’0’.

Configures the macrotick offset from the beginning of the cycle where the interrupt is to occur. The FlexRay timer 0 interrupt occurs at this offset for each cycle of the cycle set.

(2) **FRT0C.T0CC**

Timer 0 Cycle Code

Before reconfiguration of the timer, the timer has to be halted first by writing bit **FRT0C.T0RC** to ’0’.

The 7-bit timer 0 cycle code determines the cycle set used for generation of the FlexRay timer 0 interrupt. For details about the configuration of the cycle code see section 103.3.8.2.

(3) **FRT0C.T0MS**

Timer 0 Mode Select

Before reconfiguration of the timer, the timer has to be halted first by writing bit **FRT0C.T0RC** to ’0’.

Configures the timer run mode. In Single-shot mode the timer is deactivated when the timer configuration matches the configured cycle counter and macrotick value.

(4) **FRT0C.T0RC**

Timer 0 Run Control

Timer 0 can be only activated (set **FRT0C.T0RC** to '1') when the POC is either in NORMAL_ACTIVE state or in NORMAL_PASSIVE state.

Timer 0 is deactivated when leaving NORMAL_ACTIVE state or NORMAL_PASSIVE state except for transitions between the two states.

### 103.2.4.2 FRT1C [h'0048]

FlexRay Timer 1 Configuration

Relative timer.
After the specified number of macroticks has expired, the FlexRay timer 1 interrupt is asserted.
When the FlexRay timer 1 elapses, **FRSIR.TI1** and **FROS.T1IS** are set to '1' and, if enabled in **FROC.T1IE** the FlexRay timer interrupt 1 is asserted.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | - | - | - | - | - | - | - | - | - | - | - | - | - | - | T1MS | T1RC |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:30] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [29:16] | T1MC | 2h | R/W | Timer 1 Macrotick Count |
| [15:2] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [1] | T1MS | 0 | R/W | Timer 1 Mode Select<br>0 = Single-shot mode<br>1 = Continuous mode |
| [0] | T1RC | 0 | R/W | Timer 1 Run Control<br>0 = Timer 1 halted<br>1 = Timer 1 running |

(1) **FRT1C.T1MC**

Timer 1 Macrotick Count

Before reconfiguration of the timer, the timer has to be halted first by writing bit **FRT1C.T1RC** to '0'.

Valid values are 2 to 16383 MT in continuous mode
Valid values are 1 to 16383 MT in single-shot mode

When the configured macrotick count is reached the FlexRay timer 1 interrupt is generated.

(2) **FRT1C.T1MS**

Timer 1 Mode Select

Before reconfiguration of the timer, the timer has to be halted first by writing bit **FRT1C.T1RC** to ’0’.

Configures the timer run mode. In Single-shot mode the timer is deactivated when the timer configuration matches the configured cycle counter and macrotick value.

(3) **FRT1C.T1RC**

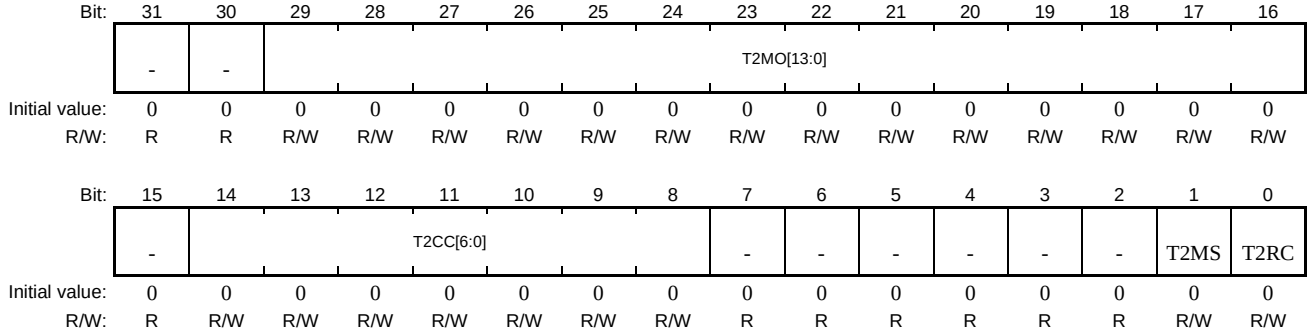
Timer 1 Run Control

Timer 1 can be activated (set **FRT1C.T1RC** to '1') as long as the POC is either in NORMAL_ACTIVE state or in NORMAL_PASSIVE state.

Timer 1 is deactivated when leaving NORMAL_ACTIVE state or NORMAL_PASSIVE state except for transitions between the two states.

### 103.2.4.3 FRT2C [h'0844]

FlexRay Timer 2 Configuration



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:30] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [29:16] | T2MO | 0 | R/W | Timer 2 Macrotick Offset |
| [15] | - | 0 | R | Reserved<br>This bit is always read as 0. The write value should be always 0 |
| [14:8] | T2CC | 0 | R/W | Timer 2 Cycle Code |
| [7:2] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [1] | T2MS | 0 | R/W | Timer 2 Mode Select<br>0: Single-shot mode<br>1: Continuous mode |
| [0] | T2RC | 0 | R/W | Timer 2 Run Control<br>0: Timer halted<br>1: Timer running |

(1) **FRT2C.T2MO**

Timer 2 Macrotick Offset

The user can only write to these bits when **FRT2C.T2RC** is '0'.

Allowed range is 0 to **FRGTUC2.MPC**.

These bits represent the timer macrotick value defining the timer expiration condition.

(2) **FRT2C.T2CC**

Timer 2 Cycle Code

The user can only write to these bits when **FRT2C.T2RC** is '0'.

These bits represent the cycle counter filter code defining the timer expiration condition. See section 103.3.8.2 for cycle filtering.

(3) **FRT2C.T2MS**

Timer 2 Mode Select

The user can only write to these bits when **FRT2C.T2RC** is '0'.

This bit represents the operation mode of the Timer 2.

0: Single-shot mode

The timer is operating in the non-repetitive (single shot) mode. Once the configured expiration criteria are matching the timer will be automatically halted.

1: Continuous mode

The timer is operating in the repetitive (continuous) mode. The timer will expire every time the configured expiration criteria are matching. The timer is not halted.

(4) **FRT2C.T2RC**

Timer 2 Run Control

The user can only set this bit to '1' when the POC is in NORMAL_ACTIVE or NORMAL_PASSIVE state.

This bit represents the activation state of the Timer 2.

When the expiration criteria are matching for a single shot timer, then this bit is cleared automatically and the Timer 2 is halted.

[Setting condition]
This bit is set by writing '1' to it when the POC is in NORMAL_ACTIVE or NORMAL_PASSIVE state.

[Clearing condition]
This bit is cleared when the POC state leaves the NORMAL_ACTIVE or NORMAL_PASSIVE state except for transitions between the two states.

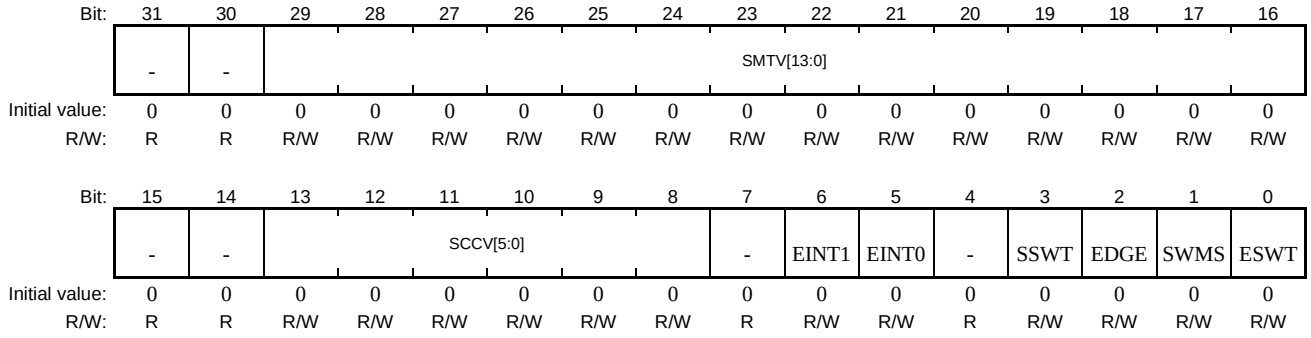
This bit is cleared when the timer is operating in the non-repetitive (single shot) mode (**FRT2C.T2MS** is '0') and the expiration criteria are matching.

This bit is cleared by writing '0' to it.

### 103.2.4.4 FRSTPW1 [h'004C]

FlexRay Stop Watch Register 1

The stop watch is activated by
a FlexRay interrupt 0 event, FlexRay interrupt 1 event or
by the Host by writing bit **FRSTPW1.SSWT** to '1'.
With the macrotick counter increment following next to the stop watch activation the actual cycle counter and macrotick values are captured in register **FRSTPW1** while the slot counter values for channel A and B are captured in register **FRSTPW2**.



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:30] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [29:16] | SMTV | 0 | R/W | Stop Watch Captured Macrotick Value |
| [15:14] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [13:8] | SCCV | 0 | R/W | Stop Watch Captured Cycle Counter Value |
| [7] | - | 0 | R | Reserved<br>This bit is always read as 0. The write value should be always 0 |
| [6] | EINT1 | 0 | R/W | Enable FlexRay Interrupt 1 Trigger<br>0 = Stop watch trigger by FlexRay interrupt 1 disabled<br>1 = FlexRay interrupt 1 event triggers stop watch |
| [5] | EINT0 | 0 | R/W | Enable FlexRay Interrupt 0 Trigger<br>0 = Stop watch trigger by FlexRay interrupt 0 disabled<br>1 = FlexRay interrupt 0 event triggers stop watch |
| [4] | - | 0 | R | Reserved<br>This bit is always read as 0. The write value should be always 0 |
| [3] | SSWT | 0 | R/W | Software Stop Watch Trigger<br>0 = Software trigger reset<br>1 = Stop watch activated by software trigger |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [2] | EDGE | 0 | R/W | Stop Watch Trigger Edge Select<br>0 = Falling edge<br>1 = Rising edge |
| [1] | SWMS | 0 | R/W | Stop Watch Mode Select<br>0 = Single-shot mode<br>1 = Continuous mode |
| [0] | ESWT | 0 | R/W | Enable Stop Watch Trigger<br>0 = Stop watch trigger disabled<br>1 = Stop watch trigger enabled |

(1) **FRSTPW1.SMTV**

Stop Watch Captured Macrotick Value

State of the macrotick counter when the stop watch event occurred.

(2) **FRSTPW1.SCCV**

Stop Watch Captured Cycle Counter Value

State of the cycle counter when the stop watch event occurred.

(3) **FRSTPW1.EINT1**

Enable FlexRay Interrupt 1 Trigger

Enables stop watch trigger by FlexRay interrupt 1 event if **FRSTPW1.ESWT** = ’1’.

(4) **FRSTPW1.EINT0**

Enable FlexRay Interrupt 0 Trigger

Enables stop watch trigger by FlexRay interrupt 0 event if **FRSTPW1.ESWT** = ’1’.

(5) **Reserved**

(6) **FRSTPW1.SSWT**

Software Stop Watch Trigger

Bits **FRSTPW1.ESWT** and **FRSTPW1.SSWT** cannot be set to ’1’ simultaneously. In this case the write access to the register is ignored, and both bits keep their previous values. Either the external stop watch trigger or the software stop watch trigger may be used.

When the Host writes this bit to ’1’ the stop watch is activated. After the actual cycle counter, slot counter and macrotick value are stored in the FlexRay Stop Watch registers and this bit is reset to ’0’.

(7) **FRSTPW1.EDGE**

Stop Watch Trigger Edge Select

(8) **FRSTPW1.SWMS**

Stop Watch Mode Select

(9) **FRSTPW1.ESWT**

Enable Stop Watch Trigger

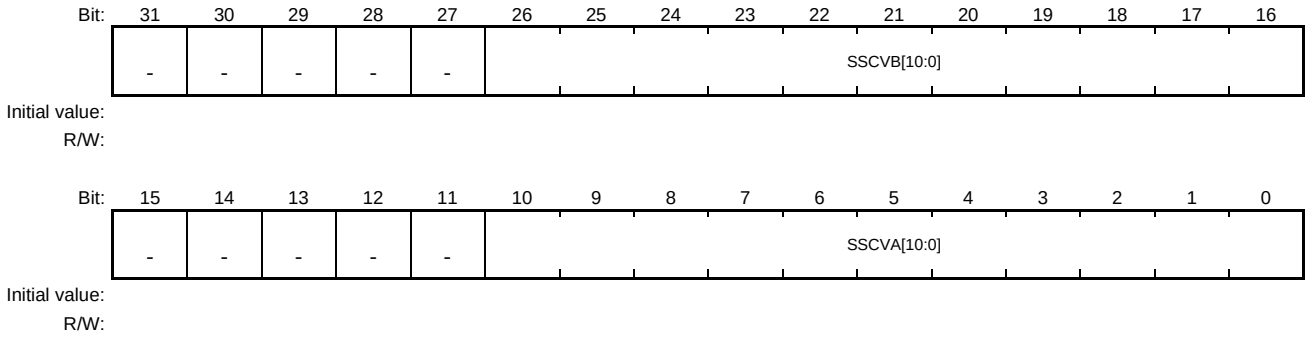
Bits **FRSTPW1.ESWT** and **FRSTPW1.SSWT** cannot be set to ’1’ simultaneously. In this case the write access to the register is ignored, and both bits keep their previous values. Either the external stop watch trigger or the software stop watch trigger may be used.

If enabled an edge on input STPWT_FLEXRAY or a FlexRay interrupt 0 event or a FlexRay interrupt 1 event activates the stop watch.

In single-shot mode this bit is reset to ’0’ after the actual cycle counter, slot counter and macrotick value are stored in the FlexRay Stop Watch registers.

### 103.2.4.5 FRSTPW2 [h'0050]

FlexRay Stop Watch Register 2



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:27] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [26:16] | SSCVB | 0 | R/W | Stop Watch Captured Slot Counter Value Channel B |
| [15:11] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [10:0] | SSCVA | 0 | R/W | Stop Watch Captured Slot Counter Value Channel A |

(1) **FRSTPW2.SSCVB**

Stop Watch Captured Slot Counter Value Channel B

State of the slot counter for channel B when the stop watch event occurred.

(2) **FRSTPW2.SSCVA**

Stop Watch Captured Slot Counter Value Channel A

State of the slot counter for channel A when the stop watch event occurred.

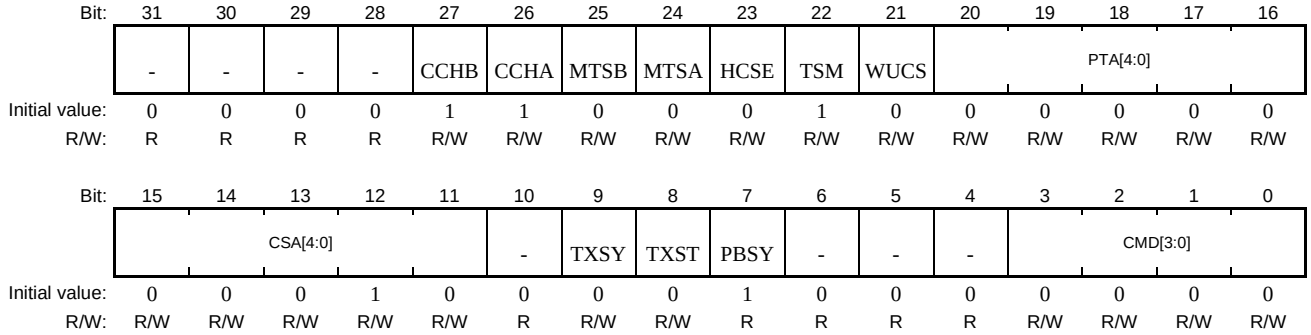
## 103.2.5 CC Control Registers

This section describes the registers provided by the CC to allow the Host to control the operation of the CC. The FlexRay protocol specification requires the Host to write application configuration data in CONFIG state only. Please consider that the configuration registers are not locked for writing in DEFAULT_CONFIG state.

The configuration data is reset when DEFAULT_CONFIG state is entered from reset. To change POC state from DEFAULT_CONFIG to CONFIG state the Host has to apply CHI command CONFIG. If the Host wants the CC to leave CONFIG state, the Host has to proceed an unlock sequence as described in section 103.2.2.1.

### 103.2.5.1 FRSUCC1 [h'0080]

FlexRay SUC Configuration Register 1



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:28] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [27] | CCHB | 1 | R/W | Connected to Channel B<br>Configures pChannels<br>0 = Not connected to channel B<br>1 = Node connected to channel B |
| [26] | CCHA | 1 | R/W | Connected to Channel A<br>Configures pChannels<br>0 = Not connected to channel A<br>1 = Node connected to channel A |
| [25] | MTSB | 0 | R/W | Select Channel B for MTS Transmission<br>0 = Channel B disabled for MTS transmission<br>1 = Channel B selected for MTS transmission |
| [24] | MTSA | 0 | R/W | Select Channel A for MTS Transmission<br>0 = Channel A disabled for MTS transmission<br>1 = Channel A selected for MTS transmission |
| [23] | HCSE | 0 | R/W | Halt due to Clock Sync Error<br>Configures pAllowHaltDueToClock<br>0 = CC will enter / remain in NORMAL_PASSIVE<br>1 = CC will enter HALT state |
| [22] | TSM | 1 | R/W | Transmission Slot Mode<br>Configures pSingleSlotEnabled<br>0 = ALL Slot Mode<br>1 = SINGLE Slot Mode |
| [21] | WUCS | 0 | R/W | Wakeup Channel Select<br>Configures pWakeupChannel<br>0 = Send wakeup pattern on channel A<br>1 = Send wakeup pattern on channel B |
| [20:16] | PTA | 0 | R/W | Passive to Active<br>Configures pAllowPassiveToActive |
| [15:11] | CSA | 2 | R/W | Cold Start Attempts<br>Configures gColdStartAttempts |
| [10] | - | 0 | R | Reserved<br>This bit is always read as 0. The write value should be always 0 |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [9] | TXSY | 0 | R/W | Transmit Sync Frame in Key Slot<br>Configures pKeySlotUsedForSync<br>0 = No sync frame transmission in key slot, node is neither sync nor coldstart node<br>1 = Key slot used to transmit sync frame, node is sync node |
| [8] | TXST | 0 | R/W | Transmit Startup Frame in Key Slot<br>Configures pKeySlotUsedForStartup<br>0 = No startup frame transmission in key slot, node is non-coldstarter<br>1 = Key slot used to transmit startup frame, node is leading or following coldstarter |
| [7] | PBSY | 1 | R | POC Busy<br>0 = POC not busy, FRSUCC1.CMD writeable<br>1 = POC is busy, FRSUCC1.CMD locked |
| [6:4] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [3:0] | CMD | 0 | R/W | CHI Command Vector<br>0000 = command_not_accepted<br>0001 = CONFIG<br>0010 = READY<br>0011 = WAKEUP<br>0100 = RUN<br>0101 = ALL_SLOTS<br>0110 = HALT<br>0111 = FREEZE<br>1000 = SEND_MTS<br>1001 = ALLOW_COLDSTART<br>1010 = RESET_STATUS_INDICATORS<br>1100 = CLEAR_RAMS<br>others = reserved |

(1) **FRSUCC1.CCHB**

Connected to Channel B

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

Configures whether the node is connected to channel B (pChannels).

(2) **FRSUCC1.CCHA**

Connected to Channel A

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

Configures whether the node is connected to channel A (pChannels).

(3) **FRSUCC1.MTSB**

Select Channel B for MTS Transmission

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

**FRSUCC1.MTSB** may also be changed outside DEFAULT_CONFIG or CONFIG state when the write to **FRSUCC1** register is directly preceded by the unlock sequence for the Configuration Lock Key as described in section 103.2.2.1. This may be combined with CHI command SEND_MTS.

If both bits **FRSUCC1.MTSA** and **FRSUCC1.MTSB** are set to '1' an MTS symbol will be transmitted on both channels when requested by writing **FRSUCC1.CMD** = "1000".

The bit selects channel B for MTS symbol transmission.

(4) **FRSUCC1.MTSA**

Select Channel A for MTS Transmission

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

**FRSUCC1.MTSA** may also be changed outside DEFAULT_CONFIG or CONFIG state when the write to **FRSUCC1** register is directly preceded by the unlock sequence for the Configuration Lock Key as described in section 103.2.2.1. This may be combined with CHI command SEND_MTS.

If both bits **FRSUCC1.MTSA** and **FRSUCC1.MTSB** are set to '1' an MTS symbol will be transmitted on both channels when requested by writing **FRSUCC1.CMD** = "1000".

The bit selects channel A for MTS symbol transmission.

(5) **FRSUCC1.HCSE**

Halt due to Clock Sync Error

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

Controls the transition to HALT state due to a clock synchronization error (pAllowHaltDueToClock).

(6) **FRSUCC1.TSM**

Transmission Slot Mode

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

Selects the initial transmission slot mode (pSingleSlotEnabled).

In SINGLE slot mode the CC may only transmit in the preconfigured key slot. The key slot ID is configured in the header section of message buffer 0 respectively message buffers 0 and 1 depending on bit **FRMRC.SPLM**.

In case **FRSUCC1.TSM** = '1', message buffer 0 respectively message buffers 0,1 can be (re)configured in DEFAULT_CONFIG or CONFIG state only. In ALL slot mode the CC may transmit in all slots.

**FRSUCC1.TSM** is a configuration bit which can only be set / reset by the Host.

The CC changes to ALL slot mode when the Host successfully applied the ALL_SLOTS command by writing **FRSUCC1.CMD** = "0101" in POC states NORMAL_ACTIVE or NORMAL_PASSIVE. The actual slot mode is monitored by **FRCCSV.SLM**.

(7) **FRSUCC1.WUCS**

Wakeup Channel Select

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

With this bit the Host selects the channel on which the CC sends the Wakeup pattern (pWakeupChannel).

(8) **FRSUCC1.PTA**

Passive to Active

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 31 even / odd cycle pairs.

Defines the number of consecutive even / odd cycle pairs that must have valid clock correction terms before the CC is allowed to transit from NORMAL_PASSIVE to NORMAL_ACTIVE state (pAllowPassiveToActive).

If set to "00000" the CC is not allowed to transit from NORMAL_PASSIVE to NORMAL_ACTIVE state.

(9) **FRSUCC1.CSA**

Cold Start Attempts

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

Must be identical in all nodes of a cluster.

Valid values are 2 to 31.

Configures the maximum number of attempts that a cold starting node is permitted to try to start up the network without receiving any valid response from another node (gColdStartAttempts).

(10) **FRSUCC1.TXSY**

Transmit Sync Frame in Key Slot

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

Defines whether the key slot is used to transmit sync frames (pKeySlotUsedForSync).

(11) **FRSUCC1.TXST**

Transmit Startup Frame in Key Slot

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

Defines whether the key slot is used to transmit startup frames (pKeySlotUsedForStartup).

**Note:** The protocol requires that both bits **FRSUCC1.TXST** and **FRSUCC1.TXSY** are set for coldstart nodes.

(12) **FRSUCC1.PBSY**

POC Busy

Signals that the POC is busy and cannot accept a command from the Host. **FRSUCC1.CMD** is locked against write accesses.

Set to ’1’ after reset during initialization of internal RAM blocks.

(13) **FRSUCC1.CMD**

CHI Command Vector

The Host may write any CHI command at any time, but certain commands are enabled only in certain POC states. If a command is not enabled, it will not be executed, the CHI command vector **FRSUCC1.CMD** will be reset to "0000" = command_not_accepted, and flag **FREIR.CNA** will be set to '1'.

In general the Host must check **FRSUCC1.PBSY** before writing a new CHI command.

In case the previous CHI command has not yet completed, **FREIR.CCL** is set to '1' together with **FREIR.CNA**; the CHI command needs to be repeated.

Except for HALT state, a POC state change command applied while the CC is already in the requested POC state neither causes a state change nor will **FREIR.CNA** be set.

Reading **FRSUCC1.CMD** shows whether the last CHI command was accepted. The actual POC state is monitored by **FRCCSV.POCS**.

**command_not_accepted**
**FRSUCC1.CMD** is reset to "0000" due to one of the following conditions:
Illegal command applied by the Host
Host applied command to leave CONFIG state without preceding config lock key
Host applied new command while execution of the previous Host command has not completed
Host writes command_not_accepted
When **FRSUCC1.CMD** is reset to "0000", **FREIR.CNA** is set, and, if enabled, an interrupt is generated.

Commands which are not accepted are not executed.

**CONFIG**
Go to POC state CONFIG when called in POC states DEFAULT_CONFIG, or READY. When called in HALT state the CC transits to POC state DEFAULT_CONFIG. When called in any other state, **FRSUCC1.CMD** will be reset to "0000" = command_not_accepted.

**READY**
Go to POC state READY when called in POC states CONFIG, NORMAL_ACTIVE, NORMAL_PASSIVE, STARTUP, or WAKEUP. When called in any other state, **FRSUCC1.CMD** will be reset to "0000" = command_not_accepted.

**WAKEUP**
Go to POC state WAKEUP when called in POC state READY. When called in any other state, **FRSUCC1.CMD** will be reset to "0000" = command_not_accepted.

**RUN**
Go to POC state STARTUP when called in POC state READY. When called in any other state, **FRSUCC1.CMD** will be reset to "0000" = command_not_accepted.

**ALL_SLOTS**
Leave SINGLE slot mode after successful startup / integration at the next end of cycle when called in POC states NORMAL_ACTIVE or NORMAL_PASSIVE. When called in any other state, **FRSUCC1.CMD** will be reset to "0000" = command_not_accepted.

**HALT**
Set halt request **FRCCSV.HRQ** and go to POC state HALT at the next end of cycle when called in POC states NORMAL_ACTIVE or NORMAL_PASSIVE. When called in any other state, **FRSUCC1.CMD** will be reset to "0000" = command_not_accepted.

**FREEZE**
Set the freeze status indicator **FRCCSV.FSI** and go to POC state HALT immediately. Can be called from any state.

**SEND_MTS**

Send single MTS symbol during the next following symbol window on the channel configured by **FRSUCC1.MTSA**, **FRSUCC1.MTSB**, when called in POC state NORMAL_ACTIVE after CC entered ALL slot mode (**FRCCSV.SLM** = "11"). When called in any other state, or when called while a previously requested MTS has not yet been transmitted, **FRSUCC1.CMD** will be reset to "0000" = command_not_accepted.

**ALLOW_COLDSTART**
The command resets **FRCCSV.CSI** to enable the node to become leading coldstarter. When called in states DEFAULT_CONFIG, CONFIG, or HALT, **FRSUCC1.CMD** will be reset to "0000" = command_not_accepted. To become leading coldstarter it is also required that both **FRSUCC1.TXST** and **FRSUCC1.TXSY** are set.

**RESET_STATUS_INDICATORS**
Resets status flags **FRCCSV.CSNI**, **FRCCSV.CSAI**, and **FRCCSV.WSV** to their default values. May be called in POC states READY and STARTUP. When called in any other state, **FRSUCC1.CMD** will be reset to "0000" = command_not_accepted.

**CLEAR_RAMS**
Sets **FRMHDS.CRAM** when called in DEFAULT_CONFIG or CONFIG state. When called in any other state, **FRSUCC1.CMD** will be reset to "0000" = command_not_accepted.

**FRMHDS.CRAM** is also set when the CC leaves reset. By setting **FRMHDS.CRAM** all internal RAM blocks are initialized to zero. During the initialization of the RAMs, **FRSUCC1.PBSY** will show POC busy. Access to the configuration and status registers is possible during execution of CHI command CLEAR_RAMS.

The initialization of the internal message RAM requires 2048 bus clock cycles. There should be no Host access to IBF or OBF during initialization of the internal RAM blocks after reset or after assertion of CHI command CLEAR_RAMS.

Before asserting CHI command CLEAR_RAMS the Host should make sure that no transfer between Message RAM and IBF / OBF or the Transient Buffer RAMs is ongoing and the data transfer handlers are disabled (**FRITS.ITS** = '0' and **FROTS.OTS** = '0'). This command also resets the Message Buffer Status registers **FRMHDS**, **FRLDTS**, **FRFSR**, **FRMHDF**, **FRTXRQ1/2/3/4.TXR**, **FRNDAT1/2/3/4**, and **FRMBSC1/2/3/4**.

**Note:** All accepted commands with exception of CLEAR_RAMS and SEND_MTS will cause a change of the POC state in the FlexRay sample clock domain after at most 8 cycles of the slower of the two clocks 'bus clock' and 'FlexRay sample clock', assumed that POC was not busy when the command was applied and that no POC state change was forced by bus activity in that time frame. Reading register **FRCCSV** will show data that is additionally delayed by synchronization from the FlexRay sample clock domain to the bus clock domain. The maximum additional delay is 12 cycles of the slower of the two clocks 'bus clock' and 'FlexRay sample clock'.

Table 103.2a below references the CHI commands from the FlexRay Protocol Specification [FR_PROT] (section 2.2.1.1, Table 2-2) to the FlexRay CHI command vector **FRSUCC1.CMD**.

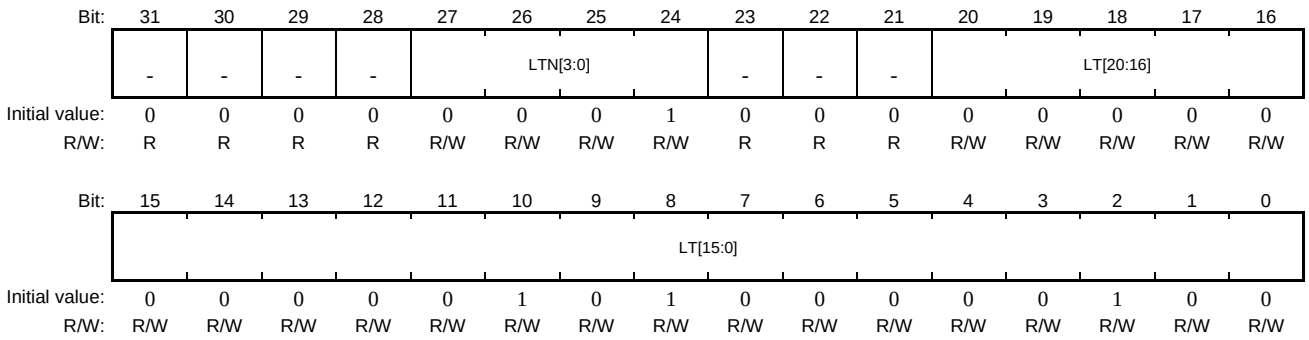
**Table 103.2a Reference to CHI Host command summary from FlexRay protocol specification**

| CHI command | Where processed (POC States) | CHI Command Vector CMD |
|---|---|---|
| ALL_SLOTS | POC:normal active, POC:normal passive | ALL_SLOTS |
| ALLOW_COLDSTART | All except POC:default config, POC:config, POC:halt | ALLOW_COLDSTART |
| CONFIG | POC:default config, POC:ready | CONFIG |
| CONFIG_COMPLETE | POC:config | Unlock sequence & READY |
| DEFAULT_CONFIG | POC:halt | CONFIG |
| FREEZE | All | FREEZE |
| HALT | POC:normal active, POC:normal passive | HALT |
| READY | All except POC:default config, POC:config, | READY |

| | | |
|---|---|---|
| | POC:ready, POC:halt | |
| RUN | POC:ready | RUN |
| WAKEUP | POC:ready | WAKEUP |

### 103.2.5.2 FRSUCC2 [h'0084]

FlexRay SUC Configuration Register 2



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:28] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [27:24] | LTN | 1 | R/W | Listen Timeout Noise<br>Configures (gListenNoise - 1) |
| [23:21] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [20:0] | LT | 504h | R/W | Listen Timeout<br>Configures pdListenTimeout |

(1) **FRSUCC2.LTN**

Listen Timeout Noise

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

The range for gListenNoise is 2 to 16.

**FRSUCC2.LTN** must be configured identical in all nodes of a cluster.

Configures the upper limit for startup and wakeup listen timeout in the presence of noise expressed as a multiple of pdListenTimeout.

**Note:** The wakeup / startup noise timeout is calculated as follows:

pdListenTimeout * gListenNoise = **FRSUCC2.LT** * (**FRSUCC2.LTN** + 1)

(2) **FRSUCC2.LT**

Listen Timeout

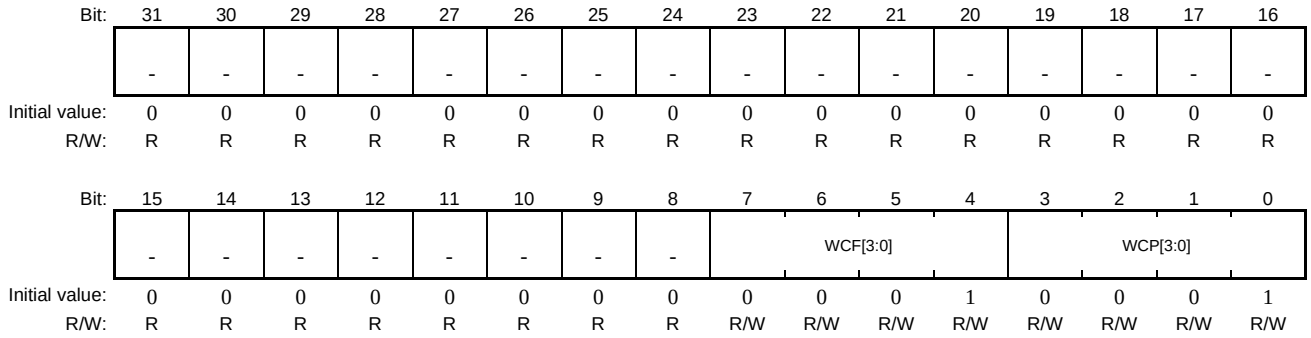
The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

The range for pdListenTimeout is 1284 to 1283846 µT.

Configures wakeup / startup listen timeout in µT.

### 103.2.5.3 FRSUCC3 [h'0088]

FlexRay SUC Configuration Register 3



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:8] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [7:4] | WCF | 1 | R/W | Maximum Without Clock Correction Fatal<br>Configures gMaxWithoutClockCorrectionFatal |
| [3:0] | WCP | 1 | R/W | Maximum Without Clock Correction Passive<br>Configures gMaxWithoutClockCorrectionPassive |

(1) **FRSUCC3.WCF**

Maximum Without Clock Correction Fatal

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

Valid values are 1 to 15 cycle pairs.

**FRSUCC3.WCF** must be identical in all nodes of a cluster.

Defines the number of consecutive even / odd cycle pairs with missing clock correction terms that will cause a transition from NORMAL_ACTIVE or NORMAL_PASSIVE to HALT state.

**Note:** The transition to HALT state is prevented if **FRSUCC1.HCSE** is not set.

(2) **FRSUCC3.WCP**

Maximum Without Clock Correction Passive

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

Valid values are 1 to 15 cycle pairs.

**FRSUCC3.WCP** must be identical in all nodes of a cluster.

Defines the number of consecutive even / odd cycle pairs with missing clock correction terms that will cause a transition from NORMAL_ACTIVE to NORMAL_PASSIVE state.

### 103.2.5.4 FRNEMC [h'008C]

FlexRay NEM Configuration Register

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | - | - | - | - | - | - | - | - | - | - | - | - | - | - | - | - |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:4] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [3:0] | NML | 0 | R/W | Network Management Vector Length<br>Configures gNetworkManagementVectorLength |

(1) **FRNEMC.NML**

Network Management Vector Length

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

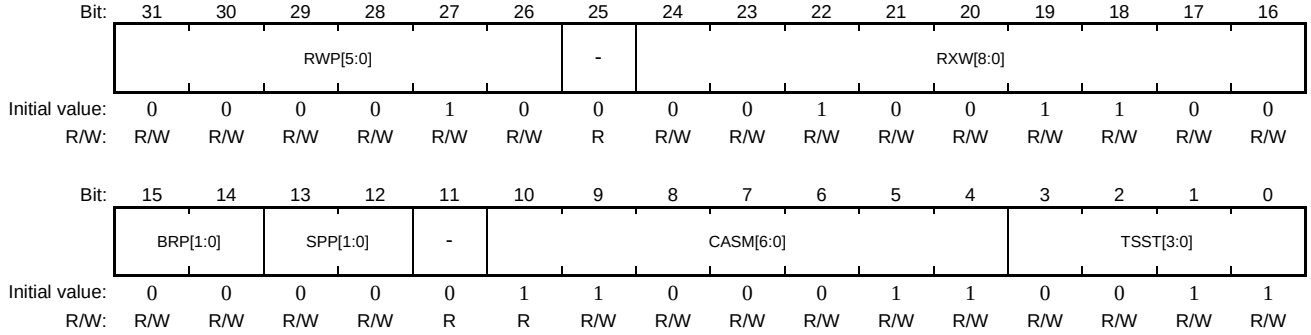
Valid values are 0 to 12 bytes.

**FRNEMC.NML** must be identical in all nodes of a cluster.

These bits configure the length of the NM vector.

### 103.2.5.5 FRPRTC1 [h'0090]

FlexRay PRT Configuration Register 1



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:26] | RWP | 2h | R/W | Repetitions of Tx Wakeup Pattern<br>Configures pWakeupPattern |
| [25] | - | 0 | R | Reserved<br>This bit is always read as 0. The write value should be always 0 |
| [24:16] | RXW | 4Ch | R/W | Wakeup Symbol Receive Window Length<br>Configures gdWakeupSymbolRxWindow |
| [15:14] | BRP | 0 | R/W | Baud Rate Prescaler<br>Configures gdSampleClockPeriod and pSamplesPerMicrotick<br>00 = 10 MBit/s<br>01 = 5 MBit/s<br>10 = 2.5 MBit/s<br>11 = 2.5 MBit/s |
| [13:12] | SPP | 0 | R/W | Strobe Point Position<br>Configures Strobe point position<br>00 = Sample 5<br>01 = Sample 4<br>10 = Sample 6<br>11 = Sample 5 |
| [11] | - | 0 | R | Reserved<br>This bit is always read as 0. The write value should be always 0 |
| [10:4] | CASM | 63h | R/W | Collision Avoidance Symbol Max<br>Configures gdCASRxLowMax |
| [3:0] | TSST | 3h | R/W | Transmission Start Sequence Transmitter<br>Configures gdTSSTransmitter |

Notes: Bit[10]=CASM[6] is fixed to 1, therefore bit[10] is "Read Only" bit: user cannot write this bit.

(1) **FRPRTC1.RWP**

Repetitions of Tx Wakeup Pattern

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 63.

Configures the number of repetitions (sequences) of the Tx wakeup symbol.

(2) **FRPRTC1.RXW**

Wakeup Symbol Receive Window Length

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

Valid values are 76 to 301 bit times.

**FRPRTC1.RXW** must be identical in all nodes of a cluster.

Configures the number of bit times used by the node to test the duration of the received wakeup pattern.

(3) **FRPRTC1.BRP**

Baud Rate Prescaler

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

The Baud Rate Prescaler configures the baud rate on the FlexRay bus. The baud rates listed below are valid with a sample clock set to 80 MHz. One bit time always consists of 8 samples independent of the configured baud rate.

00 = 10 MBit/s
gdSampleClockPeriod = 12.5 ns = 1 * 'sample clock'
pSamplesPerMicrotick = 2 (1 µT = 25 ns)

01 = 5 MBit/s
gdSampleClockPeriod = 25 ns = 2 * 'sample clock'
pSamplesPerMicrotick = 1 (1 µT = 25 ns)

10, 11 = 2.5 MBit/s
gdSampleClockPeriod = 50 ns = 4 * 'sample clock'
pSamplesPerMicrotick = 1 (1 µT = 50 ns)

(4) **FRPRTC1.SPP**

Strobe Point Position

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

Defines the sample count value for strobing. The strobed bit value is set to the voted value when the sample count is incremented to the value configured by **FRPRTC1.SPP**.

**Note:** The current revision 2.1 of the FlexRay protocol requires that **FRPRTC1.SPP** = "00". The alternate strobe point positions could be used to compensate for asymmetries in the physical layer.

(5) **FRPRTC1.CASM**

Collision Avoidance Symbol Max

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

CASM6 is fixed to ’1’.

Valid values are 67 to 99 bit times.

Configures the upper limit of the acceptance window for a collision avoidance symbol (CAS).

(6) **FRPRTC1.TSST**

Transmission Start Sequence Transmitter

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

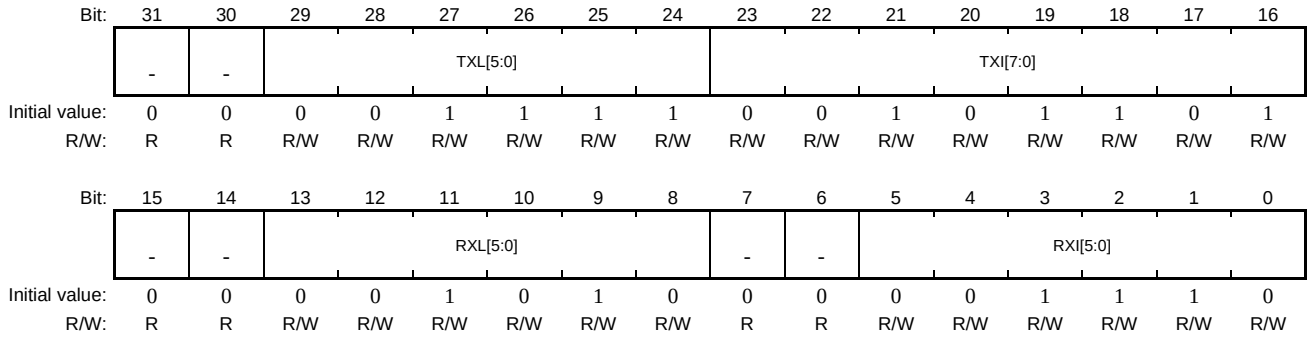
Valid values are 3 to 15 bit times.

**FRPRTC1.TSST** must be identical in all nodes of a cluster.

Configures the duration of the Transmission Start Sequence (TSS) in terms of bit times (1 bit time = 4 µT = 100ns @ 10Mbps).

### 103.2.5.6 FRPRTC2 [h'0094]

FlexRay PRT Configuration Register 2



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:30] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [29:24] | TXL | Fh | R/W | Wakeup Symbol Transmit Low<br>Configures gdWakeupSymbolTxLow |
| [23:16] | TXI | 2Dh | R/W | Wakeup Symbol Transmit Idle<br>Configures gdWakeupSymbolTxIdle |
| [15:14] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [13:8] | RXL | Ah | R/W | Wakeup Symbol Receive Low<br>Configures gdWakeupSymbolRxLow |
| [7:6] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [5:0] | RXI | Eh | R/W | Wakeup Symbol Rx Idle<br>Configures gdWakeupSymbolRxIdle |

(1) **FRPRTC2.TXL**

Wakeup Symbol Transmit Low

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

Valid values are 15 to 60 bit times.

**FRPRTC2.TXL** must be identical in all nodes of a cluster.

Configures the number of bit times used by the node to transmit the low phase of the wakeup symbol.

(2) **FRPRTC2.TXI**

Wakeup Symbol Transmit Idle

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

Valid values are 45 to 180 bit times.

**FRPRTC2.TXI** must be identical in all nodes of a cluster.

Configures the number of bit times used by the node to transmit the idle phase of the wakeup symbol.

(3) **FRPRTC2.RXL**

Wakeup Symbol Receive Low

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

Valid values are 10 to 55 bit times.

**FRPRTC2.RXL** must be identical in all nodes of a cluster.

Configures the number of bit times used by the node to test the duration of the low phase of the received wakeup symbol.

(4) **FRPRTC2.RXI**

Wakeup Symbol Rx Idle

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

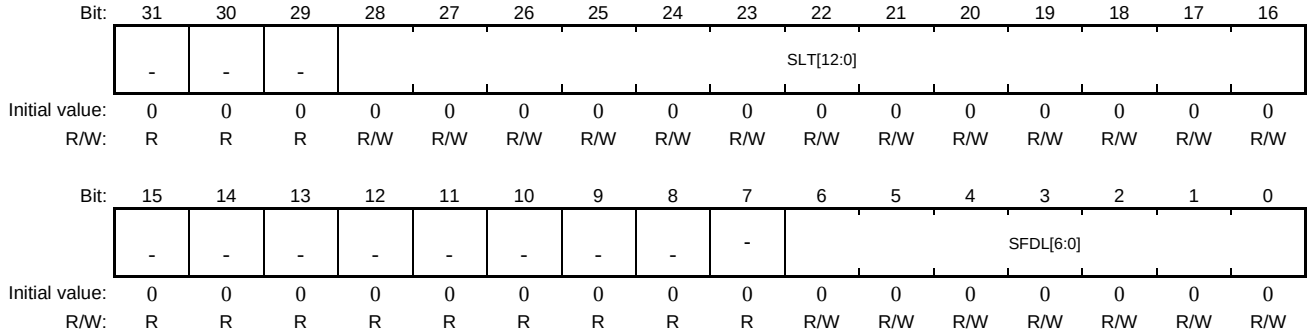
Valid values are 14 to 59 bit times.

**FRPRTC2.RXI** must be identical in all nodes of a cluster.

Configures the number of bit times used by the node to test the duration of the idle phase of the received wakeup symbol.

### 103.2.5.7 FRMHDC [h'0098]

FlexRay MHD Configuration Register



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:29] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [28:16] | SLT | 0 | R/W | Start of Latest Transmit<br>Configures pLatestTx |
| [15:7] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [6:0] | SFDL | 0 | R/W | Static Frame Data Length<br>Configures gPayloadLengthStatic |

(1) **FRMHDC.SLT**

Start of Latest Transmit

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 7981 minislots.

Configures the maximum minislot value allowed before inhibiting frame transmission in the dynamic segment of the cycle. There is no transmission in dynamic segment if **FRMHDC.SLT** is set to zero.

(2) **FRMHDC.SFDL**

Static Frame Data Length

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

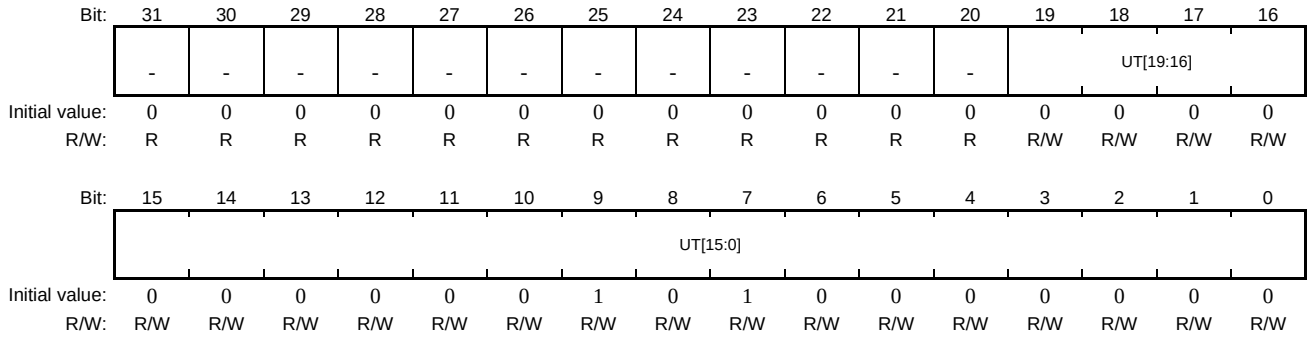
Valid values are 0 to 127.

**FRMHDC.SLT** must be identical in all nodes of a cluster.

Configures the cluster-wide payload length for all frames sent in the static segment in double bytes.

### 103.2.5.8 FRGTUC1 [h'00A0]

FlexRay GTU Configuration Register 1



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:20] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [19:0] | UT | 280h | R/W | Microtick per Cycle<br>Configures pMicroPerCycle |

(1) **FRGTUC1.UT**

Microtick per Cycle

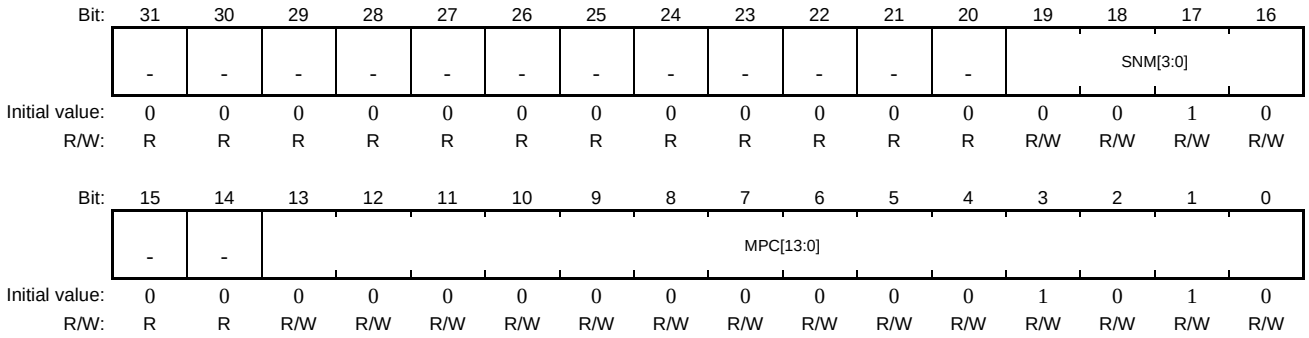
The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

Valid values are 640 to 640000 µT.

Configures the duration of the communication cycle in microticks.

### 103.2.5.9 FRGTUC2 [h'00A4]

FlexRay GTU Configuration Register 2



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:20] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [19:16] | SNM | 2h | R/W | Sync Node Max<br>Sync Node Max |
| [15:14] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [13:0] | MPC | Ah | R/W | Macrotick Per Cycle<br>Configures gMacroPerCycle |

(1) **FRGTUC2.SNM**

Sync Node Max

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 15.

**FRGTUC2.SNM** must be identical in all nodes of a cluster.

Maximum number of frames within a cluster with sync frame indicator bit SYN set to '1'.

(2) **FRGTUC2.MPC**

Macrotick Per Cycle

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

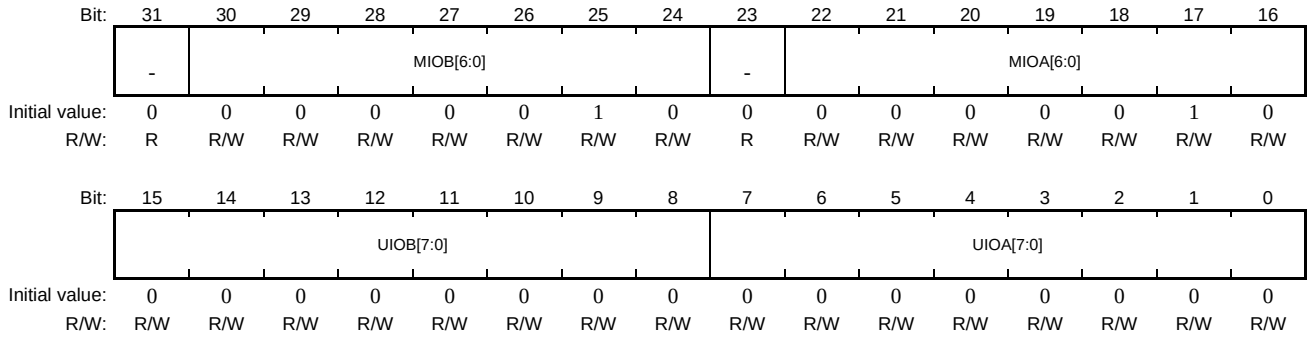
Valid values are 10 to 16000 MT.

**FRGTUC2.MPC** must be identical in all nodes of a cluster.

Configures the duration of one communication cycle in macroticks.

### 103.2.5.10 FRGTUC3 [h'00A8]

FlexRay GTU Configuration Register 3



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31] | - | 0 | R | Reserved<br>This bit is always read as 0. The write value should be always 0 |
| [30:24] | MIOB | 2h | R/W | Macrotick Initial Offset Channel B<br>Configures pMacroInitialOffset[B] |
| [23] | - | 0 | R | Reserved<br>This bit is always read as 0. The write value should be always 0 |
| [22:16] | MIOA | 2h | R/W | Macrotick Initial Offset Channel A<br>Configures pMacroInitialOffset[A] |
| [15:8] | UIOB | 0 | R/W | Microtick Initial Offset Channel B<br>Configures pMicroInitialOffset[B] |
| [7:0] | UIOA | 0 | R/W | Microtick Initial Offset Channel A<br>Configures pMicroInitialOffset[A] |

(1) **FRGTUC3.MIOB**

Macrotick Initial Offset Channel B

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 72 MT.

**FRGTUC3.MIOB** must be identical in all nodes of a cluster.

Configures the number of macroticks between the static slot boundary and the subsequent macrotick boundary of the secondary time reference point based on the nominal macrotick duration.

(2) **FRGTUC3.MIOA**

Macrotick Initial Offset Channel A

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 72 MT.

**FRGTUC3.MIOA** must be identical in all nodes of a cluster.

Configures the number of macroticks between the static slot boundary and the subsequent macrotick boundary of the secondary time reference point based on the nominal macrotick duration.

(3) **FRGTUC3.UIOB**

Microtick Initial Offset Channel B

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 240 µT.

Configures the number of microticks between the actual time reference point on channel B and the subsequent macrotick boundary of the secondary time reference point. The parameter depends on pDelayCompensation[B] and therefore has to be set for each channel independently.

(4) **FRGTUC3.UIOA**

Microtick Initial Offset Channel A

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

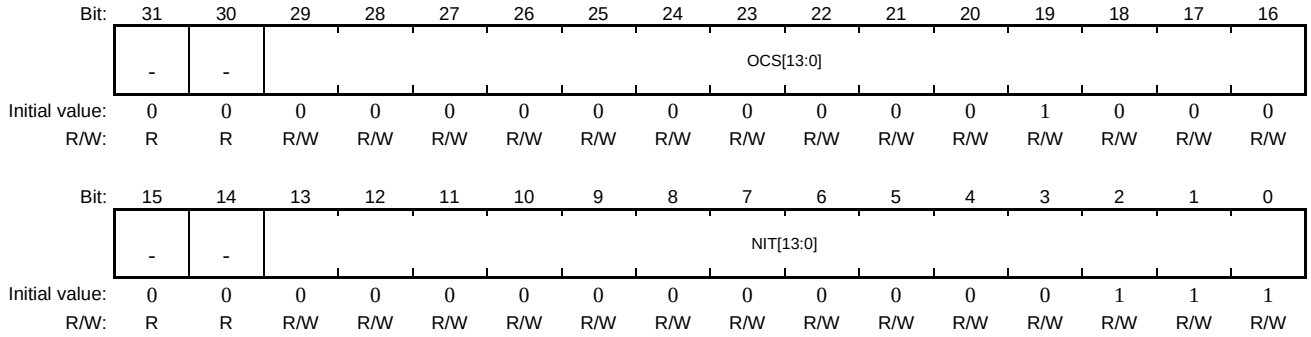
Valid values are 0 to 240 µT.

Configures the number of microticks between the actual time reference point on channel A and the subsequent macrotick boundary of the secondary time reference point. The parameter depends on pDelayCompensation[A] and therefore has to be set for each channel independently.

### 103.2.5.11 FRGTUC4 [h'00AC]

FlexRay GTU Configuration Register 4

For details about configuration of **FRGTUC4.NIT** and **FRGTUC4.OCS** see section 103.3.2.5.



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:30] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [29:16] | OCS | 8h | R/W | Offset Correction Start<br>Configures (gOffsetCorrectionStart - 1) |
| [15:14] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [13:0] | NIT | 7h | R/W | Network Idle Time Start<br>Configures (gMacroPerCycle - gdNIT - 1) |

(1) **FRGTUC4.OCS**

Offset Correction Start

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

Valid values are 8 to 15998 MT.

For cluster consisting of ERAY implementations only, it is sufficient to program **FRGTUC4.OCS** = **FRGTUC4.NIT** + 1.

**FRGTUC4.OCS** must be identical in all nodes of a cluster.

Determines the start of the offset correction within the NIT phase, calculated from start of cycle.

(2) **FRGTUC4.NIT**

Network Idle Time Start

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

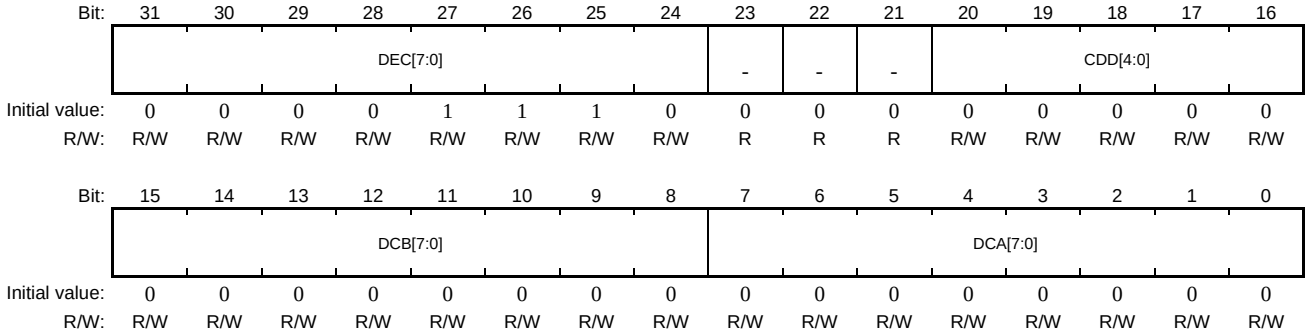
Valid values are 7 to 15997 MT.

**FRGTUC4.NIT** must be identical in all nodes of a cluster.

Configures the starting point of the Network Idle Time (NIT) at the end of the communication cycle expressed in terms of macroticks from the beginning of the cycle.

### 103.2.5.12 FRGTUC5 [h'00B0]

FlexRay GTU Configuration Register 5



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:24] | DEC | Eh | R/W | Decoding Correction<br>Configures pDecodingCorrection |
| [23:21] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [20:16] | CDD | 0 | R/W | Cluster Drift Damping<br>Configures pClusterDriftDamping |
| [15:8] | DCB | 0 | R/W | Delay Compensation Channel B<br>Configures pDelayCompensation[B] |
| [7:0] | DCA | 0 | R/W | Delay Compensation Channel A<br>Configures pDelayCompensation[A] |

(1) **FRGTUC5.DEC**

Decoding Correction

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

Valid values are 14 to 143 µT.

Configures the decoding correction value used to determine the primary time reference point.

(2) **FRGTUC5.CDD**

Cluster Drift Damping

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 20 µT.

Configures the cluster drift damping value used in clock synchronization to minimize accumulation of rounding errors.

(3) **FRGTUC5.DCB**

Delay Compensation Channel B

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 200 µT.

Used to compensate for reception delays on the indicated channel. This covers assumed propagation delay up to cPropagationDelayMax for microticks in the range of 0.0125 to 0.05µs. In practice, the minimum of the propagation delays of all sync nodes should be applied.

(4) **FRGTUC5.DCA**

Delay Compensation Channel A

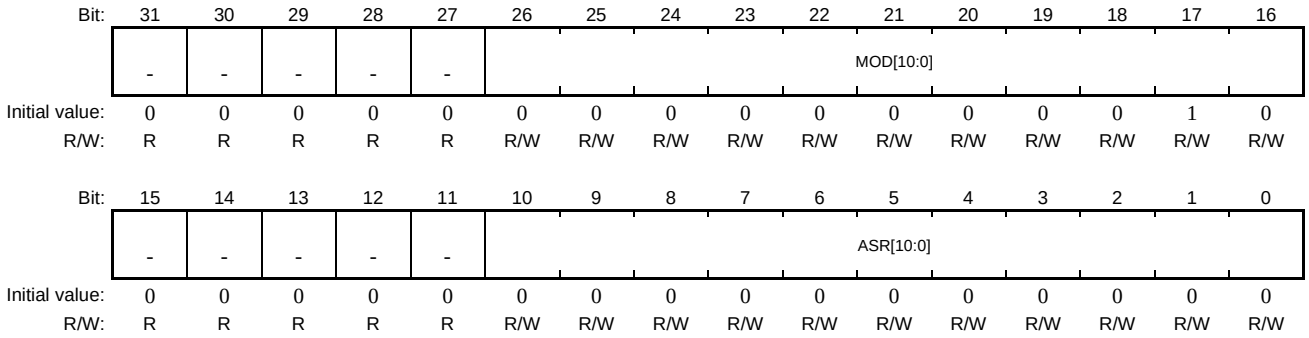
The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 200 µT.

Used to compensate for reception delays on the indicated channel. This covers assumed propagation delay up to cPropagationDelayMax for microticks in the range of 0.0125 to 0.05µs. In practice, the minimum of the propagation delays of all sync nodes should be applied.

### 103.2.5.13 FRGTUC6 [h'00B4]

FlexRay GTU Configuration Register 6



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:27] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [26:16] | MOD | 2h | R/W | Maximum Oscillator Drift<br>Configures pdMaxDrift |
| [15:11] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [10:0] | ASR | 0 | R/W | Accepted Startup Range<br>Configures pdAcceptedStartupRange |

(1) **FRGTUC6.MOD**

Maximum Oscillator Drift

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 1923 µT.

Maximum drift offset between two nodes that operate with unsynchronized clocks over one communication cycle in µT.

(2) **FRGTUC6.ASR**

Accepted Startup Range

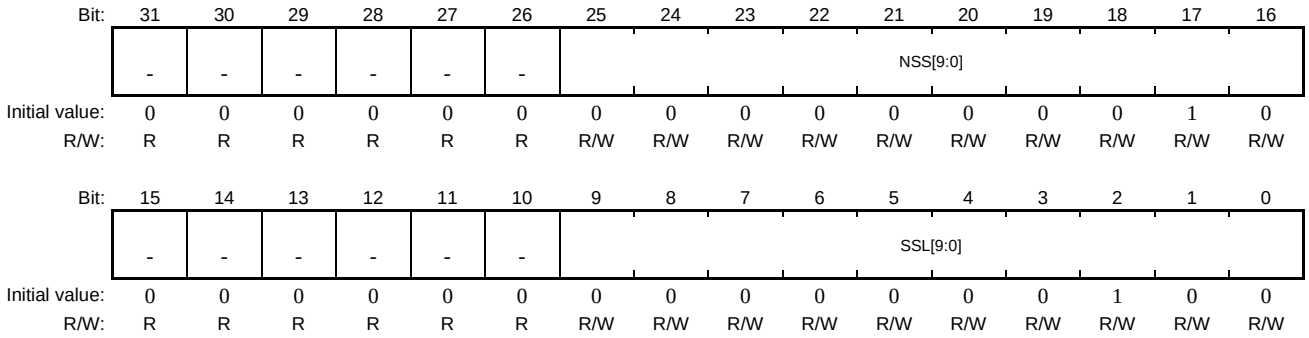
The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 1875 µT.

Number of microticks constituting the expanded range of measured deviation for startup frames during integration.

### 103.2.5.14 FRGTUC7 [h'00B8]

FlexRay GTU Configuration Register 7



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:26] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [25:16] | NSS | 2h | R/W | Number of Static Slots<br>Configures gNumberOfStaticSlots |
| [15:10] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [9:0] | SSL | 4h | R/W | Static Slot Length<br>Configures gdStaticSlot |

(1) **FRGTUC7.NSS**

Number of Static Slots

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 1023.

**FRGTUC7.NSS** must be identical in all nodes of a cluster.

Configures the number of static slots in a cycle.

(2) **FRGTUC7.SSL**

Static Slot Length

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

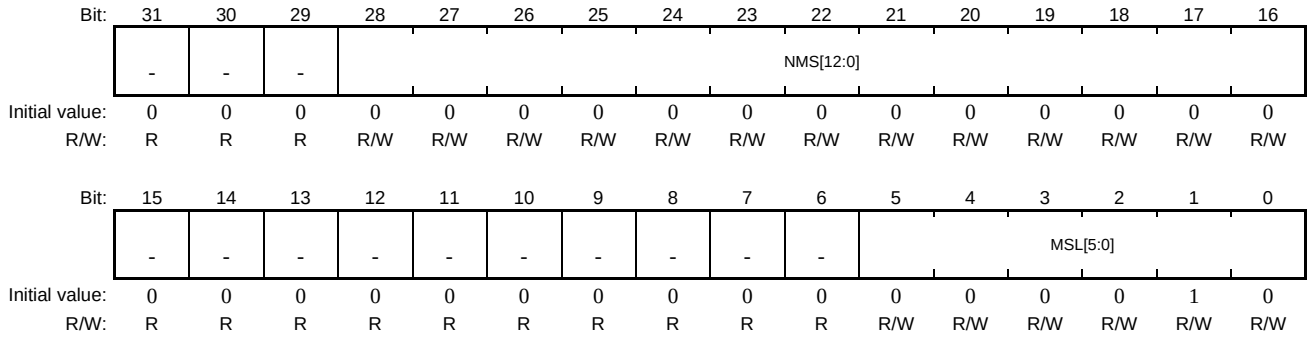
Valid values are 4 to 659 MT.

**FRGTUC7.SSL** must be identical in all nodes of a cluster.

Configures the duration of a static slot in macroticks.

### 103.2.5.15 FRGTUC8 [h'00BC]

FlexRay GTU Configuration Register 8



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:29] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [28:16] | NMS | 0 | R/W | Number of Minislots<br>Configures gNumberOfMinislots |
| [15:6] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [5:0] | MSL | 2h | R/W | Minislot Length<br>Configures gdMinislot |

(1) **FRGTUC8.NMS**

Number of Minislots

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 7986.

**FRGTUC8.NMS** must be identical in all nodes of a cluster.

Configures the number of minislots within the dynamic segment of a cycle.

(2) **FRGTUC8.MSL**

Minislot Length

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

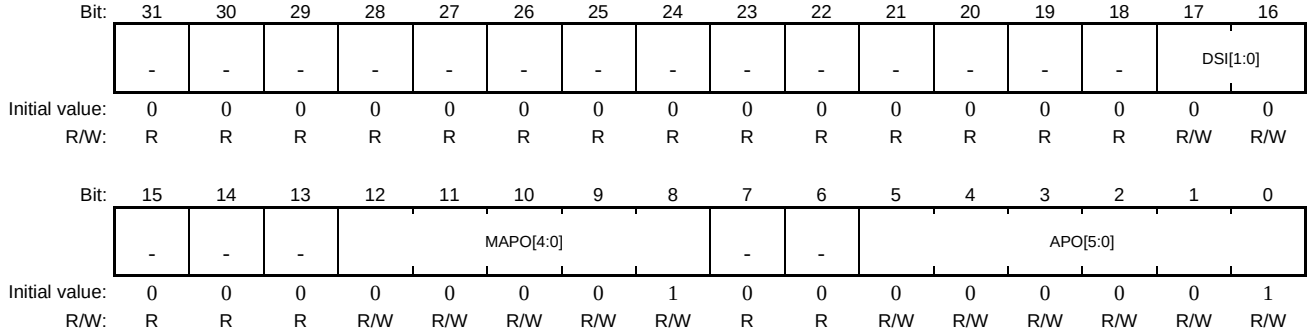
Valid values are 2 to 63 MT.

**FRGTUC8.MSL** must be identical in all nodes of a cluster.

Configures the duration of a minislot in macroticks.

### 103.2.5.16 FRGTUC9 [h'00C0]

FlexRay GTU Configuration Register 9



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:18] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [17:16] | DSI | 0 | R/W | Dynamic Slot Idle Phase<br>Configures gdDynamicSlotIdlePhase |
| [15:13] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [12:8] | MAPO | 1h | R/W | Minislot Action Point Offset<br>Configures gdMinislotActionPointOffset |
| [7:6] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [5:0] | APO | 1h | R/W | Action Point Offset<br>Configures gdActionPointOffset |

(1) **FRGTUC9.DSI**

Dynamic Slot Idle Phase

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 2 Minislot.

**FRGTUC9.DSI** must be identical in all nodes of a cluster.

Configures the duration of the dynamic slot idle phase and has to be greater or equal than the idle detection time.

(2) **FRGTUC9.MAPO**

Minislot Action Point Offset

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

Valid values are 1 to 31 MT.

**FRGTUC9.MAPO** must be identical in all nodes of a cluster.

Configures the action point offset in macroticks within the minislots of the dynamic segment.

(3) **FRGTUC9.APO**

Action Point Offset

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

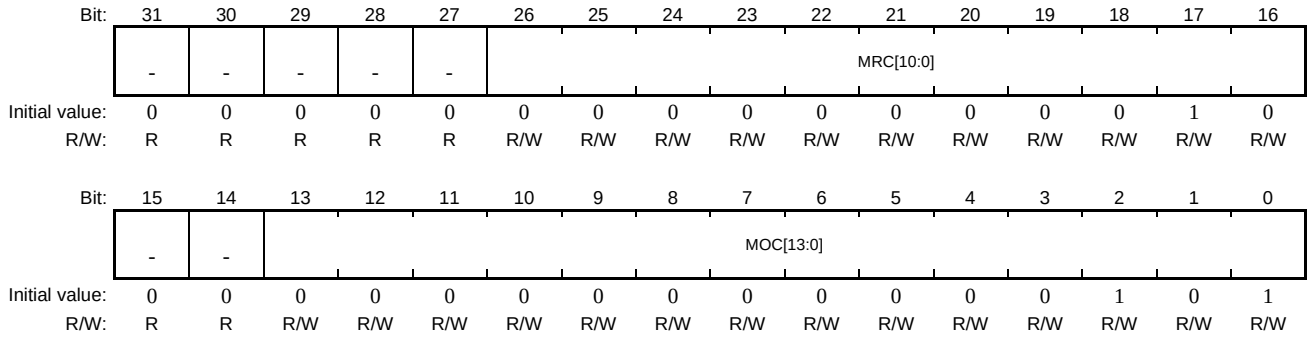
Valid values are 1 to 63 MT.

**FRGTUC9.APO** must be identical in all nodes of a cluster.

Configures the action point offset in macroticks within static slots and symbol window.

### 103.2.5.17 FRGTUC10 [h'00C4]

FlexRay GTU Configuration Register 10



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:27] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [26:16] | MRC | 2h | R/W | Maximum Rate Correction<br>Configures pRateCorrectionOut |
| [15:14] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [13:0] | MOC | 5h | R/W | Maximum Offset Correction<br>Configures pOffsetCorrectionOut |

(1) **FRGTUC10.MRC**

Maximum Rate Correction

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 1923 µT.

Holds the maximum permitted rate correction value to be applied by the internal clock synchronization algorithm. The CC checks only the internal rate correction value against the maximum rate correction value (absolute value).

(2) **FRGTUC10.MOC**

Maximum Offset Correction

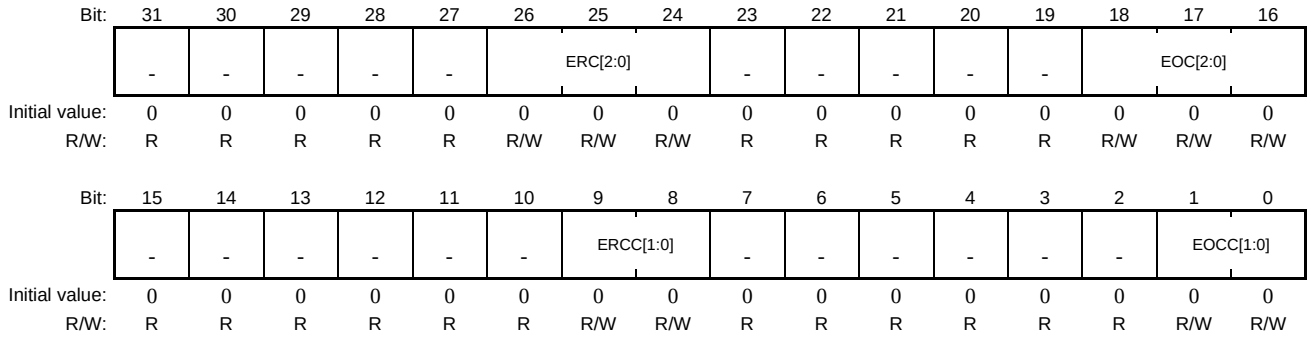
The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

Valid values are 5 to 15266 µT.

Holds the maximum permitted offset correction value to be applied by the internal clock synchronization algorithm (absolute value). The CC checks only the internal offset correction value against the maximum offset correction value.

### 103.2.5.18 FRGTUC11 [h'00C8]

FlexRay GTU Configuration Register 11



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:27] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [26:24] | ERC | 0 | R/W | External Rate Correction<br>Configures pExternRateCorrection |
| [23:19] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [18:16] | EOC | 0 | R/W | External Offset Correction<br>Configures pExternOffsetCorrection |
| [15:10] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [9:8] | ERCC | 0 | R/W | External Rate Correction Control<br>Configures vExternRateControl<br>00 = No external rate correction<br>01 = No external rate correction<br>10 = Subtract<br>11 = Add |
| [7:2] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [1:0] | EOCC | 0 | R/W | External Offset Correction Control<br>Configures vExternOffsetControl<br>00 = No external offset correction<br>01 = No external offset correction<br>10 = Subtract<br>11 = Add |

(1) **FRGTUC11.ERC**

External Rate Correction

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 7 µT.

Holds the external rate correction value in microticks to be applied by the internal clock synchronization algorithm. The value is subtracted / added from / to the calculated rate correction value. The value is applied during NIT.

(2) **FRGTUC11.EOC**

External Offset Correction

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 7 µT.

Holds the external offset correction value in microticks to be applied by the internal clock synchronization algorithm. The value is subtracted / added from / to the calculated offset correction value. The value is applied during NIT.

(3) **FRGTUC11.ERCC**

External Rate Correction Control

Should be modified only outside NIT.

By writing to **FRGTUC11.ERCC** the external rate correction is enabled as specified below.

00 = No external rate correction

01 = No external rate correction

10 = Subtract
External rate correction value subtracted from calculated rate correction value

11 = Add
External rate correction value added to calculated rate correction value

(4) **FRGTUC11.EOCC**

External Offset Correction Control

Should be modified only outside NIT.

By writing to **FRGTUC11.EOCC** the external offset correction is enabled as specified below.

00 = No external offset correction

01 = No external offset correction

10 = Subtract
External offset correction value subtracted from calculated offset correction value

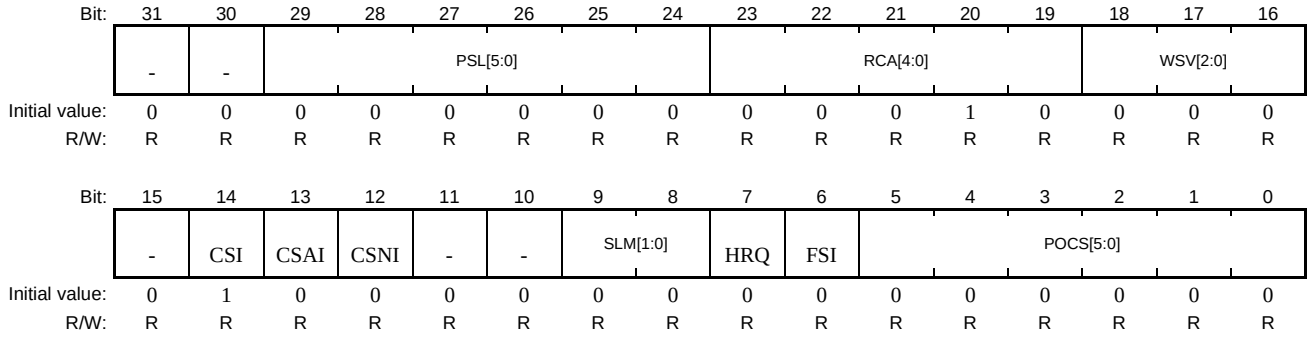
11 = Add
External offset correction value added to calculated offset correction value

### 103.2.6 CC Status Registers

During 8/16-bit accesses to status variables coded with more than 8/16-bit, the variable might be updated by the CC between two accesses (non-atomic read accesses).

#### 103.2.6.1 FRCCSV [h'0100]

FlexRay CC Status Vector



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:30] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [29:24] | PSL | 0 | R | POC Status Log<br>Status of FRCCSV.POCS immediately before entering HALT state. |
| [23:19] | RCA | 2h | R | Remaining Coldstart Attempts<br>Indicates vRemainingColdstartAttempts |
| [18:16] | WSV | 0 | R | Wakeup Status<br>Indicates vPOC!WakeupStatus |
| [15] | - | 0 | R | Reserved<br>This bit is always read as 0. The write value should be always 0 |
| [14] | CSI | 1 | R | Cold Start Inhibit<br>Indicates vColdStartInhibit<br>0 = Cold starting of node enabled<br>1 = Cold starting of node disabled |
| [13] | CSAI | 0 | R | Coldstart Abort Indicator<br>Coldstart Abort Indicator |
| [12] | CSNI | 0 | R | Coldstart Noise Indicator<br>Indicates vPOC!ColdstartNoise |
| [11:10] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [9:8] | SLM | 0 | R | Slot Mode<br>Indicates vPOC!SlotMode<br>00 = SINGLE<br>01 = reserved<br>10 = ALL_PENDING<br>11 = ALL |
| [7] | HRQ | 0 | R | Halt Request<br>Indicates vPOC!CHIHaltRequest |
| [6] | FSI | 0 | R | Freeze Status Indicator<br>Indicates vPOC!Freeze |
| [5:0] | POCS | 0 | R | Protocol Operation Control Status<br>Protocol Operation Control Status |

(1) **FRCCSV.PSL**

POC Status Log

Status of **FRCCSV.POCS** immediately before entering HALT state.

Set when entering HALT state. Set to HALT when FREEZE command is applied during HALT state and **FRCCSV.FSI** is not already set i.e. the HALT state was not reached by FREEZE command.

Reset to "00 0000" when leaving HALT state.

(2) **FRCCSV.RCA**

Remaining Coldstart Attempts

Indicates the number of remaining coldstart attempts (vRemainingColdstartAttempts).

The initial value of **FRCCSV.RCA** during CONFIG and DEFAULT_CONFIG state is also **FRSUCC1.CSA**.

The RUN command resets this counter to the maximum number of coldstart attempts as configured by **FRSUCC1.CSA**.

(3) **FRCCSV.WSV**

Wakeup Status

Indicates the status of the current wakeup attempt (vPOC!WakeupStatus).

Reset when entering Wakeup state, by CHI command RESET_STATUS_INDICATORS, or by transition from DEFAULT_CONFIG to CONFIG state

000 = UNDEFINED
Wakeup not yet executed by the CC.

001 = RECEIVED_HEADER
Set when the CC finishes wakeup due to the reception of a frame header without coding violation on either channel in WAKEUP_LISTEN state.

010 = RECEIVED_WUP
Set when the CC finishes wakeup due to the reception of a valid wakeup pattern on the configured wakeup channel in WAKEUP_LISTEN state.

011 = COLLISION_HEADER

Set when the CC stops wakeup due to a detected collision during wakeup pattern transmission by receiving a valid header on either channel.

100 = COLLISION_WUP
Set when the CC stops wakeup due to a detected collision during wakeup pattern transmission by receiving a valid wakeup pattern on the configured wakeup channel.

101 = COLLISION_UNKNOWN
Set when the CC stops wakeup by leaving WAKEUP_DETECT state after expiration of the wakeup timer without receiving a valid wakeup pattern or a valid frame header.

110 = TRANSMITTED
Set when the CC has successfully completed the transmission of the wakeup pattern.

111 = reserved

(4) **FRCCSV.CSI**

Cold Start Inhibit

Indicates that the node is disabled from cold starting (vColdStartInhibit).

The flag is set whenever the POC enters READY state due to CHI command READY.

The flag has to be reset under control of the Host by CHI command ALLOW_COLDSTART (**FRSUCC1.CMD** = "1001").

(5) **FRCCSV.CSAI**

Coldstart Abort Indicator

Indicates that a coldstart attempt was aborted.

Reset by CHI command RESET_STATUS_INDICATORS or by transition from HALT to DEFAULT_CONFIG state or from READY to STARTUP state.

(6) **FRCCSV.CSNI**

Coldstart Noise Indicator

Indicates that the cold start procedure occurred under noisy conditions (vPOC!ColdstartNoise).

Reset by CHI command RESET_STATUS_INDICATORS or by transition from HALT to DEFAULT_CONFIG state or from READY to STARTUP state.

(7) **FRCCSV.SLM**

Slot Mode

Indicates the actual slot mode of the POC (vPOC!SlotMode) in states READY, WAKEUP, STARTUP, NORMAL_ACTIVE, and NORMAL_PASSIVE.

Default value is SINGLE. Changes to ALL, depending on **FRSUCC1.TSM**.

In NORMAL_ACTIVE or NORMAL_PASSIVE state the CHI command ALL_SLOTS will change the slot mode from SINGLE over ALL_PENDING to ALL.

Set to SINGLE in all other states.

(8) **FRCCSV.HRQ**

Halt Request

Indicates that a request from the Host has been received to halt the POC at the end of the communication cycle (vPOC!CHIHaltRequest).

Reset by transition from HALT to DEFAULT_CONFIG state or when entering READY state.

(9) **FRCCSV.FSI**

Freeze Status Indicator

Indicates that the POC has entered the HALT state due to CHI command FREEZE or due to an error condition requiring an immediate POC halt (vPOC!Freeze).

Reset by transition from HALT to DEFAULT_CONFIG state.

(10) **FRCCSV.POCS**

Protocol Operation Control Status

Indicates the actual state of operation of the CC Protocol Operation Control
00 0000 = DEFAULT_CONFIG state
00 0001 = READY state
00 0010 = NORMAL_ACTIVE state
00 0011 = NORMAL_PASSIVE state
00 0100 = HALT state
00 1111 = CONFIG state

Indicates the actual state of operation of the POC in the wakeup path
01 0000 = WAKEUP_STANDBY state
01 0001 = WAKEUP_LISTEN state
01 0010 = WAKEUP_SEND state
01 0011 = WAKEUP_DETECT state

Indicates the actual state of operation of the POC in the startup path
10 0000 = STARTUP_PREPARE state
10 0001 = COLDSTART_LISTEN state
10 0010 = COLDSTART_COLLISION_RESOLUTION state
10 0011 = COLDSTART_CONSISTENCY_CHECK state
10 0100 = COLDSTART_GAP state
10 0101 = COLDSTART_JOIN State
10 0110 = INTEGRATION_COLDSTART_CHECK state
10 0111 = INTEGRATION_LISTEN state
10 1000 = INTEGRATION_CONSISTENCY_CHECK state
10 1001 = INITIALIZE_SCHEDULE state
10 1010 = ABORT_STARTUP state
10 1011 = STARTUP_SUCCESS state

others = reserved

### 103.2.6.2 FRCCEV [h'0104]

FlexRay CC Error Vector

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | - | - | - | - | - | - | - | - | - | - | - | - | - | - | - | - |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | - | - | - | PTAC[4:0] | | | | | ERRM[1:0] | | - | - | CCFC[3:0] | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:13] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [12:8] | PTAC | 0 | R | Passive to Active Count<br>Indicates vAllowPassiveToActive |
| [7:6] | ERRM | 0 | R | Error Mode<br>Indicates vPOC!ErrorMode<br>00 = ACTIVE<br>01 = PASSIVE<br>10 = COMM_HALT<br>11 = reserved |
| [5:4] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [3:0] | CCFC | 0 | R | Clock Correction Failed Counter<br>Indicates vClockCorrectionFailed |

(1) **FRCCEV.PTAC**

Passive to Active Count

Indicates the number of consecutive even / odd cycle pairs that have passed with valid rate and offset correction terms, while the node is waiting to transit from NORMAL_PASSIVE state to NORMAL_ACTIVE state. The transition takes place when **FRCCEV.PTAC** equals **FRSUCC1.PTA** -1.

Reset by transition from HALT to DEFAULT_CONFIG state or when entering READY state.

(2) **FRCCEV.ERRM**

Error Mode

Indicates the actual error mode of the POC (vPOC!ErrorMode).

Reset by transition from HALT to DEFAULT_CONFIG state or when entering READY state.

(3) **FRCCEV.CCFC**

Clock Correction Failed Counter

Indicates the clock correction failed counter of the POC (vClockCorrectionFailed).

The Clock Correction Failed Counter is incremented by one at the end of any odd communication cycle where either the missing offset correction error or missing rate correction error are active.

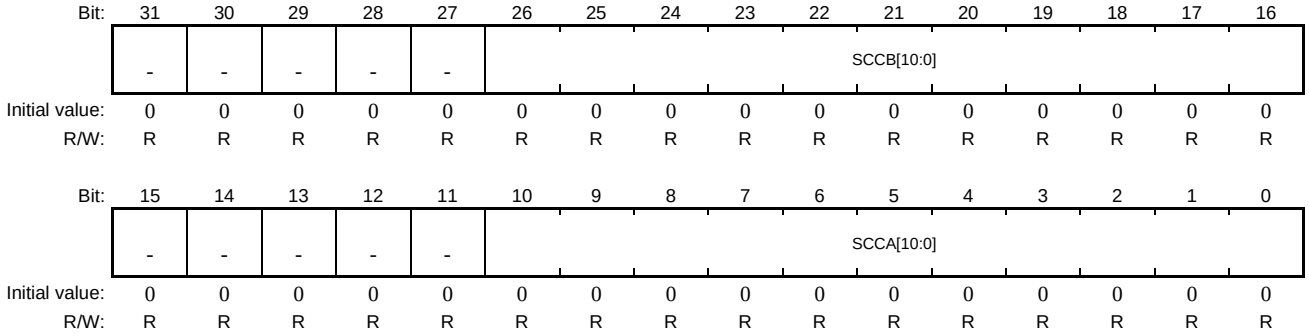
The Clock Correction Failed Counter is reset to ’0’ at the end of an odd communication cycle if neither the offset correction failed nor the rate correction failed errors are active.

The Clock Correction Failed Counter stops incrementing at 15.

Reset by transition from HALT to DEFAULT_CONFIG state or when entering READY state.

### 103.2.6.3 FRSCV [h'0110]

FlexRay Slot Counter Value



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:27] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [26:16] | SCCB | 0 | R | Slot Counter Channel B<br>Indicates vSlotCounter[B] |
| [15:11] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [10:0] | SCCA | 0 | R | Slot Counter Channel A<br>Indicates vSlotCounter[A] |

(1) **FRSCV.SCCB**

Slot Counter Channel B

Current slot counter value on channel B (vSlotCounter[B]). The value is incremented by the CC and reset at the start of a communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state.

(2) **FRSCV.SCCA**

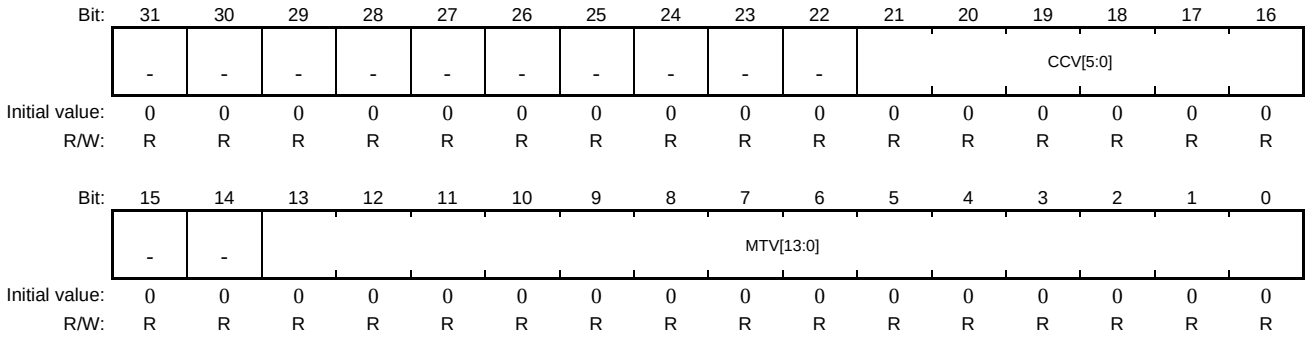
Slot Counter Channel A

Current slot counter value on channel A (vSlotCounter[A]). The value is incremented by the CC and reset at the start of a communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state.

### 103.2.6.4 FRMTCCV [h'0114]

FlexRay Macrotick and Cycle Counter Value



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:22] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [21:16] | CCV | 0 | R | Cycle Counter Value<br>Indicates vCycleCounter |
| [15:14] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [13:0] | MTV | 0 | R | Macrotick Value<br>Indicates vMacrotick |

(1) **FRMTCCV.CCV**

Cycle Counter Value

Current cycle counter value (vCycleCounter). The value is incremented by the CC at the start of a communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state.

(2) **FRMTCCV.MTV**

Macrotick Value

Current macrotick value (vMacrotick). The value is incremented by the CC and reset at the start of a communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state.

### 103.2.6.5 FRRCV [h'0118]

FlexRay Rate Correction Value

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | - | - | - | - | - | - | - | - | - | - | - | - | - | - | - | - |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | - | - | - | - | RCV[11:0] | | | | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:12] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [11:0] | RCV | 0 | R | Rate Correction Value<br>Indicates vRateCorrection |

(1) **FRRCV.RCV**

Rate Correction Value

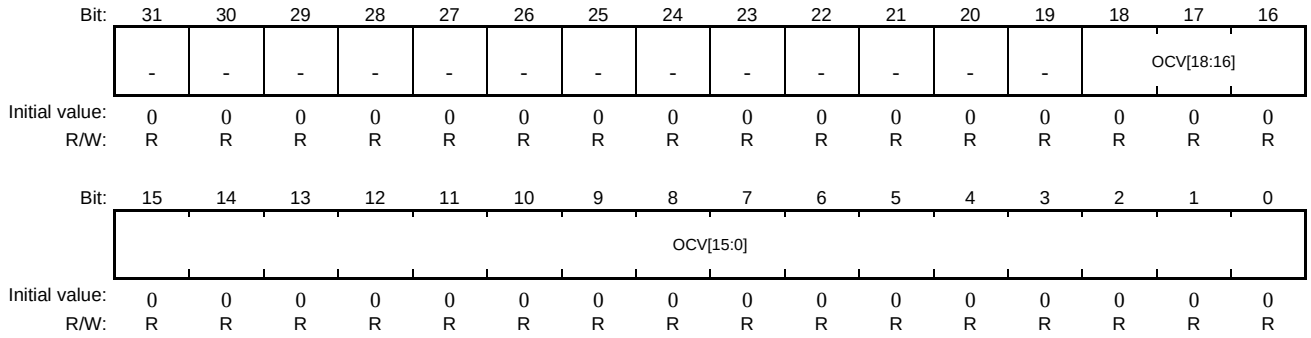
Rate correction value (vRateCorrection/ two's complement). Calculated internal rate correction value before limitation. If the **FRRCV.RCV** value exceeds the limits defined by **FRGTUC10.MRC**, flag **FRSFS.RCLR** is set to '1'.

**Note:** The external rate correction value is added to the limited rate correction value.

Reset when leaving CONFIG state or when entering STARTUP state.

### 103.2.6.6 FROCV [h'011C]

FlexRay Offset Correction Value



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:19] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [18:0] | OCV | 0 | R | Offset Correction Value<br>Indicates vOffsetCorrection |

(1) **FROCV.OCV**

Offset Correction Value

Offset correction value (vOffsetCorrection/ two's complement). Calculated internal offset correction value before limitation. If the **FROCV.OCV** value exceeds the limits defined by **FRGTUC10.MOC**, flag **FRSFS.OCLR** is set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

**Note:** The external offset correction value is added to the limited offset correction value.

### 103.2.6.7 FRSFS [h'0120]

FlexRay Sync Frame Status

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:20] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [19] | RCLR | 0 | R | Rate Correction Limit Reached<br>0 = Rate correction below limit<br>1 = Rate correction limit reached |
| [18] | MRCS | 0 | R | Missing Rate Correction Signal<br>0 = Rate correction signal valid<br>1 = Missing rate correction signal |
| [17] | OCLR | 0 | R | Offset Correction Limit Reached<br>0 = Offset correction below limit<br>1 = Offset correction limit reached |
| [16] | MOCS | 0 | R | Missing Offset Correction Signal<br>0 = Offset correction signal valid<br>1 = Missing offset correction signal |
| [15:12] | VSBO | 0 | R | Valid Sync Frames Channel B, odd communication cycle |
| [11:8] | VSBE | 0 | R | Valid Sync Frames Channel B, even communication cycle |
| [7:4] | VSAO | 0 | R | Valid Sync Frames Channel A, odd communication cycle |
| [3:0] | VSAE | 0 | R | Valid Sync Frames Channel A, even communication cycle |

(1) **FRSFS.RCLR**

Rate Correction Limit Reached

The Rate Correction Limit Reached flag signals to the Host, that the rate correction value has exceeded its limit as defined by **FRGTUC10.MRC**. The flag is updated by the CC at start of offset correction phase.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(2) **FRSFS.MRCS**

Missing Rate Correction Signal

The Missing Rate Correction flag signals to the Host, that no rate correction calculation can be performed because no pairs of even / odd sync frames were received. The flag is updated by the CC at start of offset correction phase.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(3) **FRSFS.OCLR**

Offset Correction Limit Reached

The Offset Correction Limit Reached flag signals to the Host, that the offset correction value has exceeded its limit as defined by **FRGTUC10.MOC**. The flag is updated by the CC at start of offset correction phase.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(4) **FRSFS.MOCS**

Missing Offset Correction Signal

The Missing Offset Correction flag signals to the Host, that no offset correction calculation can be performed because no sync frames were received. The flag is updated by the CC at start of offset correction phase.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(5) **FRSFS.VSBO**

Valid Sync Frames Channel B, odd communication cycle

These bits are only valid when **FRSUCC1.CCHB** is '1'.

Holds the number of valid sync frames received on channel B in the odd communication cycle. If transmission of sync frames is enabled by **FRSUCC1.TXSY** the value is incremented by one. The value is updated during the NIT of each odd communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(6) **FRSFS.VSBE**

Valid Sync Frames Channel B, even communication cycle

These bits are only valid when **FRSUCC1.CCHB** is '1'.

Holds the number of valid sync frames received on channel B in the even communication cycle. If transmission of sync frames is enabled by **FRSUCC1.TXSY** the value is incremented by one. The value is updated during the NIT of each even communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(7) **FRSFS.VSAO**

Valid Sync Frames Channel A, odd communication cycle

These bits are only valid when **FRSUCC1.CCHA** is '1'.

Holds the number of valid sync frames received on channel A in the odd communication cycle. If transmission of sync frames is enabled by **FRSUCC1.TXSY** the value is incremented by one. The value is updated during the NIT of each odd communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(8) **FRSFS.VSAE**

Valid Sync Frames Channel A, even communication cycle

These bits are only valid when **FRSUCC1.CCHA** is '1'.

Holds the number of valid sync frames received on channel A in the even communication cycle. If transmission of sync frames is enabled by **FRSUCC1.TXSY** the value is incremented by one. The value is updated during the NIT of each even communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

### 103.2.6.8 FRSWNIT [h'0124]

FlexRay Symbol Window and NIT Status

Symbol window related status information is updated by the CC at the end of the symbol window for each channel. NIT related status information is updated by the CC at the end of the NIT for each channel.

During startup the status data is not updated.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| [0] | SESA | 0 | R | Syntax Error in Symbol Window Channel A<br>0 = No syntax error detected on channel A<br>1 = Syntax error during symbol window detected on channel A |

(1) **FRSWNIT.SBNB**

Indicates a Slot Boundary Violation during NIT Channel B (vSS!BViolationB).

Reset when leaving CONFIG state or when entering STARTUP state.

(2) **FRSWNIT.SENB**

Indicates a Syntax Error during NIT Channel B (vSS!SyntaxErrorB).

Reset when leaving CONFIG state or when entering STARTUP state.

(3) **FRSWNIT.SBNA**

Indicates a Slot Boundary Violation during NIT Channel A (vSS!BViolationA).

Reset when leaving CONFIG state or when entering STARTUP state.

(4) **FRSWNIT.SENA**

Indicates a Syntax Error during NIT Channel A (vSS!SyntaxErrorA).

Reset when leaving CONFIG state or when entering STARTUP state.

(5) **FRSWNIT.MTSB**

Indicates a MTS Received on Channel B (vSS!ValidMTSB).

Media Access Test symbol received on channel B during the preceding symbol window. Updated by the CC for each channel at the end of the symbol window.

When this bit is set to ’1’, also interrupt flag **FRSIR.MTSB** is set to ’1’.

Reset when leaving CONFIG state or when entering STARTUP state.

(6) **FRSWNIT.MTSA**

Indicates a MTS Received on Channel A (vSS!ValidMTSA).

Media Access Test symbol received on channel A during the preceding symbol window. Updated by the CC for each channel at the end of the symbol window.

When this bit is set to ’1’, also interrupt flag **FRSIR.MTSA** is set to ’1’.

Reset when leaving CONFIG state or when entering STARTUP state.

(7) **FRSWNIT.TCSB**

Indicates a Transmission Conflict in Symbol Window Channel B (vSS!TxConflictB).

Reset when leaving CONFIG state or when entering STARTUP state.

(8) **FRSWNIT.SBSB**

Indicates a Slot Boundary Violation in Symbol Window Channel B (vSS!BViolationB).

Reset when leaving CONFIG state or when entering STARTUP state.

(9) **FRSWNIT.SESB**

Indicates a Syntax Error in Symbol Window Channel B (vSS!SyntaxErrorB).

Reset when leaving CONFIG state or when entering STARTUP state.

(10) **FRSWNIT.TCSA**

Indicates a Transmission Conflict in Symbol Window Channel A (vSS!TxConflictA).

Reset when leaving CONFIG state or when entering STARTUP state.

(11) **FRSWNIT.SBSA**

Indicates a Slot Boundary Violation in Symbol Window Channel A (vSS!BViolationA).

Reset when leaving CONFIG state or when entering STARTUP state.

(12) **FRSWNIT.SESA**

Indicates a Syntax Error in Symbol Window Channel A (vSS!SyntaxErrorA).

Reset when leaving CONFIG state or when entering STARTUP state.

### 103.2.6.9 FRACS [h'0128]

FlexRay Aggregated Channel Status

The aggregated channel status provides the Host with an accrued status of channel activity for all communication slots regardless of whether they are assigned for transmission or subscribed for reception.

The aggregated channel status also includes status data from the symbol window and the network idle time.

The status data is updated (set) after each slot and aggregated until it is reset by the Host.

During startup the status data is not updated.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

(1) **FRACS.SBVB**

Slot Boundary Violation on Channel B

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

One or more slot boundary violations were observed on channel B at any time during the observation period (static or dynamic slots, symbol window, and NIT).

When this flag changes from '0' to '1', interrupt flag **FREIR.EDB** is set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

(2) **FRACS.CIB**

Communication Indicator Channel B

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

One or more valid frames were received on channel B in slots that also contained any additional communication during the observation period, i.e. one or more slots received a valid frame AND had any combination of either syntax error OR content error OR slot boundary violation.

**Note:** The set condition of the flag **FRACS.CIB** is also fulfilled if there is only one single frame in the slot and the slot boundary at the end of the slot is reached during the frames channel idle recognition phase.

When this flag changes from '0' to '1', interrupt flag **FREIR.EDB** is set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

(3) **FRACS.CEDB**

Content Error Detected on Channel B

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

One or more frames with a content error were received on channel B in any static or dynamic slot during the observation period.

When this flag changes from '0' to '1', interrupt flag **FREIR.EDB** is set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

(4) **FRACS.SEDB**

Syntax Error Detected on Channel B

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

One or more syntax errors in static or dynamic slots, symbol window, and NIT were observed on channel B.

When this flag changes from '0' to '1', interrupt flag **FREIR.EDB** is set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

(5) **FRACS.VFRB**

Valid Frame Received on Channel B

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

One or more valid frames were received on channel B in any static or dynamic slot during the observation period.

Reset when leaving CONFIG state or when entering STARTUP state.

(6) **FRACS.SBVA**

Slot Boundary Violation on Channel A

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

One or more slot boundary violations were observed on channel A at any time during the observation period (static or dynamic slots, symbol window, and NIT).

When this flag changes from '0' to '1', interrupt flag **FREIR.EDA** is set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

(7) **FRACS.CIA**

Communication Indicator Channel A

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

One or more valid frames were received on channel A in slots that also contained any additional communication during the observation period, i.e. one or more slots received a valid frame AND had any combination of either syntax error OR content error OR slot boundary violation.

**Note:** The set condition of the flag **FRACS.CIA** is also fulfilled if there is only one single frame in the slot and the slot boundary at the end of the slot is reached during the frames channel idle recognition phase.

When this flag changes from '0' to '1', interrupt flag **FREIR.EDA** is set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

(8) **FRACS.CEDA**

Content Error Detected on Channel A

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

One or more frames with a content error were received on channel A in any static or dynamic slot during the observation period.

When this flag changes from '0' to '1', interrupt flag **FREIR.EDA** is set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

(9) **FRACS.SEDA**

Syntax Error Detected on Channel A

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

One or more syntax errors in static or dynamic slots, symbol window, and NIT were observed on channel A.

When this flag changes from '0' to '1', interrupt flag **FREIR.EDA** is set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

(10) **FRACS.VFRA**

Valid Frame Received on Channel A

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

One or more valid frames were received on channel A in any static or dynamic slot during the observation period.

Reset when leaving CONFIG state or when entering STARTUP state.

### 103.2.6.10 FRESIDn (n=1 to 15) [h'0130 – h'0168]

FlexRay Even Sync ID n (n=1 to 15)

Registers **FRESID1** to **FRESID15** hold the frame IDs of the sync frames received in even communication cycles used for clock synchronisation up to the limit of gSyncNodeMax. The values are sorted in ascending order, with register **FRESID1** holding the lowest received sync frame ID. If the node itself transmits a sync frame in an even communication cycle, register **FRESID1** holds the respective sync frame ID as configured in message buffer 0 and flags **FRESID1.RXEA**, **FRESID1.RXEB** are set. The value is updated during the NIT of each even communication cycle.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | - | - | - | - | - | - | - | - | - | - | - | - | - | - | - | - |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | RXEB | RXEA | - | - | - | - | EID[9:0] | | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:16] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [15] | RXEB | 0 | R | Received / Configured Even Sync ID on Channel B<br>0 = No sync frame received on channel B / node not configured to transmit sync frames<br>1 = Sync frame received on channel B / node configured to transmit sync frames |
| [14] | RXEA | 0 | R | Received / Configured Even Sync ID on Channel A<br>0 = No sync frame received on channel A / node not configured to transmit sync frames<br>1 = Sync frame received on channel A / node configured to transmit sync frames |
| [13:10] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [9:0] | EID | 0 | R | Even Sync ID (vsSyncIDListA,B even) |

(1) **FRESIDn.RXEB**

Received / Configured Even Sync ID on Channel B

Signals that a sync frame corresponding to the stored even sync ID was received on channel B or that the node is configured to be a sync node with key slot = **FRESID1.EID**.

Reset when leaving CONFIG state or when entering STARTUP state.

(2) **FRESIDn.RXEA**

Received / Configured Even Sync ID on Channel A

Signals that a sync frame corresponding to the stored even sync ID was received on channel A or that the node is configured to be a sync node with key slot = **FRESID1.EID**.

Reset when leaving CONFIG state or when entering STARTUP state.

(3) **FRESIDn.EID**

Even Sync ID (vsSyncIDListA,B even)

Sync frame ID even communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state.

### 103.2.6.11 FROSIDn (n=1 to 15) [h'0170 – h'01A8]

FlexRay Odd Sync ID n (n=1 to 15)

Registers **FROSID1** to **FROSID15** hold the frame IDs of the sync frames received in odd communication cycles used for clock synchronisation up to the limit of gSyncNodeMax. The values are sorted in ascending order, with register **FROSID1** holding the lowest received sync frame ID. If the node itself transmits a sync frame in an odd communication cycle, register **FROSID1** holds the respective sync frame ID as configured in message buffer 0 and flags **FROSID1.RXOA**, **FROSID1.RXOB** are set. The value is updated during the NIT of each odd communication cycle.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | - | - | - | - | - | - | - | - | - | - | - | - | - | - | - | - |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | RXOB | RXOA | - | - | - | - | OID[9:0] | | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:16] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [15] | RXOB | 0 | R | Received / Configured Odd Sync ID on Channel B<br>0 = No sync frame received on channel B / node not configured to transmit sync frames<br>1 = Sync frame received on channel B / node configured to transmit sync frames |
| [14] | RXOA | 0 | R | Received / Configured Odd Sync ID on Channel A<br>0 = No sync frame received on channel A / node not configured to transmit sync frames<br>1 = Sync frame received on channel A / node configured to transmit sync frames |
| [13:10] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [9:0] | OID | 0 | R | Odd Sync ID (vsSyncIDListA,B odd) |

(1) **FROSIDn.RXOB**

Received / Configured Odd Sync ID on Channel B

Signals that a sync frame corresponding to the stored odd sync ID was received on channel B or that the node is configured to be a sync node with key slot = **FROSID1.OID**.

Reset when leaving CONFIG state or when entering STARTUP state.

(2) **FROSIDn.RXOA**

Received / Configured Odd Sync ID on Channel A

Signals that a sync frame corresponding to the stored odd sync ID was received on channel A or that the node is configured to be a sync node with key slot = **FRISID1.OID**.

Reset when leaving CONFIG state or when entering STARTUP state.

(3) **FROSIDn.OID**

Odd Sync ID (vsSyncIDListA,B odd)

Sync frame ID odd communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state.

### 103.2.6.12 FRNMVn (n=1 to 3) [h'01B0 – h'01B8]

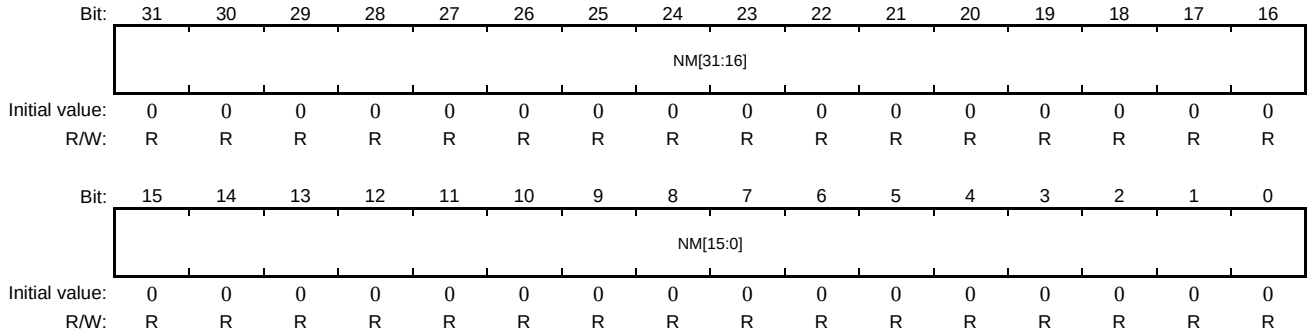
FlexRay Network Management Vector n (n=1 to 3)

The three network management registers hold the accrued NM vector (see section 103.3.7).

The CC updates the NM vector at the end of each communication cycle as long as the CC is either in NORMAL_ACTIVE or NORMAL_PASSIVE state.

NMVn-bytes exceeding the configured NM vector length are not valid.

For information about the byte alignment of the received NM vector in this register see section 103.3.17.



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:0] | NM | 0 | R | NM vector |

(1) **FRNMVn.NM**

NM vector

The three network management registers hold the accrued NM vector (configurable 0 to 12 bytes).

The accrued NM vector is generated by the CC by bit-wise ORing each NM vector received (valid static frames with PPI = '1') on each channel (see section 103.3.7).

For information about the byte alignment of the received NM vector in this register see section 103.3.17.

**FRNMVn**-bytes exceeding the configured NM vector length are not valid.

The CC updates the NM vector at the end of each communication cycle as long as the CC is either in NORMAL_ACTIVE or NORMAL_PASSIVE state.

Reset when leaving CONFIG state or when entering STARTUP state.

### 103.2.7 Message Buffer Control Registers

#### 103.2.7.1 FRMRC [h'0300]

FlexRay Message RAM Configuration

The Message RAM Configuration register defines the number of message buffers assigned to the static segment, dynamic segment, and FIFO.

The Message RAM can be divided into up three different areas; Static Buffer area, Static and Dynamic Buffer area, FIFO area. If present, the Static Buffer area is starting at Message Buffer 0.

The start of the Static and Dynamic Buffer area is configured by **FRMRC.FDB**. **FRMRC.FDB** defines the end of the Static Buffer area. If no Static Buffer area is present, the Static and Dynamic Buffer area starts at Message Buffer 0.

The start of the FIFO area is configured by **FRMRC.FFB**. **FRMRC.FFB** defines the end of the previous area, which can be either the Static Buffer area or the Static and Dynamic Buffer area. If no Static Buffer area and no Static and Dynamic Buffer area is present, the FIFO area starts at Message Buffer 0.

With **FRMRC.LCB** the end of the last configured area is configured which can be the Static Buffer area, the Static and Dynamic Buffer area or the FIFO area.

Figure 103.2 shows an example configuration of the Message RAM where all there area are configured.

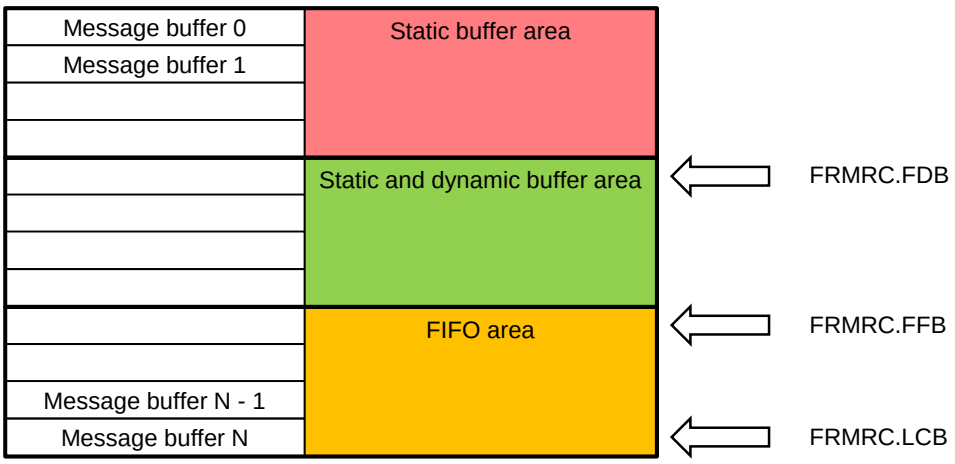


**Figure 103.2 Message RAM organisation**

**Note 1:** In case the node is configured as sync node (**FRSUCC1.TXSY** = '1') or for single slot mode operation (**FRSUCC1.TSM** = '1'), message buffer 0 resp. 1 is reserved for sync frames or single slot frames and have to be configured with the node-specific key slot ID. In case the node is neither configured as sync node nor for single slot operation message buffer 0 resp. 1 is treated like all other message buffers.

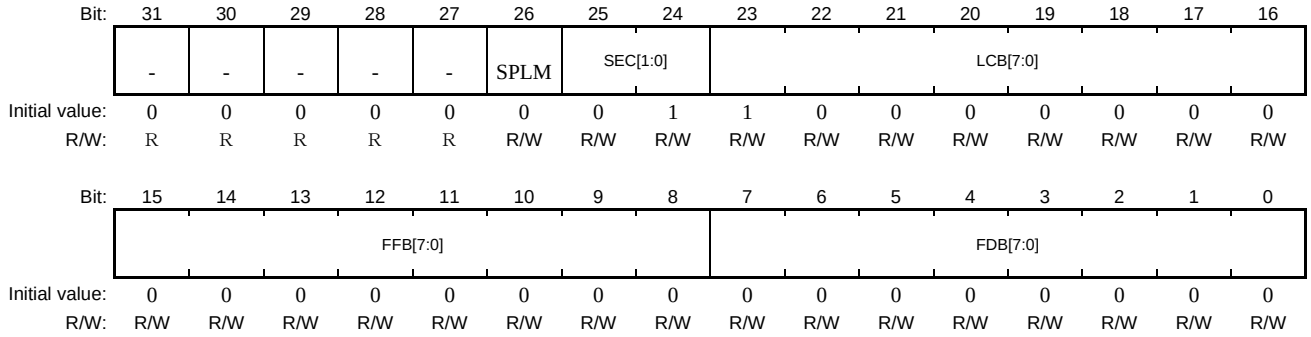
**Note 2:** The maximum number of header sections is 128. This means a maximum of 128 message buffers can be configured. The maximum length of a data section is 254 bytes. The length of the data section may be configured differently for each message buffer. For details see section 103.3.13.

**Note 3:** In case two or more message buffers are assigned to slot 1 by use of cycle filtering, all of them must be located either in the "Static Buffer area" or at the beginning of the "Static and Dynamic Buffer area" section.

**Note 4:** The FlexRay protocol specification requires that each node has to send a frame in its key slot. Therefore at least message buffer 0 is reserved for transmission in the key slot. Due to this requirement a maximum number of 127 message

buffers can be assigned to the FIFO area. Nevertheless, a non protocol conform configuration without a transmission slot in the static segment would still be operational.

**Note 5:** The payload length configured and the length of the data section need to be configured identical for all message buffers belonging to the FIFO area via **FRWRHS2.PLC** and **FRWRHS3.DP**. When the CC is not in DEFAULT_CONFIG or CONFIG state reconfiguration of message buffers belonging to the FIFO area is locked.



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:27] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [26] | SPLM | 0 | R/W | Sync Frame Payload Multiplex<br>0 = Only message buffer 0 locked against reconfiguration<br>1 = Both message buffers 0 and 1 are locked against reconfiguration |
| [25:24] | SEC | 1h | R/W | Secure Buffers<br>00 = all buffers unlocked<br>01 = static buffers locked, FIFO locked, limited transmission<br>10 = all buffers locked<br>11 = all buffers locked, limited transmission |
| [23:16] | LCB | 80h | R/W | Last Configured Buffer<br>0…127 = Number of message buffers is FRMRF.LCB + 1<br>128 = No message buffer configured |
| [15:8] | FFB | 0 | R/W | First Buffer of FIFO<br>0 = All message buffers assigned to the FIFO<br>1…127 = Message buffers from FRMRC.FFB to FRMRC.LCB assigned to the FIFO<br>128 = No message buffer assigned to the FIFO |
| [7:0] | FDB | 0 | R/W | First Dynamic Buffer<br>0 = No group of message buffers exclusively for the static segment configured<br>1…127 = Message buffers 0 to FRMRC.FDB - 1 reserved for static segment<br>128 = No dynamic message buffers configured |

(1) **FRMRC.SPLM**

Sync Frame Payload Multiplex

The user can only write to this bit when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

This bit is only evaluated if the node is configured as sync node (**FRSUCC1.TXSY** = ’1’) or for single slot mode operation (**FRSUCC1.TSM** = ’1’).

When this bit is set to ’1’ message buffers 0 and 1 are dedicated for sync frame transmission with different payload data on channel A and B.

When this bit is set to ’0’, sync frames are transmitted from message buffer 0 with the same payload data on all configured channels.

Note that the channel filter configuration for message buffer 0 resp. message buffer 1 has to be chosen accordingly.

(2) **FRMRC.SEC**

Secure Buffers

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

Not evaluated when the CC is in DEFAULT_CONFIG or CONFIG state. For temporary unlocking see section 6.13.4.3.

00 = all buffers unlocked
Reconfiguration of message buffers enabled with numbers < **FRMRC.FFB** enabled
Exception: In nodes configured for sync frame transmission or for single slot mode operation message buffer 0 (and if **FRMRC.SPLM** = ’1’, also message buffer 1) is always locked

01 = static buffers locked, FIFO locked, limited transmission
Reconfiguration of message buffers with numbers < **FRMRC.FDB** and with numbers => **FRMRC.FFB** locked and transmission of message buffers for static segment with numbers => **FRMRC.FDB** disabled

10 = all buffers locked
Reconfiguration of all message buffers locked

11 = all buffers locked, limited transmission
Reconfiguration of all message buffers locked and transmission of message buffers for static segment with numbers >= **FRMRC.FDB** disabled

(3) **FRMRC.LCB**

Last Configured Buffer

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

When a Static and Dynamic Buffer area is configured (**FRMRC.FDB** < 128), the user should configure **FRMRC.LCB** >= **FRMRC.FDB**.

When a FIFO area is configured (**FRMRC.FFB** < 128), the user should configure **FRMRC.LCB** >= **FRMRC.FFB**.

(4) **FRMRC.FFB**

First Buffer of FIFO

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

When a Static and Dynamic Buffer area is configured (**FRMRC.FDB** < 128), the user should configure **FRMRC.FFB** > **FRMRC.FDB**.

(5) **FRMRC.FDB**

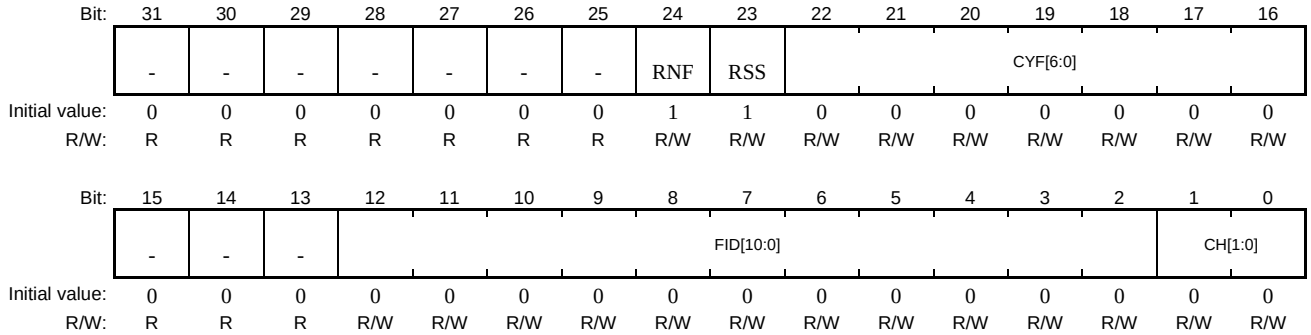
First Dynamic Buffer

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

### 103.2.7.2 FRFRF [h'0304]

FlexRay FIFO Rejection Filter

The FIFO Rejection Filter defines a user specified sequence of bits to which channel, frame ID, and cycle count of the incoming frames are compared. Together with the FIFO Rejection Filter Mask this register determines whether a message is rejected by the FIFO.



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:25] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [24] | RNF | 1 | R/W | Reject Null Frames<br>0 = Null frames are stored in the FIFO<br>1 = Reject all null frames |
| [23] | RSS | 1 | R/W | Reject in Static Segment<br>0 = FIFO also used for static segment<br>1 = Reject messages in static segment |
| [22:16] | CYF | 0 | R/W | Cycle Counter Filter |
| [15:13] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [12:2] | FID | 0 | R/W | Frame ID Filter<br>0 ... 2047 = Frame ID filter values |
| [1:0] | CH | 0 | R/W | Channel Filter<br>00 = receive on both channels<br>01 = receive only on channel B<br>10 = receive only on channel A<br>11 = no reception |

(1) **FRFRF.RNF**

Reject Null Frames

The user can only write to this bit when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

If this bit is set, received null frames are not stored in the FIFO.

(2) **FRFRF.RSS**

Reject in Static Segment

The user can only write to this bit when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

If this bit is set, the FIFO is used only for the dynamic segment.

(3) **FRFRF.CYF**

Cycle Counter Filter

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

The 7-bit cycle counter filter determines the cycle set to which frame ID and channel rejection filter are applied. In cycles not belonging to the cycle set specified by **FRFRF.CYF**, all frames are rejected. For details about the configuration of the cycle counter filter see section 103.3.8.2.

(4) **FRFRF.FID**

Frame ID Filter

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

Determines the frame ID to be rejected by the FIFO. With the additional configuration of register **FRFRFM**, the corresponding frame ID filter bits are ignored, which results in further rejected frame IDs. When **FRFRFM.MFID** is zero, a frame ID filter value of zero means that no frame ID is rejected.

(5) **FRFRF.CH**

Channel Filter

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

If reception on both channels is configured, also in static segment always both frames (from channel A and B) are stored in the FIFO, even if they are identical.

### 103.2.7.3 FRFRFM [h'0308]

FlexRay FIFO Rejection Filter Mask

The FlexRay FIFO Rejection Filter Mask specifies which of the corresponding frame ID filter bits are relevant for rejection filtering. If a bit is set, it indicates that the corresponding bit in the **FRFRF** register will not be considered for rejection filtering.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | - | - | - | - | - | - | - | - | - | - | - | - | - | - | - | - |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | - | - | - | MFID[10:0] | | | | | | | | | | | - | - |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R | R |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:13] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [12:2] | MFID | 0 | R/W | Mask Frame ID Filter<br>0 = Corresponding frame ID filter bit is used for rejection filtering<br>1 = Ignore corresponding frame ID filter bit. |
| [1:0] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |

(1) **FRFRFM.MFID**

Mask Frame ID Filter

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

### 103.2.7.4 FRFCL [h'030C]

FlexRay FIFO Critical Level

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | - | - | - | - | - | - | - | - | - | - | - | - | - | - | - | - |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | - | - | - | - | - | - | - | - | CL[7:0] | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:8] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [7:0] | CL | 80h | R/W | Critical Level |

(1) **FRFCL.CL**

Critical Level

The user can only write to these bits when **FRCCSV.POCS** is DEFAULT_CONFIG or CONFIG.

When the receive FIFO fill level **FRFSR.RFFL** is equal or greater than the critical level configured by **FRFCL.CL**, the receive FIFO critical level flag **FRFSR.RFCL** is set.

If **FRFCL.CL** is programmed to values > 128, bit **FRFSR.RFCL** is never set.

## 103.2.8 Message Buffer Status Registers

### 103.2.8.1 FRMHDS [h'0310]

FlexRay Message Handler Status

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | - | MBU[6:0] | | | | | | | - | MBT[6:0] | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | - | FMB[6:0] | | | | | | | CRAM | MFMB | FMBD | ATBF2 | ATBF1 | AMR | - | - |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R/W | R/W | R/W | R/W | R/W | R | R |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [30:24] | MBU | 0 | R | Message Buffer Updated |
| [23] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [22:16] | MBT | 0 | R | Message Buffer Transmitted |
| [15] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [14:8] | FMB | 0 | R | Faulty Message Buffer |
| [7] | CRAM | 1 | R | Clear all internal RAM's<br>0 = No execution of the CHI command CLEAR_RAMS<br>1 = Execution of the CHI command CLEAR_RAMS ongoing |
| [6] | MFMB | 0 | R/W | Multiple Faulty Message Buffers detected<br>0 = No additional faulty message buffer<br>1 = Another faulty message buffer was detected while flag FRMHDS.FMBD is set |
| [5] | FMBD | 0 | R/W | Faulty Message Buffer Detected<br>0 = No faulty message buffer<br>1 = Message buffer referenced by FRMHDS.FMB holds faulty data due to an access error |
| [4] | ATBF2 | 0 | R/W | Access Error Transient buffer RAM B<br>0 = No access error<br>1 = Access error occurred when reading the Transient buffer RAM B |
| [3] | ATBF1 | 0 | R/W | Access Error Transient buffer RAM A<br>0 = No access error<br>1 = Access error occurred when reading the Transient buffer RAM A |
| [2] | AMR | 0 | R/W | Access Error Message RAM<br>0 = No access error<br>1 = Access error occurred when reading the Message RAM |
| [1:0] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |

(1) **FRMHDS.MBU**

Message Buffer Updated

Number of message buffer that was updated last by the CC. For this message buffer the respective **ND** and / or **MBC** flag in the **FRNDAT1/2/3/4** registers and the **FRMBSC1/2/3/4** registers are also set.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(2) **FRMHDS.MBT**

Message Buffer Transmitted

Number of last successfully transmitted message buffer. If the message buffer is configured for single-shot mode, the respective **FRTXRQn.TXR** flag in the **FRTXRQ1/2/3/4** registers was reset.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(3) **FRMHDS.FMB**

Faulty Message Buffer

Access error occurred when reading from the message buffer referenced by **FRMHDS.FMB**.

Value only valid when one of the flags **FRMHDS.AMR**, **FRMHDS.ATBF1**, **FRMHDS.ATBF2** or **FRMHDS.FMBD** is set.

Flag is not updated while flag **FRMHDS.FMBD** is set.

Reset by the CHI command CLEAR_RAMS.

(4) **FRMHDS.CRAM**

Clear all internal RAM’s

Signals that execution of the CHI command CLEAR_RAMS is ongoing (all bits of all message RAM, input buffer, output buffer and transient buffer are written to ’0’).

This bit is set by the CHI command CLEAR_RAMS.

(5) **FRMHDS.MFMB**

Multiple Faulty Message Buffers detected

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This bit indicates that another faulty message buffer was detected while flag **FRMHDS.FMBD** is set

Reset by the CHI command CLEAR_RAMS.

(6) **FRMHDS.FMBD**

Faulty Message Buffer Detected

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This bit indicates that the Message buffer referenced by **FRMHDS.FMB** holds faulty data due to an access error

Reset by the CHI command CLEAR_RAMS.

(7) **FRMHDS.ATBF2**

Access Error Transient buffer RAM B

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This bit indicates that an access error occurred when reading the Transient buffer RAM B

**Note:** When **FRMHDS.ATBF2** changes from ’0’ to ’1’ **FREIR.AERR** is set to ’1’.

Reset by the CHI command CLEAR_RAMS.

(8) **FRMHDS.ATBF1**

Access Error Transient buffer RAM A

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This bit indicates that an access error occurred when reading the Transient buffer RAM A

**Note:** When **FRMHDS.ATBF1** changes from ’0’ to ’1’ **FREIR.AERR** is set to ’1’.

Reset by the CHI command CLEAR_RAMS.

(9) **FRMHDS.AMR**

Access Error Message RAM

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This bit indicates that an access error occurred when reading the Message RAM

**Note:** When **FRMHDS.AMR** changes from ’0’ to ’1’ **FREIR.AERR** is set to ’1’.

Reset by the CHI command CLEAR_RAMS.

### 103.2.8.2 FRLDTS [h’0314]

FlexRay Last Dynamic Transmit Slot

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | - | - | - | - | - | LDTB[10:0] | | | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | - | - | - | - | - | LDTA[10:0] | | | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:27] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [26:16] | LDTB | 0 | R | Last Dynamic Transmission Channel B |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [15:11] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [10:0] | LDTA | 0 | R | Last Dynamic Transmission Channel A |

(1) **FRLDTS.LDTB**

Last Dynamic Transmission Channel B

Value of vSlotCounter[B] at the time of the last frame transmission on channel B in the dynamic segment of this node.

It is updated at the end of the dynamic segment and is reset to zero if no frame was transmitted during the dynamic segment on channel B.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(2) **FRLDTS.LDTA**

Last Dynamic Transmission Channel A

Value of vSlotCounter[A] at the time of the last frame transmission on channel A in the dynamic segment of this node.

It is updated at the end of the dynamic segment and is reset to zero if no frame was transmitted during the dynamic segment on channel A.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

### 103.2.8.3 FRFSR [h'0318]

FlexRay FIFO Status Register

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | - | - | - | - | - | - | - | - | - | - | - | - | - | - | - | - |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | RFFL[7:0] | | | | | | | | - | - | - | - | - | RFO | RFCL | RFNE |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:16] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [15:8] | RFFL | 0 | R | Receive FIFO Fill Level |
| [7:3] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [2] | RFO | 0 | R | Receive FIFO Overrun<br>0 = No receive FIFO overrun detected<br>1 = A receive FIFO overrun has been detected |
| [1] | RFCL | 0 | R | Receive FIFO Critical Level<br>0 = Receive FIFO below critical level<br>1 = Receive FIFO critical level reached |
| [0] | RFNE | 0 | R | Receive FIFO Not Empty<br>0 = Receive FIFO is empty<br>1 = Receive FIFO is not empty |

(1) **FRFSR.RFFL**

Receive FIFO Fill Level

Number of FIFO buffers filled with new data not yet read by the Host. Maximum value is 128.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(2) **FRFSR.RFO**

Receive FIFO Overrun

The flag is set by the CC when a receive FIFO overrun is detected.

When a receive FIFO overrun occurs, the oldest message is overwritten with the actual received message. In addition, interrupt flag **FREIR.RFO** is set.

The flag is cleared by the next FIFO read access issued by the Host.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(3) **FRFSR.RFCL**

Receive FIFO Critical Level

This flag is set when the receive FIFO fill level **FRFSR.RFFL** is equal or greater than the critical level as configured by **FRFCL.CL**.

When **FRFSR.RFCL** changes from ’0’ to ’1’ bit **FRSIR.RFCL** is set to ’1’, and if enabled, an interrupt is generated.

The flag is cleared by the CC as soon as **FRFSR.RFFL** drops below **FRFCL.CL**.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(4) **FRFSR.RFNE**

Receive FIFO Not Empty

This flag is set by the CC when a received valid frame (data or null frame depending on rejection mask) was stored in the FIFO. In addition, interrupt flag **FRSIR.RFNE** is set.

The bit is reset after the Host has read all messages from the FIFO.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

### 103.2.8.4 FRMHDF [h'031C]

FlexRay Message Handler Constraints Flags

Some constraints exist for the Message Handler regarding bus clock frequency, Message RAM configuration, and FlexRay bus traffic (see Addendum to ERAY FlexRay IP-Module Specification). To simplify software development, constraints violations are reported by setting flags in the **FRMHDF**.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | - | - | - | - | - | - | - | - | - | - | - | - | - | - | - | - |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:9] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [8] | WAHP | 0 | R/W | Write Attempt to Header Partition<br>0 = No write attempt to header partition<br>1 = Write attempt to header partition |
| [7] | TNSB | 0 | R/W | Transmission Not Started Channel B<br>0 = No transmission not started on channel B<br>1 = Transmission not started on channel B |
| [6] | TNSA | 0 | R/W | Transmission Not Started Channel A<br>0 = No transmission not started on channel A<br>1 = Transmission not started on channel A |
| [5] | TBFB | 0 | R/W | Transient Buffer Access Failure B<br>0 = No TBF B access failure<br>1 = TBF B access failure |
| [4] | TBFA | 0 | R/W | Transient Buffer Access Failure A<br>0 = No TBF A access failure<br>1 = TBF A access failure |
| [3] | FNFB | 0 | R/W | Find Sequence Not Finished Channel B<br>0 = No find sequence not finished for channel B<br>1 = Find sequence not finished for channel B |
| [2] | FNFA | 0 | R/W | Find Sequence Not Finished Channel A<br>0 = No find sequence not finished for channel A<br>1 = Find sequence not finished for channel A |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [1] | SNUB | 0 | R/W | Status Not Updated Channel B<br>0 = No overload condition occurred when updating MBS for channel B<br>1 = MBS for channel B not updated |
| [0] | SNUA | 0 | R/W | Status Not Updated Channel A<br>0 = No overload condition occurred when updating MBS for channel A<br>1 = MBS for channel A not updated |

(1) **FRMHDF.WAHP**

Write Attempt to Header Partition

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

Outside DEFAULT_CONFIG and CONFIG state this flag is set by the CC when the message handler tries to write message data into the header partition of the Message RAM due to faulty configuration of a message buffer. The write attempt is not executed, to protect the header partition from unintended write accesses.

When this flag changes from '0' to '1', interrupt flag **FREIR.MHF** is set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(2) **FRMHDF.TNSB**

Transmission Not Started Channel B

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set by the CC when the Message Handler was not ready to start a scheduled transmission on channel B at the action point of the configured slot.

When this flag changes from '0' to '1', interrupt flag **FREIR.MHF** is set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(3) **FRMHDF.TNSA**

Transmission Not Started Channel A

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set by the CC when the Message Handler was not ready to start a scheduled transmission on channel A at the action point of the configured slot.

When this flag changes from '0' to '1', interrupt flag **FREIR.MHF** is set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(4) **FRMHDF.TBFB**

Transient Buffer Access Failure B

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set by the CC when a read or write access to TBF B requested by PRT B could not complete within the available time.

When this flag changes from '0' to '1', interrupt flag **FREIR.MHF** is set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(5) **FRMHDF.TBFA**

Transient Buffer Access Failure A

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set by the CC when a read or write access to TBF A requested by PRT A could not complete within the available time.

When this flag changes from '0' to '1', interrupt flag **FREIR.MHF** is set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(6) **FRMHDF.FNFB**

Find Sequence Not Finished Channel B

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set by the CC when the Message Handler, due to overload condition, was not able to finish a find sequence (scan of Message RAM for matching message buffer) with respect to channel B.

When this flag changes from '0' to '1', interrupt flag **FREIR.MHF** is set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(7) **FRMHDF.FNFA**

Find Sequence Not Finished Channel A

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set by the CC when the Message Handler, due to overload condition, was not able to finish a find sequence (scan of Message RAM for matching message buffer) with respect to channel A.

When this flag changes from '0' to '1', interrupt flag **FREIR.MHF** is set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(8) **FRMHDF.SNUB**

Status Not Updated Channel B

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set by the CC when the Message Handler, due to overload condition, was not able to update a message buffer’s status MBS with respect to channel B.

When this flag changes from '0' to '1', interrupt flag **FREIR.MHF** is set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(9) **FRMHDF.SNUA**

Status Not Updated Channel A

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set by the CC when the Message Handler, due to overload condition, was not able to update a message buffer’s status MBS with respect to channel A.

When this flag changes from '0' to '1', interrupt flag **FREIR.MHF** is set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

### 103.2.8.5 FRTXRQi (i=1 to 4) [h'0320 – h'032C]

FlexRay Transmission Request i (i=1 to 4)

The four registers reflect the state of the **TXR** flags of all configured message buffers. The flags are evaluated for transmit buffers only. If the number of configured message buffers is less than 128, the remaining **TXR** flags have no meaning.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | TXRo[31:16] | | | | | | | | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | TXRo[15:0] | | | | | | | | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:0] | TXRo | 0 | R | Transmission Request o |

(1) **FRTXRQi.TXRo (o=(i-1)*32 to (i*32-1))**

Transmission Request o

If the flag is set, the respective message buffer is ready for transmission respectively transmission of this message buffer is in progress.

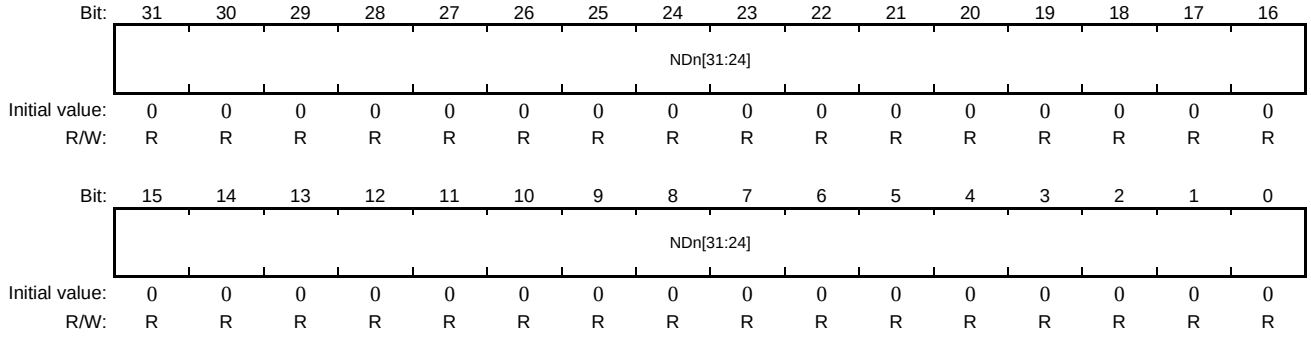
In single-shot mode the flags are reset after transmission has completed.

Reset by the CHI command CLEAR_RAMS.

### 103.2.8.6 FRNDATi (i=1 to 4) [h'0330 – h'033C]

FlexRay New Data i (i=1 to 4)

The four registers reflect the state of the **ND** flags of all configured message buffers. **ND** flags belonging to transmit buffers have no meaning. If the number of configured message buffers is less than 128, the remaining **ND** flags have no meaning.



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:0] | NDn | 0 | R | New Data n |

(1) **FRNDATi.NDn (n=(i-1)*32 to (i*32-1))**

New Data n

The flags are set when a valid received data frame matches the message buffer's filter configuration, independent of the payload length received or the payload length configured for that message buffer.

The flags are not set after reception of null frames except for message buffers belonging to the receive FIFO.

An **ND** flag is reset when the header section of the corresponding message buffer is reconfigured or when the data section has been transferred to the Output Buffer.

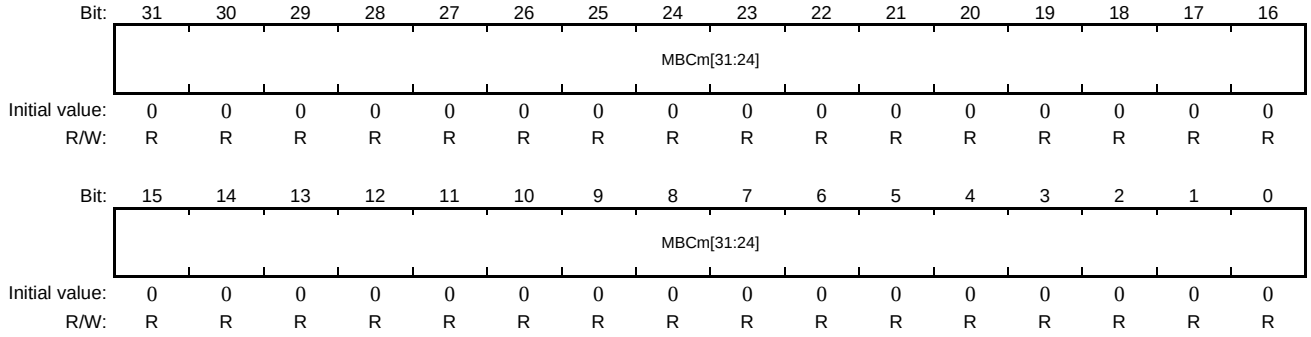
Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

### 103.2.8.7 FRMBSCi (i=1 to 4) [h'0340 – h'034C]

FlexRay Message Buffer Status Changed i (i=1 to 4)

The four registers reflect the state of the **MBC** flags of all configured message buffers. If the number of configured message buffers is less than 128, the remaining **MBC** flags have no meaning.



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:0] | MBCm | 0 | R | Message Buffer Status Changed m |

(1) **FRMBSCi.MBCm (m=(i-1)*32 to (i*32-1))**

Message Buffer Status Changed m

An **MBC** flag is set whenever the Message Handler changes one of the status flags **VFRA**, **VFRB**, **SEOA**, **SEOB**, **CEOA**, **CEOB**, **SVOA**, **SVOB**, **TCIA**, **TCIB**, **ESA**, **ESB**, **MLST**, **FTA**, **FTB** in the header section (see section 103.2.11.5 and section 103.3.13.1 of the respective message buffer.

An **MBC** flag is reset when the header section of the corresponding message buffer is reconfigured or when it has been transferred to the Output Buffer.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

### 103.2.9 Reserved

### 103.2.10 Input Buffer

Double buffer structure consisting of Input Buffer Host and Input Buffer Shadow. While the Host can write to Input Buffer Host, the transfer to the Message RAM is done from Input Buffer Shadow. The Input Buffer holds the header and data sections to be transferred to the selected message buffer in the Message RAM. It is used to configure the message buffers in the Message RAM and to update the data sections of transmit buffers.

When updating the header section of a message buffer in the Message RAM from the Input Buffer, the Message Buffer Status as described in section 103.2.11.5 is automatically reset to zero.

The header sections of message buffers belonging to the receive FIFO can only be (re)configured when the CC is in DEFAULT_CONFIG or CONFIG state. For those message buffers only the payload length configured and the data pointer need to be configured via **FRWRHS2.PLC** and **FRWRHS3.DP**. All information required for acceptance filtering is taken from the FIFO rejection filter and the FIFO rejection filter mask.

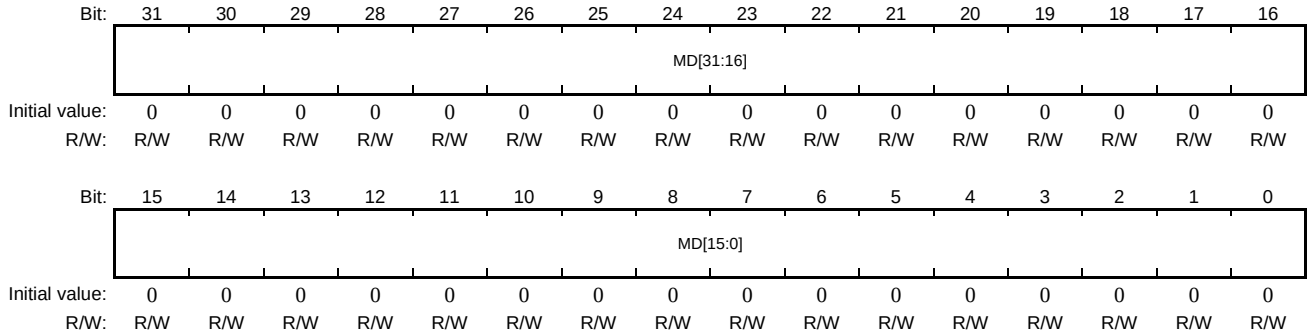
The data transfer between Input Buffer (IBF) and Message RAM is described in detail in section 103.3.12.2.(1).

When using the input data transfer function as described in section 103.3.16.1 and **FRITS.ITS** is '1', the user should not write to these registers.

#### 103.2.10.1 FRWRDSn (n=1 to 64) [h'0400 – h'04FC]

FlexRay Write Data Section n (n=1 to 64)

Holds the data words to be transferred to the data section of the addressed message buffer. The number of data words written to the Message RAM is defined by the payload length configured in **FRWRHS2.PLC**.



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:0] | MD | 0 | R/W | Message Data |

(1) **FRWRDSn.MD**

Message Data

For information about the byte alignment of the Message Data in this register see section 103.3.17.

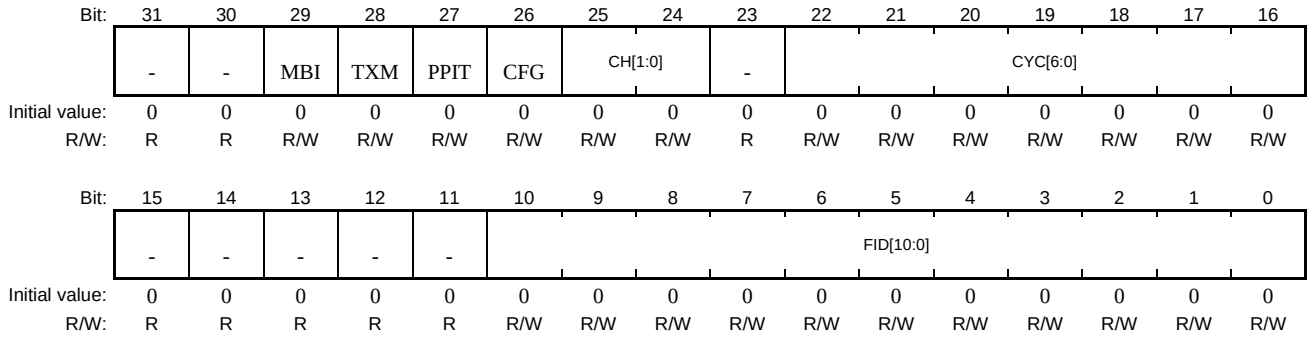
**Note 1:** In case **FRWRHS2.PLC** specifies an odd payload length, the remaining message data bytes are unused.

**Note 2:** When writing to **FRWRDSn**, each 32-bit word has to be filled up by one 32-bit access OR two consecutive 16-bit accesses OR four consecutive 8- bit accesses before the transfer from the Input Buffer to the Message RAM is started. If not all bytes of a 32- bit word have been written by the Host (8/16-bit access only), **FRWRDSn** holds partly undefined data.

Reset by the CHI command CLEAR_RAMS.

### 103.2.10.2 FRWRHS1 [h'0500]

FlexRay Write Header Section 1



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:30] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [29] | MBI | 0 | R/W | Message Buffer Interrupt<br>0 = Message buffer interrupt is disabled<br>1 = Message buffer interrupt is enabled |
| [28] | TXM | 0 | R/W | Transmission Mode<br>0 = Continuous mode<br>1 = Single-shot mode |
| [27] | PPIT | 0 | R/W | Payload Preamble Indicator Transmit<br>0 = Payload Preamble Indicator not set<br>1 = Payload Preamble Indicator set |
| [26] | CFG | 0 | R/W | Message Buffer Direction Configuration Bit<br>0 = Message buffer is configured as Receive Buffer<br>1 = Message buffer is configured as Transmit Buffer |
| [25:24] | CH | 0 | R/W | Channel Filter Control |
| [23] | - | 0 | R | Reserved<br>This bit is always read as 0. The write value should be always 0 |
| [22:16] | CYC | 0 | R/W | Cycle Code |
| [15:11] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [10:0] | FID | 0 | R/W | Frame ID |

(1) **FRWRHS1.MBI**

Message Buffer Interrupt

This bit enables the receive / transmit interrupt for the corresponding message buffer.

After a dedicated receive buffer has been updated by the Message Handler, flag **FRSIR.RXI** and /or **FRSIR.MBSI** are set. After a transmission has completed flag **FRSIR.TXI** is set.

(2) **FRWRHS1.TXM**

Transmission Mode

This bit is used to select the transmission mode (see section 103.3.9.3) for the corresponding message buffer.

(3) **FRWRHS1.PPIT**

Payload Preamble Indicator Transmit

This bit is used to control the state of the Payload Preamble Indicator in transmit frames for the corresponding message buffer.

If the bit is set in a static message buffer, the respective message buffer holds network management information.

If the bit is set in a dynamic message buffer the first two bytes of the payload segment may be used for message ID filtering by the receiver. Message ID filtering of received FlexRay frames is not supported by the FlexRay module, but can be done by the Host.

(4) **FRWRHS1.CFG**

Message Buffer Direction Configuration Bit

This bit is used to configure the corresponding buffer as transmit buffer or as receive buffer. For message buffers belonging to the receive FIFO the bit is not evaluated.

(5) **FRWRHS1.CH**

Channel Filter Control

The 2-bit channel filtering field associated with each buffer serves as a filter for receive buffers, and as a control field for transmit buffers.

| CH[1:0] | Transmit Buffer<br>transmit frame on | Receive Buffer<br>store frame received from |
|---|---|---|
| 00 | no transmission | ignore frame |
| 01 | channel A | channel A |
| 10 | channel B | channel B |
| 11 | both channels (static segment only) | channel A or B<br>(store first semantically valid frame; static segment only) |

**Note:** If a message buffer is configured for the dynamic segment and both bits of the channel filtering field are set to ’1’, no frames are transmitted resp. received frames are ignored (same function as **CH** = "00")

(6) **FRWRHS1.CYC**

Cycle Code

The 7-bit cycle code determines the cycle set used for cycle counter filtering.

For details about the configuration of the cycle code section 103.3.8.2.

(7) **FRWRHS1.FID**

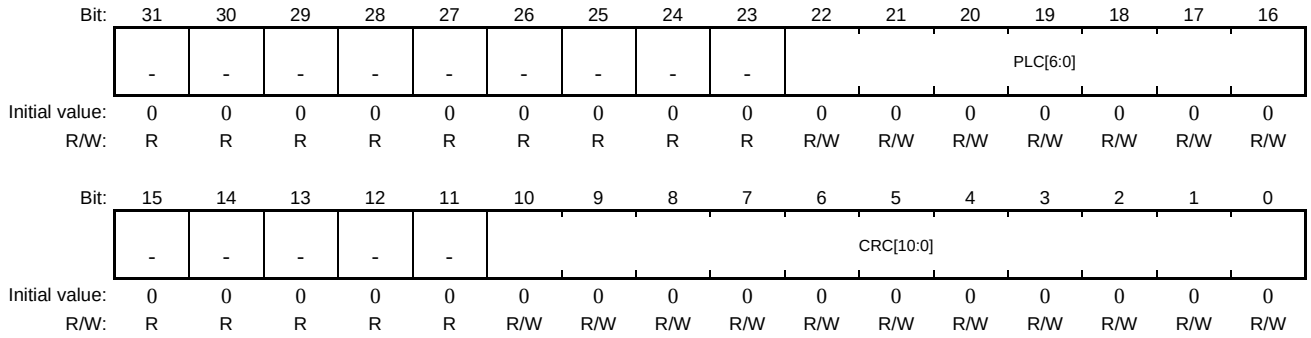
Frame ID

Frame ID of the selected message buffer. The frame ID defines the slot number for transmission / reception of the respective message.

Message buffers with frame ID = ’0’ are considered as not valid.

### 103.2.10.3 FRWRHS2 [h'0504]

FlexRay Write Header Section 2



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:23] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [22:16] | PLC | 0 | R/W | Payload Length Configured |
| [15:11] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [10:0] | CRC | 0 | R/W | Header CRC<br>Receive Buffer: Configuration not required<br>Transmit Buffer: Header CRC calculated and configured by the Host |

(1) **FRWRHS2.PLC**

Payload Length Configured

Length of data section (number of 2-byte words) as configured by the Host.

During static segment the static frame payload length as configured by **FRMHDC.SFDL** defines the payload length for all static frames. If the payload length configured by **FRWRHS2.PLC** is shorter than this value padding bytes are inserted to ensure that frames have proper physical length. The padding pattern is logical zero (see section 103.3.9.3).

(2) **FRWRHS2.CRC**

Header CRC

For receive message buffer configuration not required

For transmit message buffer the header CRC needs to be calculated and configured by the Host
For calculation of the header CRC the payload length of the frame send on the bus has to be considered. In static segment the payload length of all frames is configured by **FRMHDC.SFDL**.

### 103.2.10.4 FRWRHS3 [h'0508]

FlexRay Write Header Section 3

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | - | - | - | - | - | - | - | - | - | - | - | - | - | - | - | - |

| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:11] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [10:0] | DP | 0 | R/W | Data Pointer |

(1) **FRWRHS3.DP**

Data Pointer

Pointer to the first 32-bit word of the data section of the addressed message buffer in the Message RAM.

### 103.2.10.5 FRIBCM [h'0510]

FlexRay Input Buffer Command Mask

Configures how the message buffer in the Message RAM selected by register **FRIBCR** is updated. When IBF Host and IBF Shadow are swapped, also mask bits **FRIBCM.LHSH**, **FRIBCM.LDSH**, and **FRIBCM.STXRH** are swapped with bits **FRIBCM.LHSS**, **FRIBCM.LDSS**, and **FRIBCM.STXRS** to keep them attached to the respective Input Buffer transfer.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | - | - | - | - | - | - | - | - | - | - | - | - | - | STXRS | LDSS | LHSS |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R/W | R/W | R/W |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | - | - | - | - | - | - | - | - | - | - | - | - | - | STXRH | LDSH | LHSH |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:19] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [18] | STXRS | 0 | R/W | Set Transmission Request Shadow<br>0 = Reset TXR flag<br>1 = Set TXR flag, transmit buffer released for transmission (operation ongoing or finished) |
| [17] | LDSS | 0 | R/W | Load Data Section Shadow<br>0 = Data section is not updated<br>1 = Data section selected for transfer from Input Buffer to the Message RAM (transfer ongoing or finished) |
| [16] | LHSS | 0 | R/W | Load Header Section Shadow<br>0 = Header section is not updated<br>1 = Header section selected for transfer from Input Buffer to the Message RAM (transfer ongoing or finished) |
| [15:3] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [2] | STXRH | 0 | R/W | Set Transmission Request Host<br>0 = Reset TXR flag<br>1 = Set TXR flag, transmit buffer released for transmission |
| [1] | LDSH | 0 | R/W | Load Data Section Host<br>0 = Data section is not updated<br>1 = Data section selected for transfer from Input Buffer to the Message RAM |
| [0] | LHSH | 0 | R/W | Load Header Section Host<br>0 = Header section is not updated<br>1 = Header section selected for transfer from Input Buffer to the Message RAM |

(1) **FRIBCM.STXRS**

Set Transmission Request Shadow

(2) **FRIBCM.LDSS**

Load Data Section Shadow

(3) **FRIBCM.LHSS**

Load Header Section Shadow

(4) **FRIBCM.STXRH**

Set Transmission Request Host

If this bit is set to ’1’, the **TXR** flag for the selected message buffer is set in the **FRTXRQ1/2/3/4** registers to release the message buffer for transmission. In single-shot mode the flag is cleared by the CC after transmission has completed.

**TXR** is evaluated for transmit buffers only.

(5) **FRIBCM.LDSH**

Load Data Section Host

(6) **FRIBCM.LHSH**

Load Header Section Host

### 103.2.10.6 FRIBCR [h'0514]

FlexRay Input Buffer Command Request

When the Host writes the number of the target message buffer in the Message RAM to **FRIBCR.IBRH**,

IBF Host and IBF Shadow are swapped. In addition the message buffer numbers stored under **FRIBCR.IBRH** and **FRIBCR.IBRS** are also swapped (see section 103.3.12.2.(1)).

With this write operation the **FRIBCR.IBSYS** is set to '1'. The Message Handler then starts to transfer the contents of IBF Shadow to the message buffer in the Message RAM selected by **FRIBCR.IBRS**.

While the Message Handler transfers the data from IBF Shadow to the target message buffer in the Message RAM, the Host may write the next message into the IBF Host. After the transfer between IBF Shadow and the Message RAM has completed, **FRIBCR.IBSYS** is set back to '0' and the next transfer to the Message RAM may be started by the Host by writing the respective target message buffer number to **FRIBCR.IBRH**.

If a write access to **FRIBCR.IBRH** occurs while **FRIBCR.IBSYS** is '1', **FRIBCR.IBSYH** is set to '1'. After completion of the ongoing data transfer from IBF Shadow to the Message RAM, IBF Host and IBF Shadow are swapped, **FRIBCR.IBSYH** is reset to '0'. **FRIBCR.IBSYS** remains set to '1', and the next transfer to the Message RAM is started. In addition the message buffer numbers stored under **FRIBCR.IBRH** and **FRIBCR.IBRS** are also swapped.

Any write access to an Input Buffer register while both **FRIBCR.IBSYS** and **FRIBCR.IBSYH** are set will cause the error flag **FREIR.IIBA** to be set. In this case the write access has no effect and the Input Buffer will not be changed.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | IBSYS | - | - | - | - | - | - | - | - | IBRS[6:0] | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | IBSYH | - | - | - | - | - | - | - | - | IBRH[6:0] | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31] | IBSYS | 0 | R | Input Buffer Busy Shadow<br>0 = Transfer between IBF Shadow and Message RAM completed<br>1 = Transfer between IBF Shadow and Message RAM in progress |
| [30:23] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [22:16] | IBRS | 0 | R | Input Buffer Request Shadow |
| [15] | IBSYH | 0 | R | Input Buffer Busy Host<br>0 = No request pending<br>1 = Request while transfer between IBF Shadow and Message RAM in progress |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [14:7] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [6:0] | IBRH | 0 | R/W | Input Buffer Request Host |

(1) **FRIBCR.IBSYS**

Input Buffer Busy Shadow

Set to ’1’ after writing **FRIBCR.IBRH**.

This bit indicates that a transfer between IBF Shadow and Message RAM is in progress.

When the transfer between IBF Shadow and the Message RAM has completed, **FRIBCR.IBSYS** is set back to ’0’.

(2) **FRIBCR.IBRS**

Input Buffer Request Shadow

Number of the target message buffer actually updated / lately updated.

(3) **FRIBCR.IBSYH**

Input Buffer Busy Host

Set to ’1’ by writing **FRIBCR.IBRH** while **FRIBCR.IBSYS** is still ’1’.

This bit indicates that a transfer between IBF Shadow and Message RAM is in progress

After the ongoing transfer between IBF Shadow and the Message RAM has completed, the **FRIBCR.IBSYH** is set back to ’0’.

(4) **FRIBCR.IBRH**

Input Buffer Request Host

Selects the target message buffer in the Message RAM for data transfer from Input Buffer.

### 103.2.11 Output Buffer

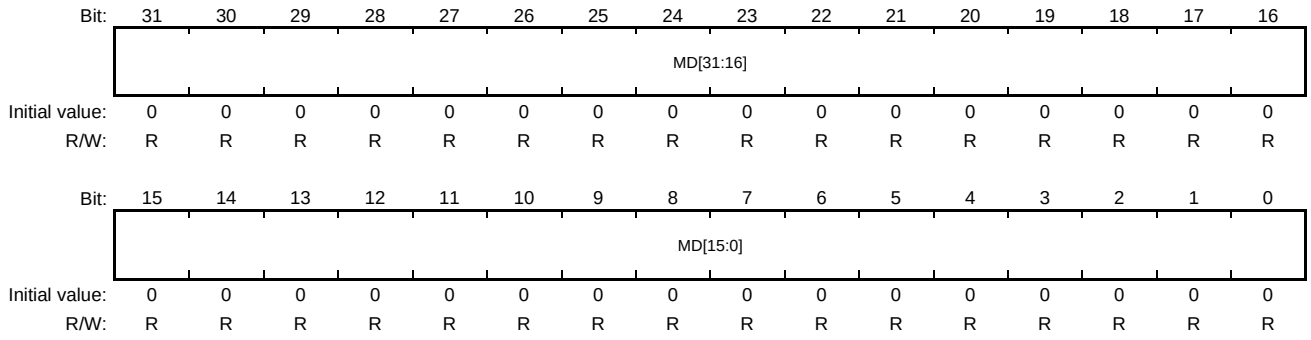
Double buffer structure consisting of Output Buffer Host and Output Buffer Shadow. Used to read out message buffers from the Message RAM. While the Host can read from Output Buffer Host, the Message Handler transfers the selected message buffer from Message RAM to Output Buffer Shadow. The data transfer between Message RAM and Output Buffer (OBF) is described in section 103.3.12.2.(2).

When using the output data transfer function as described in section 103.3.16.2 and **FROTS.OTS** is '1', the user should not write to these registers.

#### 103.2.11.1 FRRDDSn (n=1 to 64) [h'0600 – h'06FC]

FlexRay Read Data Section n (n=1 to 64)

Holds the data words read from the data section of the addressed message buffer. The number of data words read from the Message RAM is defined by the payload length configured in **FRRDHS2.PLC**.



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:0] | MD | 0 | R | Message Data |

(1) **FRRDDSn.MD**

Message Data

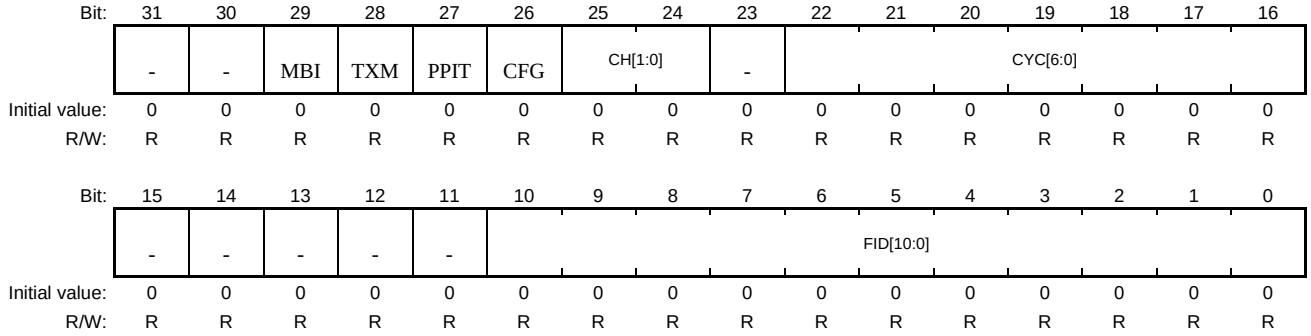
For information about the byte alignment of the Message Data in this register see section 103.3.17.

**Note:** In case **FRRDHS2.PLC** specifies an odd payload length, the remaining message data bytes are undefined.

Reset by the CHI command CLEAR_RAMS.

### 103.2.11.2 FRRDHS1 [h'0700]

FlexRay Read Header Section 1



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:30] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [29] | MBI | 0 | R | Message Buffer Interrupt |
| [28] | TXM | 0 | R | Transmission Mode |
| [27] | PPIT | 0 | R | Payload Preamble Indicator Transmit |
| [26] | CFG | 0 | R | Message Buffer Direction Configuration Bit |
| [25:24] | CH | 0 | R | Channel Filter Control |
| [23] | - | 0 | R | Reserved<br>This bit is always read as 0. The write value should be always 0 |
| [22:16] | CYC | 0 | R | Cycle Code |
| [15:11] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [10:0] | FID | 0 | R | Frame ID |

(1) **FRRDHS1.MBI**

Message Buffer Interrupt

Value as configured by the Host via **FRWRHS1.MBI**.

In case that the message buffer read from the Message RAM belongs to the receive FIFO this bit is set to '0'.

(2) **FRRDHS1.TXM**

Transmission Mode

Value as configured by the Host via **FRWRHS1.TXM**.

In case that the message buffer read from the Message RAM belongs to the receive FIFO this bit is set to '0'.

(3) **FRRDHS1.PPIT**

Payload Preamble Indicator Transmit

Value as configured by the Host via **FRWRHS1.PPIT**.

In case that the message buffer read from the Message RAM belongs to the receive FIFO this bit is set to '0'.

(4) **FRRDHS1.CFG**

Message Buffer Direction Configuration Bit

Value as configured by the Host via **FRWRHS1.CFG**.

In case that the message buffer read from the Message RAM belongs to the receive FIFO this bit is set to '0'.

(5) **FRRDHS1.CH**

Channel Filter Control

Value as configured by the Host via **FRWRHS1.CH**.

In case that the message buffer read from the Message RAM belongs to the receive FIFO these bits are set to '0'.

(6) **FRRDHS1.CYC**

Cycle Code

Value as configured by the Host via **FRWRHS1.CYC**.

In case that the message buffer read from the Message RAM belongs to the receive FIFO these bits are set to '0'.

(7) **FRRDHS1.FID**

Frame ID

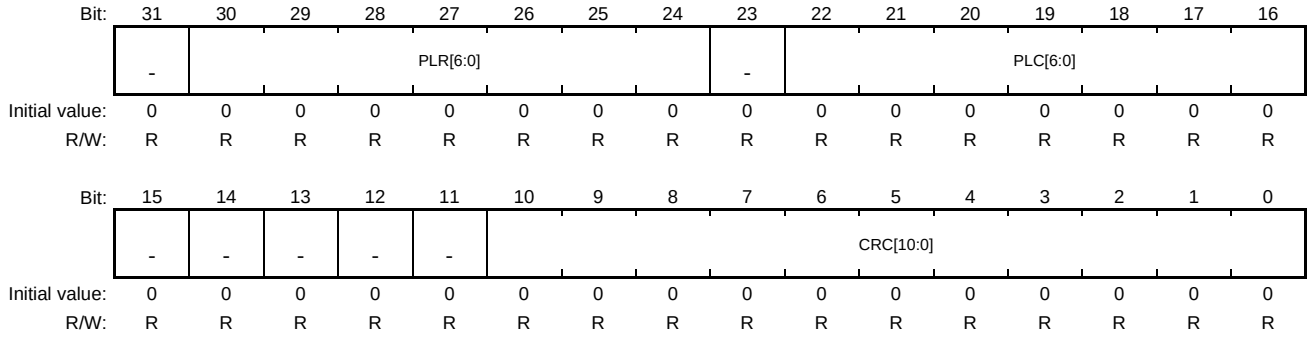
Value as configured by the Host via **FRWRHS1.FID**

In case that the message buffer read from the Message RAM belongs to the receive FIFO these bits are holding the received frame ID.

### 103.2.11.3 FRRDHS2 [h'0704]

FlexRay Read Header Section 2

**Note:** For message buffers belonging to the Static Buffer area or Static and Dynamic Buffer area **FRWRHS2** is updated from data frames only.



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31] | - | 0 | R | Reserved<br>This bit is always read as 0. The write value should be always 0 |
| [30:24] | PLR | 0 | R | Payload Length Received<br>vRF!Header!Length |
| [23] | - | 0 | R | Reserved<br>This bit is always read as 0. The write value should be always 0 |
| [22:16] | PLC | 0 | R | Payload Length Configured |
| [15:11] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [10:0] | CRC | 0 | R | Header CRC<br>vRF!Header!HeaderCRC |

(1) **FRRDHS2.PLR**

Payload Length Received

Payload length value updated from received data frames (vRF!Header!Length) (exception: if message buffer belongs to the receive FIFO **PLR** is also updated from received null frames).

(2) **FRRDHS2.PLC**

Payload Length Configured

Length of data section (number of 2-byte words) as configured by the Host.

(3) **FRRDHS2.CRC**

Header CRC

Receive Buffer: Header CRC (vRF!Header!HeaderCRC) updated from received data frames

Transmit Buffer: Header CRC calculated and configured by the Host

(4) **Data storage**

When a message is stored into a message buffer the following behaviour with respect to payload length received and payload length configured is implemented:

**FRRDHS2.PLR** > **FRRDHS2.PLC**:
The payload data stored in the message buffer is truncated to the payload length configured if **FRRDHS2.PLC** even or else truncated to **FRRDHS2.PLC** + 1.

**FRRDHS2.PLR** <= **FRRDHS2.PLC**:
The received payload data is stored into the message buffers data section. The remaining data bytes of the data section as configured by **FRRDHS2.PLC** are filled with undefined data.

**FRRDHS2.PLR** = zero:
The message buffer's data section is filled with undefined data

**FRRDHS2.PLC** = zero:
Message buffer has no data section configured. No data is stored into the message buffer's data section.

**Note 1:** The Message RAM is organized in 4-byte words. When received data is stored into a message buffer's data section, the number of 2-byte data words written into the message buffer is **FRRDHS2.PLC** rounded to the next even value.

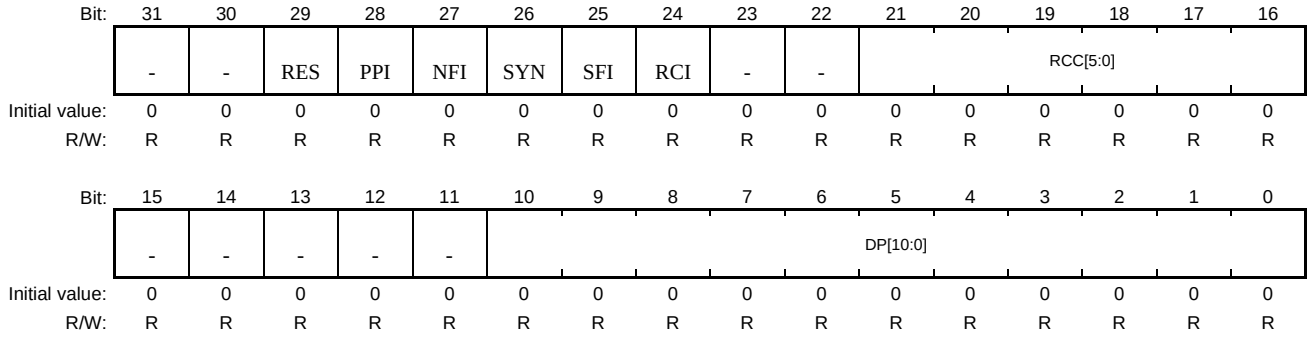
**Note 2:** **FRRDHS2.PLC** should be configured identical for all message buffers belonging to the receive FIFO.

For message buffers belonging to the Static Buffer area or Static and Dynamic Buffer area **FRWRHS2** is updated from data frames only.

### 103.2.11.4 FRRDHS3 [h'0708]

FlexRay Read Header Section 3

**Note:** For message buffers belonging to the Static Buffer area or Static and Dynamic Buffer area **FRWRHS3** is updated from data frames only.



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|

| [21:16] | RCC | 0 | R | Receive Cycle Count<br>vRF!Header!CycleCount |
| [15:11] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [10:0] | DP | 0 | R | Data Pointer |

(1) **FRRDHS3.RES**

Reserved Bit

Reflects the state of the received reserved bit (vRF!Header!Reserved). The reserved bit is transmitted as ’0’.

(2) **FRRDHS3.PPI**

Payload Preamble Indicator

The payload preamble indicator (vRF!Header!PPIndicator) defines whether a network management vector or message ID is contained within the payload segment of the received frame.

0 = PPI indicator set to '0'
The payload segment of the received frame does not contain a network management vector nor a message ID

1 = PPI indicator set to '1'
Static segment: Network management vector in the first part of the payload
Dynamic segment: Message ID in the first part of the payload

(3) **FRRDHS3.NFI**

Null Frame Indicator

The Null Frame Indicator (vRF!Header!NFIndicator) is set to ’1’ after storage of the first received data frame.

(4) **FRRDHS3.SYN**

Sync Frame Indicator

A sync frame is marked by the sync frame indicator (vRF!Header!SyFIndicator).

(5) **FRRDHS3.SFI**

Startup Frame Indicator

A startup frame is marked by the startup frame indicator (vRF!Header!SuFIndicator).

(6) **FRRDHS3.RCI**

Received on Channel Indicator

Indicates the channel from which the received data frame was taken to update the respective receive buffer (vSS!Channel).

(7) **FRRDHS3.RCC**

Receive Cycle Count

Cycle counter value updated from received data frame (vRF!Header!CycleCount).

(8) **FRRDHS3.DP**

Data Pointer

Pointer to the first 32-bit word of the data section of the addressed message buffer in the Message RAM.

Value as configured by the Host via **FRWRHS3.DP**.

### 103.2.11.5 FRMBS [h'070C]

FlexRay Message Buffer Status

The message buffer status is updated by the CC with respect to the assigned channel(s) latest at the end of the slot following the slot assigned to the message buffer.

The flags are updated only when the CC is in NORMAL_ACTIVE or NORMAL_PASSIVE state.

If only one channel (A or B) is assigned to a message buffer, the channel-specific status flags of the other channel are written to zero. If both channels are assigned to a message buffer, the channel-specific status flags of both channels are updated.

The message buffer status is updated only when the slot counter reached the configured frame ID and when the cycle counter filter matched. When the Host updates a message buffer via Input Buffer, all **FRMBS** flags are reset to zero independent of which **FRIBCM** bits are set or not.

For details about receive / transmit filtering see section 103.3.8, section 103.3.9 and section 103.3.10.

Whenever the Message Handler changes one of the flags **FRMBS.VFRA**, **FRMBS.VFRB**, **FRMBS.SEOA**, **FRMBS.SEOB**, **FRMBS.CEOA**, **FRMBS.CEOB**, **FRMBS.SVOA**, **FRMBS.SVOB**, **FRMBS.TCIA**, **FRMBS.TCIB**, **FRMBS.ESA**, **FRMBS.ESB**, **FRMBS.MLST**, **FRMBS.FTA**, **FRMBS.FTB** the respective message buffer's **MBC** flag in registers **FRMBSC1/2/3/4** is set.

| [0] | VFRA | 0 | R | Valid Frame Received on Channel A<br>0 = No valid frame received on channel A<br>1 = Valid frame received on channel A |

(1) **FRMBS.RESS**

Reserved Bit Status

Reflects the state of the received reserved bit (vRF!Header!Reserved). The reserved bit is transmitted as ’0’.

For receive buffers (**FRWRHS1.CFG** = ’0’) this bit is updated from both valid data and null frames. If no valid frame was received, the previous value is maintained. For transmit buffers the flag has no meaning and should be ignored.

(2) **FRMBS.PPIS**

Payload Preamble Indicator Status

The payload preamble indicator (vRF!Header!PPIndicator) defines whether a network management vector or message ID is contained within the payload segment of the received frame.

For receive buffers (**FRWRHS1.CFG** = ’0’) this bit is updated from both valid data and null frames. If no valid frame was received, the previous value is maintained. For transmit buffers the flag has no meaning and should be ignored.

0 = PPI indicator set to '0'
The payload segment of the received frame does not contain a network management vector or a message ID

1 = PPI indicator set to '1'
Dynamic segment: Message ID at the beginning of the payload
Static segment: Network management vector at the beginning of the payload

(3) **FRMBS.NFIS**

Null Frame Indicator Status

If set to ’0’ the PPI bit (vRF!Header!NFIndicator) was set to '0' and the payload segment of the received frame contains no usable data.

For receive buffers (**FRWRHS1.CFG** = ’0’) this bit is updated from both valid data and null frames. If no valid frame was received, the previous value is maintained. For transmit buffers the flag has no meaning and should be ignored.

(4) **FRMBS.SYNS**

Sync Frame Indicator Status

A sync frame is marked by the sync frame indicator (vRF!Header!SyFIndicator).

For receive buffers (**FRWRHS1.CFG** = ’0’) this bit is updated from both valid data and null frames. If no valid frame was received, the previous value is maintained. For transmit buffers the flag has no meaning and should be ignored.

(5) **FRMBS.SFIS**

Startup Frame Indicator Status

A startup frame is marked by the startup frame indicator (vRF!Header!SuFIndicator).

For receive buffers (**FRWRHS1.CFG** = ’0’) this bit is updated from both valid data and null frames. If no valid frame was received, the previous value is maintained. For transmit buffers the flag has no meaning and should be ignored.

(6) **FRMBS.RCIS**

Received on Channel Indicator Status

Indicates the channel on which the frame was received (vSS!Channel).

For receive buffers (**FRWRHS1.CFG** = ’0’) this bit is updated from both valid data and null frames. If no valid frame was received, the previous value is maintained. For transmit buffers the flag has no meaning and should be ignored.

(7) **FRMBS.CCS**

Cycle Count Status

Actual cycle count when status was updated.

(8) **FRMBS.FTB**

Frame Transmitted on Channel B

Indicates that this node has transmitted a data frame in the configured slot on channel B.

**Note:** The FlexRay protocol specification requires that **FRMBS.FTB** can only be reset by the Host. Therefore the Cycle Count Status **FRMBS.CCS** for this bit is only valid for the cycle where the bit is set to ’1’.

(9) **FRMBS.FTA**

Frame Transmitted on Channel A

Indicates that this node has transmitted a data frame in the configured slot on channel A.

**Note:** The FlexRay protocol specification requires that **FRMBS.FTA** can only be reset by the Host. Therefore the Cycle Count Status **FRMBS.CCS** for this bit is only valid for the cycle where this bit is set to ’1’.

0 = No data frame transmitted on channel A

(10) **FRMBS.MLST**

Message Lost

The flag is set in case the Host did not read the message before the message buffer was updated from a received data frame.

Not affected by reception of null frames except for message buffers belonging to the receive FIFO. The flag is reset by a Host write to the message buffer via IBF or when a new message is stored into the message buffer after the message buffers **ND** flag was reset by reading out the message buffer via OBF.

(11) **FRMBS.ESB**

Empty Slot Channel B

In an empty slot there is no activity detected on the bus. The condition is checked in static and dynamic slots.

(12) **FRMBS.ESA**

Empty Slot Channel A

In an empty slot there is no activity detected on the bus. The condition is checked in static and dynamic slots.

(13) **FRMBS.TCIB**

Transmission Conflict Indication Channel B

A transmission conflict indication (vSS!TxConflictB) is set if a transmission conflict has occurred on channel B.

(14) **FRMBS.TCIA**

Transmission Conflict Indication Channel A

A transmission conflict indication (vSS!TxConflictA) is set if a transmission conflict has occurred on channel A.

(15) **FRMBS.SVOB**

Slot Boundary Violation Observed on Channel B

A slot boundary violation (channel active at the start or at the end of the assigned slot) (vSS!BViolationB) was observed on channel B.

(16) **FRMBS.SVOA**

Slot Boundary Violation Observed on Channel A

A slot boundary violation (channel active at the start or at the end of the assigned slot) (vSS!BViolationA) was observed on channel A.

(17) **FRMBS.CEOB**

Content Error Observed on Channel B

A content error (vSS!ContentErrorB) was observed in the assigned slot on channel B.

(18) **FRMBS.CEOA**

Content Error Observed on Channel A

A content error (vSS!ContentErrorA) was observed in the assigned slot on channel A.

(19) **FRMBS.SEOB**

Syntax Error Observed on Channel B

A syntax error (vSS!SyntaxErrorB) was observed in the assigned slot on channel B.

(20) **FRMBS.SEOA**

Syntax Error Observed on Channel A

A syntax error was (vSS!SyntaxErrorA) observed in the assigned slot on channel A.

(21) **FRMBS.VFRB**

Valid Frame Received on Channel B

A valid frame indication (vSS!ValidFrameB) is set if a valid frame was received on channel B.

(22) **FRMBS.VFRA**

Valid Frame Received on Channel A

A valid frame indication (vSS!ValidFrameA) is set if a valid frame was received on channel A.

### 103.2.11.6 FROBCM [h'0710]

FlexRay Output Buffer Command Mask

Configures how the Output Buffer is updated from the message buffer in the Message RAM selected by **FROBCR.OBRS**.

Mask bits **FROBCM.RDSS** and **FROBCM.RHSS** are copied to the register internal storage when a Message RAM transfer is requested by **FROBCR.REQ**.

When OBF Host and OBF Shadow are swapped, mask bits **FROBCM.RDSH** and **FROBCM.RHSH** are swapped with the register internal storage to keep them attached to the respective Output Buffer transfer.

The data transfer between Output Buffer and Message RAM is described in detail in section 103.3.12.2.(2).

**Note:** After the transfer of the header section from the Message RAM to OBF Shadow has completed, the message buffer status changed flag **MBC** of the selected message buffer in the **FRMBSC1/2/3/4** registers is cleared. After the transfer of the data section from the Message RAM to OBF Shadow has completed, the new data flag **ND** of the selected message buffer in the **FRNDAT1/2/3/4** registers is cleared.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

(1) **FROBCM.RDSH**

Read Data Section Host

(2) **FROBCM.RHSH**

Read Header Section Host

(3) **FROBCM.RDSS**

Read Data Section Shadow

(4) **FROBCM.RHSS**

Read Header Section Shadow

### 103.2.11.7 FROBCR [h'0714]

FlexRay Output Buffer Command Request

After setting bit **FROBCR.REQ** to '1' while **FROBCR.OBSYS** is '0', **FROBCR.OBSYS** is automatically set to '1', **FROBCR.OBRS** is copied to the register internal storage, mask bits **FROBCM.RDSS** and **FROBCM.RHSS** are copied to register **FROBCM** internal storage, and the transfer of the message buffer selected by **FROBCR.OBRS** from the Message RAM to OBF Shadow is started. When the transfer between the Message RAM and OBF Shadow has completed, this is signaled by setting **FROBCR.OBSYS** back to '0'.

By setting bit **FROBCR.VIEW** to '1' while **FROBCR.OBSYS** is '0', OBF Host and OBF Shadow are swapped. Additionally mask bits **FROBCM.RDSH** and **FROBCM.RHSH** are swapped with the register **FROBCM** internal storage to keep them attached to the respective Output Buffer transfer. **FROBCR.OBRH** signals the number of the message buffer currently accessible by the Host.

If bits **FROBCR.REQ** and **FROBCR.VIEW** are set to '1' with the same write access while **FROBCR.OBSYS** is '0', **FROBCR.OBSYS** is automatically set to '1' and OBF Shadow and OBF Host are swapped. Additionally mask bits **FROBCM.RDSH** and **FROBCM.RHSH** are swapped with the registers internal storage to keep them attached to the respective Output Buffer transfer. Afterwards **FROBCR.OBRS** is copied to the register internal storage, and the transfer of the selected message buffer from the Message RAM to OBF Shadow is started. While the transfer is ongoing the Host can read the message buffer transferred by the previous transfer from OBF Host. When the current transfer between Message RAM and OBF Shadow has completed, this is signaled by setting **FROBCR.OBSYS** back to '0'.

Any write access to **FROBCR[15:8]** while **FROBCR.OBSYS** is set will cause the error flag **FREIR.IOBA** to be set. In this case the write access has no effect and the Output buffer will not be changed.

The data transfer between Output Buffer and Message RAM is described in detail in section 103.3.12.2.(2).

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| [31:23] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [22:16] | OBRH | 0 | R | Output Buffer Request Host |
| [15] | OBSYS | 0 | R | Output Buffer Busy Shadow<br>0 = No transfer in progress<br>1 = Transfer between Message RAM and OBF Shadow in progress |
| [14:10] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [9] | REQ | 0 | R/W | Request Message RAM Transfer<br>0 = No request<br>1 = Transfer to OBF Shadow requested |
| [8] | VIEW | 0 | R/W | View Shadow Buffer<br>0 = No action<br>1 = Swap OBF Shadow and OBF Host |
| [7] | - | 0 | R | Reserved<br>This bit is always read as 0. The write value should be always 0 |
| [6:0] | OBRS | 0 | R/W | Output Buffer Request Shadow |

(1) **FROBCR.OBRH**

Output Buffer Request Host

Number of message buffer currently accessible by the Host via **FRRDHS1/2/3**, **FRMBS**, and **FRRDDSn (n=1 to 64)**.

By writing **FROBCR.VIEW** to ’1’ OBF Shadow and OBF Host are swapped and the transferred message buffer is accessible by the Host.

(2) **FROBCR.OBSYS**

Output Buffer Busy Shadow

Set to ’1’ after setting bit **FROBCR.REQ**. When the transfer between the Message RAM and OBF Shadow has completed, **FROBCR.OBSYS** is set back to ’0’.

(3) **FROBCR.REQ**

Request Message RAM Transfer

Only writeable while **FROBCR.OBSYS** = ’0’.

Requests transfer of message buffer addressed by **FROBCR.OBRS** from Message RAM to OBF Shadow.

(4) **FROBCR.VIEW**

View Shadow Buffer

Only writeable while **FROBCR.OBSYS** = ’0’.

Toggles between OBF Shadow and OBF Host.

(5) **FROBCR.OBRS**

Output Buffer Request Shadow

Only writeable while **FROBCR.OBSYS** = ’0’.

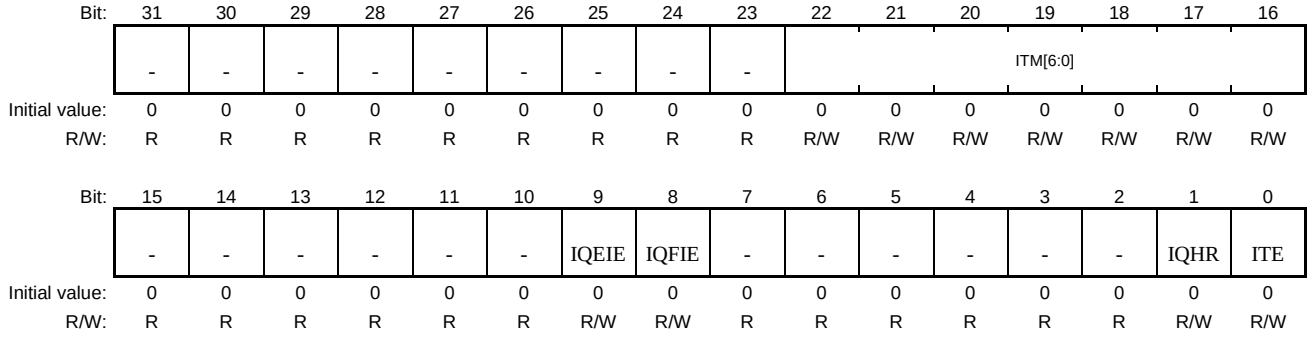
Number of source message buffer to be transferred from the Message RAM to OBF Shadow.

If the number of the first message buffer of the receive FIFO is written to this register the Message Handler transfers the message buffer addressed by the GET Index (GIDX, see section 103.3.11) to OBF Shadow.

### 103.2.12 Data transfer control register

#### 103.2.12.1 FRITC [h'0800]

FlexRay Input Transfer Configuration register



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:23] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [22:16] | ITM | 0 | R/W | Input queue Table Max<br>These bits configure the number of entries in the input pointer table the input buffer handler is capable to maintain in the input queue. |
| [15:10] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [9] | IQEIE | 0 | R/W | Input Queue Empty Interrupt Enable<br>0: Disabled<br>1: Enabled |
| [8] | IQFIE | 0 | R/W | Input Queue Full Interrupt Enable<br>0: Disabled<br>1: Enabled |
| [7:2] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [1] | IQHR | 0 | R/W | Input Queue Halt Request<br>0: Input queue run request<br>1: Input queue halt request |
| [0] | ITE | 0 | R/W | Input Transfer Enable<br>0: Operation Disable request<br>1: Operation Enable request |

(1) **FRITC.ITM**

Input queue Table Max

The user can only write to this bit when **FRITS.ITS** is '0'.

These bits configure the number of entries in the input pointer table the input buffer handler is capable to maintain in the input queue.

Valid values are h'00 (1 queue entry) to h'7F (128 queue entries).

Note that each entry requires two long words in the input pointer table.

(2) **FRITC.IQEIE**

Input Queue Empty Interrupt Enable

This bit controls the input queue empty interrupt.

0: Disabled
No interrupt will be requested and the input queue empty interrupt line will be released if pending.

1: Enabled
Input queue empty interrupt will be asserted when **FRITS.IQEIS** is '1'.

(3) **FRITC.IQFIE**

Input Queue Full Interrupt Enable

This bit controls the input queue full interrupt.

0: Disabled
No interrupt will be requested and the input queue full interrupt line will be released if pending.

1: Enabled
Input queue full interrupt will be asserted when **FRITS.IQFIS** is '1'.

(4) **FRITC.IQHR**

Input Queue Halt Request

The **IQHR** bit should not be set to '1' when **FRITS.ITS** is '0'.

This bit requests a halt of the input queue.

The status of the halt request is shown in the **FRITS.IQH** register.
Refer to section 103.3.16.1.(5) about usage of this bit.

0: Input queue run request
The input queue resumes their operation.

1: Input queue halt request
The input queue gets halted. An active input transfer will be completed but no further transfer request will start.

(5) **FRITC.ITE**

Input Transfer Enable

The user should only set this bit to '1' when **FRIBCR.IBSYS** is '0'.

The user should only set this bit to '0' when **FRITC.IQHR** '0'. Otherwise committed input transfers get lost.

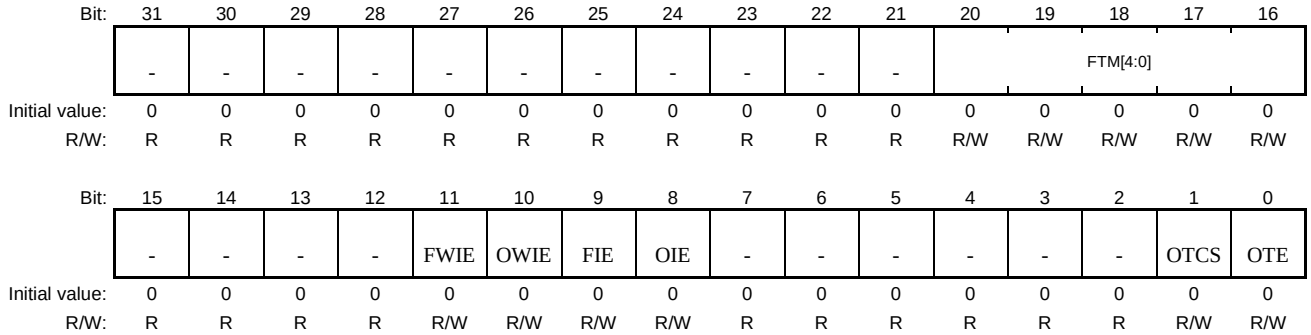
This bit controls the operation mode of the input transfer queue.
The operation status of the input transfer queue function is shown in **FRITS.ITS**.
Refer to section 103.3.16.1.(1) about usage of this bit.

0: Operation Disable request
The input transfer queue gets disabled when it becomes empty.

1: Operation Enable request
The input transfer queue gets enabled. Input data structures are transferred to the FlexRay internal message RAM.

### 103.2.12.2 FROTC [h'0804]

FlexRay Output Transfer Configuration register



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:21] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [20:16] | FTM | 0 | R/W | FIFO Table Max<br>Configures the number of FIFO entries the output transfer handler is capable to maintain in the URAM. |
| [15:12] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [11] | FWIE | 0 | R/W | FIFO transfer Warning Interrupt Enable<br>0: Disabled<br>1: Enabled |
| [10] | OWIE | 0 | R/W | Output transfer Warning Interrupt Enable<br>0: Disabled<br>1: Enabled |
| [9] | FIE | 0 | R/W | FIFO transfer Interrupt Enable<br>0: Disabled<br>1: Enabled |
| [8] | OIE | 0 | R/W | Output transfer Interrupt Enable<br>0: Disabled<br>1: Enabled |
| [7:2] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [1] | OTCS | 0 | R/W | Output Transfer Condition Select<br>0: New data only mode<br>1: New data and status changed mode |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [0] | OTE | 0 | R/W | Output Transfer Enable<br>0: Operation Disable request<br>1: Operation Enable request |

(1) **FROTC.FTM**

FIFO Table Max

The user can only write to these bits when **FROTS.OTS** is '0'.

Configures the number of FIFO entries the output transfer handler is capable to maintain in the URAM.

Valid values are h'00 (1 FIFO entry) to h'1F (32 FIFO entries).

(2) **FROTC.FWIE**

FIFO transfer Warning Interrupt Enable

This bit controls the FIFO transfer warning interrupt.

0: Disabled
No interrupt will be requested and the FIFO transfer warning interrupt line will be released if pending.

1: Enabled
FIFO transfer warning interrupt will be asserted when **FROTS.FWIS** is '1'.

(3) **FROTC.OWIE**

Output transfer Warning Interrupt Enable

This bit controls the output transfer warning interrupt.

0: Disabled
No interrupt will be requested and the output transfer warning interrupt line will be released if pending.

1: Enabled
Output transfer warning interrupt will be asserted when **FROTS.OWIS** is '1'.

(4) **FROTC.FIE**

FIFO transfer Interrupt Enable

This bit controls the FIFO transfer interrupt.

0: Disabled
No interrupt will be requested and the FIFO transfer interrupt line will be released if pending.

1: Enabled
FIFO transfer interrupt will be asserted when **FROTS.FIS** is '1'.

(5) **FROTC.OIE**

Output transfer Interrupt Enable

This bit controls the output transfer interrupt.

0: Disabled
No interrupt will be requested and the output transfer interrupt line will be released if pending.

1: Enabled
Output transfer interrupt will be asserted when **FROTS.OTIS** is '1'.

(6) **FROTC.OTCS**

Output Transfer Condition Select

The user can only write to this bit when **FROTS.OTS** is '0'.

This bit controls the output transfer condition.

0: New data only mode
The **ND** bits in the **FRNDATi** registers are used to detect a transfer condition for dedicated receive buffer

1: New data and status changed mode
The **ND** bits in the **FRNDATi** registers and the **MBC** bits in the **FRMBSC** register are used to detect a transfer condition for dedicated transmit and receive buffer

(7) **FROTC.OTE**

Output Transfer Enable

The user should only set this bit to '1' when **FROBCR.OBSYS** is '0'.

This bit controls the operation mode of the output transfer function.
The operation status of the output buffer transfer function is shown in **FROTS.OTS**.
Refer to section 103.3.16.2.(1) about usage of this bit.

0: Operation Disable request
The output buffer transfer gets disabled.
An active message buffer transfer will be completed but no further transfer will start.

1: Operation Enable request
The output buffer transfer gets enabled. Message buffers are transferred from the FlexRay internal message RAM to output data structures.

The user should not change the ERAY message RAM configuration by writing to the **FRMRC** register.

### 103.2.12.3 FRIBA [h'0808]

FlexRay Input pointer table Base Address register

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | ITA[31:16] | | | | | | | | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | ITA[15:0] | | | | | | | | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R | R |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:2] | ITA | 0 | R/W | Input Table Address<br>These bits configure the base address of the input pointer table. |
| [1:0] | ITA | 0 | R | Input Table Address<br>The address should be 32 bit aligned, thus bits[1:0] are always ‘0’. |

(1) **FRIBA.ITA**

Input Table Address

The user can only write to this bit when **FRITS.ITS** is '0'.

The address should be 32 bit aligned, thus the bits **FRIBA.ITA[1:0]** are always '0'.

These bits configure the base address of the input pointer table.

The table is used for the input transfer queue transferring message buffers from the URAM into the FlexRay internal message RAM.

The size of the input queue is configured in **FRITC.ITM**.

Note that each entry requires two long words in the input pointer table.

### 103.2.12.4 FRFBA [h’080C]

FlexRay FIFO pointer table Base Address register

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | FTA[31:16] | | | | | | | | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | FTA[15:0] | | | | | | | | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:2] | FTA | 0 | R/W | FIFO pointer Table Address<br>These bits configure the base address of the FIFO pointer table. |
| [1:0] | FTA | 0 | R | FIFO pointer Table Address<br>The address should be 32 bit aligned, thus bits[1:0] are always ‘0’. |

(1) **FRFBA.FTA**

FIFO pointer Table Address

The user can only write to this bit when **FROTS.OTS** is '0'.

The address should be 32 bit aligned, thus the bits **FRFBA.FTA[1:0]** are always '0'.

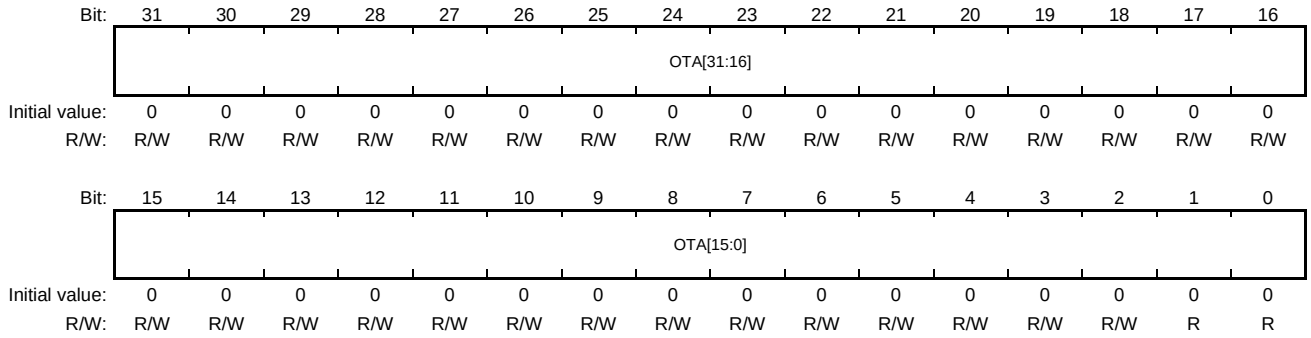
These bits configure the base address of the FIFO pointer table.

The table is used for message buffers transferred from the FlexRay internal FIFO to the URAM.

The size of the FIFO is configured in **FROTC.FTM**.

### 103.2.12.5 FROBA [h'0810]

FlexRay Output pointer table Base Address register



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:2] | OTA | 0 | R/W | Output pointer Table Address<br>These bits configure the base address of the output pointer table |
| [1:0] | OTA | 0 | R | Output pointer Table Address<br>The address should be 32 bit aligned, thus bits[1:0] are always '0' |

(1) **FROBA.OTA**

Output pointer Table Address

The user can only write to this bit when **FROTS.OTS** is '0'.

The address should be 32 bit aligned, thus the bits **FROBA.OTA[1:0]** are always '0'.

These bits configure the base address of the output pointer table.

The table is used for message buffers transferred from the FlexRay internal message RAM to the URAM.

The size of the table depends on the utilisation of the FlexRay internal message RAM and can have up to 128 entries.

### 103.2.12.6 FRIQC [h'0814]

FlexRay Input Queue Control register

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | - | - | - | - | - | - | - | - | - | - | - | - | - | - | - | - |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | - | - | - | - | - | - | - | - | - | IMBNR[6:0] | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | W | W | W | W | W | W | W |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:7] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [6:0] | IMBNR | 0 | W | Input Message Buffer NumbeR<br>Message buffer number added to the input queue |

(1) **FRIQC.IMBNR**

Input Message Buffer NumbeR

The user can only write to this bit when **FRITS.IQFP** is '0'.

The user should not write to this register when **FRITS.ITS** is '0' or when **FRITC.ITE** is '0'.

These bits are read as "0".

This value specifies the message buffer added to the input queue.
The number has to be identical to **FRWRHS4.IMBNR** (see section 103.3.16.1.(3)) of the input pointer table.
The address to the input data structure has to be provided in the input pointer table at the put index (**FRITS.IPIDX**) before writing to this register.
Writing to this register increases the input put index (**FRITS.IPIDX**).

### 103.2.12.7 FRUIR [h'0818]

FlexRay User Input transfer Request register

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | - | - | - | - | - | - | - | - | - | - | - | - | - | - | - | - |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | - | - | - | - | - | - | - | - | UIDX[7:0] | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:8] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [7:0] | UIDX | 0 | R/W | User requested Input inDeX<br>Input pointer table index requested for input transfer |

(1) **FRUIR.UIDX**

User requested Input inDeX

The user can only write to this bit when **FRITS.UIRP** is '0'.

The user should not write to this register when **FRITS.ITS** is '0'.
The user should not write to this register when **FRITS.UIRP** is '1'.
The user should not write to this register when **FRITS.IQH** is '1'.
The user should only write **FRITC.ITM+1** to this register.

This value specifies the input pointer table index for the user requested input transfer.
The address to the input data structure has to be provided in the input pointer table at the index **UIDX** before writing to this register.

When writing to this register, the requested input data structure will be transferred from input data structure position to the FlexRay internal message RAM.

In opposite to queued input transfers the related **DA** flag in the **FRDA** register is not influenced by the user input transfer.

### 103.2.12.8 FRUOR [h'081C]

FlexRay User Output transfer Request register

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | - | - | - | - | - | - | - | - | - | - | - | - | - | - | - | - |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | - | - | - | - | - | - | URDS | - | - | UMBNR[6:0] | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R/W | R | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:10] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [9] | URDS | 0 | R/W | User request Read Data Section<br>0: Data section is not transferred<br>1: Data section is transferred |
| [8:7] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [6:0] | UMBNR | 0 | R/W | User requested output Message Buffer NumbeR<br>Message buffer number requested for output transfer |

(1) **FRUOR.URDS**

User request Read Data Section

The user can only write to this bit when **FROTS.UORP** is '0'.

The user should not write to this register when **FROTS.OTS** is '0'.

The user should not write to this register when **FROTS.UORP** is '1'.

0: Data section is not transferred
The data section of the message buffer selected by the bits **UMBNR** is not requested

1: Data section is transferred
The data section of the message buffer selected by the bits **UMBNR** is requested

(2) **FRUOR.UMBNR**

User requested output Message Buffer NumbeR

The user can only write to this bit when **FROTS.UORP** is '0'.

The user should not write to this register when **FROTS.OTS** is '0'.

The user should not write to this register when **FROTS.UORP** is '1'.

The user should restrict **UMBNR** to dedicated receive and transmit buffers when the FlexRay module is not in the CONFIG state.

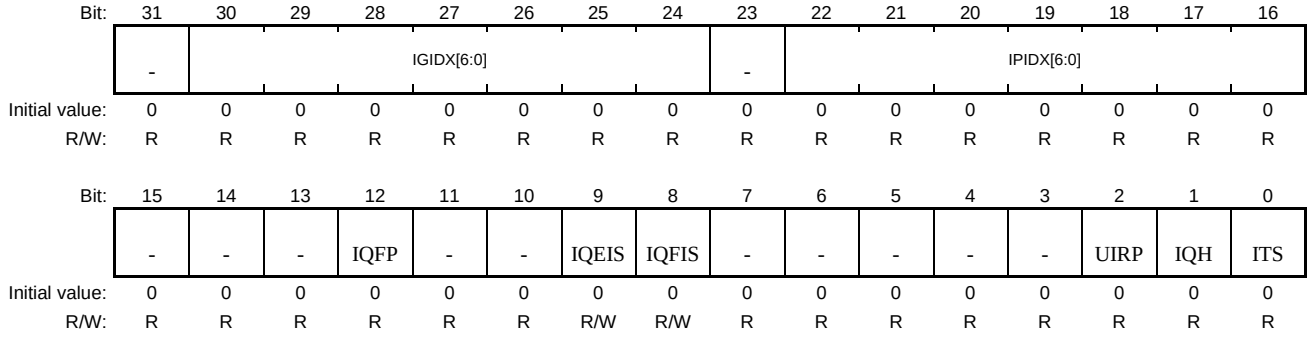
When writing to this register, the header sections and optionally the data section (configurable by **FRUOR.URDS**) of the requested message buffer will be transferred from the FlexRay internal message RAM to the output data structure position defined by the output structure data pointer in the output pointer table.

#### 103.2.12.9 Reserved

### 103.2.13 Data transfer status register

#### 103.2.13.1 FRITS [h'0820]

FlexRay Input Transfer Status register



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31] | - | 0 | R | Reserved<br>This bit is always read as 0. The write value should be always 0 |
| [30:24] | IGIDX | 0 | R | Input queue Get InDeX<br>Represents the get index of the input pointer table |
| [23] | - | 0 | R | Reserved<br>This bit is always read as 0. The write value should be always 0 |
| [22:16] | IPIDX | 0 | R | Input queue Put InDeX<br>Represents the put index of the input pointer table |
| [15:13] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [12] | IQFP | 0 | R | Input Queue Full condition Pending<br>0: Entries in the input queue are available<br>1: All entries in the input queue are occupied |
| [11:10] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [9] | IQEIS | 0 | R/W | Input Queue Empty Interrupt Status<br>0: No input queue empty condition detected<br>1: Input queue empty condition detected |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [8] | IQFIS | 0 | R/W | Input Queue Full Interrupt Status<br>0: No input queue full condition detected<br>1: Input queue full condition detected |
| [7:3] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [2] | UIRP | 0 | R | User Input transfer Request Pending<br>0: No user input transfer request pending<br>1: User input transfer request pending |
| [1] | IQH | 0 | R | Input Queue Halted<br>0: Input queue not halted<br>1: Input queue halted |
| [0] | ITS | 0 | R | Input Transfer Status<br>0: Disabled<br>1: Enabled |

(1) **FRITS.IGIDX**

Input queue Get InDeX

These bits are only valid when **FRITS.IQH** is '1'

These bits represent the input pointer index the input queue handler will transfer next.
Valid values are h'00 to **FRITC.ITM**.

The get index is incremented when the input data structure has been transferred from the URAM and the related **DA** flag in the **FRDA** register is cleared.

The index is set to h'00 when **FRITS.ITS** changes from '0' to '1'.

(2) **FRITS.IPIDX**

Input queue Put InDeX

These bits represent the index where the next input data structure pointer in the input pointer table should be stored.
Valid values are h'00 to **FRITC.ITM**.

After reaching the maximum value the put index continues from h'00.

The index is incremented when writing to **FRIQC.IMBNR**.
The index is set to h'00 when **FRITS.ITS** changes from '0' to '1'.

(3) **FRITS.IQFP**

Input Queue Full condition Pending

This bit represents that the input queue is full.

There should be no further input transfer requests, by writing to **FRIQC.IMBNR**, as long as **FRITS.IQFP** is '1'.

[Clearing condition]
This bit is cleared when there is one free entry in the input queue.

[Setting condition]
This bit is set when all entries in the input queue are occupied.

(4) **FRITS.IQEIS**

Input Queue Empty Interrupt Status

Writing '0' has no effect on the bit value.

If enabled in **FRITC.IQEIE** the input queue empty interrupt is generated when **FRITS.IQEIS** is '1'.

[Clearing condition]
This bit is cleared when writing a '1' to **FRITS.IQEIS**.
This bit is cleared when **FRITS.ITS** changes from '0' to '1'.

[Setting condition]
This bit is set when all pending input transfers have been processed and consequently the input queue becomes empty.

(5) **FRITS.IQFIS**

Input Queue Full Interrupt Status

Writing '0' has no effect on the bit value.

If enabled in **FRITC.IQFIE** the input queue full interrupt is generated when **FRITS.IQFIS** is '1'.

This flag is intended as interrupt status flag. It does not represent the current input queue status; for this status refer to **FRITS.IQFP.**

[Clearing condition]
This bit is cleared when writing a '1' to **FRITS.IQFIS**.
This bit is cleared when **FRITS.ITS** changes from '0' to '1'.

[Setting condition]
This bit is set when all entries in the input queue are occupied.

(6) **FRITS.UIRP**

User Input transfer Request Pending

This bit represents that a user input transfer is still pending.

There should be no further write access to **FRUIR.UIDX** when this bit is '1'.

[Clearing condition]
This bit is cleared when the user input transfer request is processed by the input transfer handler.

[Setting condition]
This bit is set when writing to **FRUIR.UIDX**.

(7) **FRITS.IQH**

Input Queue Halted

This bit represents the status of the input queue.

There should be no further write access to **FRUIR.UIDX** when this bit is '1'.

[Clearing condition]
This bit is cleared when **FRITC.IQHR** is set to '0'.

[Setting condition]
This bit is set immediately when the **FRITC.IQHR** is set to '1' and there is no ongoing input transfer.

This bit is set only after an ongoing input transfer has been completed and **FRITC.IQHR** is set to '1'.

(8) **FRITS.ITS**

Input Transfer Status

This bit represents the status of the input queue handler.
While this bit is '1', there should be no read or write access to the address area ERAY+h'0400 to ERAY+h'05FF and there should be no CLEAR_RAMS command applied to **FRSUCC1.CMD** register.

The input transfer queue indexes and related status flags are set to '0' when **FRITS.ITS** changes from '0' to '1'.

[Clearing condition]
This bit is cleared immediately when **FRITC.ITE** is set to '0' and there are no pending input transfers
This bit is cleared after all pending requests have been processed and **FRITC.ITE** is '0'.

[Setting condition]
This bit is set when **FRITC.ITE** is set to '1'.

### 103.2.13.2 FROTS [h'0824]

FlexRay Output Transfer Status register

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| [0] | OTS | 0 | R | Output Transfer Status<br>0: Disabled<br>1: Enabled |

(1) **FROTS.FFL**

FIFO Fill Level

These bits represent the number of available output FIFO structures in the URAM.
Valid values are h'00 to **FROTC.FTM**+1.

The value h'00 represents that the FIFO is empty.
The value **FROTC.FTM**+1 represents that the FIFO is full and no further FIFO transfers will be done.

The FIFO fill level is incremented when a FIFO data structure has been transferred from the FlexRay internal FIFO into the URAM.
The FIFO fill level is decremented when the user releases a FIFO data structure in the URAM by writing '1' to **FROTS.FDA**.
The FIFO fill level is set to h'00 when the bit **FROTS.OTS** changes from '0' to '1'.

(2) **FROTS.FGIDX**

FIFO Get InDeX

These bits represent the index where the current output data structure pointer in the FIFO pointer table is available for reading.
Valid values are h'00 to **FROTC.FTM**.
After reaching the maximum value the get index continues from h'00.

The index is incremented when a FIFO data structure is released by writing '1' to **FROTS.FDA**.
The index is set to h'00 when **FROTS.OTS** changes from '0' to '1'.

(3) **FROTS.FWP**

FIFO transfer Warning condition Pending

This bit represents the FIFO transfer warning condition.

[Clearing condition]
This bit is cleared when there are free output data structures (**FROTS.FFL** <= **FROTC.FTM**).
This bit is cleared when the **FROTS.OTS** changes from '0' to '1'.

[Setting condition]

This bit is set when the output transfer handler detects a transfer condition for FIFO message buffers but there are no free output data structures (**FROTS.FFL** = **FROTC.FTM**+1).

(4) **FROTS.OWP**

Output transfer Warning condition Pending

This bit represents the output transfer warning condition.

[Clearing condition]
This bit is cleared, when all output structure pointers that have a pending output handler transfer condition detected, are released (for dedicated transmit and receive message buffers or a user output transfer request).

[Setting condition]
This bit is set when the output transfer handler detects a transfer condition (for dedicated transmit and receive message buffers or a user output transfer request) but the related output structure pointer was not yet released by the application (data available flag is still set to '1').
This bit is set when the output transfer handler detects a transfer condition for dedicated transmit and receive message buffers but there is a pending input transfer for the same message buffer (data available flag is set to '1' due to the input transfer request).

(5) **FROTS.FDA**

FIFO Data Available

Writing '0' has no effect on the bit value.

When this bit is '1', the next valid output data structure is available.
The related data structure pointer is in the FIFO pointer table at **FROTS.FGIDX**.

Writing '1' to **FROTS.FDA**
increments **FROTS.FGIDX** and
decrements the FIFO fill level (**FROTS.FFL**)
If there are still unprocessed data structures **FROTS.FDA** remains '1'.

[Clearing condition]
This bit is cleared when writing '1' to **FROTS.FDA** and the FIFO fill level becomes h'00.
This bit is cleared when the **FROTS.OTS** changes from '0' to '1'.

[Setting condition]
This bit is set when there is at least one FIFO data structure available in the URAM.

(6) **FROTS.FWIS**

FIFO transfer Warning Interrupt Status

Writing '0' has no effect on the bit value.

If enabled in **FROTC.FWIE** the FIFO transfer warning interrupt is generated when **FROTS.FWIS** is '1'.

[Clearing condition]
This bit is cleared when writing a '1' to **FROTS.FWIS**.
This bit is cleared when the bit **FROTS.OTS** changes from '0' to '1'.

[Setting condition]
This bit is set when the output transfer handler detects a transfer condition for FIFO message buffers but there are no free output data structures (**FROTS.FFL** = **FROTC.FTM**+1).

(7) **FROTS.OWIS**

Output transfer Warning Interrupt Status

Writing '0' has no effect on the bit value.

If enabled in **FROTC.OWIE** the FIFO transfer warning interrupt is generated when **FROTS.OWIS** is '1'.

[Clearing condition]
This bit is cleared when writing a '1' to **FROTS.OWIS**.
This bit is cleared when the bit **FROTS.OTS** changes from '0' to '1'.

[Setting condition]
This bit is set when the output transfer handler detects a transfer condition (for dedicated transmit and receive message buffers or a user output transfer request) but the related output structure pointer was not yet released by the application (data available flag is still set to '1').
This bit is set when the output transfer handler detects a transfer condition for dedicated transmit and receive message buffers but there is a pending input transfer for the same message buffer (data available flag is set to '1' due to the input transfer request).

(8) **FROTS.FIS**

FIFO transfer Interrupt Status

Writing '0' has no effect on the bit value.

If enabled in **FROTC.FIE** the FIFO transfer interrupt is generated when **FROTS.FIS** is '1'.

[Clearing condition]
This bit is cleared when writing a '1' to **FROTS.FIS**.
This bit is cleared when the bit **FROTS.OTS** changes from '0' to '1'.

[Setting condition]
This bit is set when a FIFO data structure is updated by the transfer handler and **FROTS.FFL** changes from h'00 to h'01.

(9) **FROTS.OTIS**

Output transfer Interrupt Status

Writing '0' has no effect on the bit value.

If enabled in **FROTC.OIE** the output transfer interrupt is generated when **FROTS.OTIS** is '1'.

[Clearing condition]
This bit is cleared when writing a '1' to **FROTS.OTIS**.
This bit is cleared when the bit **FROTS.OTS** changes from '0' to '1'.

[Setting condition]
This bit is set when an output data structure is updated by the transfer handler (from a dedicated transmit or receive message buffer or by a user output transfer request).

(10) **FROTS.UORP**

User Output transfer Request Pending

This bit represents that a user output transfer is still pending.

There should be no further write access to **FRUOR.UMBNR** when this bit is '1'.

[Clearing condition]
This bit is cleared when the user output transfer request is processed by the output transfer handler.
This bit is cleared when the bit **FROTS.OTS** changes from '0' to '1'.

[Setting condition]
This bit is set when writing to **FRUOR.UMBNR**.

(11) **FROTS.OTS**

Output Transfer Status

This bit represents the status of the output transfer handler.
While this bit is '1', there should be no read or write access to the address area ERAY+h'0600 to ERAY+h'07FF and there should be no CLEAR_RAMS command applied to **FRSUCC1.CMD** register.

While this bit is '1', the user should not change the ERAY message RAM configuration by writing to the **FRMRC** register.

The output hander transfer indexes and related status flags are set to '0' when **FROTS.OTS** changes from '0' to '1'.

[Clearing condition]
This bit is cleared immediately when **FROTC.OTE** is set to '0' and there are no ongoing output transfers.
This bit is cleared after an ongoing transfer has been completed and **FROTC.OTE** is '0'.

[Setting condition]
This bit is set when **FROTC.OTE** is set to '1'.

### 103.2.13.3 FRAES [h'0828]

FlexRay Access Error Status register

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R/W | R/W | R/W | R/W | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:12] | - | 0 | R | Reserved<br>These bits are always read as 0. The write value should be always 0 |
| [11] | MAE | 0 | R/W | Multiple Access Errors<br>0: No multiple access errors occurred<br>1: Multiple access errors occurred |
| [10] | FAE | 0 | R/W | FIFO transfer Access Error<br>0: No access error occurred during FIFO transfer<br>1: Access error occurred during FIFO transfer |
| [9] | OAE | 0 | R/W | Output transfer Access Error<br>0: No access error occurred during output transfer<br>1: Access error occurred during output transfer |
| [8] | IAE | 0 | R/W | Input transfer Access Error<br>0: No access error occurred during input transfer<br>1: Access error occurred during input transfer |
| [7:0] | EIDX | 0 | R | Error InDeX<br>Data structure pointer index number |

(1) **FRAES.MAE**

Multiple Access Errors

Writing '0' has no effect on the bit value.

This bit represents that there were multiple access errors during a data transfer.

[Clearing condition]
This bit is cleared when writing a '1' to **FRAES.MAE**.

[Setting condition]
This bit is set when one of the bits **FRAES.FAE**, **FRAES.OAE** or **FRAES.IAE** are set and
an access to an protected address occurred during a FIFO data transfer or
an access to an protected address occurred during an output data transfer or

an access to an protected address occurred during an input data transfer

(2) **FRAES.FAE**

FIFO transfer Access Error

Writing '0' has no effect on the bit value.

This bit represent that there was an access error during a FIFO data transfer.

[Clearing condition]
This bit is cleared when writing a '1' to **FRAES.FAE**.

[Setting condition]
This bit is set when a URAM access error was detected during a FIFO transfer and the bits **FRAES.OAE**, **FRAES.IAE** and **FRAES.MAE** are '0'.

(3) **FRAES.OAE**

Output transfer Access Error

Writing '0' has no effect on the bit value.

This bit represent that there was an access error during a output data transfer.

[Clearing condition]
This bit is cleared when writing a '1' to **FRAES.OAE**.

[Setting condition]
This bit is set when a URAM access error was detected during an output transfer and the bits **FRAES.FAE**, **FRAES.IAE** and **FRAES.MAE** are '0'.

(4) **FRAES.IAE**

Input transfer Access Error

Writing '0' has no effect on the bit value.

This bit represent that there was an access error during an input data transfer.

[Clearing condition]
This bit is cleared when writing a '1' to **FRAES.IAE**.

[Setting condition]
This bit is set when a URAM access error was detected during an input transfer and the bits **FRAES.OAE**, **FRAES.FAE** and **FRAES.MAE** are '0'.

(5) **FRAES.EIDX**

Error InDeX

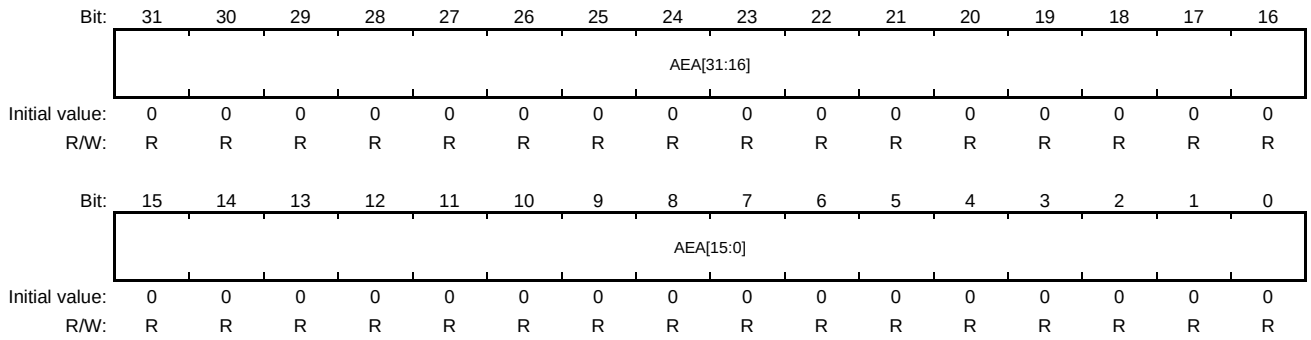
This value is only valid when one of the bits **FRAES.FAE**, **FRAES.OAE** or **FRAES.IAE** is '1'.

When the bit **FRAES.FAE** is '1', **FRAES.EIDX** holds the used FIFO put index when the access error has occurred.
When the bit **FRAES.OAE** is '1', **FRAES.EIDX** holds the used output table entry (which is related to message buffer number) when the access error has occurred.
When the bit **FRAES.IAE** is '1', **FRAES.EIDX** holds the used input pointer table get index when the access error has occurred during the input transfer or user requested input transfer.

These bits are updated when one of the bits **FRAES.FAE**, **FRAES.OAE** or **FRAES.IAE** is changing from '0' to '1'.

### 103.2.13.4 FRAEA [h'082C]

FlexRay Access Error Address register



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:0] | AEA | 0 | R | Access Error Address<br>Address in the URAM when an access error has occurred |

(1) **FRAEA.AEA**

Access Error Address

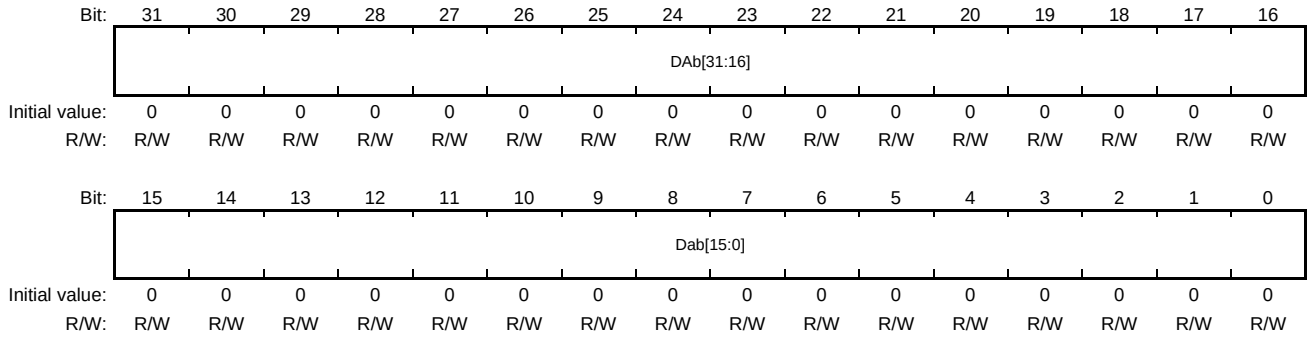
This value is only valid when one of the bits **FRAES.FAE**, **FRAES.OAE** or **FRAES.IAE** is '1'.

These bits represent the address of the access error indicated in the **FRAES** register.

These bits are updated when one of the bits **FRAES.FAE**, **FRAES.OAE** or **FRAES.IAE** is changing from '0' to '1'.

### 103.2.13.5 FRDAi (i=0 to 3) [h'0830 – h'083C]

FlexRay message Data Available register i (i 0 to 3)



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| [31:0] | DAb | 0 | R/W | Data Available b<br>0 : No data available for destination<br>1 : Data available for destination |

(1) **FRDAi.DAb (b = i*32 to ((i+1)*32)-1)**

Data Available b

The user should not write a '1' to bits that are '0'.
To maintain the status of input transfers, the user should not clear bits related to input transfers.

This register is used for input and output transfers.
Each flag corresponds to a FlexRay message buffer.

[Clearing condition]
Input transfer:
This bit is cleared when the input data structure has been transferred from the URAM. The data structure and the data structure pointer can be changed when the related flag is '0'.

Output transfer:
This bit is cleared when writing a '1' to it.

[Setting condition]
Input transfer:
This bit is set when the corresponding message buffer number has been written to **FRIQC.IMBNR**.
As long as this bit is '1', the input data structure and the data structure pointer corresponding to this input transfer request should not be changed.

Output transfer:
This bit is set when the output data structure corresponding to this message buffer has been updated.
As long as this bit is '1', the data structure is stable; no further update of the data structure will be done by the output handler. While this bit is '1', the application is allowed to change the output data structure pointer in the output pointer table for this message buffer number.

## 103.3 Operation

This chapter describes the FlexRay implementation together with the related FlexRay protocol features. More information about the FlexRay protocol itself can be found in the FlexRay protocol specification [FR_PROT].

### 103.3.1 FlexRay module operation control

#### 103.3.1.1 FlexRay Module enable

After hardware reset or after the FlexRay module has been disabled (following section 103.3.1.2) the FlexRay module is in the reset state (**FROS.OS** is '0') and the clocks of the FlexRay core module are disabled.

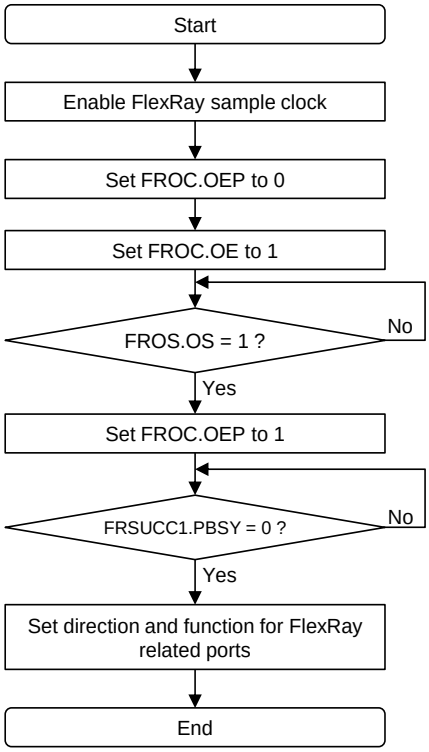


**Figure 103.3 FlexRay enable flow**

#### 103.3.1.2 FlexRay Module disable

The FlexRay module can be disabled at any time. However, it is recommended to disable the FlexRay module using the **FROC.OE** register only when the FlexRay module is in HALT, CONFIG or DEFAULT_CONFIG state. Resetting the FlexRay module in any other state will terminate any ongoing FlexRay communication.
If the data transfer function is used, it is also required to disable this function before disabling the FlexRay module (see section 103.3.16.1.(1) for suspending input transfer function and section 103.3.16.2.(1) for suspending output transfer).
The following flow should be executed to disable the FlexRay module.

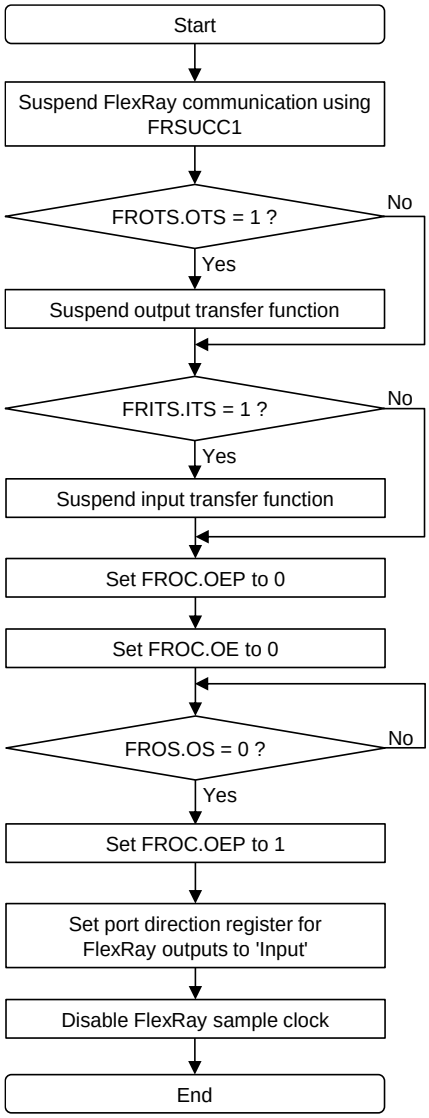

**Figure 103.3.1 FlexRay disable flow**

### 103.3.2 Communication Cycle

Communication on FlexRay networks is based on frames and symbols. The wakeup symbol (WUS) and the collision avoidance symbol (CAS) are transmitted outside the communication cycle to setup the time schedule. Frames and media access test symbols (MTS) are transmitted inside the communication cycle.

A FlexRay communication cycle consists of the following elements:

Static Segment

Dynamic Segment (optional)

Symbol Window (optional)

Network Idle Time (NIT)

Static segment, dynamic segment, and symbol window form the Network Communication Time (NCT). For each communication channel the slot counter starts at 1 and counts up until the end of the dynamic segment is reached. Both channels share the same arbitration grid which means that they use the same synchronized macrotick.

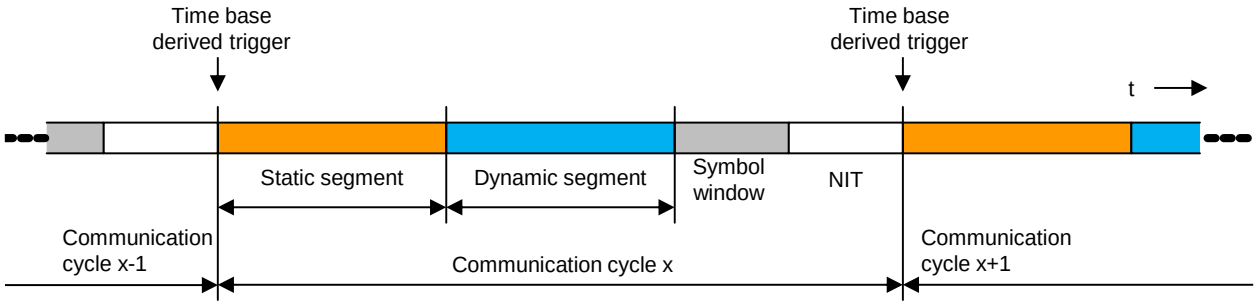

**Figure 103.4 Structure of communication cycle**

#### 103.3.2.1 Static Segment

The Static Segment is characterized by the following features:

Time slots of fixed length (optionally protected by bus guardian)

Start of frame transmission at action point of the respective static slot

Payload length same for all frames on both channels

Parameters:

Number of Static Slots **FRGTUC7.NSS**, Static Slot Length **FRGTUC7.SSL**, Payload Length Static **FRMHDC.SFDL**, Action Point Offset **FRGTUC9.APO**

#### 103.3.2.2 Dynamic Segment

The Dynamic Segment is characterized by the following features:

All controllers have bus access (no bus guardian protection possible)

Variable payload length and duration of slots, different for both channels

Start of transmission at minislot action point

Parameters:

Number of Minislots **FRGTUC8.NMS**, Minislot Length **FRGTUC8.MSL**, Minislot Action Point Offset **FRGTUC9.MAPO**, Start of Latest Transmit (last minislot) **FRMHDC.SLT**

#### 103.3.2.3 Symbol Window

During the symbol window only one media access test symbol (MTS) may be transmitted per channel. MTS symbols are send in NORMAL_ACTIVE state to test the bus guardian.

The symbol window is characterized by the following features:

Send single symbol

Transmission of the MTS symbol starts at the symbol windows action point

Parameters:

Symbol Window Action Point Offset **FRGTUC9.APO** (same as for static slots), Network Idle Time Start **FRGTUC4.NIT**

#### 103.3.2.4 Network Idle Time (NIT)

During network idle time the CC has to perform the following tasks:

Calculate clock correction terms (offset and rate)

Distribute offset correction over multiple macroticks after offset correction start

Perform cluster cycle related tasks
Parameters:

Network Idle Time Start **FRGTUC4.NIT**, Offset Correction Start **FRGTUC4.OCS**

#### 103.3.2.5 Configuration of NIT Start and Offset Correction Start

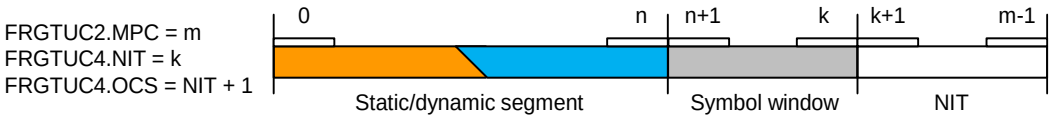

**Figure 103.5 Configuration of NIT start and offset correction start**

The number of macroticks per cycle gMacroPerCycle is assumed to be m. It is configured by programming **FRGTUC2.MPC** = m.

The static / dynamic segment starts with macrotick 0 and ends with macrotick n:
n = static segment length + dynamic segment offset + dynamic segment length - 1MT
n = gNumberOfStaticSlots • gdStaticSlot + dynamic segment offset + gNumberOfMinislots • gdMinislot - 1 MT

The static segment length is configured by **FRGTUC7.SSL** and **FRGTUC7.NSS**.
The dynamic segment length is configured by **FRGTUC8.MSL** and **FRGTUC8.NMS**.

The dynamic segment offset is:
If gdActionPointOffset <= gdMinislotActionPointOffset:

dynamic segment offset = 0 MT

Else if gdActionPointOffset > gdMinislotActionPointOffset:

dynamic segment offset = gdActionPointOffset -gdMinislotActionPointOffset

The NIT starts with macrotick k+1 and ends with the last macrotick of cycle m-1. It has to be configured by setting **FRGTUC4.NIT** = k.

For the FlexRay module the offset correction start is required to be **FRGTUC4.OCS** => **FRGTUC4.NIT** + 1 = k+1.

The length of symbol window results from the number of macroticks between the end of the static / dynamic segment and the beginning of the NIT. It can be calculated by k - n.

### 103.3.3 Communication Modes

The FlexRay Protocol Specification [FR_PROT] defines the Time-Triggered Distributed (TT-D) mode.

#### 103.3.3.1 Time-triggered Distributed (TT-D)

In TT-D mode the following configurations are possible:

Pure static: Minimum 2 static slots + symbol window (optional)

Mixed static/dynamic: Minimum 2 static slots + dynamic segment + symbol window (optional)
A minimum of two coldstart nodes needs to be configured for distributed time-triggered operation. Two fault-free coldstart nodes are necessary for the cluster startup. Each startup frame must be a sync frame, therefore all coldstart nodes are sync nodes.

### 103.3.4 Clock Synchronization

In TT-D mode a distributed clock synchronization is used. Each node individually synchronizes itself to the cluster by observing the timing of received sync frames from other nodes.

#### 103.3.4.1 Global Time

Activities in a FlexRay node, including communication, are based on the concept of a global time, even though each individual node maintains its own view of it. It is the clock synchronization mechanism that differentiates the FlexRay cluster from other node collections with independent clock mechanisms. The global time is a vector of two values; the cycle (cycle counter) and the cycle time (macrotick counter).

**Cluster specific:**

Macrotick (MT) = basic unit of time measurement in a FlexRay network, a macrotick consists of an integer number of microticks (µT)

Cycle length = duration of a communication cycle in units of macroticks (MT)

#### 103.3.4.2 Local Time

Internally, nodes time their behaviour with microtick resolution. Microticks are time units derived from the oscillator clock tick of the specific node. Therefore microticks are controller-specific units. They may have different duration in different controllers. The precision of a node's local time difference measurements is a microtick (µT).

**Node specific:**

Oscillator clock -> prescaler -> microtick (µT)

µT = basic unit of time measurement in a CC, clock correction is done in units of µTs

Cycle counter + macrotick counter = nodes local view of the global time

#### 103.3.4.3 Synchronization Process

Clock synchronization is performed by means of sync frames. Only preconfigured nodes (sync nodes) are allowed to send sync frames. In a two-channel cluster a sync node has to send its sync frame on both channels.

For synchronization in FlexRay the following constraints have to be considered:

Max. one sync frame per node in one communication cycle

Max. 15 sync frames per cluster in one communication cycle

Every node has to use a preconfigured number of sync frames (**FRGTUC2.SNM**) for clock synchronization

Minimum of two sync nodes required for clock synchronization and startup

For clock synchronization the time difference between expected and observed arrival time of sync frames received during the static segment is measured. In a two channel cluster the sync node has to be configured to send sync frames on both channels. The calculation of correction terms is done during NIT (offset: every cycle, rate: every odd cycle) by using an FTM algorithm. For details see FlexRay protocol specification [FR_PROT], chapter 8.

(1) **Offset (phase) Correction**

Only deviation values measured and stored in the current cycle used

For a two channel node the smaller value will be taken

Calculation during NIT of every communication cycle

Offset correction value calculated in even cycles used for error checking only

Checked against limit values

Correction value is a signed integer number of µTs

Correction done in odd numbered cycles, distributed over the macroticks beginning at offset correction start up to cycle end (end of NIT) to shift nodes next start of cycle (MTs lengthened / shortened)

(2) **Rate (frequency) Correction**

Pairs of deviation values measured and stored in even / odd cycle pair used
For a two channel node the average of the differences from the two channels is used
Calculated during NIT of odd numbered cycles
Cluster drift damping is performed using global damping value
Checked against limit values
Correction value is a signed integer number of µTs
Distributed over macroticks comprising the next even / odd cycle pair (MTs lengthened / shortened)

(3) **Sync Frame Transmission**

Sync frame transmission is only possible from Message buffer 0 and 1. Message buffer 1 may be used for sync frame transmission in case that sync frames should have different payloads on the two channels. In this case bit **FRMRC.SPLM** has to be programmed to '1'.

Message buffers used for sync frame transmission have to be configured with the key slot ID and can be (re)configured in DEFAULT_CONFIG or CONFIG state only. For nodes transmitting sync frames **FRSUCC1.TXSY** must be set to '1'.

(4) **External Clock Synchronization**

During normal operation, independent clusters can drift significantly. If synchronous operation across independent clusters is desired, external synchronization is necessary; even though the nodes within each cluster are synchronized. This can be accomplished with synchronous application of host-deduced rate and offset correction terms to the clusters.

External offset / rate correction value is a signed integer
External offset / rate correction value is added to calculated offset / rate correction value
Aggregated offset / rate correction term (external + internal) is not checked against configured limits

### 103.3.5 Error Handling

The implemented error handling concept is intended to ensure that, in case of a lower layer protocol error in one single node, communication between non-affected nodes can be maintained. In some cases, higher layer program activity is required for the CC to resume normal operation. A change of the error handling state will set **FREIR.PEMC** and may trigger an interrupt to the Host if enabled. The actual error mode is signaled by **FRCCEV.ERRM**.

**Table 103.3 Error modes of the POC (degradation model)**

| Error Mode | Activity |
|---|---|
| ACTIVE | Full operation, State: NORMAL_ACTIVE<br>The CC is fully synchronized and supports the cluster wide clock synchronization. The host is informed of any error condition(s) or status change by interrupt (if enabled) or by reading the error and status interrupt flags from registers **FREIR** and **FRSIR**. |
| PASSIVE | Reduced operation, State: NORMAL_PASSIVE, CC self rescue allowed<br>The CC stops transmitting frames and symbols, but received frames are still processed. Clock synchronization mechanisms are continued based on received frames. No active contribution to the cluster wide clock synchronization. The host is informed of any error condition(s) or status change by interrupt (if enabled) or by reading the error and status interrupt flags from registers **FREIR** and **FRSIR**. |
| COMM_HALT | Operation halted, State: HALT, CC self rescue not allowed<br>The CC stops frame and symbol processing, clock synchronization processing, and the macrotick generation. The host has still access to error and status information by reading the error and status interrupt flags from registers **FREIR** and **FRSIR**. The bus drivers are disabled. |

#### 103.3.5.1 Clock Correction Failed Counter

When the Clock Correction Failed Counter reaches the "maximum without clock correction passive" limit defined by **FRSUCC3.WCP**, the POC transits from NORMAL_ACTIVE to NORMAL_PASSIVE state. When it reaches the "maximum without clock correction fatal" limit defined by **FRSUCC3.WCF**, it transits from NORMAL_ACTIVE or NORMAL_PASSIVE to HALT state.

The Clock Correction Failed Counter **FRCCEV.CCFC** allows the Host to monitor the duration of the inability of a node to compute clock correction terms after the CC passed protocol startup phase. It will be incremented by one at the end of any odd communication cycle during which either the missing offset correction **FRSFS.MOCS** or the missing rate correction **FRSFS.MRCS** flag is set.

The Clock Correction Failed Counter is reset to zero at the end of an odd communication cycle if neither the missing offset correction **FRSFS.MOCS** nor the missing rate correction **FRSFS.MRCS** flag is set.

The Clock Correction Failed Counter stops incrementing when the "maximum without clock correction fatal" value **FRSUCC3.WCF** is reached (i.e. incrementing the counter at its maximum value will not cause it to wrap around back to zero). The Clock Correction Failed Counter is initialized to zero when the CC enters READY state or when NORMAL_ACTIVE state is entered.

Note: The transition to HALT state is prevented if **FRSUCC1.HCSE** is not set.

#### 103.3.5.2 Passive to Active Counter

The passive to active counter controls the transition of the POC from NORMAL_PASSIVE to NORMAL_ACTIVE state. **FRSUCC1.PTA** defines the number of consecutive even / odd cycle pairs that must have valid clock correction terms before the CC is allowed to transit from NORMAL_PASSIVE to NORMAL_ACTIVE state. If **FRSUCC1.PTA** is set to zero the CC is not allowed to transit from NORMAL_PASSIVE to NORMAL_ACTIVE state.

#### 103.3.5.3 HALT Command

In case the Host wants to stop FlexRay communication of the local node it can bring the CC into HALT state by asserting the HALT command. This can be done by writing **FRSUCC1.CMD** = "0110". In order to shut down communication on an entire FlexRay network, a higher layer protocol is required to assure that all nodes apply the HALT command at the same time.

The POC state from which the transition to HALT state took place can be read from **FRCCSV.PSL**.

When called in NORMAL_ACTIVE or NORMAL_PASSIVE state the POC transits to HALT state at the end of the current cycle. When called in any other state **FRSUCC1.CMD** will be reset to "0000" = command_not_accepted and bit **FREIR.CNA** is set to ’1’. If enabled an interrupt to the Host is generated.

#### 103.3.5.4 FREEZE Command

In case the Host detects a severe error condition it can bring the CC into HALT state by asserting the FREEZE command. This can be done by writing **FRSUCC1.CMD** = "0111". The FREEZE command triggers the entry of the HALT state immediately regardless of the actual POC state.

The POC state from which the transition to HALT state took place can be read from **FRCCSV.PSL**.

### 103.3.6 Communication Controller States

#### 103.3.6.1 Communication Controller State Diagram

(1) **Reserved**

(2) **Reserved**

#### 103.3.6.2 DEFAULT_CONFIG State

In DEFAULT_CONFIG state, the CC is stopped. All configuration registers are accessible and the pins to the physical layer are in their inactive state.

The CC enters this state

When the reset is applied (HW reset or SW reset)

When exiting from HALT state
To leave DEFAULT_CONFIG state the Host has to write **FRSUCC1.CMD** = "0001". The CC then transits to CONFIG state.

#### 103.3.6.3 CONFIG State

In CONFIG state, the CC is stopped. All configuration registers are accessible and the pins to the physical layer are in their inactive state. This state is used to initialize the CC configuration.

The CC enters this state

When exiting from DEFAULT_CONFIG state

When exiting from READY state
When the state has been entered via HALT and DEFAULT_CONFIG state, the Host can analyse status information and configuration. Before leaving CONFIG state the Host has to assure that the configuration is fault-free.

To leave CONFIG state, the Host has to perform the unlock sequence as described is section 103.2.2.1. Directly after unlocking the CONFIG state the Host has to write **FRSUCC1.CMD** to enter the next state.

**Note:** Status bits **FRMHDS[14:0]**, registers **FRTXRQ1/2/3/4**, and status data stored in the Message RAM are not affected by the transition of the POC from CONFIG to READY state.

When the CC is in CONFIG state it is also possible to bring the CC into a power saving mode by halting the module clocks (bus clock and sample clock). To do this the Host has to assure that all Message RAM transfers have finished before turning off the clocks.

#### 103.3.6.4 READY State

After unlocking CONFIG state and writing **FRSUCC1.CMD** = "0010" the CC enters READY state. From this state the CC can transit to WAKEUP state and perform a cluster wakeup or to STARTUP state to perform a coldstart or to integrate into a running cluster.

The CC enters this state

When exiting from CONFIG, WAKEUP, STARTUP, NORMAL_ACTIVE, or NORMAL_PASSIVE state by writing **FRSUCC1.CMD** = "0010" (READY command).

The CC exits from this state

To CONFIG state by writing **FRSUCC1.CMD** = "0001" (CONFIG command)

To WAKEUP state by writing **FRSUCC1.CMD** = "0011" (WAKEUP command)

To STARTUP state by writing **FRSUCC1.CMD** = "0100" (RUN command)
Internal counters and the CC status flags are reset when the CC enters STARTUP state.

**Note:** Status bits **FRMHDS[14:0]**, registers **FRTXRQ1/2/3/4**, and status data stored in the Message RAM are not affected by the transition of the POC from READY to STARTUP state.

### 103.3.6.5 WAKEUP State

The description below is intended to help configuring wakeup for the FlexRay IP-module. A detailed description of the wakeup procedure together with the respective SDL diagrams can be found in the FlexRay protocol specification [FR_PROT], section 7.1.

The CC enters this state

When exiting from READY state by writing **FRSUCC1.CMD** = "0011" (WAKEUP command).
The CC exits from this state to READY state

After complete non-aborted transmission of wakeup pattern

After WUP reception

After detecting a WUP collision

After reception of a frame header

By writing **FRSUCC1.CMD** = "0010" (READY command)
The cluster wakeup must precede the communication startup in order to ensure that all nodes in a cluster are awake. The minimum requirement for a cluster wakeup is that all bus drivers are supplied with power. A bus driver has the ability to wake up the other components of its node when it receives a wakeup pattern on its channel. At least one node in the cluster needs an external wakeup source.

The Host completely controls the wakeup procedure. It is informed about the state of the cluster by the bus driver and the CC and configures bus guardian (if available) and CC to perform the cluster wakeup. The CC provides to the Host the ability to transmit a special wakeup pattern on each of its available channels separately. The CC needs to recognize the wakeup pattern only during WAKEUP state.

Wakeup may be performed on only one channel at a time. The Host has to configure the wakeup channel while the CC is in CONFIG state by writing **FRSUCC1.WUCS**. The CC ensures that ongoing communication on this channel is not disturbed. The CC cannot guarantee that all nodes connected to the configured channel awake upon the transmission of the wakeup pattern, since these nodes cannot give feedback until the startup phase. The wakeup procedure enables single-channel devices in a two-channel system to trigger the wakeup, by only transmitting the wakeup pattern on the single channel to which they are connected. Any coldstart node that deems a system startup necessary will then wake the remaining channel before initiating communication startup.

The wakeup procedure tolerates any number of nodes simultaneously trying to wakeup a single channel and resolves this situation such that only one node transmits the pattern. Additionally the wakeup pattern is collision resilient, so even in the presence of a fault causing two nodes to simultaneously transmit a wakeup pattern, the resulting collided signal can still wake the other nodes.

After wakeup the CC returns to READY state and signals the change of the wakeup status to the Host by setting flag **FRSIR.WST**. The wakeup status vector can be read from **FRCCSV.WSV**. If a valid wakeup pattern was received also either flag **FRSIR.WUPA** or flag **FRSIR.WUPB** is set.

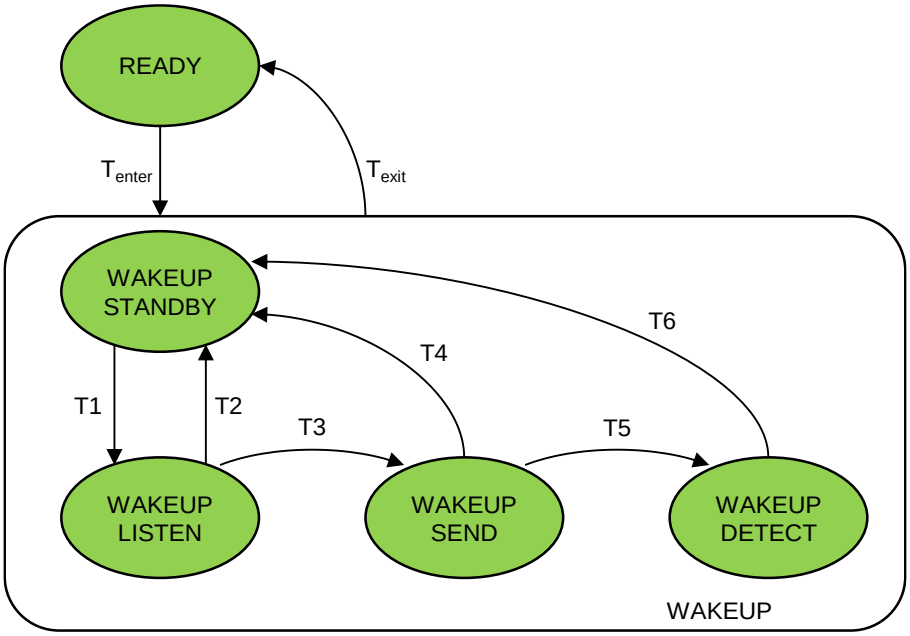

**Figure 103.6 Structure of POC state WAKEUP**

**Table 103.6 State transitions WAKEUP**

| T# | Condition | From | To |
|---|---|---|---|
| enter | Host commands change to WAKEUP state by writing **FRSUCC1.CMD** = "0011" (WAKEUP command) | READY | WAKEUP |
| 1 | CHI command WAKEUP triggers wakeup FSM to transit to WAKEUP_LISTEN state | WAKEUP_STANDBY | WAKEUP_LISTEN |
| 2 | Received WUP on wakeup channel selected by bit **FRSUCC1.WUCS** OR frame header on either available channel | WAKEUP_LISTEN | WAKEUP_STANDBY |
| 3 | Timer event | WAKEUP_LISTEN | WAKEUP_SEND |
| 4 | Complete, non-aborted transmission of wakeup pattern | WAKEUP_SEND | WAKEUP_STANDBY |
| 5 | Collision detected | WAKEUP_SEND | WAKEUP_DETECT |
| 6 | Wakeup timer expired OR WUP detected on wakeup channel selected by bit **FRSUCC1.WUCS** OR frame header received on either available | WAKEUP_DETECT | WAKEUP_STANDBY |
| exit | Wakeup completed (after T2 or T4 or T6) OR Host commands change to READY state by writing **FRSUCC1.CMD** = "0010" (READY command). This command also resets the wakeup FSM to WAKEUP_STANDBY state | WAKEUP | READY |

The WAKEUP_LISTEN state is controlled by the wakeup timer and the wakeup noise timer. The two timers are controlled by the parameters listen timeout **FRSUCC2.LT** and listen timeout noise **FRSUCC2.LTN**. Listen timeout enables a fast cluster wakeup in case of a noise free environment, while listen timeout noise enables wakeup under more difficult conditions regarding noise interference.

In WAKEUP_SEND state the CC transmits the wakeup pattern on the configured channel and checks for collisions. After return from wakeup the Host has to bring the CC into STARTUP state by CHI command RUN.

In WAKEUP_DETECT state the CC attempts to identify the reason for the wakeup collision detected in WAKEUP_SEND state. The monitoring is bounded by the expiration of listen timeout as configured by **FRSUCC2.LT**. Either the detection of a wakeup pattern indicating a wakeup attempt by another node or the reception of a frame header

indicating ongoing communication, causes the direct transition to READY state. Otherwise WAKEUP_DETECT is left after expiration of listen timeout; in this case the reason for wakeup collision is unknown.

The Host has to be aware of possible failures of the wakeup and act accordingly. It is advisable to delay any potential startup attempt of the node having instigated the wakeup by the minimal time it takes another coldstart node to become awake and to be configured.

The FlexRay Protocol Specification [FR_PROT] recommends that two different CCs shall awake the two channels.

(1) **Host activities**

The host must coordinate the wakeup of the two channels and must decide whether, or not, to wake a specific channel. The sending of the wakeup pattern is initiated by the Host. The wakeup pattern is detected by the remote BDs and signaled to their local Host.

**Wakeup procedure controlled by Host (single-channel wakeup):**

Configure the CC in CONFIG state
- Select wakeup channel by programming bit **FRSUCC1.WUCS**

Check local BDs whether a WUP was received

Activate BD of selected wakeup channel

Command CC to enter READY state

Command CC to start wakeup on the configured channel by writing **FRSUCC1.CMD** = "0011"
- CC enters WAKEUP
- CC returns to READY state and signals status of wakeup attempt to the Host

Wait predefined time to allow the other nodes to wakeup and configure themselves

Coldstart node:
- In a dual channel cluster wait for WUP on the other channel
- Reset coldstart inhibit flag **FRCCSV.CSI** by writing **FRSUCC1.CMD** = "1001" (ALLOW_COLDSTART command)

Command CC to enter startup by writing **FRSUCC1.CMD** = "0100" (RUN command)

**Wakeup procedure triggered by BD:**

Wakeup recognized by BD

BD triggers power-up of Host (if required)

BD signals wakeup event to Host

Host configures its local CC

If necessary, Host commands wakeup of second channel and waits predefined time to allow the other nodes to wakeup and configure themselves

Host commands CC to enter STARTUP state by writing **FRSUCC1.CMD** = "0100" (RUN command)

(2) **Wakeup pattern (WUP)**

The wakeup pattern (WUP) is composed of at least two wakeup symbols (WUS). Wakeup symbol and wakeup pattern are configured by registers **FRPRTC1** and **FRPRTC2**.

Single channel wakeup, wakeup symbol may not be sent on both channels at the same time

Wakeup symbol collision resilient for at least two sending nodes (two overlapping wakeup symbols always recognizable)

Wakeup symbol must be configured identical in all nodes of a cluster

Wakeup symbol transmit low time configured by **FRPRTC2.TXL**

Wakeup symbol idle time used to listen for activity on the bus, configured by **FRPRTC2.TXI**

A wakeup pattern composed of at least two Tx-wakeup symbols needed for wakeup

Number of repetitions configurable by **FRPRTC1.RWP** (2 to 63 repetitions)

Wakeup symbol receive window length configured by **FRPRTC1.RXW**

Wakeup symbol receive low time configured by **FRPRTC2.RXL**

Wakeup symbol receive idle time configured by **FRPRTC2.RXI**

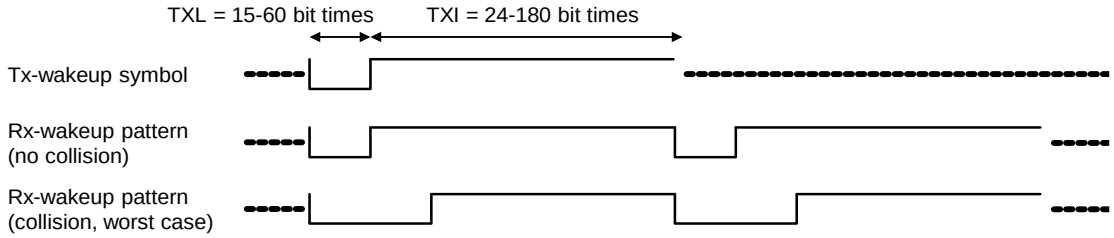

**Figure 103.7 Timing of wakeup pattern**

#### 103.3.6.6 STARTUP State

The description below is intended to help configuring startup for the FlexRay IP-module. A detailed description of the startup procedure together with the respective SDL diagrams can be found in the FlexRay protocol specification [FR_PROT], section 7.2.

Any node entering STARTUP state that has coldstart capability should assure that both channels attached have been awakened before initiating coldstart.

It cannot be assumed that all nodes and stars need the same amount of time to become completely awake and to be configured. Since at least two nodes are necessary to start up the cluster communication, it is advisable to delay any potential startup attempt of the node having instigated the wakeup by the minimal amount of time it takes another coldstart node to become awake, to be configured and to enter startup. It may require several hundred milliseconds (depending on the hardware used) before all nodes and stars are completely awakened and configured.

Startup is performed on all channels synchronously. During startup, a node only transmits startup frames. Startup frames are both sync frames and null frames during startup.

A fault-tolerant, distributed startup strategy is specified for initial synchronization of all nodes. In general, a node may enter NORMAL_ACTIVE state via (see Figure 103.8):

Coldstart path initiating the schedule synchronization (leading coldstart node)

Coldstart path joining other coldstart nodes (following coldstart node)

Integration path integrating into an existing communication schedule (all other nodes)

A coldstart attempt begins with the transmission of a collision avoidance symbol (CAS). Only a coldstart node that had transmitted the CAS transmits frames in the first four cycles after the CAS, it is then joined firstly by the other coldstart nodes and afterwards by all other nodes.

A coldstart node has bits **FRSUCC1.TXST** and **FRSUCC1.TXSY** set to ’1’. Message buffer 0 holds the key slot ID which defines the slot number where the startup frame is send. In the frame header of the startup frame the startup frame indicator bit is set.

In clusters consisting of three or more nodes, at least three nodes shall be configured to be coldstart nodes. In clusters consisting of two nodes, both nodes must be coldstart nodes. At least two fault-free coldstart nodes are necessary for the cluster to startup.

Each startup frame must also be a sync frame; therefore each coldstart node will also be a sync node. The number of coldstart attempts is configured by **FRSUCC1.CSA**.

A non-coldstart node requires at least two startup frames from distinct nodes for integration. It may start integration before the coldstart nodes have finished their startup. It will not finish its startup until at least two coldstart nodes have finished their startup.

Both non-coldstart nodes and coldstart nodes start passive integration via the integration path as soon as they receive sync frames from which to derive the TDMA schedule information. During integration, the node has to adapt its own clock to the global clock (rate and offset) and has to make its cycle time consistent with the global schedule observable at the network. Afterwards, these settings are checked for consistency with all available network nodes. The node can only leave the integration phase and actively participate in communication when these checks are passed.

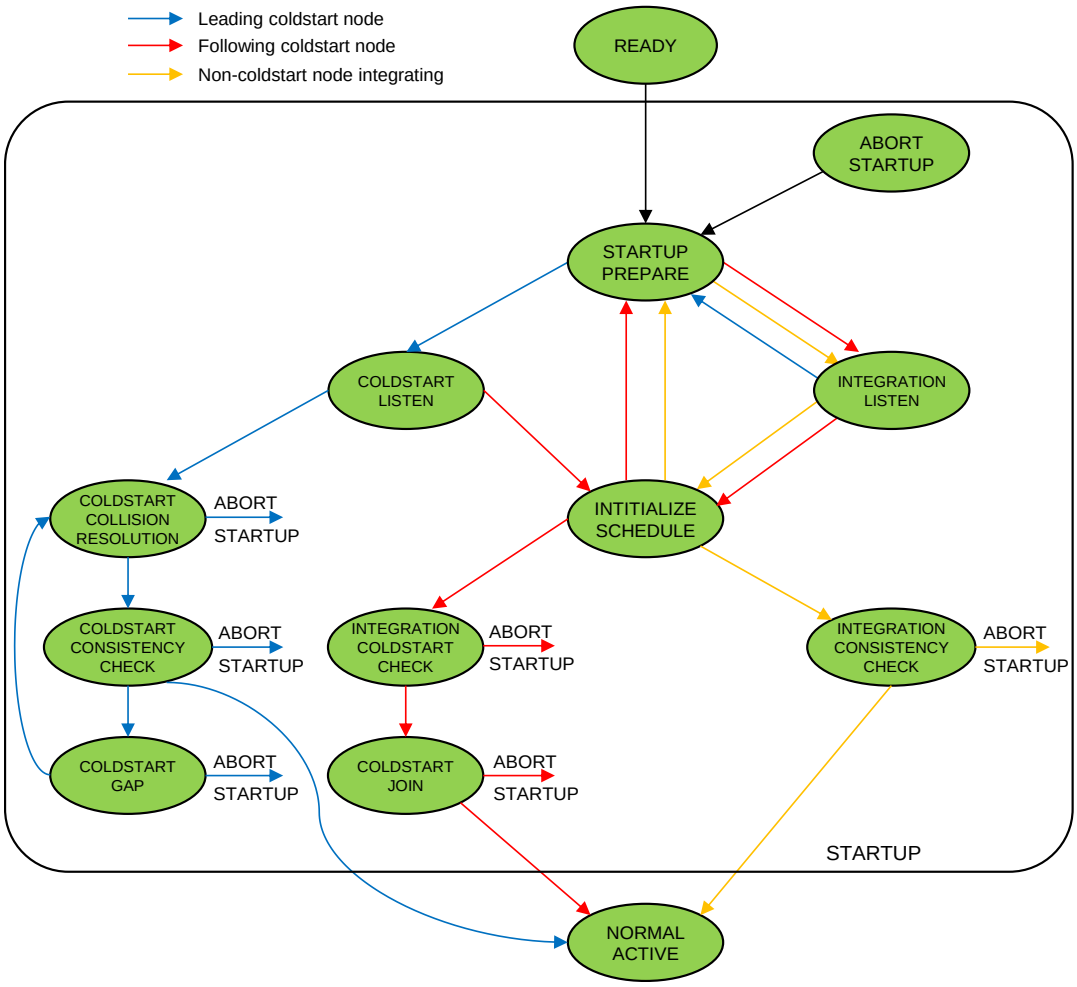

**Figure 103.8 State diagram time-triggered startup**

(1) **Coldstart Inhibit Mode**

In coldstart inhibit mode the node is prevented from initializing the TDMA communication schedule. If bit **FRCCSV.CSI** is set, the node is not allowed to initialize the cluster communication, i.e. entering the coldstart path is prohibited. The node is allowed to integrate to a running cluster or to transmit startup frames after another coldstart node started the initialization of the cluster communication.

The coldstart inhibit bit **FRCCSV.CSI** is set whenever the POC enters READY state. The bit has to be cleared under control of the Host by CHI command ALLOW_COLDSTART (**FRSUCC1.CMD** = "1001")

(2) **Startup Timeouts**

The CC supplies two different µT timers supporting two timeout values, startup timeout and startup noise timeout. The two timers are started when the CC enters the COLDSTART_LISTEN state. The expiration of either of these timers causes the node to leave the initial sensing phase (COLDSTART_LISTEN state) with the intention of starting up communication.

**Note:** The startup and startup noise timers are identical with the wakeup and wakeup noise timers and use the same configuration values **FRSUCC2.LT** and **FRSUCC2.LTN**.

**(a) Startup Timeout**

The startup timeout limits the listen time used by a node to determine if there is already communication between other nodes or at least one coldstart node actively requesting the integration of others. The startup timer is configured by programming **FRSUCC2.LT** (see section 103.2.5.2 ).

The startup timeout is:
pdListenTimeout = **FRSUCC2.LT**

The startup timer is restarted upon:

Entering the COLDSTART_LISTEN state

Both channels reaching idle state while in COLDSTART_LISTEN state
The startup timer is stopped:

If communication channel activity is detected on one of the configured channels while the node is in the COLDSTART_LISTEN state

When the COLDSTART_LISTEN state is left
Once the startup timeout expires, neither an overflow nor a cyclic restart of the timer is performed. The timer status is kept for further processing by the startup state machine.

**(b) Startup Noise Timeout**

At the same time the startup timer is started for the first time (transition from STARTUP_PREPARE state to COLDSTART_LISTEN state), the startup noise timer is started. This additional timeout is used to improve reliability of the startup procedure in the presence of noise. The startup noise timeout is configured by programming **FRSUCC2.LTN** (see section 103.2.5.2).

The startup noise timeout is:
pdListenTimeout * gListenNoise = **FRSUCC2.LT** * (**FRSUCC2.LTN** + 1)

The startup noise timer is restarted upon:

Entering the COLDSTART_LISTEN state

Reception of correctly decoded headers or CAS symbols while the node is in COLDSTART_LISTEN state
The startup noise timer is stopped when the COLDSTART_LISTEN state is left.

Once the startup noise timeout expires, neither an overflow nor a cyclic restart of the timer is performed. The status is kept for further processing by the startup state machine. Since the startup noise timer won't be restarted when random

channel activity is sensed, this timeout defines the fall-back solution that guarantees that a node will try to start up the communication cluster even in the presence of noise.

(3) **Path of leading Coldstart Node (initiating coldstart)**

When a coldstart node enters COLDSTART_LISTEN, it listens to its attached channels.

If no communication is detected, the node enters the COLDSTART_COLLISION_RESOLUTION state and commences a coldstart attempt. The initial transmission of a CAS symbol is succeeded by the first regular cycle. This cycle has the number zero.

From cycle zero on, the node transmits its startup frame. Since each coldstart node may perform a coldstart attempt, it may occur that several nodes simultaneously transmit the CAS symbol and enter the coldstart path. This situation is resolved during the first four cycles after CAS transmission.

As soon as a node that initiates a coldstart attempt receives a CAS symbol or a frame header during these four cycles, it re-enters the COLDSTART_LISTEN state. Thereby, only one node remains in this path. In cycle four, other coldstart nodes begin to transmit their startup frames.

After four cycles in COLDSTART_COLLISION_RESOLUTION state, the node that initiated the coldstart enters the COLDSTART_CONSISTENCY_CHECK state. It collects all startup frames from cycle four and five and performs the clock correction. If the clock correction does not deliver any errors and it has received at least one valid startup frame pair, the node leaves COLDSTART_CONSISTENCY_CHECK and enters NORMAL_ACTIVE state.

The number of coldstart attempts that a node is allowed to perform is configured by **FRSUCC1.CSA**. The number of remaining coldstarts attempts can be read from **FRCCSV.RCA**. The number of remaining coldstart attempts is reduced by one for each attempted coldstart. A node may enter the COLDSTART_LISTEN state only if this value is larger than one and it may enter the COLDSTART_COLLISION_RESOLUTION state only if this value is larger than zero. If the number of coldstart attempts is one, coldstart is inhibited but integration is still possible.

(4) **Path of following Coldstart Node (responding to leading Coldstart Node)**

When a coldstart node enters the COLDSTART_LISTEN state, it tries to receive a valid pair of startup frames to derive its schedule and clock correction from the leading coldstart node.

As soon as a valid startup frame has been received the INITIALIZE_SCHEDULE state is entered. If the clock synchronization can successfully receive a matching second valid startup frame and derive a schedule from this, the INTEGRATION_COLDSTART_CHECK state is entered.

In INTEGRATION_COLDSTART_CHECK state it is assured that the clock correction can be performed correctly and that the coldstart node from which this node has initialized its schedule is still available. The node collects all sync frames and performs clock correction in the following double-cycle. If clock correction does not signal any errors and if the node continues to receive sufficient frames from the same node it has integrated on, the COLDSTART_JOIN state is entered.

In COLDSTART_JOIN state following coldstart nodes begin to transmit their own startup frames and continue to do so in subsequent cycles. Thereby, the leading coldstart node and the nodes joining it can check if their schedules agree with each other. If the clock correction signals any error, the node aborts the integration attempt. If a node in this state sees at least one valid startup frame during all even cycles in this state and at least one valid startup frame pair during all double cycles in this state, the node leaves COLDSTART_JOIN state and enters NORMAL_ACTIVE state. Thereby it leaves STARTUP at least one cycle after the node that initiated the coldstart.

(5) **Path of Non-coldstart Node**

When a non-coldstart node enters the INTEGRATION_LISTEN state, it listens to its attached channels.

As soon as a valid startup frame has been received, the INITIALIZE_SCHEDULE state is entered. If the clock synchronization can successfully receive a matching second valid startup frame and derive a schedule from this, the INTEGRATION_CONSISTENCY_CHECK state is entered.

In INTEGRATION_CONSISTENCY_CHECK state the node verifies that the clock correction can be performed correctly and that enough coldstart nodes (at least 2) are sending startup frames that agree with the node's own schedule. Clock correction is activated, and if any errors are signaled, the integration attempt is aborted.

During the first even cycle in this state, either two valid startup frames or the startup frame of the node that this node has integrated on must be received; otherwise the node aborts the integration attempt.

During the first double-cycle in this state, either two valid startup frame pairs or the startup frame pair of the node that this node has integrated on must be received; otherwise the node aborts the integration attempt.

If after the first double-cycle less than two valid startup frames are received within an even cycle, or less than two valid startup frame pairs are received within a double-cycle, the startup attempt is aborted.

Nodes in this state need to see two valid startup frame pairs for two consecutive double-cycles each to be allowed to leave STARTUP and enter NORMAL_OPERATION. Consequently, they leave startup at least one double-cycle after the node that initiated the coldstart and only at the end of a cycle with an odd cycle number.

#### 103.3.6.7 NORMAL_ACTIVE State

As soon as the node that transmitted the first CAS symbol (resolving the potential access conflict and entering STARTUP via coldstart path) and one additional node have entered the NORMAL_ACTIVE state, the startup phase for the cluster has finished. In the NORMAL_ACTIVE state, all configured messages are scheduled for transmission. This includes all data frames as well as the sync frames. Rate and offset measurement is started in all even cycles (even / odd cycle pairs required).

In NORMAL_ACTIVE state the CC supports regular communication functions

The CC performs transmissions and reception on the FlexRay bus as configured

Clock synchronization is running

The Host interface is operational

The CC exits from that state to

HALT state by writing **FRSUCC1.CMD** = "0110" (HALT command, at the end of the current cycle)

HALT state by writing **FRSUCC1.CMD** = "0111" (FREEZE command, immediately)

HALT state due to change of the error state from ACTIVE to COMM_HALT

NORMAL_PASSIVE state due to change of the error state from ACTIVE to PASSIVE

READY state by writing **FRSUCC1.CMD** = "0010" (READY command)

#### 103.3.6.8 NORMAL_PASSIVE State

NORMAL_PASSIVE state is entered from NORMAL_ACTIVE state when the error state changes from ACTIVE to PASSIVE.

In NORMAL_PASSIVE state, the node is able to receive all frames (node is fully synchronized and performs clock synchronization). Contrary to the NORMAL_ACTIVE state, the node does not actively participate in communication, i.e. neither symbols nor frames are transmitted.

In NORMAL_PASSIVE state

The CC performs reception on the FlexRay bus

The CC does not transmit any frames or symbols on the FlexRay bus

Clock synchronization is running

The Host interface is operational

The CC exits from this state to
HALT state by writing **FRSUCC1.CMD** = "0110" (HALT command, at the end of the current cycle)
HALT state by writing **FRSUCC1.CMD** = "0111" (FREEZE command, immediately)
HALT state due to change of the error state from PASSIVE to COMM_HALT
NORMAL_ACTIVE state due to change of the error state from PASSIVE to ACTIVE. The transition takes place when **FRCCEV.PTAC** equals **FRSUCC1.PTA** - 1
To READY state by writing **FRSUCC1.CMD** = "0010" (READY command)

#### 103.3.6.9 HALT State

In this state all communication (reception and transmission) is stopped.

The CC enters this state
By writing **FRSUCC1.CMD** = "0110" (HALT command) while the CC is in NORMAL_ACTIVE or NORMAL_PASSIVE state
By writing **FRSUCC1.CMD** = "0111" (FREEZE command) from all states
When exiting from NORMAL_ACTIVE state because the clock correction failed counter reached the "maximum without clock correction fatal" limit and **FRSUCC1.HCSE** is set
When exiting from NORMAL_PASSIVE state because the clock correction failed counter reached the "maximum without clock correction fatal" limit and **FRSUCC1.HCSE** is set
The CC exits from this state to DEFAULT_CONFIG state
By writing **FRSUCC1.CMD** = "0001" (CONFIG command)
When the CC enters HALT state, all configuration and status data is maintained for analysing purposes.

When the Host writes **FRSUCC1.CMD** = "0110" (HALT command), the CC sets bit **FRCCSV.HRQ** and enters HALT state at the next end of cycle.

When the Host writes **FRSUCC1.CMD** = "0111" (FREEZE command), the CC enters HALT state immediately and sets bit **FRCCSV.FSI**.

The POC state from which the transition to HALT state took place can be read from **FRCCSV.PSL**.

### 103.3.7 Network Management

The accrued Network Management (NM) vector can be read from registers **FRNMV1/2/3**. The CC performs a bit-wise OR operation over all NM vectors out of all received valid NM frames with the Payload Preamble Indicator (PPI) bit set. Only static frames may be configured to hold NM information. The CC updates the NM vector at the end of each cycle.

The length of the NM vector can be configured from 0 to 12 bytes by **FRNEMC.NML**. The NM vector length must be configured identically in all nodes of a cluster.

To configure a transmit buffer to send FlexRay frames with the PPI bit set, bit PPIT in the header section of the respective transmit buffer has to be set via **FRWRHS1.PPIT**. In addition the Host has to write the NM information to the data section of the respective transmit buffer.

The evaluation of the NM vector has to be done by the application running on the Host.

For information about the byte alignment of the received NM vector in the **FRNMV1/2/3** registers see section 103.3.17.

**Note 1:** In case a message buffer is configured for transmission / reception of network management frames, the payload length configured in header 2 of that message buffer should be equal or greater than the length of the NM vector configured by **FRNEMC.NML**.

**Note 2:** When the CC transits to HALT state, the cycle count is not incremented and therefore the NM vector is not updated. In this case **FRNMV1/2/3** holds the value from the cycle before.

### 103.3.8 Filtering and Masking

Filtering is done by comparison of the configuration of assigned message buffers against actual slot and cycle counter values and channel ID (channel A, B). A message buffer is only updated / transmitted if the required matches occur.

Filtering is done on:

Slot Counter

Cycle Counter

Channel ID

The following filter combinations for acceptance / transmit filtering are allowed:

Slot Counter + Channel ID

Slot Counter + Cycle Counter + Channel ID

All configured filters must match in order to store a received message in a message buffer.

**Note:** For the FIFO the acceptance filter is configured by the FIFO Rejection Filter (**FRFRF**) and the FIFO Rejection Filter Mask (**FRFRFM**).

A message will be transmitted in the time slot corresponding to the configured frame ID on the configured channel(s). If cycle counter filtering is enabled the configured cycle filter value must also match.

#### 103.3.8.1 Slot Counter Filtering

Every transmit and receive buffer contains a frame ID stored in the header section. This frame ID is compared against the actual slot counter value in order to assign receive and transmit buffers to the corresponding slot.

If two or more message buffers are configured with the same frame ID and channel ID, and if they have a matching cycle counter filter value for the same slot, then the message buffer with the lowest message buffer number is used.

#### 103.3.8.2 Cycle Counter Filtering

Cycle counter filtering is based on the notion of a cycle set. For filtering purposes, a match is detected if any one of the elements of the cycle set is matched. The cycle set is defined by the cycle code field in header section 1 of each message buffer.

If message buffer 0 resp. 1 is configured to hold the startup / sync frame or the single slot frame by bits **FRSUCC1.TXST**, **FRSUCC1.TXSY**, and **FRSUCC1.TSM**, cycle counter filtering for message buffer 0 resp. 1 shall be disabled.

**Note:** Sharing of a static time slot via cycle counter filtering between different nodes of a FlexRay network is not allowed.

The set of cycle numbers belonging to a cycle set is determined as described in Table 103.7.

**Table 103.7 Definition of cycle set**

| Cycle Code | Matching Cycle Counter Values |
|---|---|
| 0b000000x | all Cycles |
| 0b000001c | every second Cycle at (Cycle Count)mod2 = c |

| | | | |
|---|---|---|---|
| 0b00001cc | every fourth Cycle | at (Cycle Count)mod4 | = cc |
| 0b0001ccc | every eighth Cycle | at (Cycle Count)mod8 | = ccc |
| 0b001cccc | every sixteenth Cycle | at (Cycle Count)mod16 | = cccc |
| 0b01ccccc | every thirty-second Cycle | at (Cycle Count)mod32 | = ccccc |
| 0b1cccccc | every sixty-fourth Cycle | at (Cycle Count)mod64 | = cccccc |

Table 103.8 below gives some examples for valid cycle sets to be used for cycle counter filtering:

**Table 103.8 Examples for valid cycle sets**

| Cycle Code | Matching Cycle Counter Values |
|---|---|
| 0b0000011 | 1-3-5-7- …. -63 |
| 0b0000100 | 0-4-8-12- …. -60 |
| 0b0001110 | 6-14-22-30- …. -62 |
| 0b0011000 | 8-24-40-56 |
| 0b0100011 | 3-35 |
| 0b1001001 | 9 |

The received message is stored only if the cycle counter value of the cycle during which the message is received matches an element of the receive buffer's cycle set. Other filter criteria must also be met.

The content of a transmit buffer is transmitted on the configured channel(s) when an element of the cycle set matches the current cycle counter value. Other filter criteria must also be met.

#### 103.3.8.3 Channel ID Filtering

There is a 2-bit channel filtering field (CH) located in the header section of each message buffer in the Message RAM. It serves as a filter for receive buffers, and as a control field for transmit buffers (see Table 103.9).

**Table 103.9 Channel filtering configuration**

| CH[1:0] | Transmit Buffer<br>transmit frame | Receive Buffer<br>store valid receive frame |
|---|---|---|
| 00 | no transmission | ignore frame |
| 01 | on channel A | received on channel A |
| 10 | on channel B | received on channel B |
| 11 | on both channels<br>(static segment only) | received on channel A or B<br>(store first semantically valid frame, static segment only) |

The contents of a transmit buffer is transmitted on the channels specified in the channel filtering field when the slot counter filtering and cycle counter filtering criteria are also met. Only in static segment a transmit buffer may be set up for transmission on both channels (CH = "11").

Valid received frames are stored if they are received on the channels specified in the channel filtering field when the slot counter filtering and cycle counter filtering criteria are also met. Only in static segment a receive buffer may be setup for reception on both channels (CH = "11").

**Note:** If a message buffer is configured for the dynamic segment and both bits of the channel filtering field are set to '1', no frames are transmitted resp. received frames are ignored (same function as CH = "00").

#### 103.3.8.4 FIFO Filtering

For FIFO filtering there is one rejection filter and one rejection filter mask available. The FIFO filter consists of channel filter **FRFRF.CH**, frame ID filter **FRFRF.FID**, and cycle counter filter **FRFRF.CYF**. Registers **FRFRF** and **FRFRFM** can be configured in DEFAULT_CONFIG or CONFIG state only. The filter configuration in the header section of message buffers belonging to the FIFO is ignored.

The 7-bit cycle counter filter determines the cycle set to which frame ID and channel rejection filter are applied. In cycles not belonging to the cycle set specified by **FRFRF.CYF**, all frames are rejected.

A valid received frame is stored in the FIFO if channel ID, frame ID, and cycle counter are not rejected by the configured rejection filter and rejection filter mask, and if there is no matching dedicated receive buffer.

### 103.3.9 Transmit Process

#### 103.3.9.1 Static Segment

For the static segment, if there are several messages pending for transmission, the message with the frame ID corresponding to the next sending slot is selected for transmission.

The data section of transmit buffers assigned to the static segment can be updated until the end of the preceding time slot. This means that a transfer from the Input Buffer has to be started by writing to the Input Buffer Command Request register latest at this time.

#### 103.3.9.2 Dynamic Segment

In the dynamic segment, if several messages are pending, the message with the highest priority (lowest frame ID) is selected next. In the dynamic segment different slot counter sequences on channel A and channel B are possible (concurrent sending of different frame IDs on both channels).

The data section of transmit buffers assigned to the dynamic segment can be updated until the end of the preceding slot. This means that a transfer from the Input Buffer has to be started by writing to the Input Buffer Command Request register latest at this time.

The start of latest transmit configured by **FRMHDC.SLT** defines the maximum minislot value allowed before inhibiting new frame transmission in the dynamic segment of the current cycle.

#### 103.3.9.3 Transmit Buffers

FlexRay message buffers can be configured as transmit buffers by programming bit CFG in the header section of the respective message buffer to ’1’ via **FRWRHS1**.

There exist the following possibilities to assign a transmit buffer to the CC channels:

Static segment: channel A or channel B,
channel A and channel B

Dynamic segment: channel A or channel B

Message buffer 0 resp. 1 is dedicated to hold the startup frame, the sync frame, or the designated single slot frame as configured by **FRSUCC1.TXST**, **FRSUCC1.TXSY**, and **FRSUCC1.TSM**. In this case, it can be reconfigured in DEFAULT_CONFIG or CONFIG state only. This ensures that any node transmits at most one startup / sync frame per communication cycle. Transmission of startup / sync frames from other message buffers is not possible.

All other message buffers configured for transmission in static or dynamic segment are reconfigurable during runtime depending on the configuration of **FRMRC.SEC** (see section 103.3.12.1 ). Due to the organization of the data partition in the Message RAM (reference by data pointer), reconfiguration of the configured payload length and the data pointer in the header section of a message buffer may lead to erroneous configurations.

If a message buffer is reconfigured (header section updated) during runtime, it may happen that this message buffer is not send out in the respective communication cycle.

The CC does not have the capability to calculate the header CRC. The Host is supposed to provide the header CRCs for all transmit buffers. If network management is required, the Host has to set the **FRWRHS1.PPIT** bit in the header

section of the respective message buffer to ’1’ and write the network management information to the data section of the message buffer (see section 103.3.7).

The payload length field configures the payload length in 2-byte words. If the configured payload length of a static transmit buffer is shorter than the payload length configured for the static segment by **FRMHDC.SFDL**, the CC generates padding bytes to ensure that frames have proper physical length. The padding pattern is logical zero.

**Note:** In case of an odd payload length (**FRWRHS2.PLC** = 1,3,5,...) the application has to write zero to the last 16 bit of the message buffers data section to ensure that the padding pattern is all zero.

Each transmit buffer provides a transmission mode flag **FRWRHS1.TXM** that allows the Host to configure the transmission mode for the transmit buffer. If this bit is set, the transmitter operates in the single-shot mode. If this bit is cleared, the transmitter operates in the continuous mode.

In single-shot mode the CC resets the respective **TXR** flag after transmission has completed. Now the Host may update the transmit buffer.

In continuous mode, the CC does not reset the respective transmission request flag **TXR** after successful transmission. In this case a frame is sent out each time the filter criteria match. The **TXR** flag can be reset by the Host by writing the respective message buffer number to the **FRIBCR** register while bit **FRIBCM.STXRH** is set to ’0’.

If two or more transmit buffers meet the filter criteria simultaneously, the transmit buffer with the lowest message buffer number will be transmitted in the respective slot.

#### 103.3.9.4 Frame Transmission

The following steps are required to prepare a message buffer for transmission:

Configure the transmit buffer in the Message RAM via **FRWRHS1**, **FRWRHS2**, and **FRWRHS3**

Write the data section of the transmit buffer via **FRWRDSn**

Transfer the configuration and message data from Input Buffer to the Message RAM by writing the number of the target message buffer to register **FRIBCR**

If configured in register **FRIBCM**, the transmission request flag **TXR** for the respective message buffer will be set as soon as the transfer has completed, and the message buffer is ready for transmission.

Check whether the message buffer has been transmitted by checking the respective **TXR** bit (**FRTXRQn.TXR** = ’0’) in the **FRTXRQ1/2/3/4** registers (single-shot mode only).

After transmission has completed, the respective **TXR** flag in the **FRTXRQ1/2/3/4** register is reset (single-shot mode), and, if bit **MBI** in the header section of the message buffer is set, flag **FRSIR.TXI** is set to ’1’. If enabled, an interrupt is generated.

#### 103.3.9.5 Null Frame Transmission

If in static segment the Host does not set the transmission request flag before transmit time, the CC transmits a null frame with the null frame indication bit set to ’0’ and the payload data set to zero.

In the following cases the CC transmits a null frame:

If the message buffer with the lowest message buffer number matching the filter criteria does not have its transmission request flag set (**TXR** = ’0’).

No transmit buffer configured for the slot has a cycle counter filter that matches the current cycle. In this case, no message buffer status **FRMBS** is updated.

Null frames are not transmitted in the dynamic segment.

### 103.3.10 Receive Process

#### 103.3.10.1 Dedicated Receive Buffers

A portion of the FlexRay message buffers can be configured as dedicated receive buffers by programming bit **CFG** in the header section of the respective message buffer to ’0’ via **FRWRHS1**.

The following possibilities exist to assign a receive buffer to the CC channels:

Static segment: channel A or channel B,
channel A and channel B (the CC stores the first semantically valid frame)

Dynamic segment: channel A or channel B

The CC transfers the payload data of valid received messages from the shift register of the FlexRay channel protocol controller (channel A or B) to the receive buffer with the matching filter configuration. A receive buffer stores all frame elements except the frame CRC.

All message buffers configured for reception in static or dynamic segment are reconfigurable during runtime depending on the configuration of **FRMRC.SEC** (see section 103.3.12.1). If a message buffer is reconfigured (header section updated) during runtime it may happen that in the respective communication cycle a received message is lost.

If two or more receive buffers meet the filter criteria simultaneously, the receive buffer with the lowest message buffer number is updated with the received message.

#### 103.3.10.2 Frame Reception

The following steps are required to prepare a dedicated message buffer for reception:

Configure the receive buffer in the Message RAM via **FRWRHS1**, **FRWRHS2**, and **FRWRHS3**

Transfer the configuration from Input Buffer to the Message RAM by writing the number of the target message buffer to register **FRIBCR**

Once these steps are performed, the message buffer functions as an active receive buffer and participates in the internal acceptance filtering process which takes place every time the CC receives a message. The first matching receive buffer is updated from the received message.

If a valid payload segment was stored in the data section of a message buffer, the respective **ND** flag in the **FRNDAT1/2/3/4** registers is set, and, if bit **MBI** in the header section of that message buffer is set, flag **FRSIR.RXI** is set to ’1’. If enabled, an interrupt is generated.

In case that bit **ND** was already set when the Message Handler updates the message buffer, bit **FRMBS.MLST** of the respective message buffer is set and the unprocessed message data is lost.

If no frame, a null frame, or a corrupted frame was received in a slot, the data section of the message buffer configured for this slot is not updated. In this case only the respective message buffer status **FRMBS** is updated.

When the Message Handler changed the message buffer status **FRMBS** in the header section of a message buffer, the respective **MBC** flag in the **FRMBSC1/2/3/4** registers is set, and if bit **MBI** in the header section of that message buffer is set, flag **FRSIR.MBSI** is set to ’1’. If enabled an interrupt is generated.

If the payload length of a received frame **PLR** is longer than the value programmed by **PLC** in the header section of the respective message buffer, the data field stored in the message buffer is truncated to that length.

To read a receive buffer from the Message RAM via the Output Buffer, proceed as described in section 103.3.12.2.(2).

**Note:** The **ND** and **MBC** flags are automatically cleared by the Message Handler when the payload data and the header of a received message have been transferred to the Output Buffer, respectively.

#### 103.3.10.3 Null Frame Reception

The payload segment of a received null frame is not copied into the matching dedicated receive buffer. If a null frame has been received, only the message buffer status **FRMBS** of the matching message buffer is updated from the received null frame. All bits in header 2 and 3 of the matching message buffer remain unchanged. They are updated from received data frames only.

When the Message Handler changed the message buffer status **FRMBS** in the header section of a message buffer, the respective **MBC** flag in the **FRMBSC1/2/3/4** register is set, and if bit **MBI** in the header section of that message buffer is set, flag **FRSIR.MBSI** is set to '1'. If enabled, an interrupt is generated.

### 103.3.11 FIFO Function

#### 103.3.11.1 Description

A group of the message buffers can be configured as a cyclic First-In-First-Out (FIFO) buffer. The group of message buffers belonging to the FIFO is contiguous in the register map starting with the message buffer referenced by **FRMRC.FFB** and ending with the message buffer referenced by **FRMRC.LCB**. Up to 127 message buffers can be assigned to the FIFO.

Every valid incoming message not matching with any dedicated receive buffer but passing the programmable FIFO filter is stored into the FIFO. In this case frame ID, payload length, receive cycle count, and the message buffer status **FRMBS** of the addressed FIFO message buffer are overwritten with frame ID, payload length, receive cycle count, and the status from the received frame. Bit **FRSIR.RFNE** shows that the FIFO is not empty, bit **FRSIR.RFCL** is set when the receive FIFO fill level **FRFSR.RFFL** is equal or greater than the critical level as configured by **FRFCL.CL**, bit **FREIR.RFO** shows that a FIFO overrun has been detected. If enabled, interrupts are generated.

If null frames are not rejected by the FIFO rejection filter, the null frames will be treated like data frames when they are stored into the FIFO.

There are two index registers associated with the FIFO. The PUT Index Register (PIDX) is an index to the next available location in the FIFO. When a new message has been received it is written into the message buffer addressed by the PIDX register. The PIDX register is then incremented and addresses the next available message buffer. If the PIDX register is incremented past the highest numbered message buffer of the FIFO, the PIDX register is loaded with the number of the first (lowest numbered) message buffer in the FIFO chain. The GET Index Register (GIDX) is used to address the next message buffer of the FIFO to be read. The GIDX register is incremented after transfer of the contents of a message buffer belonging to the FIFO to the Output Buffer. The PUT Index Register and the GET Index Register are not accessible by the Host.

The FIFO is completely filled when the PUT index (PIDX) reaches the value of the GET index (GIDX). When the next message is written to the FIFO before the oldest message has been read, both PUT index and GET index are incremented and the new message overwrites the oldest message in the FIFO. This will set FIFO overrun flag **FREIR.RFO**.

A FIFO non empty status is detected when the PUT index (PIDX) differs from the GET index (GIDX). In this case flag **FRSIR.RFNE** is set. This indicates that there is at least one received message in the FIFO. The FIFO empty, FIFO not empty, and the FIFO overrun states are explained in Figure 103.9 for a three message buffer FIFO.

The programmable FlexRay FIFO Rejection Filter (**FRFRF**) defines a filter pattern for messages to be rejected. The FIFO filter consists of channel filter, frame ID filter, and cycle counter filter. If bit **FRFRF.RSS** is set to '1', all messages received in the static segment are rejected by the FIFO. If bit **FRFRF.RNF** is set to '1', received null frames are not stored in the FIFO.

The FlexRay FIFO Rejection Filter Mask (**FRFRFM**) specifies which bits of the frame ID filter in the FIFO Rejection Filter register are marked 'don't care' for rejection filtering.

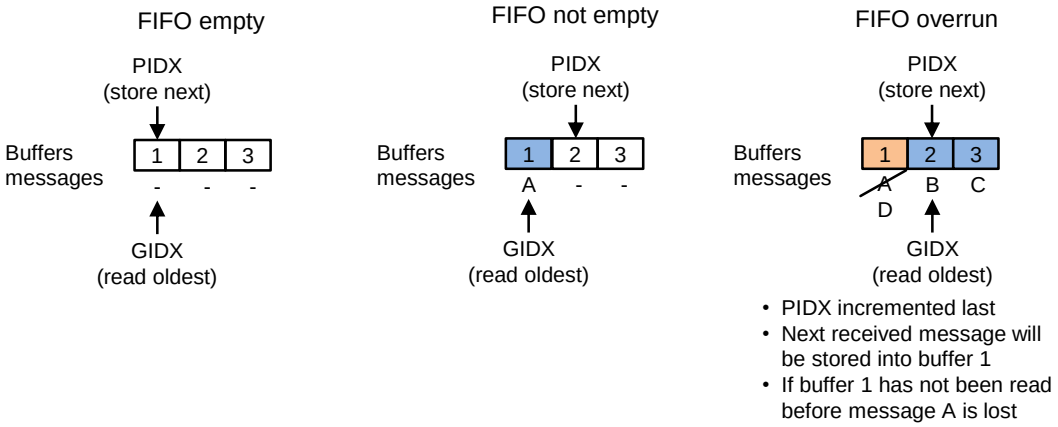

**Figure 103.9 FIFO status: empty, not empty, overrun**

### 103.3.11.2 Configuration of the FIFO

(Re)configuration of message buffers belonging to the FIFO is only possible when the CC is in DEFAULT_CONFIG or CONFIG state. While the CC is in DEFAULT_CONFIG or CONFIG state, the FIFO function is not available.

For all message buffers belonging to the FIFO the payload length configured should be programmed to the same value via **FRWRHS2.PLC**. The data pointer to the first 32-bit word of the data section of the respective message buffer in the Message RAM has to be configured via **FRWRHS3.DP**.

All information required for acceptance filtering is taken from the FIFO rejection filter and the FIFO rejection filter mask. The values configured in the header sections of the message buffers belonging to the FIFO are, with exception of **DP** and **PLC**, irrelevant.

**Note 1:** It is recommended to program the **MBI** bits of the message buffers belonging to the FIFO to ’0’ via **FRWRHS1.MBI** to avoid generation of RX interrupts.

**Note 2:** If the payload length of a received frame is longer than the value programmed by **FRWRHS2.PLC** in the header section of the respective message buffer, the data field stored in a message buffer of the FIFO is truncated to that length.

### 103.3.11.3 Access to the FIFO

(1) **Using output buffer**

For FIFO access outside DEFAULT_CONFIG and CONFIG state, the Host has to trigger a transfer from the Message RAM to the Output Buffer by writing the number of the first message buffer of the FIFO (referenced by **FRMRC.FFB**) to the register **FROBCR**. The Message Handler then transfers the message buffer addressed by the GET Index Register (GIDX) to the Output Buffer. After this transfer the GET Index Register (GIDX) is incremented.

(2) **Using data transfer function**

Messages received into the FIFO can be also transferred into the URAM using the Output data transfer function as described in section 103.3.16.2.

### 103.3.12 Message Handling

The Message Handler controls data transfers between the Input / Output Buffer and the Message RAM and between the Message RAM and the two Transient Buffers.

Access to the message buffers stored in the Message RAM is done under control of the Message Handler state machine. This avoids conflicts between accesses of the two FlexRay channel protocol controllers and the Host to the Message RAM.

Frame IDs of message buffers assigned to the static segment have to be in the range from 1 to **FRGTUC7.NSS**. Frame IDs of message buffers assigned to the dynamic segment have to be in the range from **FRGTUC7.NSS** + 1 to 2047.

Received messages with no matching dedicated receive buffer (static or dynamic segment) are stored in the receive FIFO (if configured) if they pass the FIFO rejection filter.

This section describes the Host access to the Message buffer content using the input buffer and output buffer function. In section 103.3.16 the access to the Message buffer content using the data transfer function is described.

#### 103.3.12.1 Reconfiguration of Message Buffers

In case that an application needs to operate with more than 128 different messages, static and dynamic message buffers may be reconfigured during FlexRay operation. This is done by updating the header section of the respective message buffer via Input Buffer registers **FRWRHS1/2/3**.

Reconfiguration has to be enabled via control bits **FRMRC.SEC** in the Message RAM Configuration register.

If a message buffer has not been transmitted / updated from a received frame before reconfiguration starts, the respective message is lost.

The point in time when a reconfigured message buffer is ready for transmission / reception according to the reconfigured frame ID depends on the actual state of the slot counter when the update of the header section has completed. Therefore it may happen that a reconfigured message buffer is not transmitted / updated from a received frame in the cycle where it was reconfigured.

The Message RAM is scanned according to Table 103.10 below:

**Table 103.10 Scan of Message RAM**

| Start of Scan in Slot | Scan for Slots |
|---|---|
| 1 | 2…15, 1 (next cycle) |
| 8 | 16…23, 1 (next cycle) |
| 16 | 24…31, 1 (next cycle) |
| 24 | 32…39, 1 (next cycle) |
| … | … |

A Message RAM scan is terminated with the start of NIT regardless whether it has completed or not. The scan of the Message RAM for slots 2 to 15 starts at the beginning of slot 1 of the actual cycle. The scan of the Message RAM for slot 1 is done in the cycle before by checking in parallel to each scan of the Message RAM whether there is a message buffer configured for slot 1 of the next cycle.

The number of the first dynamic message buffer is configured by **FRMRC.FDB**. In case a Message RAM scan starts while the CC is in dynamic segment, the scan starts with the message buffer number configured by **FRMRC.FDB**.

In case a message buffer should be reconfigured to be used in slot 1 of the next cycle, the following has to be considered:
If the message buffer to be reconfigured for slot 1 is part of the "Static Buffers", it will only be found if it is reconfigured

before the last Message RAM scan in the static segment of the actual cycle evaluates this message buffer.
If the message buffer to be reconfigured for slot 1 is part of the "Static + Dynamic Buffers", it will be found if it is reconfigured before the last Message RAM scan in the actual cycle evaluates this message buffer.
The start of NIT terminates the Message RAM scan. In case the Message RAM scan has not evaluated the reconfigured message buffer until this point in time, the message buffer will not be considered for the next cycle.

**Note:** Reconfiguration of message buffers may lead to the loss of messages and therefore has to be used very carefully. In worst case (reconfiguration in consecutive cycles) it may happen that a message buffer is never transmitted / updated from a received frame.

### 103.3.12.2 Host access to Message RAM

The message transfer between Input Buffer and Message RAM as well as between Message RAM and Output Buffer is triggered by the Host by writing the number of the target / source message buffer to be accessed to **FRIBCR** or **FROBCR** register.

The **FRIBCM** and **FROBCM** registers can be used to write / read header and data section of the selected message buffer separately.

If bit **FRIBCM.STXR** is set to = ’1’, the transmission request flag **FRTXRQn.TXR** of the selected message buffer is automatically set after the message buffer has been updated. If bit **FRIBCM.STXR** is reset to ’0’, the transmission request flag **FRTXRQn.TXR** of the selected message buffer is reset. This can be used to stop transmission from message buffers operated in continuous mode.

Input Buffer (IBF) and Output Buffer (OBF) are build up as a double buffer structure. One half of this double buffer structure is accessible by the Host (IBF Host / OBF Host), while the other half (IBF Shadow / OBF Shadow) is accessed by the Message Handler for data transfers between IBF / OBF and Message RAM.

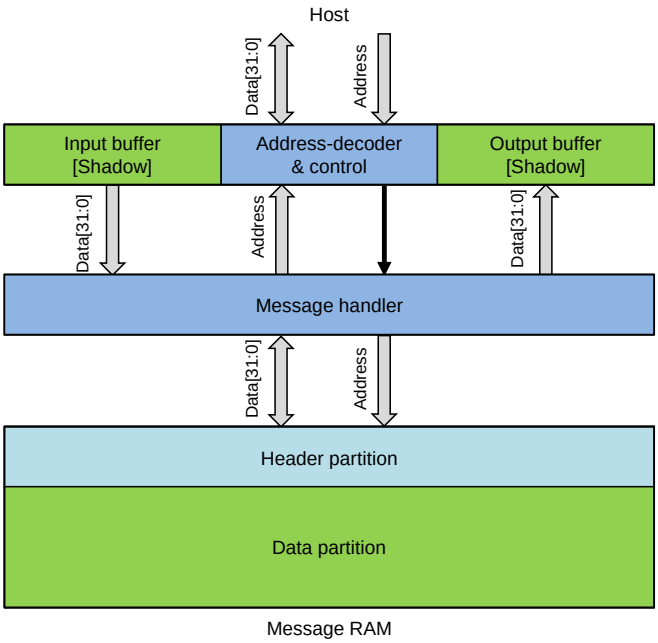

**Figure 103.10 Host access to Message RAM**

(1) **Data Transfer from Input Buffer to Message RAM**

To configure / update a message buffer in the Message RAM, the Host has to write the data to **FRWRDSn** and the header to **FRWRHS1**/**2**/**3**. The specific action is selected by configuring the FlexRay Input Buffer Command Mask **FRIBCM**.

When the Host writes the number of the target message buffer in the Message RAM to **FRIBCR.IBRH**, IBF Host and IBF Shadow are swapped (see Figure 103.11).

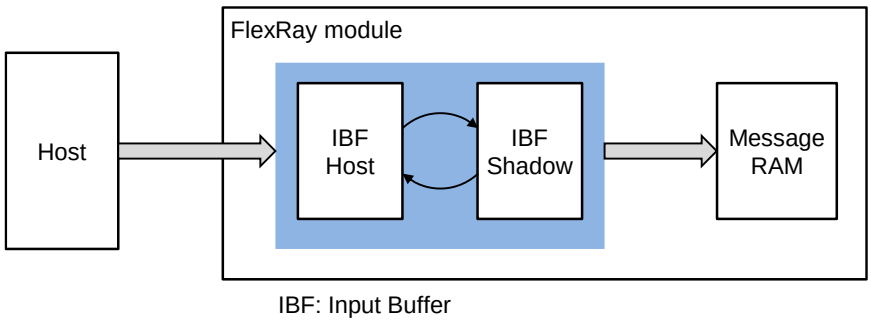

**Figure 103.11 Double buffer structure Input Buffer**

In addition the bits in the **FRIBCM** and **FRIBCR** registers are also swapped to keep them attached to the respective IBF section (see Figure 103.12).

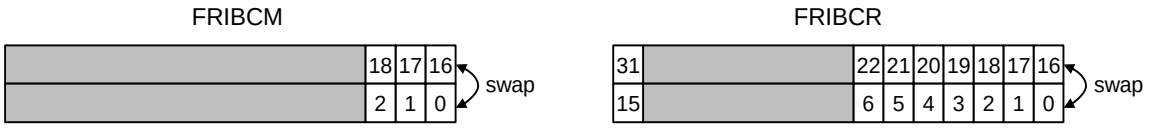

**Figure 103.12 Swapping of FRIBCM and FRIBCR bits**

With this write operation bit **FRIBCR.IBSYS** is set to '1'. The Message Handler then starts to transfer the contents of IBF Shadow to the message buffer in the Message RAM selected by **FRIBCR.IBRS**.

While the Message Handler transfers the data from IBF Shadow to the target message buffer in the Message RAM, the Host may write the next message to IBF Host. After the transfer between IBF Shadow and the Message RAM has completed, bit **FRIBCR.IBSYS** is set back to '0' and the next transfer to the Message RAM may be started by the Host by writing the respective target message buffer number to **FRIBCR.IBRH**.

If a write access to **FRIBCR.IBRH** occurs while **FRIBCR.IBSYS** is '1', **FRIBCR.IBSYH** is set to '1'. After completion of the ongoing data transfer from IBF Shadow to the Message RAM, IBF Host and IBF Shadow are swapped, **FRIBCR.IBSYH** is reset to '0', **FRIBCR.IBSYS** remains set to '1', and the next transfer to the Message RAM is started. In addition the message buffer numbers stored under **FRIBCR.IBRH** and **FRIBCR.IBRS** and the command mask flags are also swapped.

**Example of a 8/16/32-bit Host access sequence:**
Configure / update n-th message buffer via IBF
Wait until **FRIBCR.IBSYH** is reset
Write data section to **FRWRDSn**
Write header section to **FRWRHS1/2/3**
Write Command Mask: write **FRIBCM.STXRH**, **FRIBCM.LDSH**, **FRIBCM.LHSH**
Demand data transfer to target message buffer: write **FRIBCR.IBRH**
Configure / update (n+1)th message buffer via IBF
Wait until **FRIBCR.IBSYH** is reset
Write data section to **FRWRDSn**
Write header section to **FRWRHS1/2/3**

Write Command Mask: write **FRIBCM.STXRH**, **FRIBCM.LDSH**, **FRIBCM.LHSH**

Demand data transfer to target message buffer: write **FRIBCR.IBRH**

…

**Note:** Any write access to IBF while **FRIBCR.IBSYH** is '1' will set error flag **FREIR.IIBA** to '1'. In this case the write access has no effect.

**Table 103.11 Assignment of FRIBCM bits**

| Pos. | Access | Bit | Function |
|---|---|---|---|
| 18 | r | STXRS | Set Transmission Request Shadow ongoing or finished |
| 17 | r | LDSS | Load Data Section Shadow ongoing or finished |
| 16 | r | LHSS | Load Header Section Shadow ongoing or finished |
| 2 | r/w | STXRH | Set Transmission Request Host |
| 1 | r/w | LDSH | Load Data Section Host |
| 0 | r/w | LHSH | Load Header Section Host |

**Table 103.12 Assignment of FRIBCR bits**

| Pos. | Access | Bit | Function |
|---|---|---|---|
| 31 | r | IBSYS | IBF Busy Shadow, signals ongoing transfer from IBF Shadow to Message RAM |
| 22…16 | r | IBRS | IBF Request Shadow, number of message buffer currently / lately updated |
| 15 | r | IBSYH | IBF Busy Host, transfer request pending for message buffer referenced by IBRH |
| 6…0 | r/w | IBRH | IBF Request Host, number of message buffer to be updated next |

(2) **Data Transfer from Message RAM to Output Buffer**

To read a message buffer from the Message RAM, the Host has to write to register **FROBCR** to trigger the data transfer as configured in **FROBCM**. After the transfer has completed, the Host can read the transferred data from **FRRDDSn**, **FRRDHS1**/**2**/**3**, and **FRMBS**.

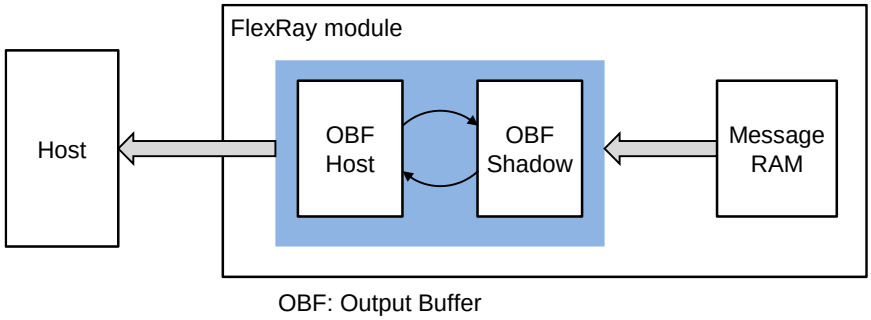

**Figure 103.13 Double buffer structure Output Buffer**

OBF Host and OBF Shadow as well as bits **FROBCM.RHSS**, **FROBCM.RDSS**, **FROBCM.RHSH**, **FROBCM.RDSH** and bits **FROBCR.OBRS**, **FROBCR.OBRH** are swapped under control of bits **FROBCR.VIEW** and **FROBCR.REQ**.

Writing bit **FROBCR.REQ** to ’1’ copies bits **FROBCM.RHSS**, **FROBCM.RDSS** and bits **FROBCR.OBRS** to an internal storage (see Figure 103.14).

After setting **FROBCR.REQ** to ’1’, **FROBCR.OBSYS** is set to ’1’, and the transfer of the message buffer selected by **FROBCR.OBRS** from the Message RAM to OBF Shadow is started. After the transfer between the Message RAM and OBF Shadow has completed, the **FROBCR.OBSYS** bit is set back to ’0’. Bits **FROBCR.REQ** and **FROBCR.VIEW** can only be set to ’1’ while **FROBCR.OBSYS** is ’0’.

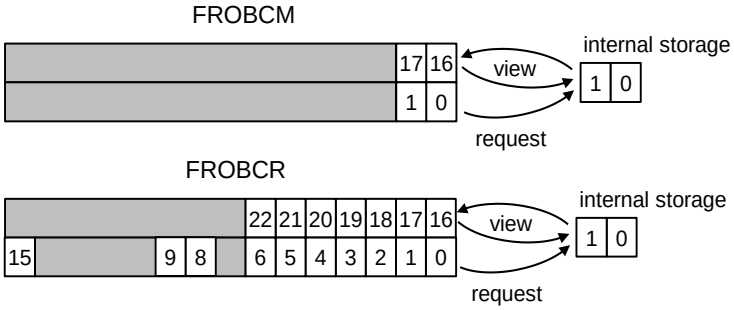

**Figure 103.14 Swapping of FROBCM and FROBCR bits**

OBF Host and OBF Shadow are swapped by setting bit **FROBCR.VIEW** to ’1’ while bit **FROBCR.OBSYS** is ’0’ (see Figure 103.13).

In addition bits **FROBCR.OBRH** and bits **FROBCM.RHSH**, **FROBCM.RDSH** are swapped with the registers internal storage thus assuring that the message buffer number stored in **FROBCR.OBRH** and the mask configuration stored in **FROBCM.RHSH**, **FROBCM.RDSH** matches the transferred data stored in OBF Host (see Figure 103.14).

Now the Host can read the transferred message buffer from OBF Host while the Message Handler may transfer the next message from the Message RAM to OBF Shadow.

If bits **REQ** and **VIEW** are set to ’1’ with the same write access while **FROBCR.OBSYS** is ’0’, **FROBCR.OBSYS** is automatically set to ’1’ and OBF Shadow and OBF Host are swapped. Additionally mask bits **FROBCM.RDSH** and **FROBCM.RHSH** are swapped with the registers internal storage to keep them attached to the respective Output Buffer transfer. Afterwards **FROBCR.OBRS** is copied to the register internal storage, mask bits **FROBCM.RDSS** and **FROBCM.RHSS** are copied to register **FROBCM** internal storage, and the transfer of the selected message buffer from the Message RAM to OBF Shadow is started. While the transfer is ongoing the Host can read the message buffer transferred by the previous transfer from OBF Host. When the current transfer between Message RAM and OBF Shadow has completed, this is signaled by setting **FROBCR.OBSYS** back to ’0’.

**Example of an 8/16/32-bit Host access to a single message buffer:**
If a single message buffer has to be read out, two separate write accesses to **FROBCR.REQ** and **FROBCR.VIEW** are necessary:

Wait until **FROBCR.OBSYS** is reset

Write Output Buffer Command Mask **FROBCM.RHSS**, **FROBCM.RDSS**

Request transfer of message buffer to OBF Shadow by writing **FROBCR.OBRS** and **FROBCR.REQ** (in case of and 8-bit Host interface, **FROBCR.OBRS** has to be written before **FROBCR.REQ**).

Wait until **FROBCR.OBSYS** is reset

Toggle OBF Shadow and OBF Host by writing **FROBCR.VIEW** = ’1’

Read out transferred message buffer by reading **FRRDDSn**, **FRRDHS1**/**2**/**3**, and **FRMBS**

**Example of an 8/16/32-bit Host access sequence:**
Request transfer of 1st message buffer to OBF Shadow

Wait until **FROBCR.OBSYS** is reset

Write Output Buffer Command Mask **FROBCM.RHSS**, **FROBCM.RDSS** for 1st message buffer

Request transfer of 1st message buffer to OBF Shadow by writing **FROBCR.OBRS** and **FROBCR.REQ** (in case of an 8-bit Host interface, **FROBCR.OBRS** has to be written before **FROBCR.REQ**).

Toggle OBF Shadow and OBF Host to read out 1st transferred message buffer and request transfer of 2nd message buffer:

Wait until **FROBCR.OBSYS** is reset

Write Output Buffer Command Mask **FROBCM.RHSS**, **FROBCM.RDSS** for 2nd message buffer

Toggle OBF Shadow and OBF Host and start transfer of 2nd message buffer to OBF Shadow simultaneously by writing **FROBCR.OBRS** of 2nd message buffer, **FROBCR.REQ**, and **FROBCR.VIEW** (in case of and 8-bit Host interface, **FROBCR.OBRS** has to be written before **FROBCR.REQ** and **FROBCR.VIEW**).

Read out 1st transferred message buffer by reading **FRRDDSn**, **FRRDHS1**/**2**/**3**, and **FRMBS**

…

Demand access to last requested message buffer without request of another message buffer:

Wait until **FROBCR.OBSYS** is reset

Demand access to last transferred message buffer by writing **FROBCR.VIEW**

Read out last transferred message buffer by reading **FRRDDSn**, **FRRDHS1/2/3**, and **FRMBS**

**Table 103.13 Assignment of FROBCM bits**

| Pos. | Access | Bit | Function |
|---|---|---|---|
| 17 | r | RDSH | Data Section available for Host access |
| 16 | r | RHSH | Header Section available for Host access |
| 1 | r/w | RDSS | Read Data Section Shadow |
| 0 | r/w | RHSS | Read Header Section Shadow |

**Table 103.14 Assignment of FROBCR bits**

| Pos. | Access | Bit | Function |
|---|---|---|---|
| 22…16 | r | OBRH | OBF Request Host,<br>number of message buffer available for Host access |
| 15 | r | OBSYS | OBF Busy Shadow,<br>signals ongoing transfer from Message RAM to OBF Shadow |
| 9 | r/w | REQ | Request Transfer from Message RAM to OBF Shadow |
| 8 | r/w | VIEW | View OBF Shadow, swap OBF Shadow and OBF Host |
| 6…0 | r/w | OBRS | OBF Request Shadow, number of message buffer for next request |

### 103.3.12.3 FlexRay Protocol Controller access to Message RAM

The two Transient Buffers (TBF A,B) are used to buffer the data for transfer between the two FlexRay Protocol Controllers and the Message RAM.

Each Transient Buffer is build up as a double buffer, able to store two complete FlexRay messages. There is always one buffer assigned to the corresponding Protocol Controller while the other one is accessible by the Message Handler.

If e.g. the Message Handler writes the next message to be send to Transient Buffer Tx, the FlexRay Channel Protocol Controller can access Transient Buffer Rx to store the message it is actually receiving. During transmission of the message stored in Transient Buffer Tx, the Message Handler transfers the last received message stored in Transient Buffer Rx to the Message RAM (if it passes acceptance filtering) and updates the respective message buffer.

Data transfers between the Transient Buffers and the shift registers of the FlexRay Channel Protocol Controllers are done in words of 32 bit. This enables the use of a 32 bit shift register independent of the length of the FlexRay messages.

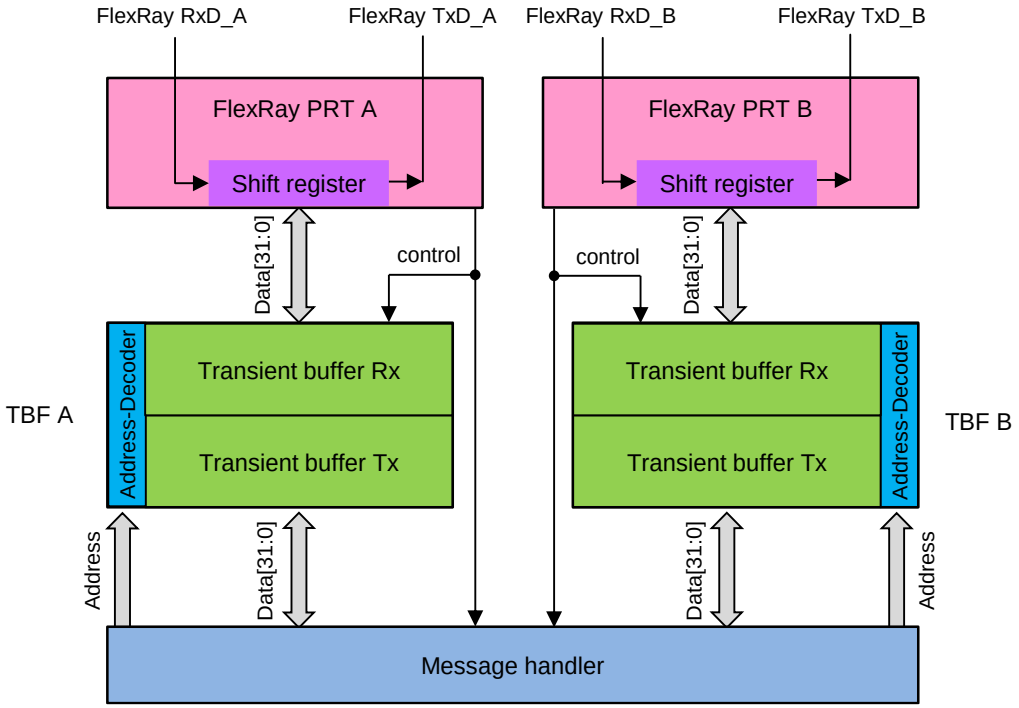

**Figure 103.15 Access to Transient Buffers**

### 103.3.13 Message RAM

To avoid conflicts between Host access to the Message RAM and FlexRay message reception / transmission, the Host cannot directly access the message buffers in the Message RAM. These accesses are handled via the Input and Output Buffers. The Message RAM is able to store up to 128 message buffers depending on the configured payload length.

The Message RAM is able to store up to 2048 32-bit words. To achieve the required flexibility with respect to different numbers of data bytes per FlexRay frame (0…254), the Message RAM has a structure as shown in **Figure 103.16**.

The data partition is allowed to start at Message RAM word number: (**FRMRC.LCB** + 1) * 4

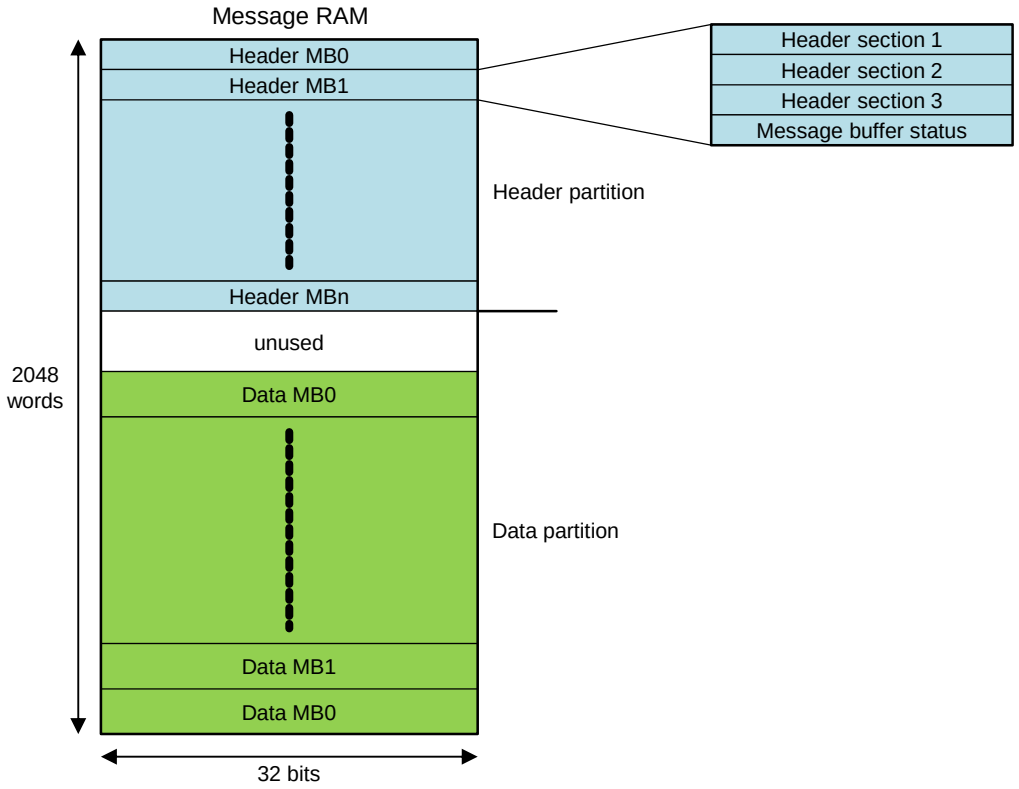

**Figure 103.16 Configuration example of message buffers in the Message RAM**

**Header Partition**
Stores header sections of the configured message buffers:

Supports a maximum of 128 message buffers

Each message buffer has a header section of four 32 bit words

Header section 3 of each message buffer holds the 11-bit data pointer to the respective data section in the data partition

**Data Partition**
Flexible storage of data sections with different length. Some maximum values are:

30 message buffers with 254 byte data section each

Or 56 message buffers with 128 byte data section each

Or 128 message buffers with 48 byte data section each

**Restriction:** header partition + data partition may not occupy more than 2048 32-bit words.

### 103.3.13.1 Header Partition

The elements used for configuration of a message buffer as well as the actual message buffer status are stored in the header partition of the Message RAM as listed in received valid data frames only.

Table 103.3 below. Configuration of the header sections of the message buffers is done via IBF (**FRWRHS1/2/3**). Read access to the header sections are done via OBF (**FRRDHS1/2/3** + **FRMBS**). The data pointer has to be calculated by the programmer to define the starting point of the data section for the respective message buffer in the data partition of the Message RAM. The data pointer should not be modified during runtime. For message buffers belonging to the receive FIFO (re)configuration is possible in DEFAULT_CONFIG or CONFIG state only.

The header section of each message buffer occupies four 32-bit words in the header partition of the Message RAM. The header of message buffer 0 starts with the first word in the Message RAM.

For transmit buffers the Header CRC has to be calculated by the Host.

Payload Length Received **PLR**, Receive Cycle Count **RCC**, Received on Channel Indicator **RCI**, Startup Frame Indicator **SFI**, Sync Frame Indicator **SYN**, Null Frame Indicator **NFI**, Payload Preamble Indicator **PPI**, and Reserved Bit **RES** are updated from received valid data frames only.

**Table 103.15 Header section of a message buffer in the Message RAM**

| Bit Word | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 0 | | | MBI | TXM | PPIT | CFG | CH | | | Cycle code | | | | | | | | | | | | Frame ID | | | | | | | | | | |

| 2 | | | RES | PPI | NFI | SYN | SFI | RCI | | | Receive cycle count | | | | | | | | | | | Data pointer | | | | | | | | | | |
| 3 | | | RESS | PPIS | NFIS | SYNS | SFIS | RCIS | | | Cycle count status | | | | | | FTB | FTA | | MLST | ESB | ESA | TCIB | TCIA | SVOB | SVOA | CEOB | CEOA | SEOB | SEOA | VFRB | VFRA |
| … | … | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| … | … | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

Frame configuration
Filter configuration
Message buffer control
Message RAM configuration
Updated from received data frame
Message buffer status (MBS)
unused

(1) **Header section 1 (word 0)**

Write access via **FRWRHS1**, read access via **FRRDHS1**:

Frame ID - Slot counter filtering configuration
Cycle Code - Cycle counter filtering configuration
CH - Channel filtering configuration
CFG - Message buffer direction configuration: receive / transmit
PPIT - Payload Preamble Indicator Transmit
TXM - Transmit mode configuration: single-shot / continuous
MBI - Message buffer receive / transmit interrupt enable

(2) **Header section 2 (word 1)**

Write access via **FRWRHS2**, read access via **FRRDHS2**:

Header CRC - Transmit Buffer: Configured by the Host (calculated from frame header)
- Receive Buffer: Updated from received frame

Payload Length Configured - Length of data section (2-byte words) as configured by the Host
Payload Length Received - Length of payload segment (2-byte words) stored from received frame

(3) **Header section 3 (word 2)**

Write access via **FRWRHS3**, read access via **FRRDHS3**:

Data Pointer - Pointer to the beginning of the corresponding data section in the data partition
Read access via **FRRDHS3** , valid for receive buffers only, updated from received frames:
Receive Cycle Count - Cycle count from received frame
RCI - Received on Channel Indicator

SFI - Startup Frame Indicator
SYN - Sync Frame Indicator
NFI - Null Frame Indicator
PPI - Payload Preamble Indicator
RES - Reserved bit

(4) **Message Buffer Status FRMBS (word 3)**

Read access via **FRMBS**, updated by the CC at the end of the configured slot.

VFRA - Valid Frame Received on channel A
VFRB - Valid Frame Received on channel B
SEOA - Syntax Error Observed on channel A
SEOB - Syntax Error Observed on channel B
CEOA - Content Error Observed on channel A
CEOB - Content Error Observed on channel B
SVOA - Slot boundary Violation Observed on channel A
SVOB - Slot boundary Violation Observed on channel B
TCIA - Transmission Conflict Indication channel A
TCIB - Transmission Conflict Indication channel B
ESA - Empty Slot Channel A
ESB - Empty Slot Channel B
MLST - Message LoST
FTA - Frame Transmitted on Channel A
FTB - Frame Transmitted on Channel B
Cycle Count Status - Actual cycle count when status was updated
RCIS - Received on Channel Indicator Status
SFIS - Startup Frame Indicator Status
SYNS - Sync Frame Indicator Status
NFIS - Null Frame Indicator Status
PPIS - Payload Preamble Indicator Status
RESS - Reserved bit Status

### 103.3.13.2 Data Partition

The data partition of the Message RAM stores the data sections of the message buffers configured for reception / transmission as defined in the header partition. The number of data bytes for each message buffer can vary from 0 to 254. To optimize the data transfer between the shift registers of the two FlexRay Protocol Controllers and the Message RAM as well as between the Host interface and the Message RAM, the physical width of the Message RAM is set to 4 bytes.

The data partition starts after the last word of the header partition. When configuring the message buffers in the Message RAM the programmer has to assure that the data pointers point to addresses within the data partition. Table 103.16 below shows an example how the data sections of the configured message buffers can be stored in the data partition of the Message RAM.

The beginning and the end of a message buffer’s data section is determined by the data pointer and the payload length configured in the message buffer’s header section, respectively. This enables a flexible usage of the available RAM space for storage of message buffers with different data length.

If the size of the data section is an odd number of 2-byte words, the remaining 16 bits in the last 32bit word are unused (see Table 103.16 below).

**Table 103.16 Example for structure of the data partition in the Message RAM**

| Bit Word | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

### 103.3.13.3 Message Data Integrity Check

There is a data integrity checking mechanism implemented in the FlexRay core to assure the integrity of the data stored in the related RAM. Each RAM has a checksum generator / checker attached as shown in Figure 103.17.

When data is written to a RAM, the local checksum generator generates the checksum. The checksum is stored together with the respective data word. The checksum is checked each time a data word is read from a RAM.

If a checksum error is detected, the respective access error flag is set. The access error flags **FRMHDS.AMR**, **FRMHDS.ATBF1**, **FRMHDS.ATBF2** and the faulty message buffer indicators **FRMHDS.FMBD**, **FRMHDS.MFMB**, **FRMHDS.FMB** are located in the FlexRay Message Handler Status register. These single access error flags control the error interrupt flag **FREIR.AERR**.

Figure 103.17 shows the data paths between the Input Buffer, Transient Buffer and Message RAM.

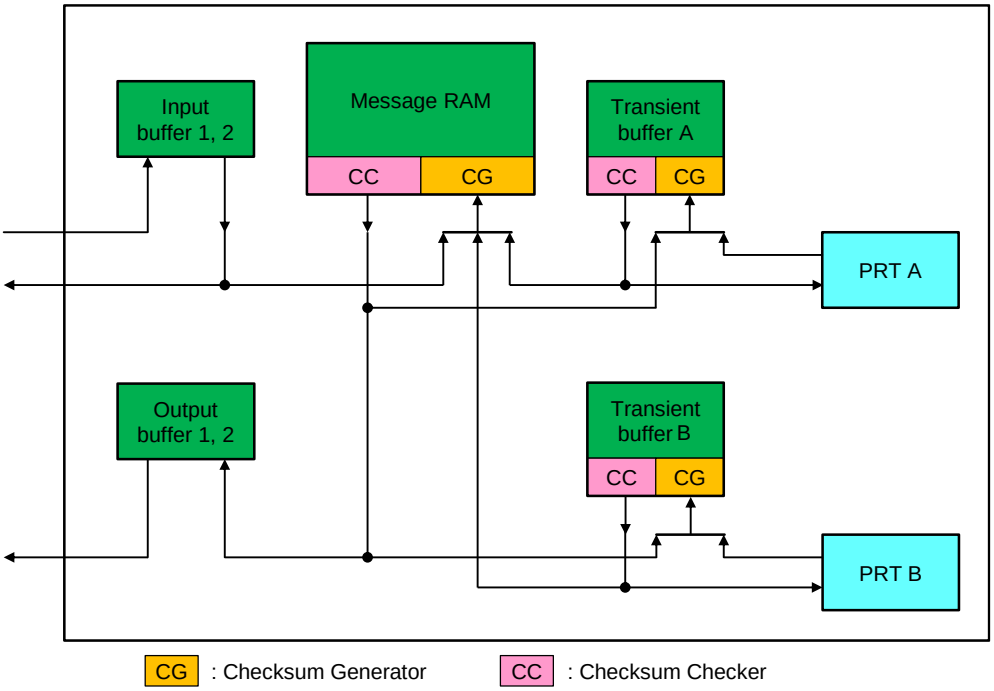

**Figure 103.17 Checksum generation and check**

When an access error has been detected the following actions will be performed:

**In all cases**

The respective access error flag in **FRMHDS** register is set

The access error flag **FREIR.AERR** is set and, if enabled, a module interrupt to the Host will be generated.

**Additionally in specific cases**

1) Access error during data transfer from Input Buffer 1,2 to Message RAM when reading header section of respective message buffer from Message RAM.

**FRMHDS.AMR** is set

**FRMHDS.FMBD** bit is set to indicate that **FRMHDS.FMB** points to a faulty message buffer

**FRMHDS.FMB** indicates the number of the faulty message buffer

The data section of the respective message buffer is not updated

Transmit buffer: Transmission request for the respective message buffer is not set

2) Access error during scan of header sections in Message RAM

**FRMHDS.AMR** is set

**FRMHDS.FMBD** bit is set to indicate that **FRMHDS.FMB** points to a faulty message buffer

**FRMHDS.FMB** indicates the number of the faulty message buffer

Ignore message buffer (message buffer is skipped)

3) Access error during data transfer from Message RAM to Transient Buffer 1, 2

**FRMHDS.AMR** is set

**FRMHDS.FMBD** bit is set to indicate that **FRMHDS.FMB** points to a faulty message buffer

**FRMHDS.FMB** indicates the number of the faulty message buffer

Frame not transmitted, frames already in transmission are invalidated by setting the frame CRC to zero

4) Access error during data transfer from Transient Buffer 1, 2 to Message RAM when reading header section of respective message buffer from Message RAM:

**FRMHDS.AMR** is set

**FRMHDS.FMBD** bit is set to indicate that **FRMHDS.FMB** points to a faulty message buffer

**FRMHDS.FMB** indicates the number of the faulty message buffer

The data section of the respective message buffer is not updated

5) Access error during data transfer from Message RAM to Output Buffer

The access error flag **FRMHDS.AMR** is set

**FRMHDS.FMBD** bit is set to indicate that **FRMHDS.FMB** points to a faulty message buffer

**FRMHDS.FMB** indicates the number of the faulty message buffer

6) Access error during a data transfer from Transient Buffer 1, 2 to Protocol Controller 1, 2

**FRMHDS.ATBF1, 2** bit is set

Frames already in transmission are invalidated by setting the frame CRC to zero

7) Access error during data transfer from Transient Buffer 1, 2 to Message RAM when reading Transient Buffer RAM 1, 2:

**FRMHDS.ATBF1, 2** bit is set

**FRMHDS.FMBD** bit is set to indicate that **FRMHDS.FMB** points to a faulty message buffer

**FRMHDS.FMB** indicates the number of the faulty message buffer

8) Access error during data read of Transient Buffer RAM 1, 2:

When an access error occurs when the Message Handler read a frame with network management information (PPI = '1') from the Transient Buffer RAM 1, 2 the corresponding network management vector register **FRNMV1/2/3** is not updated from this frame.

#### 103.3.13.4 Host Handling of Access Errors

Access error caused by transient bit flips can be fixed by:

(1) **Self-healing**

Access errors located in the Data Section of Message RAM, Transient Buffer RAM A or Transient Buffer RAM B are overwritten with the next write access to the disturbed bit(s) caused by Host access or by FlexRay communication.

(2) **CLEAR_RAMS Command**

When called in DEFAULT_CONFIG or CONFIG state POC command CLEAR_RAMS initializes the message RAM to zero.

(3) **Temporary Unlocking of Header Section**

An access error in the header section of a locked message buffer can be fixed by a transfer from the Input Buffer to the locked buffer Header Section. For this transfer, the write access to the **FRIBCR** (specifying the message buffer number) must be immediately preceded by the unlock sequence normally used to leave CONFIG state (see section 103.2.2.1).

For that single transfer the respective message buffer header is unlocked, regardless whether it belongs to the FIFO or whether its locking is controlled by **FRMRC.SEC**, and will be updated with new data.

### 103.3.14 Module Interrupt

In general, interrupts provide a close link to the protocol timing as they are triggered almost immediately when an error or status change is detected by the CC, a frame is received or transmitted, a configured timer interrupt is activated, or a stop watch event occurred. This enables the Host to react very quickly on specific error conditions, status changes, or

timer events. On the other hand too many interrupts can cause the Host to miss deadlines required for the application. Therefore the CC supports enable / disable controls for each individual interrupt source separately.

An interrupt may be triggered when

An error was detected

A status flag is set

A timer reaches a preconfigured value

A message transfer from Input Buffer to Message RAM or from Message RAM to Output Buffer has completed

A message transfer from the URAM to Message RAM or from Message RAM to URAM has completed

A stop watch event occurred

Tracking status and generating interrupts when a status change or an error occurs are two independent tasks. Regardless of whether an interrupt is enabled or not, the corresponding status is tracked and indicated by the CC. The Host has access to the actual status and error information by reading registers **FREIR**, **FRSIR**, **FROS**, **FROTS** and **FRITS**.

The general purpose interrupt lines to the Host, FlexRay Interrupt 0, FlexRay Interrupt 1, are controlled by the enabled interrupts in **FREIES** and **FRSIES**. In addition each of the two interrupt lines can be enabled / disabled separately by programming bit **FRILE.EINT0** and **FRILE.EINT1**.

The input data transfer interrupt lines to the Host, FlexRay input queue empty interrupt, FlexRay input queue full interrupt, are controlled by the enabled interrupts in **FRITS**. In addition each of the input data transfer interrupts can be enabled / disabled separately by programming the related bits in **FRITC.**

The output data transfer interrupt lines to the Host, FlexRay FIFO transfer warning interrupt, FlexRay output transfer warning interrupt, FlexRay FIFO transfer interrupt, FlexRay output transfer interrupt, are controlled by the enabled interrupts in **FROTS**. In addition each of the output data transfer interrupts can be enabled / disabled separately by programming the related bits in **FROTC.**

The three timer interrupts lines to the Host are controlled by the enabled interrupts in **FROS**. In addition each of the interrupt lines can be enabled / disabled separately by programming bit **FROC.T0IE**, **FROC.T1IE** and **FROC.T2IE**.

### 103.3.15 Assignment of FlexRay Configuration Parameters

**Table 103.17 FlexRay configuration parameters**

| Parameter | Bit(field) |
|---|---|
| pKeySlotusedForStartup | **FRSUCC1.TXST** |
| pKeySlotUsedForSync | **FRSUCC1.TXSY** |

| pExternOffsetCorrection | **FRGTUC11.EOC** |
| pExternRateCorrection | **FRGTUC11.ERC** |

### 103.3.16 Usage of data transfer

A mechanism is implemented to allow storage of FlexRay messages directly into the URAM (user RAM) and have transfers between the FlexRay internal message RAM and the URAM and vice versa with minimum CPU support. The data in the URAM should be indexed by data structure pointers located in data pointer tables stored in the URAM.
Data transfer from the URAM to the FlexRay internal message RAM (input transfer) needs to be initiated by the application. These transfers can be used to configure message buffers or to update transmit data.
A data transfer from the FlexRay internal message RAM to the URAM (output transfer) is initiated automatically by a reception into a receive message buffer or FlexRay internal FIFO or by a change in the slot status. It can be initiated also by a specific user transfer request.
The input and output data transfer can be activated independently. When the input data transfer is activated the application should not directly access message buffers using the FlexRay input buffer. When the output data transfer is activated the application should not directly access message buffers using the FlexRay output buffer.

### 103.3.16.1 Input data transfer

When the automatic input data transfer function is enabled, committed input data structures are transferred from the URAM to the FlexRay internal message RAM with minimum CPU support.

(1) **Activation and deactivation**

The input data transfer function should be activated before usage. The activation of the input transfer handler initializes the input queue put index (**FRITS.IPIDX**) and get index (**FRITS.IGIDX**) to zero. Also the interrupt status flags in the **FRITS** register (**IQEIS** and **IQFIS**) are set to '0'.

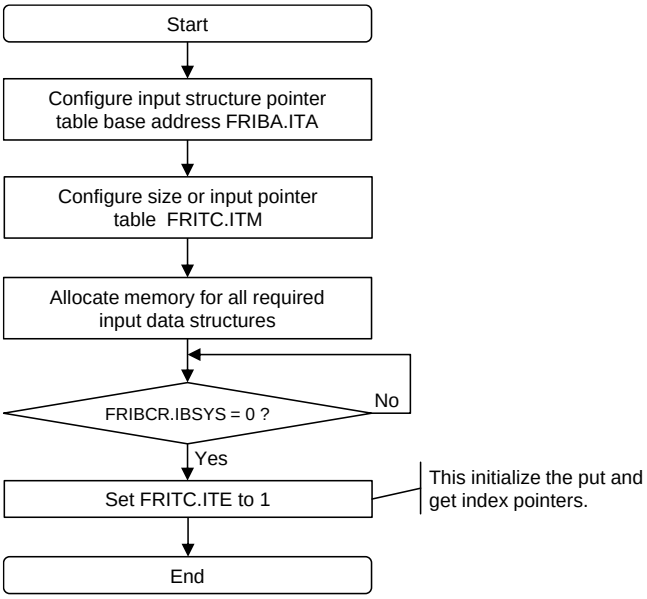

**Figure 103.18 Input transfer enable flow**

A deactivation request of the input transfer function can be made at any time. The input queue put index and the input queue status are maintained independently from the input transfer function state.

Before the transfer function gets disabled (status indicated by **FRITS.ITS**), user requested input transfers and all committed input transfers will be completed.

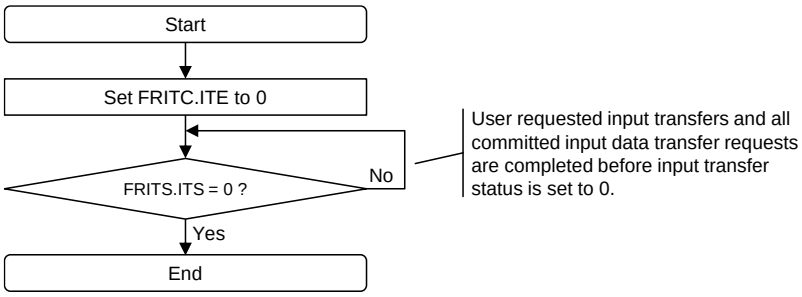

**Figure 103.19 Input transfer disable flow**

(2) **Input data structure**

The application has to reserve a location in the URAM to provide the content for message buffer configuration (input data structure).
The location of this input data structure needs to be defined by an input data structure pointer also located in the URAM.

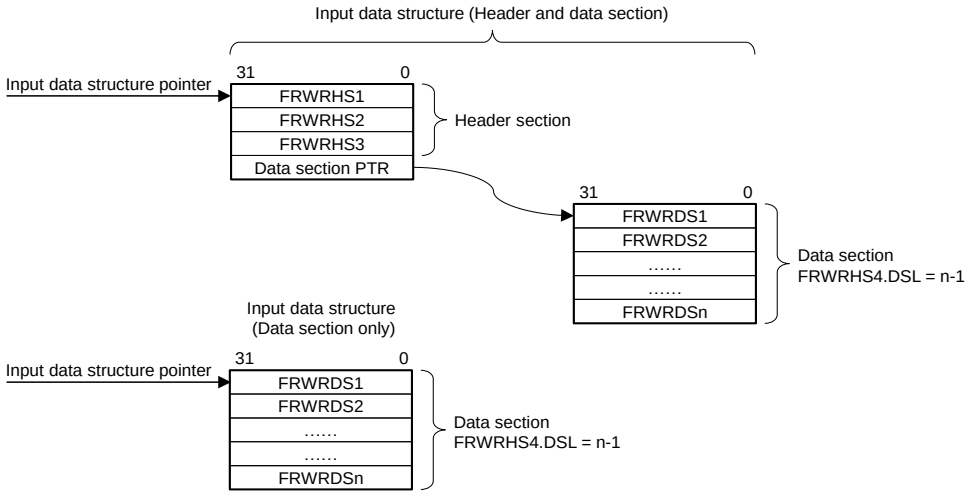

**Figure 103.20 Input data structure**

In general the input data structure consists of two sections, the header and the data section.
The header section consists of **FRWRHS1**, **FRWRHS2**, **FRWRHS3** and the data section pointer.

For information about the bit alignment and bit function within the header section refer to section 103.3.13.1.

Depending on the settings in the control field (**FRWRHS4**) located in the input pointer table, the data structure pointer is a reference to the address of **FRWRHS1** or **FRWRDS1**. The data structure pointer has to be aligned to a 32 bit address.

If the bit **LHS** in the address related to **FRWRHS4** is set to '1' it is required to provide a valid header section. In this case **FRWRHS1** is the first element of the data structure.

If the bit **LHS** in the address related to **FRWRHS4** is set to '0' a header section is not required. In this case **FRWRDS1** is the first element of the data structure.

If the bit **LDS** in the address related to **FRWRHS4** is set to '1' it is required to provide a valid data section. The pointer to the data section is a reference to the address of the first payload long word (**FRWRDS1**) and has to be aligned to a 32 bit address.

If the bit **LDS** in the address related to **FRWRHS4** is set to '0' a data section is not required. The data section pointer is not evaluated by the input handler.

The byte order for the FlexRay payload data in the input data structure is determined by **FROC.BEC**. For information about the payload data alignment within the data section refer to section 103.3.13.2 and section 103.3.17.

The length of the data section and the size to be allocated in the URAM depends on the configuration of the bits **DSL** in the address related to **FRWRHS4**.

For the transfer into the FlexRay core internal message RAM the number of 16 bit words configured by **FRWRHS2.PLC** is used. The application has to ensure, that a proper number of data words is provided in the URAM. In case the buffer is configured by **FRWRHS2.PLC** to hold an odd payload length, the application has to write zero to the last 16 bit of the payload section to ensure that the padding data is all zero.

(3) **Input pointer table**

To transfer data from the input data structures located in the URAM to the FlexRay internal message RAM the related input data structure pointer and control field needs to be added to the input pointer table which is located in the URAM. The location of the first element of this table is identified by the input pointer table base address (**FRIBA.ITA**). This base address has to be aligned to a 32 bit address.

The maximum number of input requests that can be queued is defined by the Input queue Table Max register (**FRITC.ITM**).

Each Input pointer table entry requires two long words. The required address range of the input pointer table for the queued transfer requests can be calculated by

$$input_pointer_table_size[bytes] = (((\mathrm{FRITC.ITM} + 1) * 2) * 4)$$

**Equation 4-1**

The input pointer entry for the user requested input transfer should be added after the end of the input pointer table. The pointer table index related to this entry and hence the number to be written to **FRUIR.UIDX**, is **FRITC.ITM**+1. The address in the input pointer table related to the user requested input transfer (user input address) can be calculated by

$$user_input_address = \mathrm{FRIBA.ITA} + input_pointer_table_size$$

**Equation 4-2**

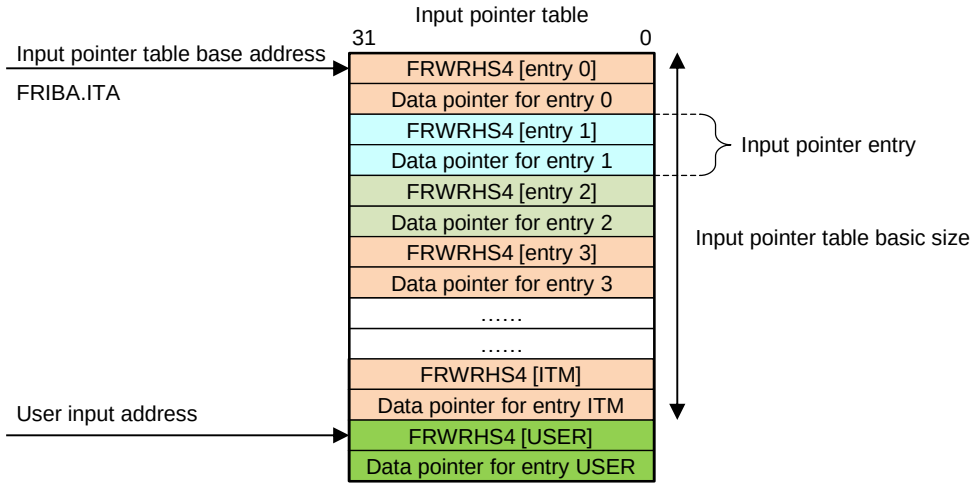

**Figure 103.21 Input pointer table**

The input pointer table holds the control field **FRWRHS4** and the pointers to the URAM location where the message buffer content (header section and/or data section) is stored.
The application has to write **FRWRHS4** and the input data structure pointer at the addresses in the input pointer table related to the put index position before a transfer request is initiated.

**FRWRHS4:**

| b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 |
|---|---|---|---|---|---|---|---|
| — | — | — | — | — | — | — | — |
| b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |

**Bit Functions**

| Bit | Symbol | Bit Name | Function |
|---|---|---|---|
| b[31:22] | - | Reserved | The read value is undefined. The write value should be always '0'. |
| b[21:16] | DSL | Data Section Length | Specifies the length of the data section in terms of 32 bit values. |
| b[15:12] | - | Reserved | The read value is undefined. The write value should be always '0'. |
| b11 | INV | Invalidate entry | 0: The data structure is valid and will be transferred to the FlexRay internal message RAM.<br>1: The data structure is invalid. FlexRay internal message RAM is not updated using this input pointer entry. |
| b10 | STR | Set transmission request | 0: The bit **FRTXRQn.TXR** for the message buffer selected by the bits **IMBNR** is set to '0'. No data from this message buffer is transmitted. |

| Bit | Symbol | Bit Name | Function |
|---|---|---|---|
| | | | 1: The bit **FRTXRQn.TXR** for the message buffer selected by the bits **IMBNR** is set to '1' to release the message buffer for transmission The application should not set the bit **STR** to '1' for receive buffers. |
| b9 | LDS | Load data section | 0: No update of data section.<br>1: Data section for the message buffer selected by the bits **IMBNR** is updated. |
| b8 | LHS | Load header section | 0: no update of header section.<br>1: Header section for the message buffer selected by the bits **IMBNR** is updated. |
| b7 | - | Reserved | The read value is undefined. The write value should be always '0'. |
| b[6:0] | IMBNR | Message buffer number to be updated | Selects the target message buffer number in the FlexRay internal message RAM for transfer |

Note that the **LHS** bit should not be set for protected message buffers.

The bit **LDS** defines if the data section of the message buffer selected by the bits **IMBNR** should be updated.
If **LDS** is set to '1' (**DSL** + 1) 32 bit words of payload data are transferred from the URAM to the message buffer selected by the bits **IMBNR**.
If **LDS** is set to '0' no payload data is transferred from the URAM.
Note that the payload transferred is independent from the configured payload length (bits **PLC** in the address related to **FRWRHS2**).

The bit **INV** can be used to invalidate a committed data structure. This bit should be only used to cancel the transfer of committed data structures when the input queue is halted (see section 103.3.16.1.(5)).

When this bit is set to '1' the message buffer number **IMBNR** is not updated. When the bit is set to '0' the message buffer number **IMBNR** is updated.

(4) **Transfer function of input data structure**

To use the input data structure transfer function the input transfer has to be activated (see section 103.3.16.1.(1)). The activation process requires the setup of the input pointer table (see section 103.3.16.1.(3)) in order to specify the source location (input data structures) for the data structures to be transferred. When the input transfer gets enabled the get index pointer is initialized to zero.

All FlexRay internal message buffers can be updated using the input transfer queue which is built in the input pointer table. The application has to write the pointer and control field (table entry) to the data structure to be transferred into the input pointer table. For that purpose the application has to maintain a put index for the input pointer table that indicates where the pointer has to be written to.
To commit this table entry to the input handler, the application has to write the target message buffer number to the input queue control register (**FRIQC.IMBNR**). Afterwards the application has to increment the application internal put index. By writing to the input queue control register the data available flag (**FRDAi.DA[IMBNR]**) is automatically set to '1'. The input transfer handler also maintains the put index pointer in the status register (**FRITS.IPIDX**).

In case the input queue gets full (number of queued input transfer requests is equal to the input queue table size) **FRITS.IQFP** and **FRITS.IQFIS** are set to '1'. The input queue full condition pending flag (**FRITS.IQFP**) changes from '1' to '0' when there are entries in the input queue available, whereby the input queue full interrupt status flag (**FRITS.IQFIS**) needs to be cleared by the application.
The application should not make any further write access to the bit **IMBNR** in the **FRIQC** register as long as the bit **IQFP** in the **FRITS** register is '1'.

In case the input queue gets empty (number of queued input transfer requests changes to zero) **FRITS.IQEIS** is set to '1'. The input queue empty interrupt status flag (**FRITS.IQEIS**) needs to be cleared by the application.

The transfer of the input data structures to the FlexRay message RAM is controlled by a get index pointer which is handled inside the FlexRay module and flagged in **FRITS.IGIDX**. Note that the index is referring to the input entry and not the address offset in the input pointer table.
If the input queue is not empty, the transfer handler reads out the input pointer table entry of the transfer queue and starts the transfer of the input data structure from the address the input pointer is referring to. When all required data words are transferred to the FlexRay module, the data available flag for the transferred message buffer number is set to '0' and the get index in the transfer handler is incremented by one.

In case of an invalidated data structure (see section 103.3.16.1.(5)) no FlexRay internal message buffer is updated and the related data available flag is automatically set to '0'. The change of the data available flag can be used to confirm the cancellation a transmit request

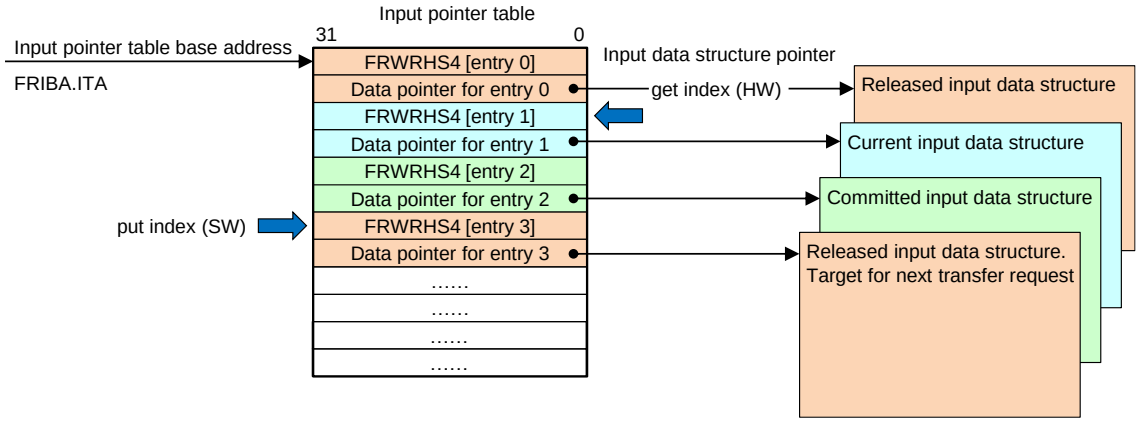

**Figure 103.22 Input pointer table**

Receive message buffers can be also configured using the input data transfer by setting up the required header sections and mark only the header section (**FRWRHS4.LDS** = '0', **FRWRHS4.LHS** = '1') to be updated in the FlexRay module.

(5) **Halting the input queue**

Committed data structures cannot be removed, but can be invalidated or updated when the input queue is halted.
To cancel data structures already committed to the input queue, the queue can be halted by writing a '1' to **FRITC.IQHR**.

After the ongoing input transfer has been completed the queue is halted and **FRITS.IQH** changes from '0' to '1'.

To invalidate an entry of the input queue **FRWRHS4.INV** has to be set to '1'. All other bits in **FWRHS4** should be unchanged.

Following flow shall be used to analyse whether a committed message has been already transferred to the FlexRay internal message RAM or not.

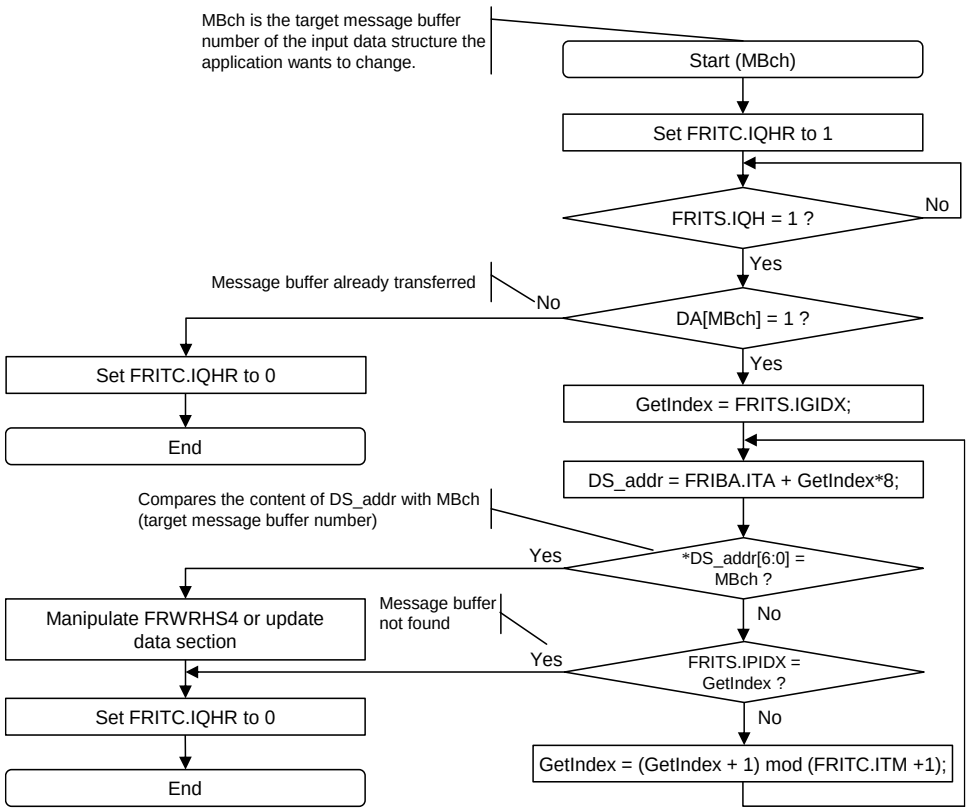

**Figure 103.23** Input table analysis

In case the message buffer was already transferred to the FlexRay internal message RAM, the user input transfer request can be used to bypass the actual queue and update the required message buffer (see section 103.3.16.2.(6)).

(6) **Transfer function of user requested input transfers**

To use this function the input transfer has to be activated (see section 103.3.16.1.(1)).

The application is capable, by using **FRUIR.UIDX,** to request a transfer of an input data structure. The user input transfer request is serviced first.

The application has to write the pointer and control field (table entry) to the data structure to be transferred into the input pointer table. The table entry for the user input transfer request should be added after the end of the input pointer table (see section 103.3.16.1.(3)).
To commit this table entry to the input handler, the application has to write the index (**FRITC.ITM**+1) to the user input transfer request register (**FRUIR.UIDX**).

By writing to the user input transfer request register, the user input transfer request pending flag (**FRITS.UIRP**) is automatically set to '1'.
As long this flag is '1' the application should not make any further user input transfer requests.

The user input transfer request pending flag (**FRITS.UIRP**) changes from '1' to '0' when the requested input transfer is completed. As next the pending transfers are processed.

### 103.3.16.2 Output data transfer

When the output data transfer function is enabled, received messages (either in dedicated message buffers or in the FlexRay receive FIFO) are transferred to the URAM by the output data handler. The output data handler can also transfer the message buffer content to the URAM on application request. When enabled the output handler is also capable to initiate a transfer when the message buffer status has changed.

(1) **Activation and deactivation**

The output data transfer function should be activated before usage. The activation of the output transfer hander will initialize the FIFO put and get index pointer and FIFO fill level (**FROTS.FGIDX** and **FROTS.FFL**) to zero, set the bits **FROTS.FDA**, **FROTS.OWP**, **FROTS.FWP** and **FROTS.UORP** to '0'. Also the interrupt status flags **FROTS.OTIS**, **FROTS.FIS**, **FROTS.OWIS** and **FROTS.FWIS**) are set to '0'.
The activation has no influence to the data available flags (**FRDAi.DA**) which are related to the dedicated buffers; these flags have to be cleared by the application.

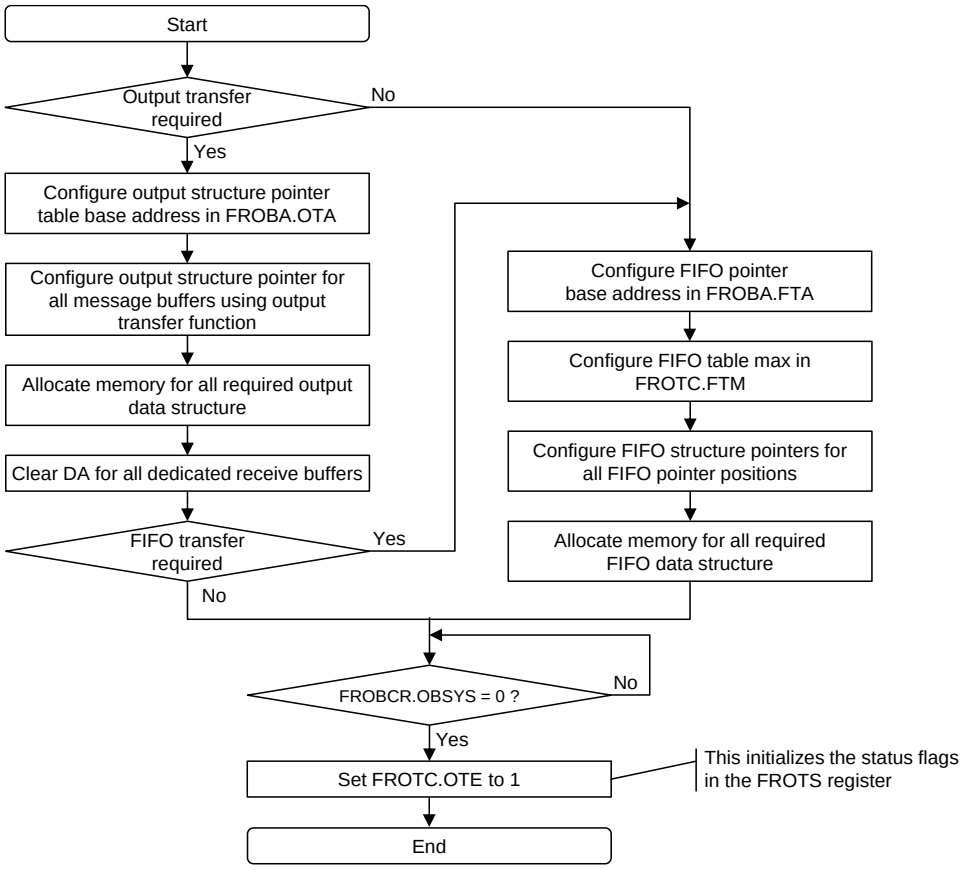

**Figure 103.24 Output transfer enable flow**

A deactivation request of the output data transfer function can be made at any time. An ongoing transfer will be completed and the completion of this transfer will be flagged. During this time **FROTS.OTS** remains '1'.
When **FROTS.OTS** changes from '1' to '0', the output transfer function is deactivated. The data available status flags and the FIFO get index are still maintained when the output transfer function is disabled.

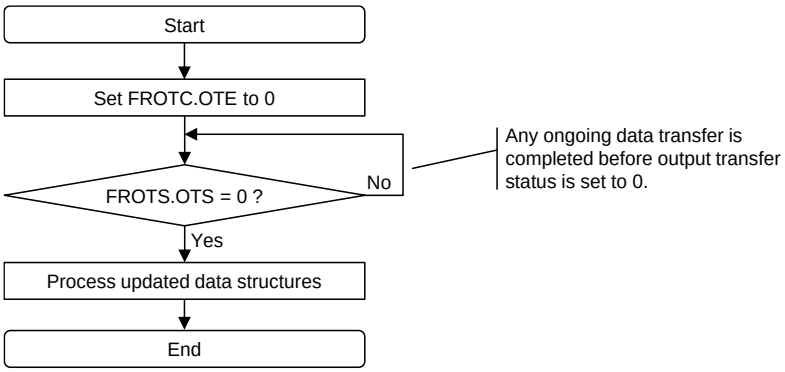

**Figure 103.25 Output transfer disable flow**

(2) **Output transfer data structure**

The data in the URAM is stored in an output data structure. The location of the output data structures are determined by output data structure pointers also located in the URAM. The output data structure and indexing is visualized in Figure 103.26.

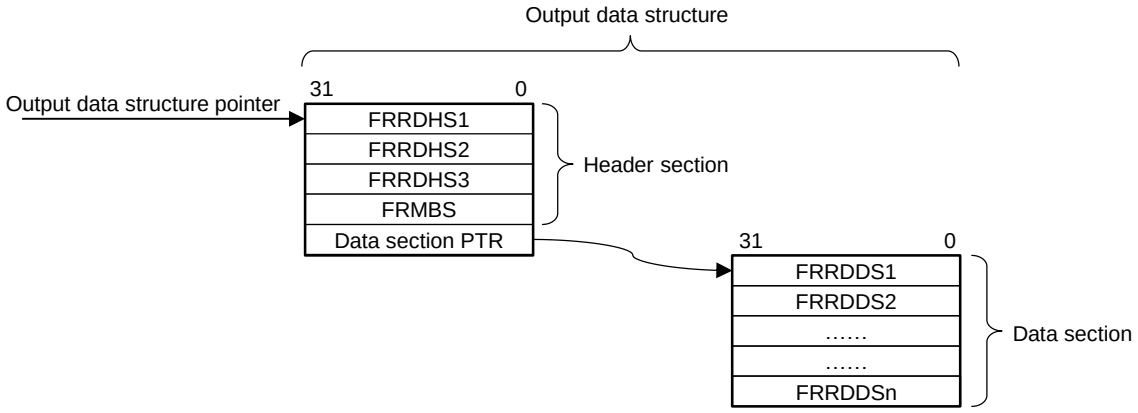

**Figure 103.26 Output data structure**

The output data structure consists of two sections, the header and data section. The header section consists of **FRRDHS1**, **FRRDHS2**, **FRRDHS3**, **FRMBS** and the data section pointer. **FRRDHS1** is the first element of the structure and has to be aligned to a 32 bit address. The data structure pointer is a reference to the address of **FRRDHS1**. For information about the bit alignment and bit function within the header section refer to section 103.3.13.1.

**FRRDDS1** is the first element of the data section. The data section pointer is a reference to the address of **FRRDDS1** and has to be aligned to a 32 bit address. The byte order for the FlexRay payload data in the output data structure is determined by the bit **BEC** in the **FROC** register. For information about the payload data alignment within the data section refer to section 103.3.13.2.

The length of the data section as well as the total structure size to be allocated in the URAM depends on the configured payload length (**FRRDHS2.PLC**) of the related message buffer. In case the configured payload length is an odd number

of words or the received payload length (**FRRDHS2.PLR**) is smaller than the configured payload length, the remaining data words in the URAM are unused and should not be used by the application.

The output data structure is identical for all three kinds of output transfers. In case only the header section is transferred the data section pointer is not evaluated by the output handler and the data section remains unchanged.

(3) **Output pointer table**

For the output data transfer function the application needs to setup an output pointer table in the URAM.
The location of the first element of this table should be programmed into the output pointer table base address (**FROBA.OTA**). This base address has to be aligned to a 32 bit address.
The size of the output pointer table is defined by the maximum of: the last configured dedicated message buffer and the highest message buffer number which will be used for the user output transfer request.

The output pointer table holds pointers (output data structure pointers) to the URAM location where a memory space is reserved for the target message buffer content (header section and data section).
There is a fixed linear relationship between the address of the entries in the output pointer table and the number of the related message buffers (see Figure 103.27): the output pointer table starts with the entry for message buffer number 0 at the address configured in **FROBA.OTA** and continues in ascending order for each following message buffer number, by 32 bit aligned address (e.g. message buffer 1 at address **OTA** + 4, message buffer 2 at address **OTA** + 8, etc.) for all possible message buffers.

When a set **ND** bit is the only transfer condition (**FROTC.OTCS** is set to 0) only message buffers configured as a dedicated receive buffer or that will be used for user output transfer requests need have valid pointer entries.

When a set **ND** bit or a set **MBC** bit is the transfer condition (**FROTC.OTCS** is set to 1) all dedicated receive buffer and dedicated transmit buffers need to have valid pointer entries.

(4) **FIFO output pointer table**

The FlexRay module internal FIFO can be extended by a queued buffer structure in the URAM.
If the FlexRay module internal FIFO is used the application needs to setup the FIFO output pointer table. The location of the first element of this table is identified by the FIFO pointer table base address (**FRFBA.FTA**). This base address has to be aligned to a 32 bit address.
The size of the FIFO pointer table and hence the maximum number of messages that can be added to the queue, is defined by FIFO Table Max (**FROTC.FTM**).

The FIFO pointer table holds pointers (output data structure pointers) to the URAM location where a memory space is reserved the target message buffer content (header section and data section). For each table entry a data pointer shall be configured in this table.

(5) **Transfer function of dedicated message buffers**

To use this transfer function the output transfer has to be activated (see section 103.3.16.2.(1)). The activation process requires to setup the output pointer table (see section 103.3.16.2.(3)) in order to specify the destination location (output data structures) for the data to transfer. Figure 103.27 shows how the output pointer table references the output data structures.

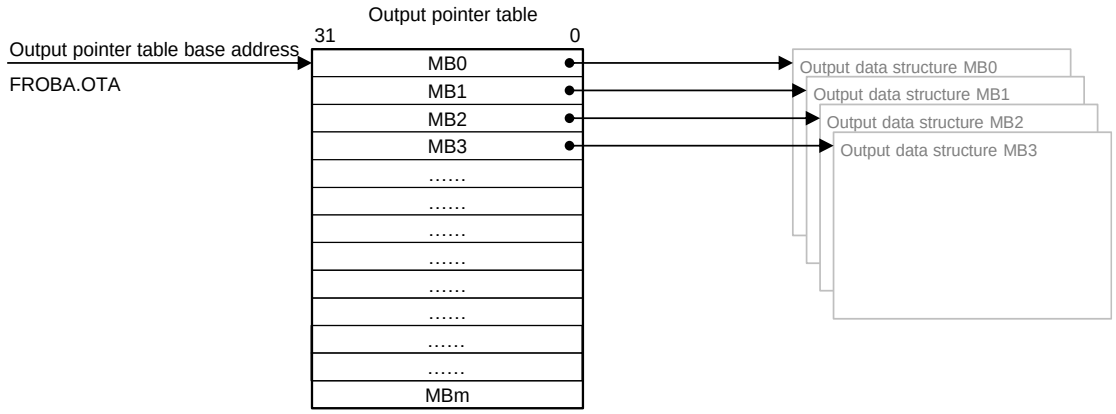

**Figure 103.27 Output data structure and indexing**

With **FROTC.OTCS** the output transfer condition can be selected between the 'New data only mode' and the 'New data and status changed mode'.

In the 'New data only mode' an output data transfer is initiated when a valid FlexRay data frame has been stored into a dedicated receive buffer which causes the related **ND** flag in the **FRNDATn** register to set. The **ND** flag in the **FRNDATn** register is automatically set to '0' during the transfer procedure. The header section is also transferred and hence the **MBC** flag in the **FRMBSCn** register is set to '0'.

In the 'New data and status changed mode' an output data transfer is initiated as described in the 'New data only mode'. In addition an output data transfer is initiated when only the message buffer status has been changed which causes the related **MBC** flag in the **FRMBSCn** register to be set. In this case only the header section is transferred. The **MBC** flag in the **FRMBSCn** register is automatically set to '0' during the transfer procedure.

After transferring the message buffer data from the FlexRay internal message RAM to the output data structure the corresponding data available flag in the **FRDAi** (i from 0 to 3) registers is set to '1'. The update of the output data structure is also flagged by the setting of the output transfer interrupt status flag (**FROTS.OTIS**).

As long as the data available flag remains '1' the corresponding output data structure will not be updated.

In the case
the data available flag is '1' and a valid received message was stored or
when **FROTC.OTCS** is '1' and the message buffer status was updated,
the output transfer warning interrupt flag (**FROTS.OWIS**) is set to '1' notifying the application that new data is available but the output data structure transfer cannot be processed. In addition **FROTS.OWP** is set to '1' that continuously flags that status of the output transfer warning condition.

If a valid receive message in the FlexRay internal message RAM is overwritten by an additional receive message, the message lost flag (**FRMBS.MLST**) is set to '1'. This flag can be evaluated after the message buffer has been transferred into an output data structure.

Following sections are giving a guidance how output data structures can be handled.

**(a) Data section copy method**

One option is to copy the information from the output data structure to a different location of the URAM and then release the output data structure by clearing the related data available flag. The application should use the copied information for further processing.

**(b) Data structure pointer method**

A different option is to modify the output data structure pointer in the output pointer table and to release the output data structure by clearing the related data available flag. The changed output data pointer should refer to a free data structure. The application should use the old data structure for further processing.

**(c) Data section pointer method**

A third option is to modify the data section pointer in the output data structure and to release the output data structure by clearing the related data available flag. The changed data section pointer should refer to a free memory area. The application should use the old data section for further processing by forwarding the data section pointer.

(6) **Transfer function of FIFO message buffers**

To use this buffer transfer function the output transfer has to be activated (see section 103.3.16.2.(1)). The activation process requires the setup of the FIFO pointer table (see section 103.3.16.2.(4)) in order to specify a location in the URAM reserved for the storage of the required output data structures.

A FIFO data transfer is initiated when a valid FlexRay data frame has been stored in the FlexRay internal FIFO.
After transfers from the internal FIFO to the output data structure, the FIFO interrupt status flag (**FROTS.FIS**) and **FROTS.FDA** are set to '1'. The bit **FROTS.FIS** can be used as an interrupt source. The bit **FROTS.FDA** indicates that the FIFO is not empty.
Up to **FROTC.FTM** output structures configured in the **FROTC** register can be queued.

The transfer to the extended FIFO buffer structure is controlled by index pointers. This put index is controlled by the FIFO transfer handler and is incremented after transferring a message to the output data structure.
The FIFO reception handler also maintains a get index which is flagged in **FROTS.FGIDX**. The value of this get index is known by the application by either reading the status or maintaining a software variable. The get index (initially set to the zero) is incremented by one when the application releases the oldest entry of the FIFO queue by writing '1' to **FROTS.FDA**. By comparing the put index and the get index the FIFO handler knows about the current fill level of the queued buffer structure.
The current FIFO fill level is flagged in **FROTS.FFL**. When **FROTS.FDA** is '1', there is at least one entry in the FIFO queue.

In case the queued buffer structure in the URAM is full (**FROTS.FFL** = **FROTC.FTM**+1), no further transfers are initialized, new messages remain in the FlexRay internal FIFO and the FIFO transfer warning interrupt status flag (**FROTS.FWIS**) is set to '1'.
In case the FlexRay internal FIFO structure becomes full, messages in the FlexRay internal FIFO structure may get overwritten. The related status flags and configuration registers of the FlexRay core module can be used to generate desired warning notifications.

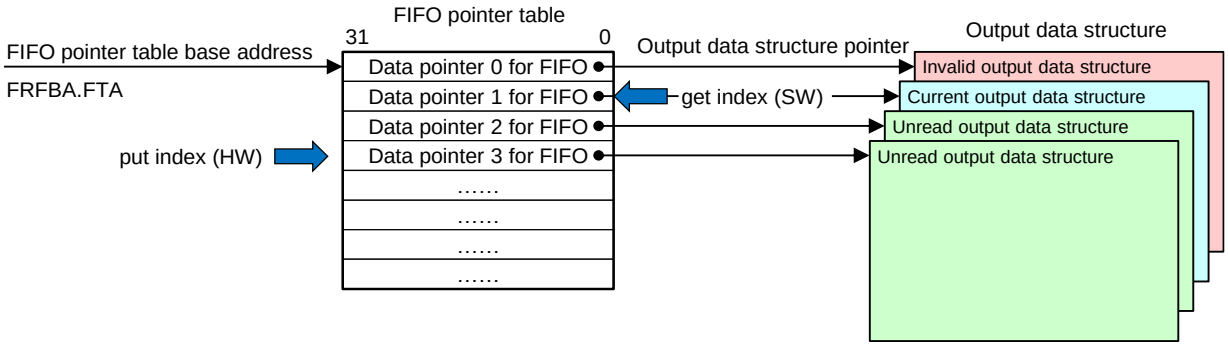

**Figure 103.28 FIFO pointer table**

(7) **Transfer function of user output transfer requests**

To use this transfer function the output transfer has to be activated (see section 103.3.16.2.(1)). The activation process requires to setup the output pointer table (see section 103.3.16.2.(3)) in order to specify the location in the URAM reserved for the transfer of the data (output data structures).

The application is capable, by using **FRUOR.UMBNR**, to request a transfer of dedicated message buffer to an output data structure. Except in CONFIG state, message buffers which are part of the FlexRay internal FIFO should not be requested.
The header section is always transferred to the output data structure. The transfer of the data section can be enabled by setting **FRUOR.URDS** to '1'. The selected message buffer content is stored in the output data structure location determined by the pointers in the output pointer table.
The data available status and transfer blocking by the **DA** bits in the **FRDAi** register is also used for the user requested transfers. Therefore the **DA** bit in the **FRDAi** register related to the requested buffer number (**FRUOR.UMBNR**) should be released before making the transfer request.
After writing to **FRUOR.UMBNR**, the bit **FROTS.UORP** is set to '1' to indicate that there is a pending user transfer request. When the transfer has been processed the bit **FROTS.UORP** is set to '0', the bit **FROTS.OTIS** is set to '1' and the **DA** bit in the **FRDAi** register related to the requested buffer number (**FRUOR.UMBNR**) is set to '1'.
User output transfer requests cannot be queued. The application should check the bit **FROTS.UORP** before writing to **FRUOR.UMBNR**.

User output transfer requests should not be made for message buffers which are pending in the input transfer queue.

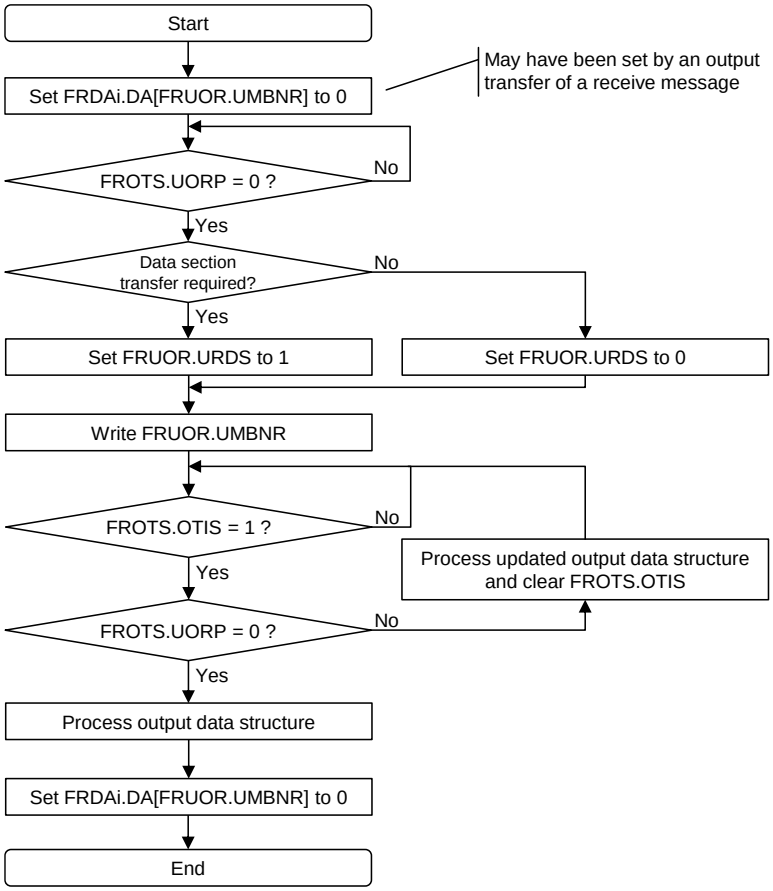

**Figure 103.29 User output transfer request flow**

Note that it may be possible that the data structure addressed by a user request is being updated due to a receive message buffer update (which causes the bit **DA** in the **FRDAi** register being set). This set **DA** flags inhibits the user output transfer request. Therefore polling **FROTS.UORP** is not a secure method to identify when the transfer of a requested message buffer has been completed. The bits **FROTS.OTIS** or the **DA** bit in the **FRDAi** register can be used instead. The exact flow depends on the software architecture.

#### 103.3.16.3 Data structure transfer scheduling

Cyclically the different types of transfer requests are checked. In order to guarantee a certain transfer time the different types of transfers have different priorities.

Use requested input transfers have highest priority followed by the transfer of data structures committed into the active input transfer queue. No new output transfer will be started as long as there is a pending input transfer request.

The three output transfer request types are checked in a specific order:

1) All dedicated message buffers in ascending order
   When **FROTC.OTCS** is set to '0', set flags in the **FRNDATn** register are causing a transfer of the message buffer to the output data structure if the destination area is free (**DA** bit in the **FRDAi** register is ‘0’).
   When **FROTC.OTCS** is set to '1', set flags in the **FRNDATn** register or set flags in the **FRMBSC1/2/3/4** register are causing a transfer of the message buffer to the output data structure if the destination area is free (**DA** bit in the **FRDAi** register is ‘0’).

2) FlexRay internal FIFO
   When the FlexRay internal FIFO is not empty and there is a free destination area, one FIFO message is transferred into the output data structure addressed by the FIFO pointer table.
3) User output request
   If there is a pending user output transfer request, one message buffer is transferred into the corresponding output data structure.

The check sequence is suspended when an input transfer occurs.

#### 103.3.16.4 Behaviour in case of data transfer access error

The memory areas accessed by the data transfer function may be protected by a memory protection unit (MPU). When the MPU flags an access to a protected address caused by an input or output transfer, an access error event is generated and the related bit in the **FRAES** register is set.

The ongoing transfer is immediately terminated but succeeding transfers are processed and may generate further access errors. Any following access errors are only flagged in **FRAES.MAE**. The other status flags are not updated.

(1) **Access error during input transfer**

When an access error occurs during an input transfer:

The ongoing transfer is immediately terminated. The FlexRay internal message RAM will not be updated

The address, the FlexRay module wanted to access to, is captured in the **FRAEA** register

**FRAES.IAE** is set to '1'

The input pointer table index is flagged in **FRAES.EIDX**

In case of an normal input transfer the to the transfer related **DA** flag in the **FRDAi** register is set to '0'

In case of an user input transfer request **FRITS.UIRP** is set to '0'

With the given status information the application is able to identify and correct the faulty data structure.
In addition the application needs to clear the input access error flag (**FRAES.IAE**).

(2) **Access error during output transfer**

When an access error occurs during an output transfer:

The ongoing transfer is immediately terminated but the update of the data structure may have started.
The address, the FlexRay module wanted to access to, is captured in the **FRAEA** register
**FRAES.OAE** is set to '1'
The output pointer table index is flagged in **FRAES.EIDX**
In case of an normal output transfer the to the transfer related **DA** flag in the **FRDAi** register remains '0' and no outputt transfer interrupt is generated
In case of an user output transfer request **FROTS.UORP** is set to '0'
With the given status information the application is able to identify and correct the faulty data structure. The data structure in the URAM cannot be treated as valid.
In addition the application needs to clear the output access error flag (**FRAES.OAE**).

The FlexRay module internal transfer of the message buffer is completed before the URAM access error is detected. The output transfer will not be re-initiated. To avoid loss of data, the application can perform a user output transfer request of this message buffer to a correct URAM location.

(3) **Access error during FIFO transfer**

When an access error occurs during an FIFO transfer:

The ongoing transfer is immediately terminated
The address, the FlexRay module wanted to access to, is captured in the **FRAEA** register
**FRAES.FAE** is set to '1'
The FIFO pointer table index is flagged in **FRAES.EIDX**
The FIFO index pointer are not changed and hence the FIFO status flags are unchanged
With the given status information the application is able to identify and correct the faulty data structure.
In addition the application needs to clear the FIFO access error flag (**FRAES.FAE**).

The data in the URAM cannot be treated as valid and is not released to the application. The message cannot be recovered.

### 103.3.16.5 Behaviour in case of RAM read errors

The FlexRay internal message RAM has an ECC checking mechanism. In case a not correctable RAM read error occurs the application has to analyse the status in the **FRMHDS** register and react as described in section 103.3.16.3. The input and output transfer handler reacts also on these errors detected in the message RAM when the error is related to an active transfer.

In addition the Transient Buffer RAM A and Transient Buffer RAM B have an ECC checking mechanism as well. Not correctable RAM read errors does not impact the data transfer functionality but have to be handled as described in section 103.3.13.1.(4).

In all cases data causing a read error is never transferred to the URAM. If there is no recovery available in the application, the message is lost.

(1) **Read error during transfer from TBF to MBF**

This internal transfer is done for each valid received FlexRay message.

A read error can only occur when reading the header section in the FlexRay Message RAM (see read error flags in **FRMHDS**). In this case the message buffer needs to be re-configured.

For dedicated receive message buffers the related **ND** flag in the **FRNDATn** register will not get set. Consequently the affected message buffer will not be transferred to the output data structure.

For the FlexRay internal FIFO buffers the **ND** flag in the **FRNDATn** register is not set but the FlexRay internal FIFO put index is incremented. Due to this, a transfer procedure from the FlexRay internal FIFO buffer to the output buffer is started. However if the read error is still present in the header section the update of the output data structure will not start (see 6.16.5.2); thus the data in the URAM remains correct.

Note that the correction or any other reconfiguration of FIFO related message buffers while there are pending FIFO transfers may result in incorrect data in the URAM. It is strongly recommended to deactivate the output data transfer before starting the reconfiguration and flush the FlexRay internal FIFO before to reactivate the output data transfer.

(2) **Read error during transfer from MBF to OBF**

This internal transfer is done for every output data transfer (dedicated reception, FIFO, user requested).

A read error can occur in the header and data section (see read error flags in **FRMHDS**). In both cases the message gets lost. If the error is located in the header section, the message buffer needs to be re-configured. If the error is located in the data section, the error is corrected with the next data section update.

When a read error occurs during the transfer from the message RAM to the output buffer the output data structure will not be updated and the data available will not be set to '1', the FIFO put index and the FIFO fill level is not changed.

In case of an user output transfer request **FROTS.UORP** is set to '0' even if there was no update of the output data structure.

(3) **Read error during transfer from IBF to MBF**

This internal transfer is done for every input data transfer.

A read error can occur only when there is no update of the header section requested (the bit **LHS** in **FRWRHS4** is set to "0") due to the reading of the header section from the message RAM (see read error flags in **FRMHDS**). In this case the message buffer needs to be re-configured.

When a read error occurs during the input data transfer the actually transferred message in the input queue gets lost.

(4) **Message RAM read errors**

Read errors when reading the header section are flagged in the **FRMHDS** register.

Depending on the buffer type and set buffer protection a reconfiguration of the message buffer may not be possible.

The input transfer function cannot be used to reconfigure a locked message buffer using the method described in section 103.3.13.4.(3)

Before reconfiguring a locked buffers the user should disable the input transfer function and the output transfer function.

#### 103.3.16.6 Reserved

### 103.3.17 Byte alignment

The alignment of the bytes received by the FlexRay protocol and the alignment of the bytes required by the application may be different. The FlexRay module provides with **FROC.BEC** a byte alignment function to support different byte ordering styles.

Figure 103.30 shows the payload byte alignment within a FlexRay frame.

**Figure 103.30 Byte alignment on the FlexRay bus**

### 103.3.17.1 Little endian alignment

When **FROC.BEC** is '0' the byte alignment is set to Little endian.

(1) **FRNMVn (n=1 to 3)**

The byte alignment of the NMV bytes is as below.

(2) **FRWRDSn (n=1 to 64)**

The byte alignment for the message payload in the FlexRay input buffer and in the input data structure is as below.

FRWRDSn.MD[7:0]= $Data_{4n-4}$
FRWRDSn.MD[15:8]= $Data_{4n-3}$
FRWRDSn.MD[23:16]= $Data_{4n-2}$
FRWRDSn.MD[31:24]= $Data_{4n-1}$

Transmission order on the FlexRay bus is **FRWRDSn.MD**[7:0], **FRWRDSn.MD**[15:8], **FRWRDSn.MD**[23:16], **FRWRDSn.MD**[31:24] with the most significant bit transmitted first.

(3) **FRRDDSn (n=1 to 64)**

The byte alignment for the message payload in the FlexRay output buffer and in the output data structure is as below.

FRRDDSn.MD[7:0]= $Data_{4n-4}$
FRRDDSn.MD[15:8]= $Data_{4n-3}$
FRRDDSn.MD[23:16]= $Data_{4n-2}$
FRRDDSn.MD[31:24]= $Data_{4n-1}$

Reception order on the FlexRay bus is **FRRDDSn.MD**[7:0], **FRRDDSn.MD**[15:8], **FRRDDSn.MD**[23:16], **FRRDDSn.MD**[31:24] with the most significant bit received first.

### 103.3.17.2 Big endian alignment

When **FROC.BEC** is '1' the byte alignment is set to Big endian.

(1) **FRNMVn (n=1 to 3)**

The byte alignment of the NMV bytes is as below.

(2) **FRWRDSn (n=1 to 64)**

The byte alignment for the message payload in the FlexRay input buffer and in the input data structure is as below.

FRWRDSn.MD[7:0]= $Data_{4n-1}$
FRWRDSn.MD[15:8]= $Data_{4n-2}$
FRWRDSn.MD[23:16]= $Data_{4n-3}$
FRWRDSn.MD[31:24]= $Data_{4n-4}$

Transmission order on the FlexRay bus is **FRWRDSn.MD**[31:24], **FRWRDSn.MD**[23:16], **FRWRDSn.MD**[15:8], **FRWRDSn.MD**[7:0] with the most significant bit transmitted first.

(3) **FRRDDSn (n=1 to 64)**

The byte alignment for the message payload in the FlexRay output buffer and in the output data structure is as below.

FRRDDSn.MD[7:0]= $Data_{4n-1}$
FRRDDSn.MD[15:8]= $Data_{4n-2}$
FRRDDSn.MD[23:16]= $Data_{4n-3}$
FRRDDSn.MD[31:24]= $Data_{4n-4}$

Reception order on the FlexRay bus is **FRRDDSn.MD**[31:24], **FRRDDSn.MD**[23:16], **FRRDDSn.MD**[15:8], **FRRDDSn.MD**[7:0] with the most significant bit received first.

## 103.4 Usage Notes

No description on this section

## 103.5 Safety Mechanism

### 103.5.1 EDC/ECC for FlexRay

#### 103.5.1.1 Overview

EDC/ECC protection is applied to internal buffers (MBF, TBF A, TBF B) of FlexRay.

#### 103.5.1.2 Hardware description

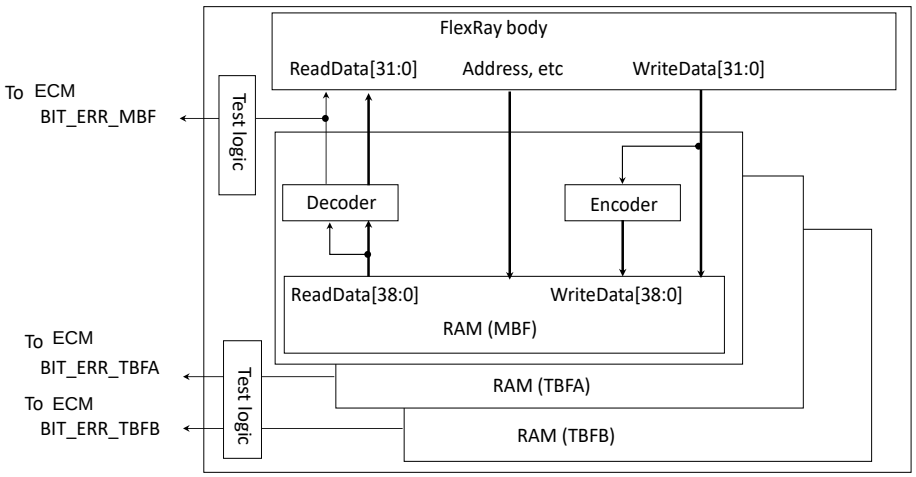

**Figure 103.31 EDC protection for FlexRay module internal buffers.**

**Table 103.18 Register configuration**

| Register name | Abbreviation | R/W | Address | Initial Value | Access size | |

# 104. PCIe Controller

## 104.1 Overview

This module performs PCIe controls, and transfers data between this LSI internal bus (AXI bus) and the PCI devices connected to the PCIe Controller. This module facilitates the design of systems using the PCI Express while at the same time permitting high-speed data transfers in a compact system.

This module functions as a bus bridge connecting the PCI Express to this LSI internal bus (AXI bus), and provides transfer channels between PCI Express devices and devices connected to the LSI internal bus (AXI bus).

This LSI incorporates a PCI Express physical module that supports dual lanes and one channel.

This module has two modes: a Root Port and an Endpoint and can operate as a Root Port or Endpoint that is defined in the PCI Express specification.

This module supports AVS.

Note:

### 104.1.1 Features

This module has the following features.

- The AXI bus clocks are S0D2_HSCφ.
- The AXI bus support 32bit address.
- The APB bus clocks are S0D4_HSCφ.
- Functions as a bridge that connects the PCI Express to the LSI internal bus (AXI bus)
  - Generates a PCIe packet from the AXI bus transaction to the PCI area
  - Generates a AXI bus transaction from a PCI Express packet
- Supports high-speed data transfer between PCI Express devices and internal bus (AXI bus) via the internal DMAC
- Supports the subset of PCI Express Base Specification Revision 4.0 (Sep. 27, 2017)
- Operates as a PCI Express Endpoint or a PCI Express Root Port
- Supports the requester and completer functions for the PCIe transaction
- Incorporates configuration registers and the following capability structures
  - Power management capability structure
  - MSI capability structure (supports masking function and pending bits.)
  - PCI Express capability structure
  - Advanced Error Reporting (AER) Capability structure
  - Device Serial Number Capability structure
  - Vendor-Specific Extended Capability ( for RAS DP, RAS D.E.S., and PTM. )
  - Latency Tolerance Reporting (LTR) Capability structure
  - Secondary PCI Express Extended Capability structure
  - L1 PM Substates Extended Capability structure
  - Precision Time Management (PTM) Capability structure
  - Data Link Feature Extended Capability structure
  - Physical Layer 16.0 GT/s Extended Capability structure
  - Lane Margining at the Receiver Extended Capability structure
- Supports interrupts by INTx and MSI

- Supports one lane (x1), two lanes (x2) or four lanes (x4).
- Supports multiple speeds (2.5 GT/s, 5.0 GT/s, 8.0 GT/s and 16.0 GT/s).
- Automatically performs link training and link configurations
- Supports the D+/D-line automatic swap function (lane polarity inversion)
- Achieves QoS through transaction ordering.
- Supports only VC0.
- Automatically performs flow control by managing six types of credits
- Automatic handling function by hardware
- Buffer for holding error packet headers and error indication status provided
- Supports the link power control function (L0, L0s, L1 states and L1 PM Substates)
- Supports device power control function (D0, $D3_{hot}$, and $D3_{cold}$ states).
- Supports 256-byte max payload size.
- Supports completion timeout disable.
- Supports Multi-Function Device (Up to two functions)
- Supports FLR(Function Level Reset)
- Resizable BAR

Note: This module does not support the following PCI Express functions.

- Expansion ROM for system boot
- Card bus
- Phantom function
- Power-management event (PME) handling by hardware
- Slot function (including Hot Plug)
- SR-IOV
  - However supports for external SR-IOV capable EndPoint devices is provided in RootComplex mode
- BIST function
- ARI forwarding function
- Port arbitration function
- MSI-X interrupt
  - However supports MSI-X by INTC-AP
- Surprise Down error function
- TLP Prefix
- Peer-to-peer transfer
- ECRC Generation and Checking
- M-PCIe

Note: The configuration parameter of the PCIe controller in this document is shown as below.

- CC_MAX_MSTR_TAGS_AXI : 64
- CC_NUM_DMA_RD_CHAN : 8
- CC_NUM_DMA_WR_CHAN : 8
- CX_ACS_ENABLE : false (0)
- CX_ARI_ENABLE : false (0)
- CX_ATOMIC_ROUTING_EN : false (0)
- CX_ATU_MAX_REGION_SIZE : 4G (0)
- CX_ATU_MIN_REGION_SIZE : 4k (4096)
- CX_ATU_NUM_INBOUND_REGIONS : 16
- CX_ATU_NUM_OUTBOUND_REGIONS : 16
- CX_AUTO_LANE_FLIP_CTRL_EN : true (1)
- CX_COMM_NFTS : 200
- CX_GEN3_EQ_COEFQ_DEPTH : 8
- CX_IDO_ENABLE : false (0)
- CX_L1_SUBSTATES_ENABLE : true (1)

- CX_LBC_EXT_AW : 32
- CX_NPRFX : 0
- CX_PIPE_VER : PIPE4.4.1 (2)
- CX_PIPE43_P0_P1CPM : 1: P0 -> P1.CPM
- CX_PIPE43_P1CPM_ENCODING : 0x4
- CX_PTM_ENABLE : true (1)
- CX_PTM_EXTERNAL_MASTER_TIME : true (1)
- CX_SRIOV_ENABLE : false (0)
- DEFAULT_CLK_PM_CAP : 0x0
- DEFAULT_L0S_EXIT_LATENCY : 2us to 4us (0x6)
- DEFAULT_L1_EXIT_LATENCY : 32us to 64us (0x6)
- DEFAULT_TARGET : Drop (0x0)
- FLT_Q_ADDR_WIDTH : 64
- MULTI_DEVICE_AND_BUS_PER_FUNC_EN : false (0)
- SLAVE_BUS_ADDR_WIDTH : 64
- CX_NL : x4
- DEFAULT_FAST_LINK_SCALING_FACTOR : false (0)
- CC_DMA_EFETCH_EN : true (1)

### 104.1.2 Block Diagram

Figure 104.1 shows a block diagram of the PCIe Controller.

The PCIe Controller comprises a bridge, PCIe Controller, and PCIe Controller physical unit.

The bridge provides the bridge function of connecting the internal bus (AXI bus and APB bus) to the PCI Express controller.

The PCIe Controller is a block that controls the PCI Express packet transmission and reception, and it implements the functions of transaction and data link layers that are defined by the PCI Express standards. The configuration registers defined by the PCI Express standards are installed in this block.

The PCIe Controller physical unit is a block that controls PCI Express transmission paths and implements the physical layer function that is defined by the PCI Express standards.

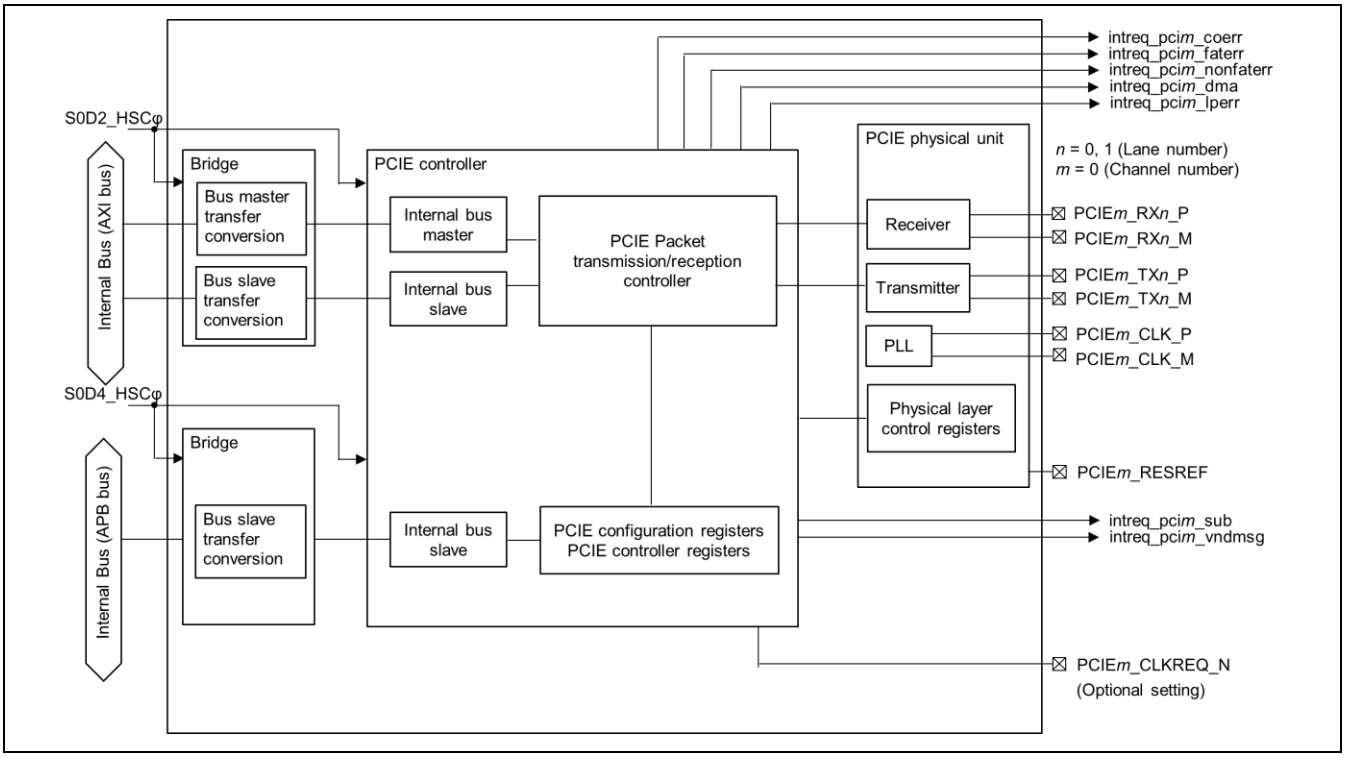

**Figure 104.1 Block Diagram**

### 104.1.3 External Pins

Table 104.1 shows the pin configuration.

**Table 104.1 Pin Configuration**

| Signal Name | Signal Conforming to PCI Standard | I/O | Description |
|---|---|---|---|
| PCIE*m*_CLK_P<br>PCIE*m*_CLK_M | REFCLK+<br>REFCLK- | Input | Reference clock inputs to the PLL incorporated in the PCIe Controller module (differential inputs). 100-MHz clock should be applied. |
| PCIE*m*_TX*n*_P<br>PCIE*m*_TX*n*_M<br>(*n*=0,1) | PETp*N*<br>PETn*N*<br>(*N*=0,1) | Output | Transmit data pins used by a physical module, where 2.5, 5.0, 8.0 or 16.0 GHz signals are propagated. (Differential output) |
| PCIE*m*_RX*n*_P<br>PCIE*m*_RX*n*_M<br>(*n*=0,1) | PERp*N*<br>PERn*N*<br>(*N*=0,1) | Input | Receive data pins used by a physical module, where 2.5, 5.0, 8.0 or 16.0 GHz signals are propagated. (Differential input) |
| PCIE*m*_RESREF | - | InOut | Reference Resistor Connection<br>Attach a 200-Ω ±1% ±100 ppm/°C precision resistor-to-ground on the board. |
| PCIE*m*_CLKREQ_N | CLKREQ# | I/O | Open drain pins to enable or disable the platform reference clocks.<br>These pins appear by pin multiplexing setting. |

*m=0*

### 104.1.4 Register Configuration

Table 104.3 shows the PCIe Controller registers. In Table 104.3, the Address Offset columns show an offset for register from the PCIe Controller base address.The actual access address is obtained by adding each offset to the PCIe Controller base address. Table 104.2 shows the PCIe Controller base address. These registers should be accessed through the APB bus. Only the little endian mode can be used for this module.

**Table 104.2 PCIe Controller Base Address**

Notes: 1. APB: APB bus (internal bus)
PCI: PCI local bus
'—' in R/W column: Access prohibited.
For details of R/W attribute for each bit, see section 104.2, Register Description.
2. Depends on the setting of the local address mask register 0.
3. R/W changes by the state. RootPort:R/W.EndPoint:R.
4. Depends on the setting of the local address mask register 1.
5. Depends on the setting of the local address mask register 2.
6. Depends on the setting of the local address mask register 3.
7. Depends on the setting of the local address mask register 4.
8. Depends on the setting of the local address mask register 5.
9. *m* is channel number. (*m* = 0)

Do not write to any addresses other than listed above. Operations cannot be guaranteed if writing is attempted. Values read from addresses other than those listed above are undefined.

### 104.1.5 Address Map

Table 104.5 shows the PCIe Controller Address Map.

**Table 104.5 PCIe Controller Address Map**

| Address | Space name | Note |
|---|---|---|
| H'3000_0000 – H'3FFF_FFFF | PCIE0 Memory | |
| H'E65D_0000 – H' E65D_0FFF | PCIE0 PCI Configuration for Function 0 | Common address in Root Complex mode and Endpoint mode |
| H'E65D_1000 – H' E65D_1FFF | PCIE0 PCI Configuration for Function 1 | Endpoint mode only |
| H'E65D_2000 – H' E65D_27FF | PCIE0 PCI shadow register for Function 0 | Common address in Root Complex mode and Endpoint mode |
| H'E65D_2800 – H' E65D_2FFF | PCIE0 PCI shadow register for Function 1 | Endpoint mode only |
| H'E65D_3000 – H' E65D_7FFF | PCIE0 PCIe Control Register | Common for All functions |
| H'FE00_0000 – H' FE3F_FFFF | PCIE0 Configuration for Remote | This area can be used for Memory |

### 104.1.6 Connected Module

**Table 104.6** Connected modules

| Module name | Connected module name | Function of connected module |
|---|---|---|
| PCIEC | AP-System Core | Access the Registers |
| | CPG | Output clocks |
| | Module Standby | Control to stop clocks |
| | Software Reset | Execute software reset |
| | INTC-AP, REALTIME CORE | Control to interrupt |
| | IMP-X6 | Image Processing |
| | RT-DMAC | DMA controller |

## 104.2 Register Description

[Legend for the Register Description]

A bit assignment figure is shown for each register. The initial value and R/W attribute are indicated for each bit.

| | |
|---|---|
| Bit: | Bit number or bit range |
| Bit Name: | Bit name or field name |
| Initial value: | Register value after a reset |
| —: | Undefined value |
| R/W: | Readable/writable. The written value can be read. |
| RW1C: | Readable/writable. The bit is initialized when 1 is written. Writing 0 is ignored. |
| R: | Read-only. The write value should always be 0. (If there is a direction on a read or write value in the Description column, set the bit as directed.) |
| RWS*: | Sticky-read write bit. Readable/writable. The bit is not initialized by a hot reset. |
| RW1CS*: | Sticky-read-only status bit. The bit is initialized when 1 is written. Writing 0 is ignored. The bit is not initialized by a hot reset. |
| RSVDP: | Reserved and Preserved – Reserved for future RW implementations. Register bits are read-only and must return zero when read. Software must preserve the value read for writes to bits. |

Note: * RWS and RW1CS are only used for the configuration registers. For details, see section 104.4.1, Write/Read Attributes of Configuration Registers.

### 104.2.1 PCI Configuration Register 0 function *i* (PCICONF0F*i*) *i* = 0, 1

**Common to Header TYPE00/01**

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | DEVICE_ID | | | | | | | | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 0 | 0 | 1 | 0 |
| PCI R/W | *1 | *1 | *1 | *1 | *1 | *1 | *1 | *1 | *1 | *1 | *1 | *1 | *1 | *1 | *1 | *1 |
| Internal bus R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | VENDOR_ID | | | | | | | | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 1 | 1 | 0 | 0 | 1 | 0 | 0 | 0 | 1 | 0 | 0 | 1 | 0 |
| PCI R/W | *1 | *1 | *1 | *1 | *1 | *1 | *1 | *1 | *1 | *1 | *1 | *1 | *1 | *1 | *1 | *1 |
| Internal bus R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

Note: *1: R/W changes by the TYPE. TYPE00: R, TYPE01: -

| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 31to 16 | DEVICE_ID | H'0032 | *1 | R | Device ID<br>Indicates the device ID.<br>Reflects a value set in the IDSETR0.Device ID set.<br>Indicates the device ID assigned to the PCI device vendor. |
| 15 to 0 | VENDOR_ID | H'1912 | *1 | R | Vendor ID<br>Indicates the vendor ID.<br>Reflects a value set in the IDSETR0.Vendor ID set.<br>Indicates the PCI device vendor ID. |

### 104.2.2 PCI Configuration Register 1 function *i* (PCICONF1F*i*) *i* = 0, 1

**Common to Header TYPE00/01**

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | DPE | SSE | RMA | RTA | STA | DEVSEL TIMING | | MDPE | FBBTCAP | — | 66MCAP | CAPL | INTST | — | — | IMMR |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 |
| PCI R/W | RW1C | RW1C | RW1C | RW1C | RW1C | R | R | RW1C | R | R | R | R | R | R | R | R |
| Internal bus R/W | RW1C | RW1C | RW1C | RW1C | RW1C | R | R | RW1C | R | R | R | R | R | R | R | R |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | INTDIS | — | SERRE | IDSS | PERS | VGAPS | MWIE | SC | BME | MSE | IOSE |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| PCI R/W | R | R | R | R | R | R/W | R | R/W | R | R/W | R | R | R | R/W | *1 | *1 |
| Internal bus R/W | R | R | R | R | R | R/W | R | R/W | R | R/W | R | R | R | R/W | R/W | R/W |

Note: *1: R/W changes by the TYPE. TYPE00: R, TYPE01: -

| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 31 | DPE | 0 | RW1C | RW1C | Detected Parity Error<br>Indicates that a parity error has been detected on the primary bus side.<br>• Root Port:<br>This bit is set by a Function whenever it receives a Poisoned TLP, regardless of the state the Parity Error Response bit in the Command register.<br>The bit is set when the Poisoned TLP is received by a Function's primary side.<br>• Endpoint:<br>This bit is set by a Function whenever it receives a Poisoned TLP, regardless of the state the Parity Error Response bit in the Command register. |
| 30 | SSE | 0 | RW1C | RW1C | Signaled System Error<br>Indicates that a system error has been detected.<br>• Root Port:<br>This bit is set when a Function sends an ERR_FATAL or ERR_NONFATAL Message, and the SERR# Enable bit in the Command register is 1b..<br>• Endpoint:<br>This bit is set when a Function sends an ERR_FATAL or ERR_NONFATAL message, and the SERR# Enable bit in the Command register is 1b.<br>For Functions that do not send ERR_FATAL or ERR_NONFATAL messages, the controller hardwires this bit to 0b. |

| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 29 | RMA | 0 | RW1C | RW1C | Received Master Abort<br>This bit is set when a Requester receives a Completion with Unsupported Request Completion status.<br>• Root Port:<br>The bit is set when the Unsupported Request is received by a Function's primary side.<br>• Endpoint:<br>For Functions that do not make Non-Posted Requests on their own behalf, the controller hardwires this bit to 0b. |
| 28 | RTA | 0 | RW1C | RW1C | Received Target Abort<br>This bit is set when a Requester receives a Completion with Completer Abort Completion status.<br>• Root Port:<br>The bit is set when the Completer Abort is received by a Function's primary side.<br>• Endpoint:<br>For Functions that do not make Non-Posted Requests on their own behalf, the controller hardwires this bit to 0b. |
| 27 | STA | 0 | RW1C | RW1C | Signaled Target Abort<br>This bit is set when a Function completes a Posted or Non-Posted Request as a Completer Abort error.<br>• Root Port:<br>This applies to a Function when the Completer Abort was generated by its primary side.<br>• Endpoint:<br>The controller hardwires this bit to 0b for Functions that do not signal Completer Abort. |
| 26, 25 | DEVSEL TIMING | All 0 | R | R | DEVSEL Timing<br>Fixed to 0. These bits are not used for PCI Express. |
| 24 | MDPE | 0 | RW1C | RW1C | Master Data Parity Error<br>This bit is set by a Function if the Parity Error Response bit in the Command register is 1b and either of the following two conditions occurs. If the Parity Error Response bit is 0b, this bit is never set.<br>• Root Port:<br>1. Port receives a Poisoned Completion going downstream<br>2. Port transmits a Poisoned Request upstream<br>• Endpoint:<br>1. Function receives a Poisoned Completion<br>2. Function transmits a Poisoned Request |
| 23 | FBBTCAP | 0 | R | R | Fast Back to Back Transaction Capable<br>Fixed to 0. This bit is not used for PCI Express. |
| 22 | — | 0 | R | R | Reserved<br>This bit is always read as 0. The write value should always be 0. |

| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 21 | 66MCAP | 0 | R | R | 66 MHz Capable<br>This bit is always read as 0. The write value should always be 0.<br>This bit is not used for PCI Express. |
| 20 | CAPL | 1 | R | R | Capabilities List<br>Indicates that the extended capabilities list exists in the PCI compatible configuration space. This IP supports the extended capabilities list.<br>This bit must not be set to a value other than 1. |
| 19 | INTST | 0 | R | R | Interrupt Status<br>When set, indicates that an INTx emulation interrupt is pending internally in the Function.<br>Setting the Interrupt Disable bit has no effect on the state of this bit.<br>For Functions that do not generate INTx interrupts, the controller hardwires this bit to 0b. |
| 18 to 17 | — | All 0 | R | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 16 | IMMR | 0 | R | R | Immediate Readiness.<br>This optional bit, when set, indicates the Function is guaranteed to be ready to successfully complete valid configuration accesses at any time following any reset that the host is capable of issuing Configuration Requests to this Function. |
| 15 to 11 | — | All 0 | R | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 10 | INTDIS | 0 | R/W | R/W | Interrupt Disable<br>Controls the ability of a Function to generate INTx emulation interrupts. When set, Functions are prevented from asserting INTx interrupts. |
| 9 | — | 0 | R | R | Reserved<br>This bit is always read as 0. The write value should always be 0. |
| 8 | SERRE | 0 | R/W | R/W | SERR# Enable.<br>Enables an error message transmission when a non-fatal/fatal error is detected.<br>Setting this bit to 1 enables an error message transmission. |
| 7 | IDSS | 0 | R | R | IDSEL Stepping/Wait Cycle Control<br>This bit is always read as 0. The write value should always be 0. This bit is not used for PCI Express. |
| 6 | PERS | 0 | R/W | R/W | Parity Error Response<br>This bit controls the logging of poisoned TLPs in the Master Data Parity Error bit in the Status register. |
| 5 | VGAPS | 0 | R | R | VGA Plate Snoop<br>This bit is always read as 0. The write value should always be 0. This bit is not used for PCI Express. |

| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 4 | MWIE | 0 | R | R | Memory Write and Invalidate Enable<br>This bit is always read as 0. The write value should always be 0.<br>This bit is not used for PCI Express. |
| 3 | SC | 0 | R | R | Special Cycle Enable<br>This bit is always read as 0. The write value should always be 0.<br>This bit is not used for PCI Express. |
| 2 | BME | 0 | R/W | R/W | Bus Master Enable<br>• Root Port:<br>This bit controls forwarding of Memory or I/O requests by a port in the Upstream direction.<br>When this bit is 0b, Memory and I/O Requests received at a Root Port must be handled as Unsupported Requests (UR) For Non-Posted Requests a Completion with UR completion status must be returned.<br>This bit does not affect forwarding of Completions in either the Upstream or Downstream direction.<br>The forwarding of Requests other than Memory or I/O Requests is not controlled by this bit.<br>• Endpoint:<br>Controls the ability of a Function to issue Memory and I/O Read/Write requests.<br>・When this bit is set, the Function is allowed to issue Memory or I/O Requests.<br>・When this bit is clear, the Function is not allowed to issue any Memory or I/O Requests.<br>Requests other than Memory or I/O Requests are not controlled by this bit. |
| 1 | MSE | 0 | *1 | R/W | Memory Space Enable<br>Enables an access to memory space.<br>When this bit is 0, the memory request to this device is handled as an unsupported request. |
| 0 | IOSE | 0 | *1 | R/W | IO Space Enable<br>Enables an access to I/O space.<br>When this bit is 0, the IO request to this device is handled as an unsupported request. |

| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
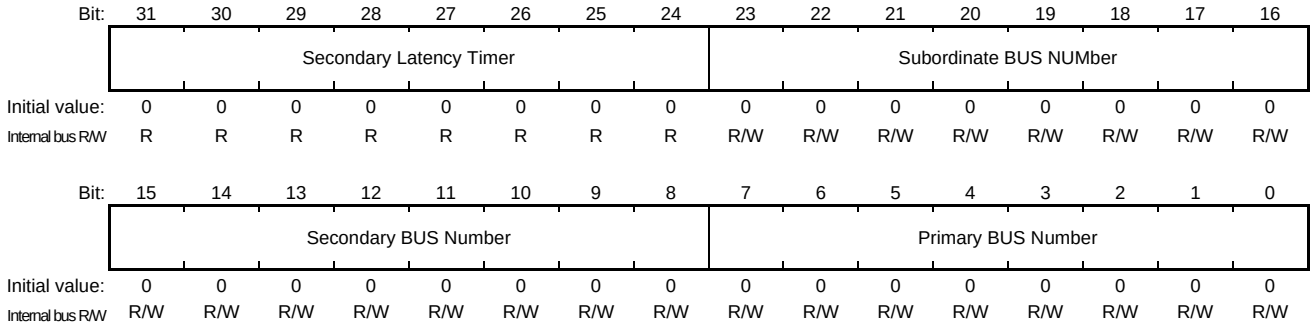
| 31 to 4 | BAR2_START | 0 | R/W | R/W | BAR2 Base Address.<br>▪ Memory Space: Base Address.<br>▪ IO Space : Base Address. |
| 3 | BAR2_PRFCH | 0 | R | R | BAR2 Prefetchable.<br>▪ Memory Space: Set to one if data is pre-fetchable.<br>BAR2 Base Address.<br>▪ IO Space : Base Address. |
| 2 to 1 | BAR2_TYPE | H'2 | R | R | BAR2 Type.<br>■ Memory Space:<br>Base Address registers that map into Memory Space can be 32 bits or 64 bits wide (to support mapping into a 64-bit address space). The bit encoding is as follows:<br>00 : Base register is 32 bits wide and can be mapped anywhere in the 32 address bit Memory Space.<br>10 : Base register is 64 bits wide and can be mapped anywhere in the 64 address bit Memory Space.<br>01/11 : Reserved.<br>BAR2 Base Address.<br>■ IO Space:<br>Bit 2 is Base Address.<br>Bit 1 is reserved and must return 0. |
| 0 | BAR2_MIO | 0 | R | R | BAR2 Memory Space Indicator.<br>This bit is used to determine whether the register maps into Memory or I/O Space. Base Address registers that map to Memory Space must return a 0b. Base Address registers that map to I/O Space must return a 1b. |

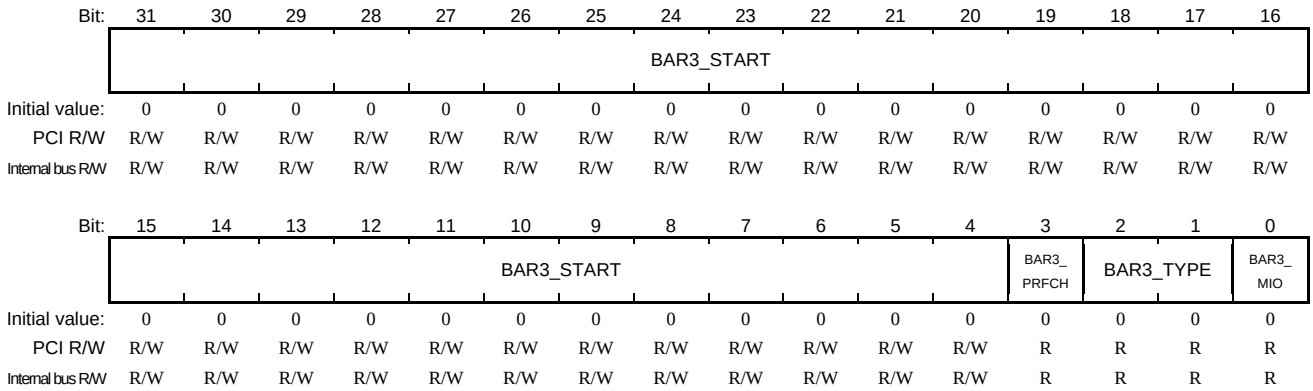
**Header TYPE01**



| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 24 | Secondary Latency Timer | All 0 | R | Secondary Latency Timer<br>Fixed to 0. These bits are not used for PCI Express. |
| 23 to 16 | Subordinate BUS NUMber | All 0 | R/W | Subordinate Bus Number<br>The Subordinate Bus Number register is used to record the bus number of the highest numbered PCI bus segment which is behind (or subordinate to) the bridge. |
| 15 to 8 | Secondary BUS Number | All 0 | R/W | Secondary Bus Number<br>The Secondary Bus Number register is used to record the bus number of the PCI bus segment to which the secondary interface of the bridge is connected. |
| 7 to 0 | Primary BUS Number | All 0 | R/W | Primary Bus Number<br>This register is not used by PCIExpress Functions. It is implemented for compatibility with legacy software. |

### 104.2.8 PCI Configuration Register 7 function *i* (PCICONF7F*i*) *i* = 0, 1

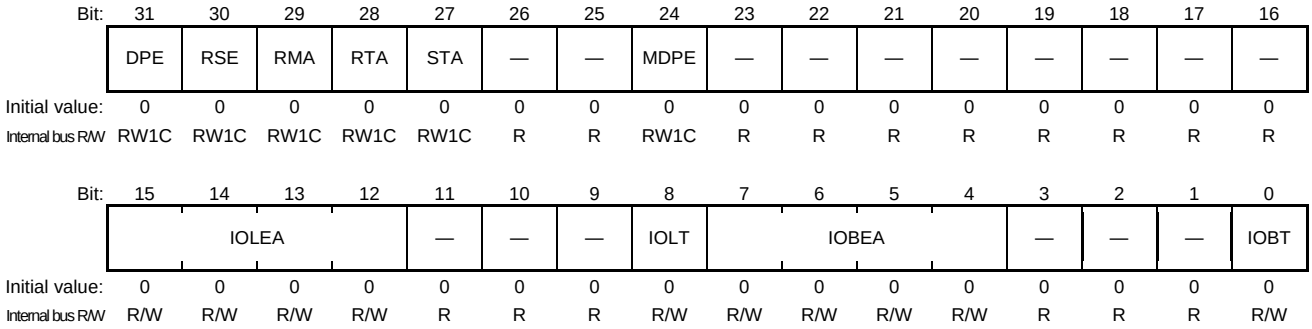
**Header TYPE00**



| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 31 to 4 | BAR3_START | 0 | R/W | R/W | BAR3 Base Address.<br>▪ Memory Space: Base Address.<br>▪ IO Space : Base Address. |
| 3 | BAR3_PRFCH | 0 | R | R | BAR3 Prefetchable.<br>▪ Memory Space: Set to one if data is pre-fetchable.<br>BAR3 Base Address.<br>▪ IO Space : Base Address. |
| 2 to 1 | BAR3_TYPE | H'0 | R | R | BAR3 Type.<br>■ Memory Space:<br>Base Address registers that map into Memory Space can be 32 bits or 64 bits wide (to support mapping into a 64-bit address space). The bit encoding is as follows:<br>00 : Base register is 32 bits wide and can be mapped anywhere in the 32 address bit Memory Space.<br>10 : Base register is 64 bits wide and can be mapped anywhere in the 64 address bit Memory Space.<br>01/11 : Reserved.<br>BAR3 Base Address.<br>■ IO Space:<br>Bit 2 is Base Address.<br>Bit 1 is reserved and must return 0. |
| 0 | BAR3_MIO | 0 | R | R | BAR3 Memory Space Indicator.<br>This bit is used to determine whether the register maps into Memory or I/O Space. Base Address registers that map to Memory Space must return a 0b. Base Address registers that map to I/O Space must return a 1b. |

### Header TYPE01

- Secondary status register



| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 | DPE | 0 | RW1C | Detected Parity Error<br>Indicates that a parity error has been detected on the secondary bus side.<br>This bit is set to 1 upon reception of a poisoned TLP. |
| 30 | RSE | 0 | RW1C | Received System Error<br>Indicates that a system error has been detected.<br>This bit is set to 1 upon reception of an ERR_FATAL/NON_FATAL message. |
| 29 | RMA | 0 | RW1C | Received Master Abort<br>Indicates that a master abort has been detected on the secondary bus side.<br>This bit is set to 1 upon reception of a completion with the unsupported request completion status. |
| 28 | RTA | 0 | RW1C | Received Target Abort<br>Indicates that a target abort has been detected on the secondary bus side.<br>This bit is set to 1 upon reception of a completion with the completer abort completion status. |
| 27 | STA | 0 | RW1C | Signaled Target Abort<br>Indicates that a target abort has been transmitted to the secondary bus side.<br>This bit is set to 1 upon transmission of a completion with the completer abort completion status. |
| 26, 25 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 24 | MDPE | 0 | RW1C | Master Data Parity Error<br>Indicates that a master data parity error has occurred on the secondary bus side. This bit is set when either of the following conditions is satisfied.<br>1. A poisoned completion has been received.<br>2. A poisoned request has been transmitted. |
| 23 to 16 | — | 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 15 to 12 | IOLEA | All 0 | R/W | IO Limit End Address<br>These bits correspond to the address[15:12] of IO address range. |
| 11 to 9 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 8 | IOLT | 0 | R/W | IO Limit Type<br>This bit encodes the IO addressing capability of the bridge.<br>0: 16-bit I/O address<br>1: 32-bit I/O address |
| 7 to 4 | IOBEA | All 0 | R/W | IO Base End Address<br>According to the PCI standard, sets the address[15:12] of the base address of the IO transaction to be transferred to the primary bus.<br>In this IP, this field has no effect on the hardware. |
| 3 to 1 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 0 | IOBT | 0 | R/W | IO Base Type<br>According to the PCI standard, indicates the base address decoding format of the IO transactions to be transferred to the primary bus.<br>0: 16-bit I/O address<br>1: 32-bit I/O address |

### 104.2.9 PCI Configuration Register 8 function *i* (PCICONF8F*i*) *i* = 0, 1

**Header TYPE00**

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

/W

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 25 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 24 | DLLSTCHG | 0 | RW1C | Data Link Layer State Changed<br>This bit is Set when the value reported in the Data Link Layer Link Active bit of the Link Status register is changed |
| 23 | EMLKSTS | 0 | R | Electromechanical Interlock Status<br>Indicates the Electromechanical Interlock state.<br>0: Not locked by Electromechanical Interlock.<br>1: Locked by Electromechanical Interlock |
| 22 | PRDETST | 0 | R | Presence Detect State<br>Indicates that the adapter is inserted in the slot.<br>0: The slot is empty.<br>1: The adapter is inserted in the slot. |
| 21 | MRLSENST | 0 | R | MRL Sensor State<br>Indicates the MRL sensor state.<br>0: MRL Closed.<br>1: MRL Open |
| 20 | COMCPL | 0 | RW1C | Command Completed<br>Indicates that the Hot Plug command has been completed.<br>0: The Hot Plug command is being executed.<br>1: The Hot Plug command execution has been completed. |
| 19 | PRDETCHG | 0 | RW1C | Presence Detect Changed<br>This bit is Set when the value reported in the Presence Detect State bit is changed. |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 18 | MRLSENCHG | 0 | RW1C | MRL Sensor Changed<br>If an MRL sensor is implemented, this bit is Set when a MRL Sensor state change is detected. If an MRL sensor is not implemented, this bit must not be Set. |
| 17 | PWFALDET | 0 | RW1C | Power Fault Detect<br>Indicates that the power fault has been detected. |
| 16 | ATBTNPRES | 0 | RW1C | Attention Button Pressed<br>Indicates that the attention button has been pressed. |
| 15 to 13 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 12 | DLLSTCHGE | 0 | RW | Data Link Layer State Change Enable<br>If the Data Link Layer Link Active Reporting capability is 1b, this bit enables software notification when Data Link Layer Link Active bit is changed. |
| 11 | EMLKCON | 0 | R | Electro Mechanical Interlock Control<br>If an Electromechanical Interlock is implemented, a write of 1b to this bit causes the state of the interlock to toggle.<br>This function is not supported. This bit is Reserved, always read as 0, the write value should always be 0. |
| 10 | PWCONCON | 0 | RW | Power Controller Control<br>If a Power Controller is implemented, this bit when written sets the power state of the slot per the defined encodings.<br>0: Power On<br>1: Power Off |
| 9, 8 | PWINDCON | B’11 | RW | Power Indicator Control<br>If a Power Indicator is implemented, writes to this field set the Power Indicator to the written state.<br>B’00: Reserved<br>B’01: On<br>B’10: Blink<br>B’11: Off |
| 7, 6 | ATINDCON | B’11 | RW | Attention Indicator Control<br>If an Attention Indicator is implemented, writes to this field set the Attention Indicator to the written state.<br>B’00: Reserved<br>B’01: On<br>B’10: Blink<br>B’11: Off |
| 5 | HOTPLGINTE | 0 | RW | Hot Plug Interrupt Enable<br>When Set, this bit enables generation of an interrupt on enabled hot-plug events. |
| 4 | COMCPLINTE | 0 | RW | Command Completed Interrupt Enable<br>If Command Completed notification is supported (if the No Command Completed Support bit in the Slot Capabilities register is 0b), when Set, this bit enables software notification when a hot-plug command is completed by the Hot-Plug Controller. |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 3 | PRDETCHGE | 0 | RW | Presence Detect Changed Enable<br>When Set, this bit enables software notification on a presence detect changed event. |
| 2 | MRLSENCHGE | 0 | RW | MRL Sensor Changed Enable<br>When Set, this bit enables software notification on a MRL sensor changed event |
| 1 | PWFALDETE | 0 | RW | Power Fault Detect Enable<br>When Set, this bit enables software notification on a power fault event. |
| 0 | ATBTNPRESE | 0 | RW | Attention Button Pressed Enable<br>When Set to 1b, this bit enables software notification on an attention button pressed event. |

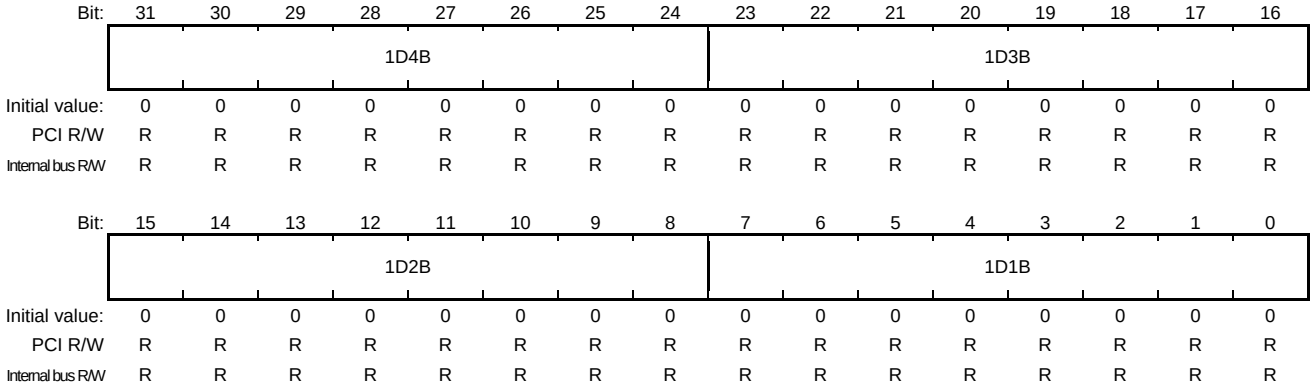
### 104.2.45 Advanced Error Reporting Capability Register 7 function *i* (AERCAP7F*i*) *i* = 0, 1

**Common to Header TYPE00/01**

- Header Log Register First

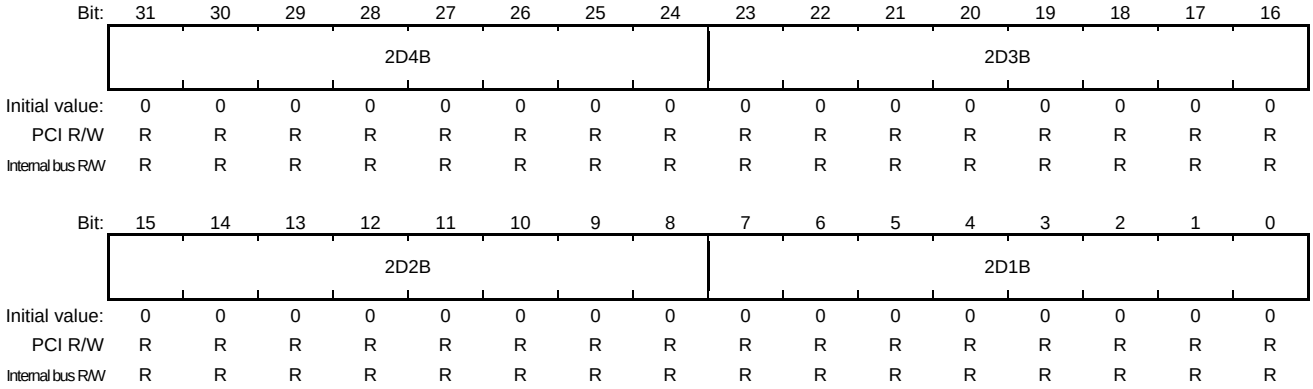


| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 31 to 24 | 1D4B | 0 | R | R | Byte 3 of Header log register of First 32 bit Data Word |
| 23 to 16 | 1D3B | 0 | R | R | Byte 2 of Header log register of First 32 bit Data Word |
| 15 to 8 | 1D2B | 0 | R | R | Byte 1 of Header log register of First 32 bit Data Word |
| 7 to 0 | 1D1B | 0 | R | R | Byte 0 of Header log register of First 32 bit Data Word |

### 104.2.46 Advanced Error Reporting Capability Register 8 function *i* (AERCAP8F*i*) *i* = 0, 1

**Common to Header TYPE00/01**

- Header Log Register Second

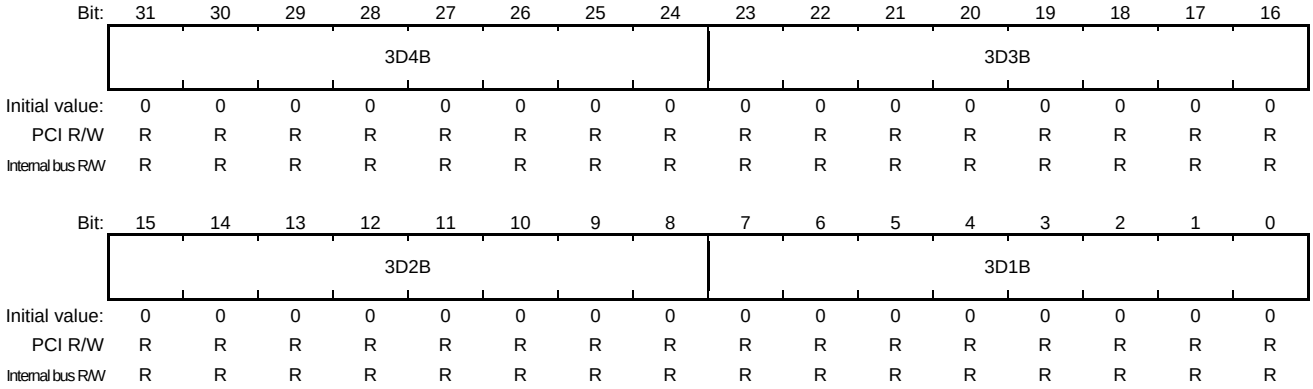


| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 31 to 24 | 2D4B | 0 | R | R | Byte 3 of Header log register of Second 32 bit Data Word |
| 23 to 16 | 2D3B | 0 | R | R | Byte 2 of Header log register of Second 32 bit Data Word |
| 15 to 8 | 2D2B | 0 | R | R | Byte 1 of Header log register of Second 32 bit Data Word |
| 7 to 0 | 2D1B | 0 | R | R | Byte 0 of Header log register of Second 32 bit Data Word |

### 104.2.47 Advanced Error Reporting Capability Register 9 function *i* (AERCAP9F*i*) *i* = 0, 1

**Common to Header TYPE00/01**

- Header Log Register Third

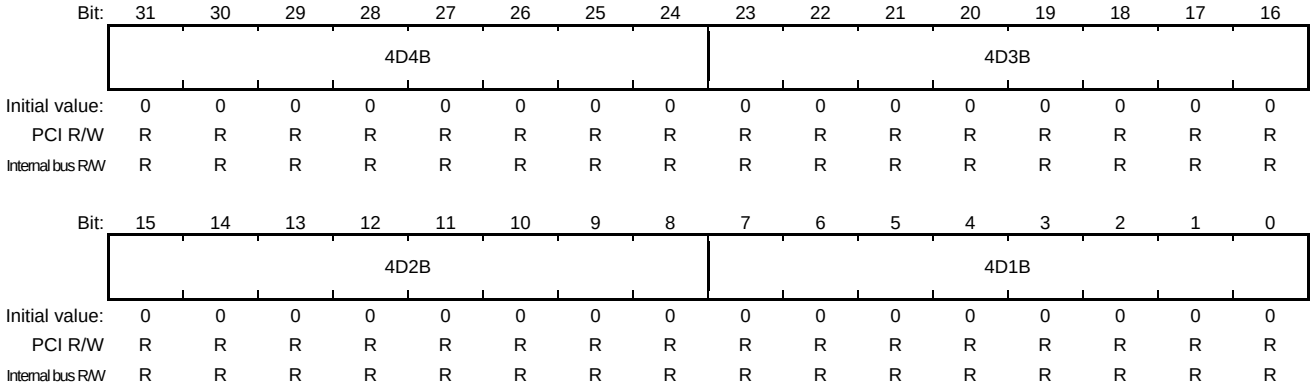


| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 31 to 24 | 3D4B | 0 | R | R | Byte 3 of Header log register of Third 32 bit Data Word |
| 23 to 16 | 3D3B | 0 | R | R | Byte 2 of Header log register of Third 32 bit Data Word |
| 15 to 8 | 3D2B | 0 | R | R | Byte 1 of Header log register of Third 32 bit Data Word |
| 7 to 0 | 3D1B | 0 | R | R | Byte 0 of Header log register of Third 32 bit Data Word |

### 104.2.48 Advanced Error Reporting Capability Register 10 function *i* (AERCAP10F*i*) *i* = 0, 1

**Common to Header TYPE00/01**

- Header Log Register Fourth



| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 31 to 24 | 4D4B | 0 | R | R | Byte 3 of Header log register of Fourth 32 bit Data Word |
| 23 to 16 | 4D3B | 0 | R | R | Byte 2 of Header log register of Fourth 32 bit Data Word |
| 15 to 8 | 4D2B | 0 | R | R | Byte 1 of Header log register of Fourth 32 bit Data Word |
| 7 to 0 | 4D1B | 0 | R | R | Byte 0 of Header log register of Fourth 32 bit Data Word |

### 104.2.49 Advanced Error Reporting Capability Register 11 function *i* (AERCAP11F*i*) *i* = 0

**Header TYPE01 only**

- Root Error Command Register

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 31 to 20 | NOFSET | H'178 | R | R | Next Capability Offset |
| 19 to 16 | CVERSION | H'1 | R | R | Capability Version<br>Indicates the version of the capability structure present. |
| 15 to 0 | EXTCI | H'19 | R | R | Secondary PCI Express Extended Capability ID<br>Indicates the nature and format of the extended capability. |

### 104.2.56 Secondary PCI Express Extended Capability Register 1 function 0 (SEXPECAP1F0)

**Common to Header TYPE00/01**

- Link Control 3 Register

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| PCI R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |
| Internal bus R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

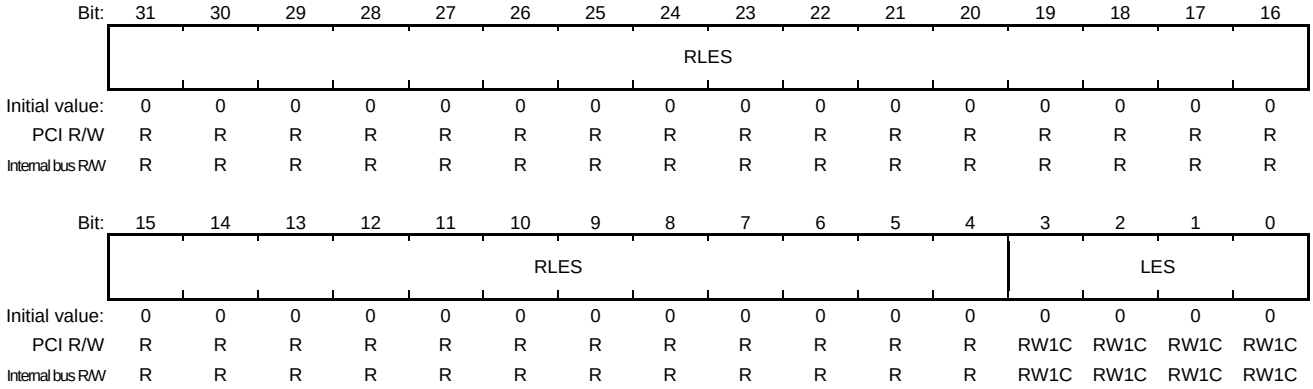
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | EQRIE | PEQ |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| PCI R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R/W | R/W |
| Internal bus R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R/W | R/W |

| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 31 to 2 | — | All 0 | R | R | Reserved<br>These bits are always read as 0.The write value should always be 0. |
| 1 | EQRIE | 0 | R/W | R/W | Link Equalization Request Interrupt Enable<br>When Set, this bit enables the generation of an interrupt to indicate that the Link Equalization 8.0 GT/s Request bit or the Link Equalization Request 16.0 GT/s bit has been set. |
| 0 | PEQ | 0 | R/W | R/W | Perform Equalization<br>When this bit is 1b and a 1b is written to the Retrain Link bit with the Target Link Speed field set to 8.0 GT/s or higher, the Downstream Port must perform Link Equalization. |

### 104.2.57 Secondary PCI Express Extended Capability Register 2 function 0 (SEXPECAP2F0)

**Common to Header TYPE00/01**

- Lane Error Status Register



| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 31 to 4 | RLES | All 0 | R | R | Reserved for future use.<br>These bits are always read as 0.The write value should always be 0. |
| 3 to 0 | LES | All 0 | RW1C | RW1C | Lane Error Status Bits per Lane.<br>Each bit indicates if the corresponding Lane detected a Lane-based error. A value of 1b indicates that a Lane based-error was detected on the corresponding Lane Number. |

### 104.2.58 Secondary PCI Express Extended Capability Register 3 function 0 (SEXPECAP3F0)

**Common to Header TYPE00/01**

- Lane Equalization Control Register for lanes 1 and 0.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | URPH1 | | | UTP1 | | | | — | DRPH1 | | | DTP1 | | | |

| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 31 to 4 | — | All 0 | R | R | Reserved for future use<br>These bits are always read as 0.The write value should always be 0. |
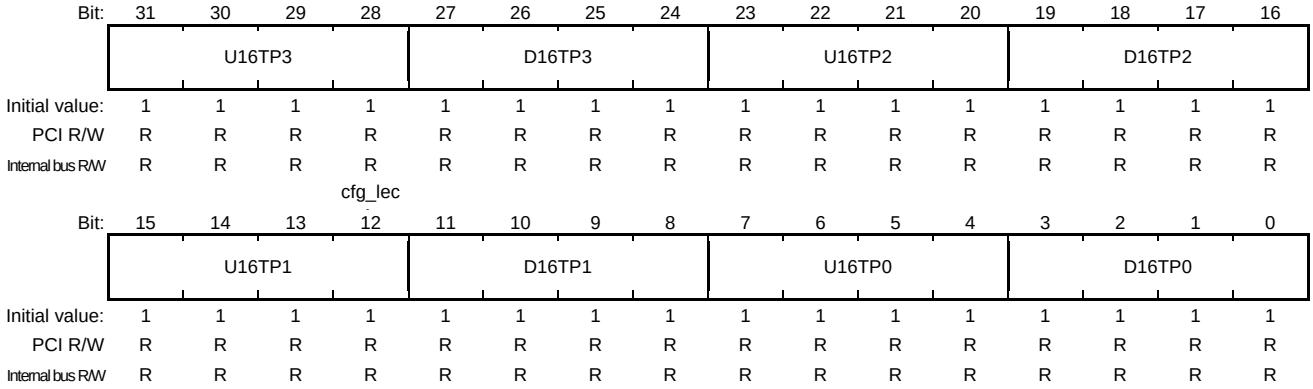
| 3 to 0 | SRDS | All 0 | RW1C | RW1C | Second Retimer Data Parity Mismatch Status<br>Each bit indicates if the corresponding Lane detected a Data Parity mismatch. A value of 1b indicates that a mismatch was detected on the corresponding Lane Number. |

### 104.2.67 Physical Layer 16.0 GT/s Extended Capability Register 7 function 0 (PHY16ECAP7F0)

**Common to Header TYPE00/01**

- 16.0 GT/s Lane Equalization Control Register for Lane 0-3

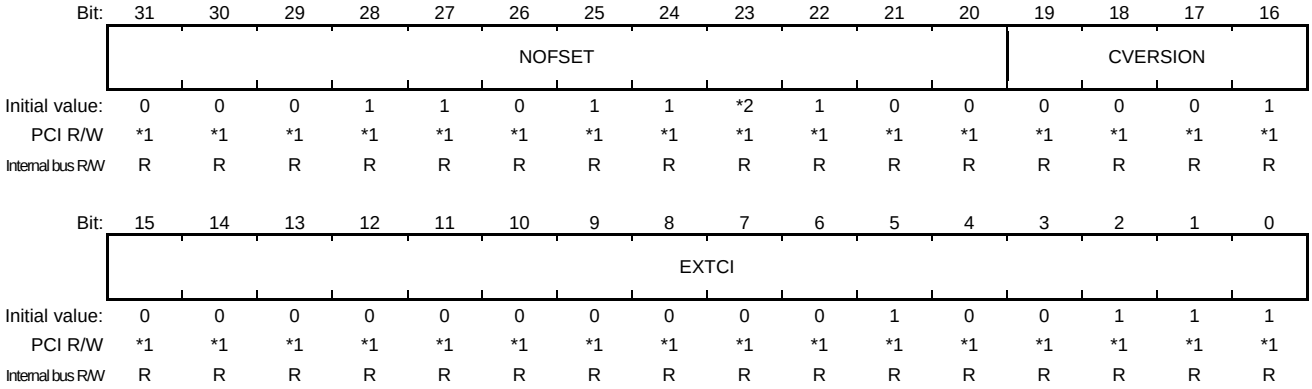


| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 31 to 28 | U16TP3 | H'F | R | R | Upstream Port 16.0 GT/s Transmitter Preset3<br>Field contains the Transmit Preset value sent or received during 16.0 GT/s Link Equalization. |
| 27 to 24 | D16TP3 | H'F | R | R | Downstream Port 16.0 GT/s Transmitter Preset3<br>Transmitter Preset used for 16.0 GT/s equalization by this Port when the Port is operating as a Downstream Port. This field is ignored when the Port is operating as an Upstream Port. |
| 23 to 20 | U16TP2 | H'F | R | R | Upstream Port 16.0 GT/s Transmitter Preset2<br>Field contains the Transmit Preset value sent or received during 16.0 GT/s Link Equalization. |
| 19 to 16 | D16TP2 | H'F | R | R | Downstream Port 16.0 GT/s Transmitter Preset2<br>Transmitter Preset used for 16.0 GT/s equalization by this Port when the Port is operating as a Downstream Port. This field is ignored when the Port is operating as an Upstream Port. |
| 15 to 12 | U16TP1 | H'F | R | R | Upstream Port 16.0 GT/s Transmitter Preset1<br>Field contains the Transmit Preset value sent or received during 16.0 GT/s Link Equalization. |
| 11 to 8 | D16TP1 | H'F | R | R | Downstream Port 16.0 GT/s Transmitter Preset1<br>Transmitter Preset used for 16.0 GT/s equalization by this Port when the Port is operating as a Downstream Port. This field is ignored when the Port is operating as an Upstream Port. |
| 7 to 4 | U16TP0 | H'F | R | R | Upstream Port 16.0 GT/s Transmitter Preset0<br>Field contains the Transmit Preset value sent or received during 16.0 GT/s Link Equalization. |
| 3 to 0 | D16TP0 | H'F | R | R | Downstream Port 16.0 GT/s Transmitter Preset0<br>Transmitter Preset used for 16.0 GT/s equalization by this Port when the Port is operating as a Downstream Port. This field is ignored when the Port is operating as an Upstream Port. |

### 104.2.68 Lane Margining at the Receiver Extended Capability Register 0 function 0 (LNMGNCAP0F0)

**Common to Header TYPE00/01**

- Margining Extended Capability Header



Note: *1: R/W changes by the TYPE. TYPE00:R, TYPE01:-

| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 31 to 20 | NOFSET | H'1B<br>*2 | *1 | R | Next Capability Offset<br>*2Note: For initial value, in RC mode bit [23] is 1, in EP mode this bit is 0. Thus intial value can be H'1BC or H'1B4, depends on the device mode. |
| 19 to 16 | CVERSION | H'1 | *1 | R | Capability Version<br>Indicates the version of the capability structure present. |
| 15 to 0 | EXTCI | H'27 | *1 | R | PCI Express Extended Capability ID<br>Indicates the nature and format of the extended capability. |

### 104.2.69 Lane Margining at the Receiver Extended Capability Register 1 function 0 (LNMGNCAP1F0)

**Common to Header TYPE00/01**

- Margining Port Capabilities and Status Register

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
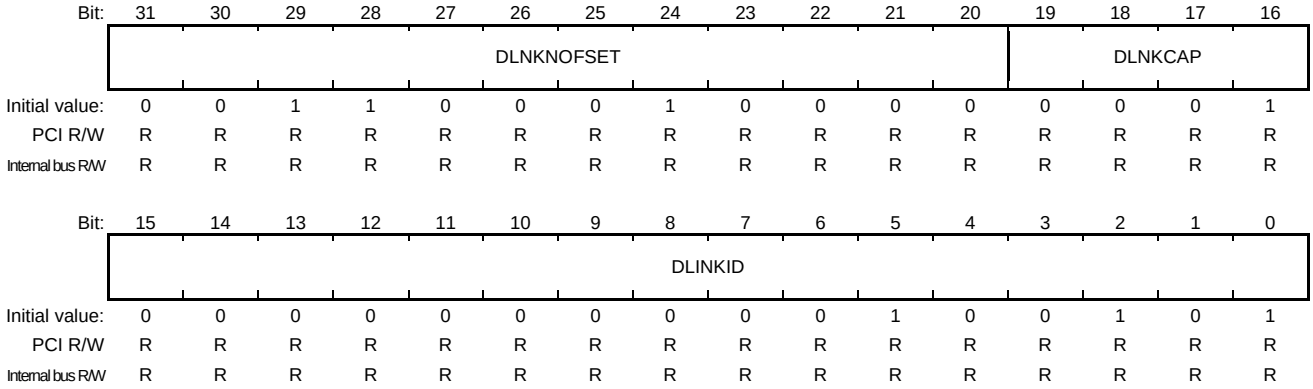
| 31 to 28 | RAMIUERR | H'0 | R | R | RAM index where an uncorrected error (2-bit ECC) has been detected. |
| 27 | — | 0 | R | R | Reserved<br>This bit is always read as 0. The write value should always be 0. |
| 26 to 0 | RAMAUERR | H'0 | R | R | RAM Address where an uncorrected error (2-bit ECC) has been detected. |

### 104.2.138 Data Link Feature Extended Capability Register 0 function 0 (DLFECAP0F0)

### Common to Header TYPE00/01

- Data Link Feature Extended Capability Header

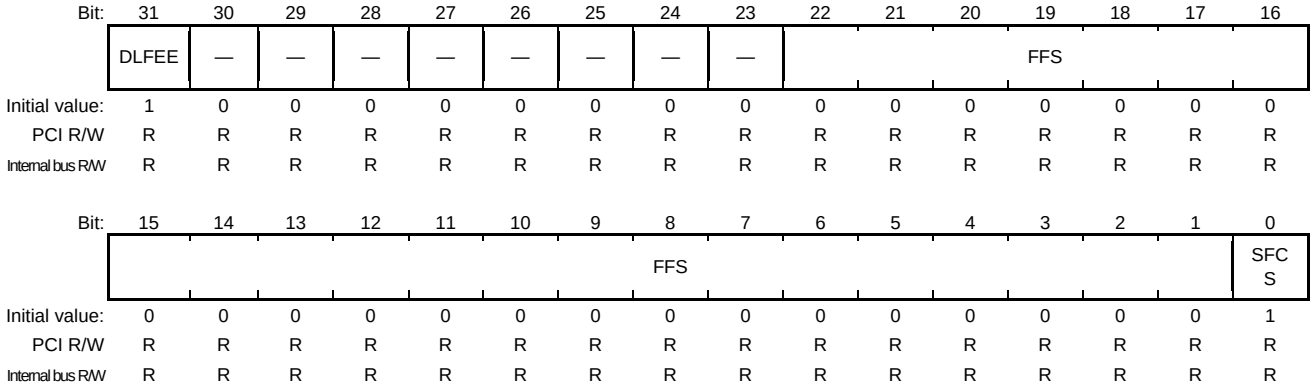


| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 31 to 20 | DLNKNOFSET | H'310 | R | R | Next Capability Offset |
| 19 to 16 | DLNKCAP | H'1 | R | R | Capability Version<br>Indicates the version of the capability structure present. |
| 15 to 0 | DLINKID | H'25 | R | R | PCI Express Extended Capability ID<br>Indicates the nature and format of the extended capability. |

### 104.2.139 Data Link Feature Extended Capability Register 1 function 0 (DLFECAP1F0)

### Common to Header TYPE00/01

- Data Link Feature Capabilities

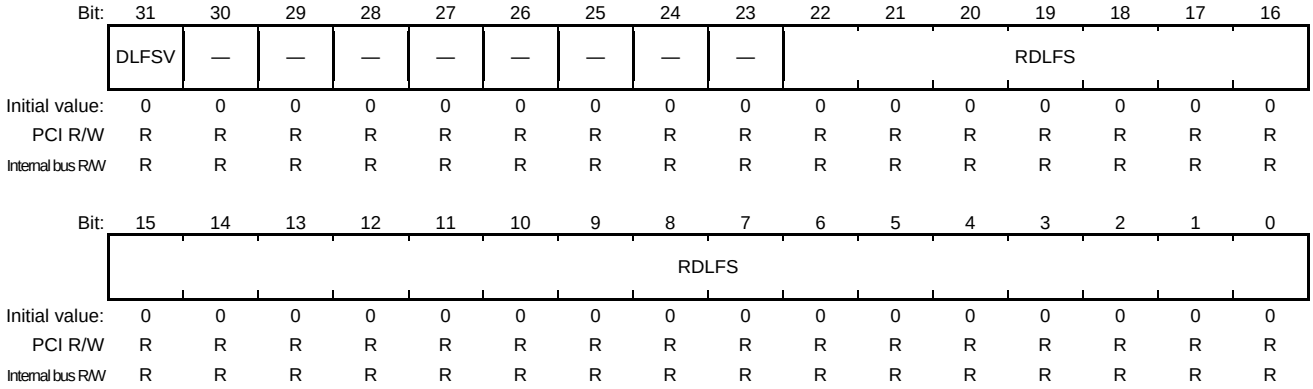


| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 31 | DLFEE | 1 | R | R | Data Link Feature Exchange Enable<br>If Set, this bit indicates that this Port will enter the DL_Feature negotiation state. |
| 30 to 23 | — | All 0 | R | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 22 to 1 | FFS | H'0 | R | R | Local Data Link Feature Supported<br>This field contains the Feature Supported value used when this Port sends a Data Link Feature DLLP. |
| 0 | SFCS | 1 | R | R | Local Scaled Flow Control Supported<br>This bit indicates that this Port supports the Scaled Flow Control Feature. |

### 104.2.140 Data Link Feature Extended Capability Register 2 function 0 (DLFECAP2F0)

### Common to Header TYPE00/01

- Data Link Feature Status Register

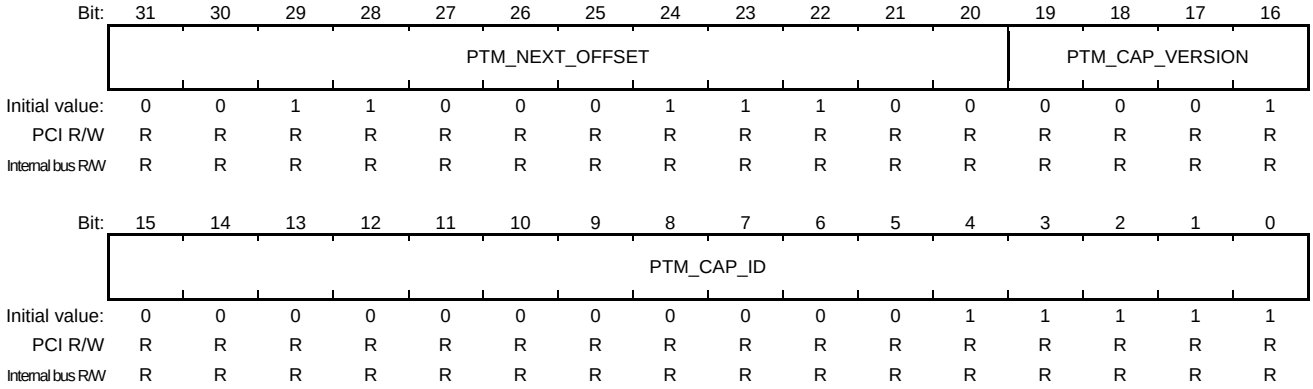


| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 31 | DLFSV | 0 | R | R | Remote Data Link Feature Supported Valid<br>This bit indicates that the Port has received a Data Link Feature DLLP in state DL_Feature and that the Remote Data Link Feature Supported field is meaningful. |
| 30 to 23 | — | All 0 | R | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 22 to 0 | RDLFS | H'0 | R | R | Remote Data Link Feature Supported<br>These bits indicate that the Remote Port supports the corresponding Data Link Feature. |

### 104.2.141 Precision Time Management (PTM) Capability Register 0 function 0 (PTMCAP0F0)

**Common to Header TYPE00/01**

- Precision Time Measurement Capability Header.



| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 31 to 20 | PTM_NEXT_OFFSET | H'31C | R | R | Precision Time Measurement PCI Express Extended Capability Next Offset. |
| 19 to 16 | PTM_CAP_VERSION | H'1 | R | R | Precision Time Measurement PCI Express Extended<br>Capability Version. |
| 15 to 0 | PTM_CAP_ID | H'1F | R | R | Precision Time Measurement PCI Express Extended Capability ID. |

### 104.2.142 Precision Time Management (PTM) Capability Register 1 function 0 (PTMCAP1F0)

### Common to Header TYPE00/01

- PTM Capability Register

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
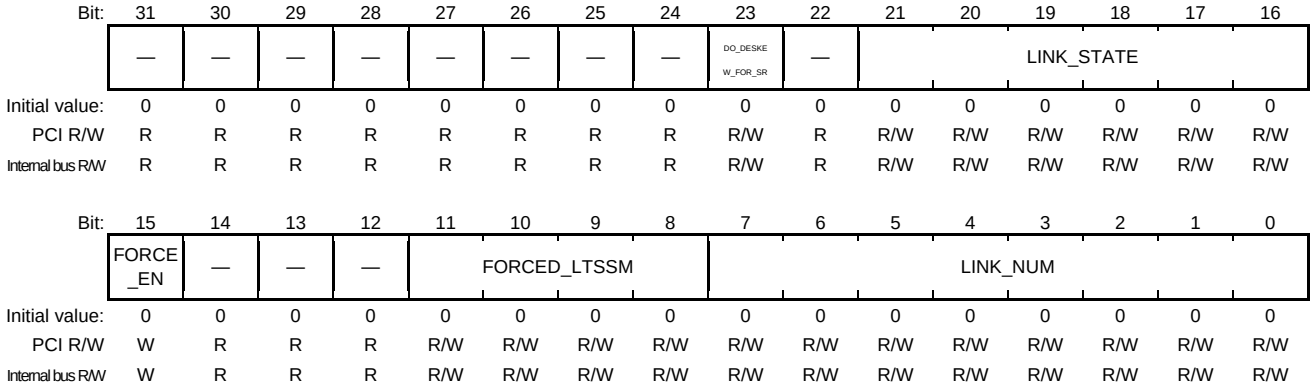
| 31 to 0 | VENDOR_SPEC_ DLLP | H'FFF FFFFF | R/W | R/W | Vendor Specific DLLP Register.<br>Used to send a specific PCI Express DLLP.<br>Your application writes the 8-bit DLLP Type and 24-bits of Payload data into this register, then sets the field VENDOR_SPECIFIC_DLLP_REQ of PRTLGC4 to send the DLLP.<br>■ [7:0] = Type<br>■ [31:8] = Payload (24 bits)<br>The dllp type is in bits [7:0] while the remainder is the vendor defined payload. |

### 104.2.190 Port Logic Registers 2 (PRTLGC2)

### Common to Header TYPE00/01

- Port Force Link Register



| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 31 to 24 | — | All 0 | R | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 23 | DO_DESKEW_FOR_ SRIS | 0 | R/W | R/W | Use the transitions from TS2 to Logical Idle Symbol, SKP OS to Logical Idle Symbol, and FTS Sequence to SKP OS to do deskew for SRIS instead of using received SKP OS if DO_DESKEW_FOR_SRIS is set to 1. |
| 22 | — | 0 | R | R | Reserved<br>This bit is always read as 0. The write value should always be 0. |
| 21 to 16 | LINK_STATE | H'0 | R/W | R/W | Forced LTSSM State.<br>The LTSSM state that the controller is forced to when you set the FORCE_EN bit (Force Link). |
| 15 | FORCE_EN | 0 | W | W | Force Link.<br>The controller supports a testing and debug capability to allow your software to force the LTSSM state machine into a specific state, and to force the controller to transmit a specific Link Command.<br>Asserting this bit triggers the following actions:<br>■ Forces the LTSSM to the state specified by the Forced LTSSM State field.<br>■ Forces the controller to transmit the command specified by the Forced Link Command field.<br>This is a self-clearing register field. Reading from this register field always returns a "0". |
| 14 to 12 | — | All 0 | R | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |

| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 11 to 8 | FORCED_LTSSM | H'0 | R/W | R/W | Forced Link Command.<br>The link command that the controller is forced to transmit when you set FORCE_EN bit (Force Link). |
| 7 to 0 | LINK_NUM | H'0 | R/W | R/W | Link Number.<br>Not used for endpoint. Not used for M-PCIe. |

### 104.2.191 Port Logic Registers 3 (PRTLGC3)

### Common to Header TYPE00/01

- Ack Frequency and L0-L1 ASPM Control Register

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 31 | — | 0 | R | R | Reserved<br>This bit is always read as 0. The write value should always be 0. |
| 30 | ENTER_ASPM | 0 | R/W | R/W | ASPM L1 Entry Control.<br>1: Core enters ASPM L1 after a period in which it has been idle.<br>0: Core enters ASPM L1 only after idle period during which both receive and transmit are in L0s. |
| 29 to 27 | L1_ENTRANCE_LATENCY | H'0 | R/W | R/W | L1 Entrance Latency.<br>Value range is:<br>000: 1 us<br>001: 2 us<br>010: 4 us<br>011: 8 us<br>100: 16 us<br>101: 32 us<br>110 or 111: 64 us<br>Note: Programming this timer with a value greater that 32us has no effect unless extended sync is used, or all of the credits are infinite. |
| 26 to 24 | L0S_ENTRANCE_LATENCY | H'0 | R/W | R/W | L0s Entrance Latency.<br>Values correspond to:<br>000: 1 us<br>001: 2 us<br>010: 3 us<br>011: 4 us<br>000: 5 us<br>101: 6 us<br>110 or 111: 7 us<br>This field is applicable to STALL while in L0 for M-PCIe. |

| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 23 to 16 | COMMON_CLK_N_FTS | H'0 | R | R | Common Clock N_FTS.<br>This is the N_FTS when common clock is used.<br>Define by parameter CX_COMM_NFTS. |
| 15 to 8 | ACK_N_FTS | H'BE | R/W | R/W | N_FTS.<br>The number of Fast Training Sequence ordered sets to be transmitted when transitioning from L0s to L0.<br>The maximum number of FTS ordered-sets that a component can request is 255.<br>The controller does not support a value of zero; a value of zero can cause the LTSSM to go into the recovery state when exiting from L0s.<br>This field is reserved (fixed to '0') for M-PCIe. |
| 7 to 0 | ACK_FREQ | H'0 | R/W | R/W | Ack Frequency. The controller accumulates the number of pending ACKs specified here (up to 255) before scheduling an ACK DLLP.<br>■ 0: Indicates that this Ack Frequency Counter feature is turned off. The controller generates a low-priority ACK request for every TLP that it receives. The controller waits until the ACK Latency Timer expires, then converts the current low-priority ACK request to a high-priority ACK request and schedules the DLLP for transmission to the remote link partner.<br>■ 1-255: Indicates that the controller will schedule a highpriority ACK after receiving this number of TLPs. It might schedule the ACK before receiving this number of TLPs if the ACK Latency Timer expires, but never later.<br>For a typical system, you do not have to modify the default setting. |

### 104.2.192 Port Logic Registers 4 (PRTLGC4)

### Common to Header TYPE00/01

- Port Link Control Register

|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
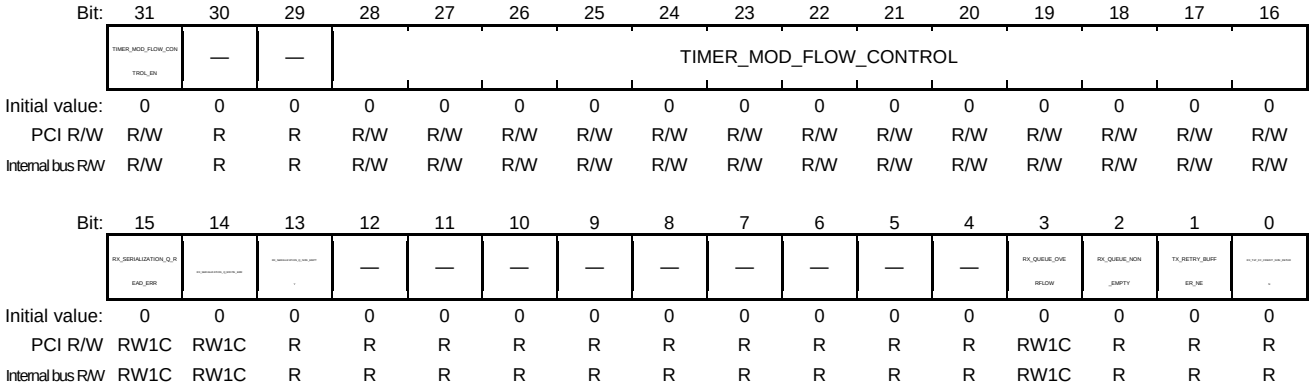
| | TX_CPL_HEADER_FC_CREDIT | | | | TX_CPL_DATA_FC_CREDIT | | | | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| PCI R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |
| Internal bus R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 31 to 20 | — | All 0 | R | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 19 to 12 | TX_CPL_HEADER_FC_CREDIT | H'0 | R | R | Transmit Completion Header FC Credits.<br>The Completion Header credits advertised by the receiver at the other end of the link, updated with each UpdateFC DLLP. |
| 11 to 0 | TX_CPL_DATA_FC_CREDIT | H'0 | R | R | Transmit Completion Data FC Credits.<br>The Completion Data credits advertised by the receiver at the other end of the link, updated with each UpdateFC DLLP. |

### 104.2.203 Port Logic Registers 15 (PRTLGC15)

### Common to Header TYPE00/01

- Queue Status



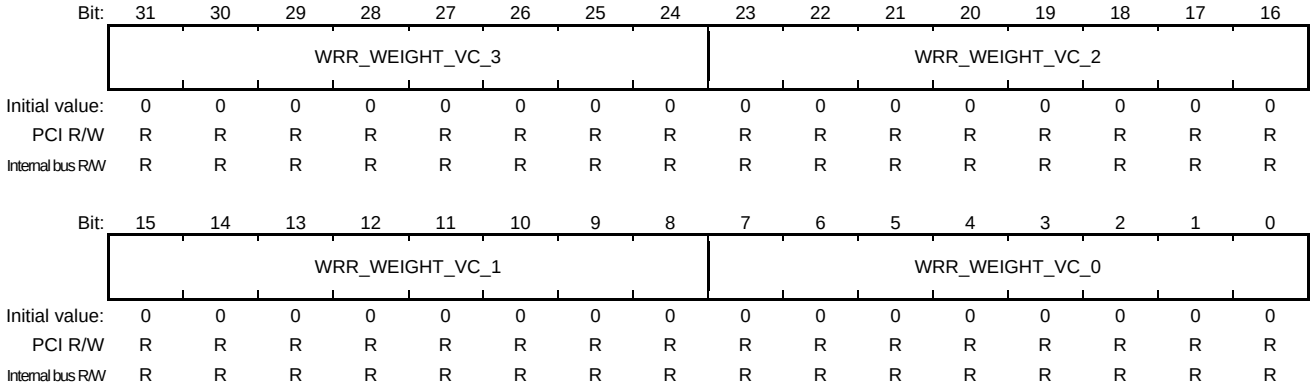
| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 31 | TIMER_MOD_FLOW_CONTROL_EN | 0 | R/W | R/W | FC Latency Timer Override Enable.<br>When this bit is set, the value from the "FC Latency Timer Override Value" field in this register will override the FC latency timer value that the controller calculates according to the PCIe specification. |
| 30 to 29 | — | All 0 | R | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 28 to 16 | TIMER_MOD_FLOW_CONTROL | H'0 | R/W | R/W | FC Latency Timer Override Value.<br>When you set the "FC Latency Timer Override Enable" in this register, the value in this field will override the FC latency timer value that the controller calculates according to the PCIe specification. |
| 15 | RX_SERIALIZATION_Q_READ_ERR | 0 | RW1C | RW1C | Receive Serialization Read Error.<br>Indicates the serialization queue has attempted to read an incorrectly formatted TLP. |
| 14 | RX_SERIALIZATION_Q_WRITE_ERR | 0 | RW1C | RW1C | Receive Serialization Queue Write Error.<br>Indicates insufficient buffer space available to write to the serialization queue. |
| 13 | RX_SERIALIZATION_Q_NON_EMPTY | 0 | R | R | Receive Serialization Queue Not Empty.<br>Indicates there is data in the serialization queue. |
| 12 to 4 | — | All 0 | R | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 3 | RX_QUEUE_OVERFLOW | 0 | RW1C | RW1C | Receive Credit Queue Overflow.<br>Indicates insufficient buffer space available to write to the P/NP/CPL credit queue. |
| 2 | RX_QUEUE_NON_EMPTY | 0 | R | R | Receive Credit Queue Not Empty.<br>Indicates there is data in one or more of the receive buffers. |
| 1 | TX_RETRY_BUFFER_NE | 0 | R | R | Transmit Retry Buffer Not Empty.<br>Indicates that there is data in the transmit retry buffer. |

| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 0 | RX_TLP_FC_CREDIT_NON_RETURN | 0 | R | R | Received TLP FC Credits Not Returned.<br>Indicates that the controller has received a TLP but has not yet sent an UpdateFC DLLP indicating that the credits for that TLP have been restored by the receiver at the other end of the link. |

### 104.2.204 Port Logic Registers 16 (PRTLGC16)

### Common to Header TYPE00/01

- VC Transmit Arbitration Register 1

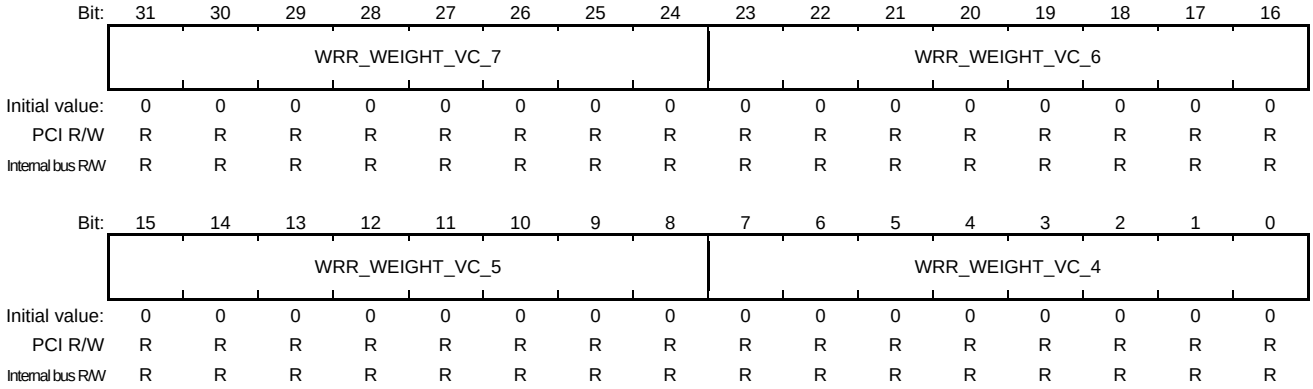


| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 31 to 24 | WRR_WEIGHT_VC_3 | H'0 | R | R | WRR Weight for VC3 |
| 23 to 16 | WRR_WEIGHT_VC_2 | H'0 | R | R | WRR Weight for VC2 |
| 15 to 8 | WRR_WEIGHT_VC_1 | H'0 | R | R | WRR Weight for VC1 |
| 7 to 0 | WRR_WEIGHT_VC_0 | H'0 | R | R | WRR Weight for VC0 |

### 104.2.205 Port Logic Registers 17 (PRTLGC17)

### Common to Header TYPE00/01

- VC Transmit Arbitration Register 2

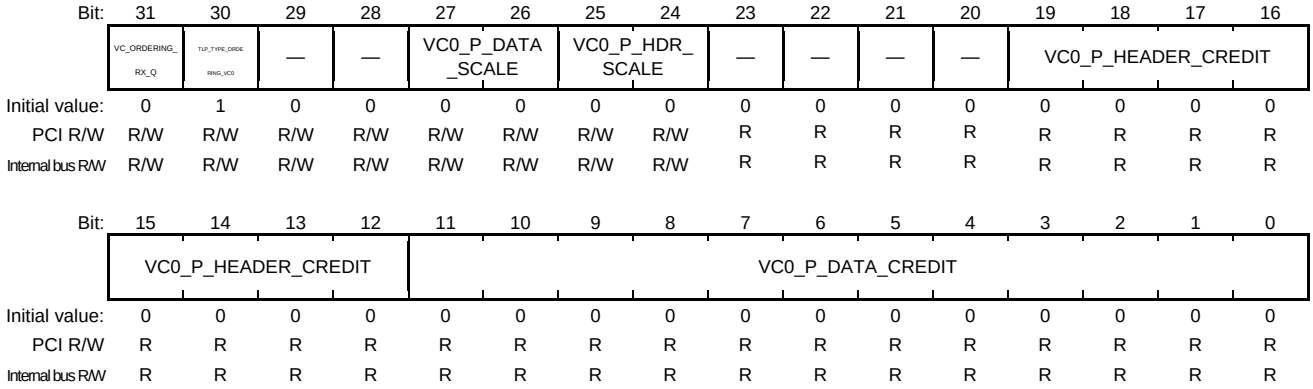


| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 31 to 24 | WRR_WEIGHT_VC_7 | H'0 | R | R | WRR Weight for VC7 |
| 23 to 16 | WRR_WEIGHT_VC_6 | H'0 | R | R | WRR Weight for VC6 |
| 15 to 8 | WRR_WEIGHT_VC_5 | H'0 | R | R | WRR Weight for VC5 |
| 7 to 0 | WRR_WEIGHT_VC_4 | H'0 | R | R | WRR Weight for VC4 |

### 104.2.206 Port Logic Registers 18 (PRTLGC18)

### Common to Header TYPE00/01

- Segmented-Buffer VC0 Posted Receive Queue Control



| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 31 | VC_ORDERING_ RX_Q | 0 | R/W | R/W | VC Ordering for Receive Queues.<br>Determines the VC ordering rule for the receive queues, used only in the segmented-buffer configuration:<br>1: Strict ordering, higher numbered VCs have higher priority<br>0: Round robin |
| 30 | TLP_TYPE_ ORDERING_VC0 | 1 | R/W | R/W | TLP Type Ordering for VC0.<br>Determines the TLP type ordering rule for VC0 receive queues, used only in the segmented-buffer configuration:<br>1: PCIe ordering rules (recommended)<br>0: Strict ordering: posted, completion, then non-posted |
| 29 to 28 | — | All 0 | R/W | R/W | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 27 to 26 | VC0_P_DATA_SCALE | H'0 | R/W | R/W | VC0 Scale Posted Data Credites. |
| 25 to 24 | VC0_P_HDR_SCALE | H'0 | R/W | R/W | VC0 Scale Posted Header Credites. |
| 23 to 20 | — | All 0 | R | R | Reserved.<br>This bit is always read as 0. The write value should always be 0. |
| 19 to 12 | VC0_P_HEADER_ CREDIT | H'0 | R | R | VC0 Posted Header Credits.<br>The number of initial posted header credits for VC0, used only in the segmented-buffer configuration. |
| 11 to 0 | VC0_P_DATA_CREDIT | H'0 | R | R | VC0 Posted Data Credits.<br>The number of initial posted data credits for VC0, used only in the segmented-buffer configuration. |

### 104.2.207 Port Logic Registers 19 (PRTLGC19)

### Common to Header TYPE00/01

- Segmented-Buffer VC0 Non-Posted Receive Queue Control

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | VC0_NP_DATA_SCALE | | VC0_NP_HDR_SCALE | | — | — | — | — | VC0_NP_HEADER_CREDIT | | | |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | PRE_DET_LANE | | | NUM_OF_LANES | | | | | FAST_TRAINING_SEQ | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| PCI R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 31 to 22 | — | All 0 | R | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 21 | GEN1_EI_INFERENCE | 0 | R/W | R/W | Electrical Idle Inference Mode at Gen1 Rate.<br>Programmable mode to determine inferred electrical idle (EI) in Recovery.<br>0: Use RxElecIdle signal to infer Electrical Idle<br>1: Use RxValid signal to infer Electrical Idle |
| 20 | SEL_DEEMPHASIS | 0 | R/W | R/W | Used to set the de-emphasis level for upstream ports.<br>This bit selects the level of de-emphasis the link operates at.<br>0: -6 dB<br>1: -3.5 dB<br>This field is reserved (fixed to '0') for M-PCIe. |
| 19 | CONFIG_TX_COMP_<br>RX | 0 | R/W | R/W | Config Tx Compliance Receive Bit.<br>When set to 1, signals LTSSM to transmit TS ordered sets with the compliance receive bit assert (equal to "1"). This field is reserved (fixed to '0') for M-PCIe. |
| 18 | CONFIG_PHY_TX_<br>CHANGE | 0 | R/W | R/W | Config PHY Tx Swing.<br>Controls the PHY transmitter voltage swing level. The controller drives the mac_phy_txswing output from this register bit field.<br>0: Full Swing<br>1: Low Swing<br>This field is reserved (fixed to '0') for M-PCIe. |
| 17 | DIRECT_SPEED_<br>CHANGE | 0 | R/W | R/W | Directed Speed Change.<br>Writing "1" to this field instructs the LTSSM to initiate a speed change to Gen2 or Gen3 after the link is initialized at Gen1 speed. |
| 16 | AUTO_LANE_<br>FLIP_CTRL_EN | 0 | R/W | R/W | Enable Auto flipping of the lanes.<br>You must set the CX_AUTO_LANE_FLIP_CTRL_EN configuration parameter to include the hardware for this feature in the controller. |

| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 15 to 13 | PRE_DET_LANE | H'0 | R/W | R/W | Predetermined Lane for Auto Flip.<br>This field defines which physical lane is connected to logical Lane0 by the flip operation performed in Detect.<br>H'0: Connect logical Lane0 to physical lane 0 or<br>CX_NL-1 or CX_NL/2-1 or CX_NL/4-1 or CX_NL/8-1, depending on which lane is detected<br>H'1: Connect logical Lane0 to physical lane 1<br>H'2: Connect logical Lane0 to physical lane 3<br>H'3: Connect logical Lane0 to physical lane 7<br>H'4: Connect logical Lane0 to physical lane 15 |
| 12 to 8 | NUM_OF_LANES | H'0 | R/W | R/W | Predetermined Number of Lanes.<br>Defines the number of lanes which are connected and not bad.<br>H'1: 1 lane<br>H'2: 2 lanes<br>H'3: 3 lanes |
| 7 to 0 | FAST_TRAINING_SEQ | H'0 | R/W | R/W | Sets the Number of Fast Training Sequences (N_FTS) that the controller advertises as its N_FTS during Gen2 or Gen3 link training. |

### 104.2.210 Port Logic Registers 22 (PRTLGC22)

### Common to Header TYPE00/01

- PHY Status Register.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
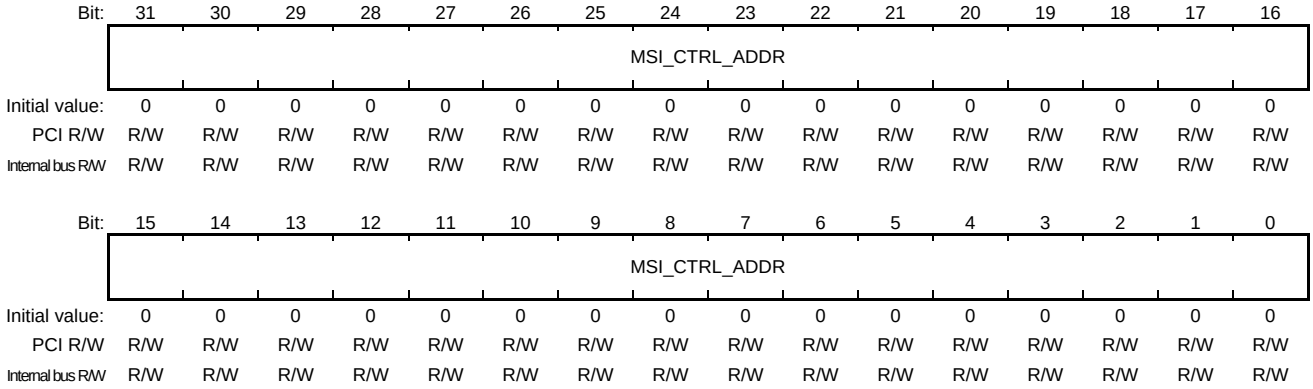
| 31 to 21 | — | All 0 | R | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 20 to 16 | TARGET_MAP_INDEX | H'0 | R/W | R/W | The number of the PF Function on which the Target Values are set.<br>This register does not respect the Byte Enable setting. any write will affect all register bits. |
| 15 to 13 | — | All 0 | R | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 12 to 7 | TARGET_MAP_VF | H'0 | R | R | Target Values for each BAR on the VF Function selected by the index number.<br>This register does not respect the Byte Enable setting. any write will affect all register bits.<br>Not support virtual channel capability structure. Read value must be H'0. |
| 6 | TARGET_MAP_ROM | 0 | R/W | R/W | Target Value for the ROM page of the PF Function selected by the index number. This register does not respect the Byte Enable setting. any write will affect all register bits. |
| 5 to 0 | TARGET_MAP_PF | H'0 | R/W | R/W | Target Values for each BAR on the PF Function selected by the index number.<br>This register does not respect the Byte Enable setting. any write will affect all register bits. |

### 104.2.213 Port Logic Registers 25 (PRTLGC25)

**Header TYPE00 Only**

- Integrated MSI Reception Module (iMRM) Address Register.

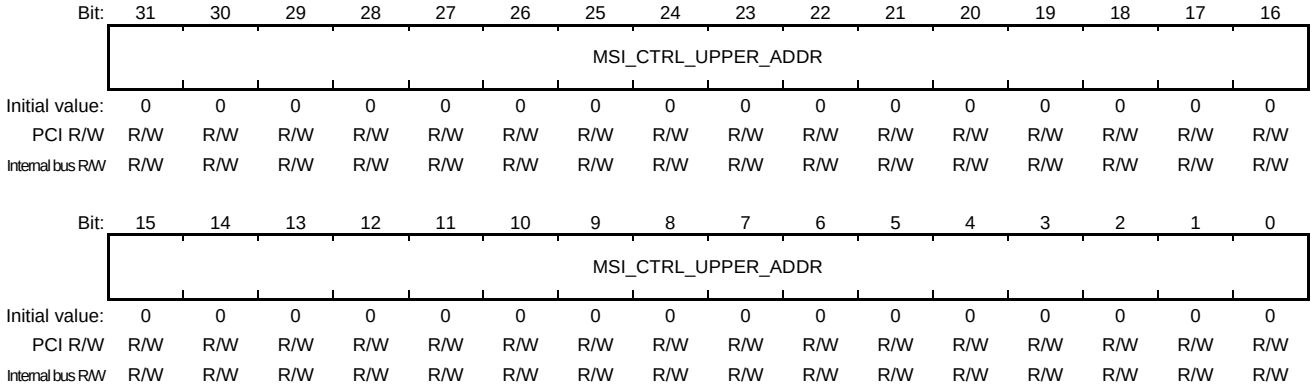


| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 31 to 0 | MSI_CTRL_ADDR | H'0 | R/W | R/W | Integrated MSI Reception Module Address.<br>System specified address for MSI memory write transaction termination. |

### 104.2.214 Port Logic Registers 26 (PRTLGC26)

### Header TYPE00 Only

- Integrated MSI Reception Module Upper Address Register



| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 31 to 0 | MSI_CTRL_UPPER_ ADDR | H'0 | R/W | R/W | Integrated MSI Reception Module Upper Address.<br>System specified upper address for MSI memory write transaction termination. |

### 104.2.215 Port Logic Registers 27+3**i* (PRTLGC27+3**i*) (*i* = 0 to 7)

**Header TYPE00 Only**

- Integrated MSI Reception Module Interrupt#i Enable Register.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Internal bus R/W | R | R | R | R | R/W | R/W | R | R/W | R | R | R | R | R | R | R | R/W |

Note: *1: R/W changes by the TYPE. TYPE00: R/W, TYPE01: -

| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 31 to 26 | — | All 0 | R | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 25 to 24 | RATE_SHADOW_SEL | H'0 | R/W | R/W | Rate Shadow Select.<br>This register value decide the Data Rate of shadow register.<br>H'0: Gen3 Data Rate is selected for shadow register.<br>H'1: Gen4 Data Rate is selected for shadow register.<br>H'2: Gen5 Data Rate is selected for shadow register.<br>H'3: Reserved. |
| 23 | GEN3_EQ_INVREQ_EVAL_DIFF_DISABLE | 0 | R/W | R/W | Eq InvalidRequest and RxEqEval Different Time Assertion Disable.<br>Disable the assertion of Eq InvalidRequest and RxEqEval at different time. |

| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 22 | USP_SEND_8GT_EQ_TS2_DISABLE | 1 | *1 | R/W | Upstream Port Send 8GT/s or 16GT/s EQ TS2 Disable.<br>The base spec defines that USP can optionally send 8GT or 16GT EQ TS2 and it means USP can set DSP TxPreset value in Gen4 or Gen5 Data Rate. If this register set to 0, USP sends 8GT or 16GT EQ TS2. If this register set to 1, USP does not send 8GT or 16GT EQ TS2. This applies to upstream ports only.<br>If RATE_SHADOW_SEL==00b, this register is RSVD.<br>If RATE_SHADOW_SEL==01b, this register is for Gen4 data rate.<br>If RATE_SHADOW_SEL==10b, this register is for Gen5 data rate. |
| 21 | AUTO_EQ_DISABLE | 0 | *1 | R* | Autonomous Equalization Disable.<br>When the controller is in L0 state at Gen3 data rate and equalization was completed successfully in Autonomous EQ Mechanism, setting this bit in DSP will not direct the controller to Recovery state to perform Gen4 equalization.<br>Note *:<br>If RATE_SHADOW_SEL==00b, this register is RSVD.<br>If RATE_SHADOW_SEL==01b, this register is for Gen4 data rate.<br>If RATE_SHADOW_SEL==10b, this register is for Gen5 data rate. |
| 20 to 19 | — | All 0 | R | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 18 | GEN3_DC_BALANCE_DISABLE | 0 | R/W | R/W | DC Balance Disable. Disable DC Balance feature. |
| 17 | GEN3_DLLP_XMT_DELAY_DISABLE | 0 | R/W | R/W | DLLP Transmission Delay Disable.<br>Disable delay transmission of DLLPs before equalization. |
| 16 | GEN3_EQUALIZATION_DISABLE | 0 | R/W | R/W | Equalization Disable. Disable equalization feature.<br>This bit cannot be changed once the LTSSM starts link training. |
| 15 to 14 | — | All 0 | R | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 13 | RXEQ_RGRDLESS_RXTS | 0 | *1 | R/W | When set to '1', the controller as Gen3 EQ master asserts RxEqEval to instruct the PHY to do Rx adaptation and evaluation after a 500ns timeout from a new preset request.<br>0: mac_phy_rxeqeval asserts after 1us and 2 TS1 received from remote partner.<br>1: mac_phy_rxeqeval asserts after 500ns regardless of TS's received or not |

| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 12 | RXEQ_PH01_EN | 0 | *1 | R/W | Rx Equalization Phase 0/Phase 1 Hold Enable.<br>When this bit is set the upstream port holds phase 0 (the downstream port holds phase 1) for 10ms.<br>The programmable bits [RXEQ_PH01_EN, EQ_PHASE_2_3] can be used to obtain the following variations of the equalization procedure:<br>00: Tx equalization only in phase 2/3<br>01: No Tx equalization, no Rx equalization<br>10: Tx equalization in phase 2/3, Rx equalization in phase 0/1<br>11: No Tx equalization, Rx equalization in phase 0/1<br>If RATE_SHADOW_SEL==01b, this register is for Gen4 data rate.<br>If RATE_SHADOW_SEL==10b, this register is for Gen5 data rate. |
| 11 | EQ_REDO | 0 | R/W | R/W | Equalization Redo Disable.<br>Disable autonomous mechanism for requesting to redo the equalization process. |
| 10 | EQ_EIEOS_CNT | 0 | R/W | R/W | Equalization EIEOS Count Reset Disable.<br>Disable requesting reset of EIEOS count during equalization. |
| 9 | EQ_PHASE_2_3 | 0 | *1 | R/W | Equalization Phase 2 and Phase 3 Disable.<br>This applies to downstream ports only.<br>If RATE_SHADOW_SEL==00b, this register is for Gen3<br>data rate.<br>If RATE_SHADOW_SEL==01b, this register is for<br>Gen4 data rate.<br>If RATE_SHADOW_SEL==10b, this register<br>is for Gen5 data rate. |
| 8 | DISABLE_<br>SCRAMBLER_GEN_3 | 0 | R/W | R/W | Disable Scrambler for Gen3 and Gen4 Data Rate.<br>The Gen3 and Gen4 scrambler/descrambler within the controller needs to be disabled when the scrambling function is implemented outside of the controller (for example within the PHY). |
| 7 to 1 | — | All 0 | R | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |

| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 0 | GEN3_ZRXDC_ NONCOMPL | 1 | R/W | R/W | Gen3 Receiver Impedance ZRX-DC Not Compliant.<br>Receivers that operate at 8.0 GT/s with an impedance otherthan the range defined by the ZRX-DC parameter for 2.5GT/s (40-60 Ohms) must meet additional behavior requirements in the following LTSSM states: Polling, Rx_L0s, L1, L2, and Disabled.<br>0: The receiver complies with the ZRX-DC parameter for<br>2.5 GT/s when operating at 8 GT/s or higher.<br>1: The receiver does not comply with the ZRX-DC parameter<br>for 2.5 GT/s when operating at 8 GT/s or higher. |

| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 31 to 24 | — | H'FF | R | R | Reserved<br>These bits are always read as 0. The write value should always be H'FF. |
| 23 to 1 | — | All 0 | R | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 0 | AUTO_FLUSH_EN | 1 | R/W | R/W | Enables automatic flushing of pending requests before sending the reset request to the application logic to reset PCIEC. The flushing process is initiated if any of the following events occur:<br>■ Hot reset request. A downstream port (DSP) can "hot reset" an upstream port (USP) by sending two consecutive TS1 ordered sets with the hot reset bit asserted.<br>■ Warm (Soft) reset request. Generated when exiting from D3 to D0.<br>■ Link down reset request. The link has gone down and the controller is requesting a reset.<br>If you disable automatic flushing, you are responsible for resetting PCIEC. |

### 104.2.230 Port Logic Registers 63 (PRTLGC63)

### Common to Header TYPE00/01

- AXI Bridge Slave Error Response Register

| Internal bus R/W | R | R | R | R | R | R | R | R | R/W | R | R | R/W | R/W | R | R/W | R |

| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 31 to 8 | — | All 0 | R | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |

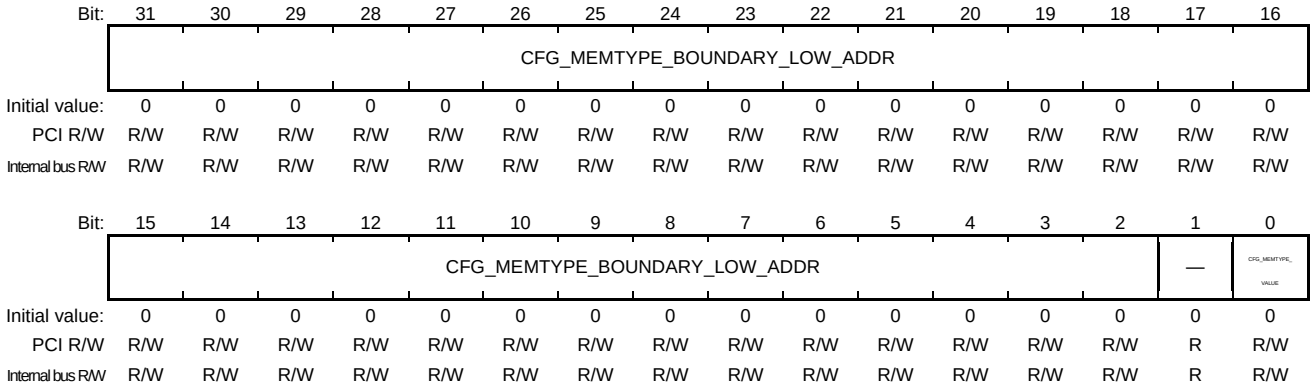
| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 7 | AX_MSTR_ZEROL READ_FW | 0 | R/W | R/W | AXI Master Zero Length Read Forward to the application.<br>The PCIEC AXI bridge is able to terminate in order with the Posted transactions the zero length read, implementing the PCIe express flush semantics of the Posted transactions.<br>■ 0x0: The zero length Read is terminated at the PCIe AXI bridge master<br>■ 0x1: The zero length Read is forward to the internal bus. |
| 6 to 5 | — | All 0 | R | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 4 to 3 | AX_MSTR_ORDR_ P_EVENT_SEL | All 0 | R/W | R/W | AXI Master Posted Ordering Event Selector.<br>This field selects how the master interface determines when a P write is completed when enforcing the PCIe ordering rule, "NP must not pass P" at the AXI Master Interface. The AXI protocol does not support ordering between channels.<br>Therefore, NP reads can pass P on your AXI bus fabric. This can result in an ordering violation when the read overtakes a P that is going to the same address. Therefore, the bridge master does not issue any NP requests until all outstanding P writes reach their destination. It does this by waiting for the all of the write responses on the B channel. This can affect the performance of the master read channel. For scenarios where the interconnect serializes the AXI master "AW", "W" and "AR" channels,you can increase the performance by reducing the need to wait until the complete Posted transaction has effectively reached the application slave.<br>■ 00: B'last event: wait for the all of the write responses on the B channel thereby ensuring that the complete Posted transaction has effectively reached the application slave (default).<br>■ 01: AW'last event: wait until the complete Posted transaction has left the AXI address channel at the bridge master.<br>■ 10: W'last event: wait until the complete Posted transaction has left the AXI data channel at the bridge master.<br>■ 11: Reserved<br>Note 2: This setting will not affect:<br>■ MSI interrupt catcher and P data ordering. This is always driven by the B'last event.<br>■ DMA read engine TLP ordering. This is always driven by the B'last event.<br>■ NP write transactions which are always serialized with P write transactions. |
| 2 | — | 0 | R | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 1 | AX_SNP_EN | 0 | R/W | R/W | AXI Serialize Non-Posted Requests Enable. This field enables the AXI Bridge to serialize same ID Non-Posted Read/Write Requests on the wire. Serialization implies one outstanding same ID NP Read or Write on the wire and used to avoid AXI RAR and WAW hazards at the remote link partner. |

| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 0 | — | 0 | R | R | Reserved<br>This bit is always read as 0. The write value should always be 0. |

### 104.2.233 Port Logic Registers 66 (PRTLGC66)

#### Common to Header TYPE00/01

- ACE Cache Coherency Control Register 1

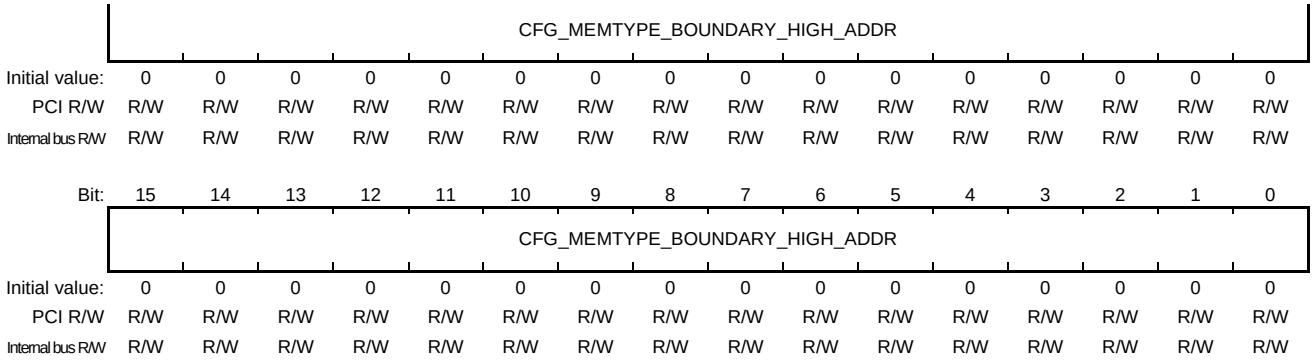


| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 31 to 2 | CFG_MEMTYPE_BOUNDARY_LOW_ADDR | All 0 | R/W | R/W | Boundary Lower Address For Memory Type. Bits [31:0] of dword-aligned address of the boundary for Memory type.<br>The two lower address LSBs are "00". Addresses up to but not including this value are in the lower address space region; addresses equal or greater than this value are in the upper address space region. |
| 1 | — | All 0 | R | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 0 | CFG_MEMTYPE_VALUE | 0 | R/W | R/W | Sets the memory type for the lower and upper parts of the address space:<br>■ 0: lower = Peripheral; upper = Memory<br>■ 1: lower = Memory type; upper = Peripheral |

### 104.2.234 Port Logic Registers 67 (PRTLGC67)

#### Header TYPE01 Only

- ACE Cache Coherency Control Register 2

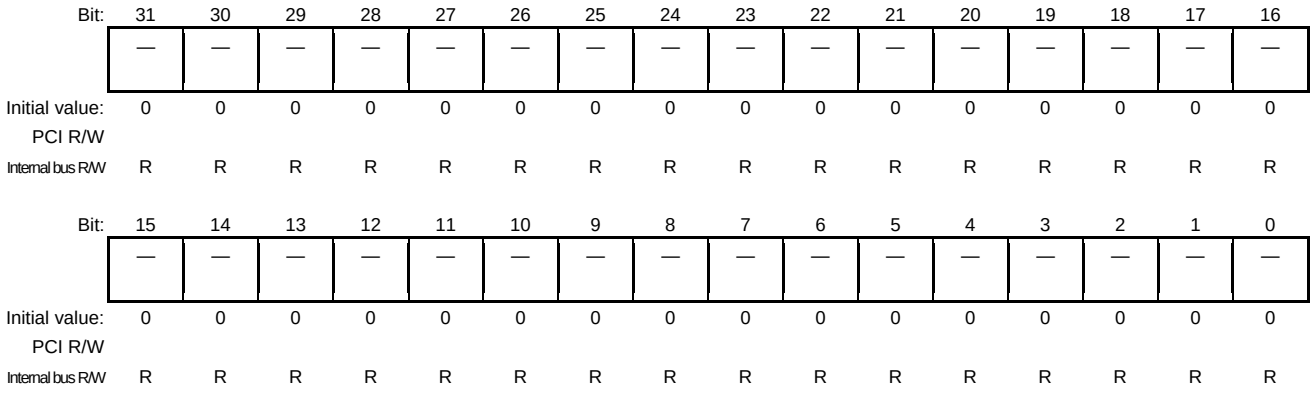


| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 31 to 0 | CFG_MEMTYPE_BOUNDARY_HIGH_ADDR | All 0 | R/W | R/W | Boundary Upper Address For Memory Type.<br>Bits [63:32] of the 64-bit DWORD-aligned address of the boundary for Memory type. |

### 104.2.235 Port Logic Registers 68 (PRTLGC68)

**Common to Header TYPE00/01**

- ACE Cache Coherency Control Register 3 (V4H/V4M does not support ACE Lite)

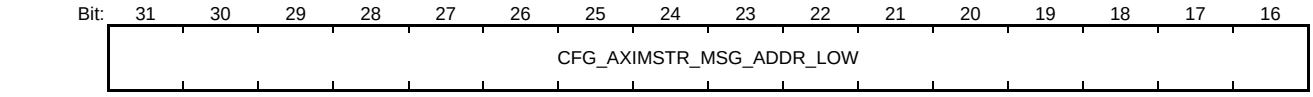


| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 31 to 0 | — | All 0 | | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |

### 104.2.236 Port Logic Registers 69 (PRTLGC69)

**Common to Header TYPE00/01**

- Lower 20 bits of the programmable AXI address where Messages coming from wire are mapped to.



| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 31 to 19 | — | All 0 | R | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 18 | CHK_REG_COMPLETE | 0 | R/W1C | R/W1C | The system has completed a checking cycle. |
| 17 | CHK_REG_LOGIC_ERROR | 0 | R/W1C | R/W1C | The system has detected an error in its own checking logic. |
| 16 | CHK_REG_COMPARISON_ERROR | 0 | R/W1C | R/W1C | The system has detected that there is a bit error in the CDM Register Data. |
| 15 to 2 | — | All 0 | R | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 1 | CHK_REG_CONTINUOUS | 0 | R/W | R/W | Set Continuous Checking Sequence. |
| 0 | CHK_REG_START | 0 | R/W | R/W | Begins a checking sequence. |

### 104.2.244 Port Logic Registers 83 (PRTLGC83)

**Common to Header TYPE00/01**

- CDM Register Checking First and Last address to check

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | CHK_REG_END_ADDR | | | | | | | | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 1 | 0 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |
| PCI R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | CHK_REG_START_ADDR | | | | | | | | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| PCI R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 31 to 16 | CHK_REG_END_ADDR | H'BFF | R/W | R/W | The last address that is checked by the system. |
| 15 to 0 | CHK_REG_START_ADDR | All 0 | R/W | R/W | The first address that is checked by the system. |

### 104.2.245 Port Logic Registers 84 (PRTLGC84)

**Common to Header TYPE00/01**

- CDM Register Checking Error Address

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | CHK_REG_ERR_ADDR | | | | | | | | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| PCI R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |
| Internal bus R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | CHK_REG_ERR_ADDR | | | | | | | | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| PCI R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |
| Internal bus R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 31 to 0 | CHK_REG_ERR_ADDR | All 0 | R | R | The address at which an error has been detected. Valid only when the CDM Register Checker Comparison Error bit is set in the status register. |

### 104.2.246 Port Logic Registers 85 (PRTLGC85)

**Common to Header TYPE00/01**

- CDM Register Checking error PF Numbers

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | – | – | – | – | – | – | – | – | – | – | – | – | – | – | – | – |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| PCI R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |
| Internal bus R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | – | – | – | – | – | – | – | – | – | – | – | CHK_REG_PF_ERR_NUMBER | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| PCI R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |
| Internal bus R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | PCI R/W | Internal Bus R/W | Description |
|---|---|---|---|---|---|
| 31 to 5 | — | All 0 | R | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 4 to 0 | CHK_REG_PF_ERR_NUMBER | All 0 | R | R | The PF number at which the error was detected. Valid only when the CDM Register Checker Comparison Error bit is set in the status register. |

### 104.2.247 Port Logic Registers 86 (PRTLGC86)

**Common to Header TYPE00/01**

- LTR Latency Register

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

|---|---|---|---|---|---|
| 31 to 10 | — | All 0 | R | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 9 to 0 | AUX_CLK_FREQ | H'00A | R/W | R/W | The aux_clk frequency in MHz. This value is used to provide a 1 us reference for counting time during low-power states with aux_clk when the PHY has removed the pipe_clk.<br>Frequencies lower than 1 MHz are possible but with a loss of accuracy in the time counted. If the actual frequency (f) of aux_clk does not exactly match the programmed frequency (f_prog), then there is an error in the time counted by the controller that can be expressed in percentage as: err% = (f_prog/f-1)*100. For example if f=2.5 MHz and f_prog=3 MHz, then err% =(3/2.5-1)*100 =20%, meaning that the time counted by the controller on aux_clk will be 20% greater than the time in us programmed in the corresponding time register (for example T_POWER_ON). |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 23 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 22 to 20 | CTRL_1_FUNC_NUM | All 0 | R/W | Function Number.<br>■ When the address of an outbound TLP is matched to this region and the FUNC_BYPASS field in the "ATU Capabilities Registers [1+i*18]" is '0', then the function number used in generating the function part of the requester ID (RID) field of the TLP is taken from this 5-bit register.<br>■This field is swapped before AXI decomposition occurs so that the correct "Max_Read_Request_Size" and "Max_Payload_Size" values are used. |
| 19 to 14 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 13 | INCREASE_REGION_SIZE | 0 | R/W | Increase the maximum ATU Region size. When set, the maximum ATU Region size is determined by CX_ATU_MAX_REGION_SIZE. When clear, the maximum ATU Region size is 4 GB (default). |
| 12 | — | 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 11 | — | 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 10 to 9 | ATTR | All 0 | R/W | When the address of an outbound TLP is matched to this region, then the ATTR field of the TLP is changed to the value in this register. |
| 8 | TD | 0 | R/W | This is a reserved field. Do not use. |
| 7 to 5 | TC | All 0 | R/W | When the address of an outbound TLP is matched to this region, then the TC field of the TLP is changed to the value in this register. |
| 4 to 0 | TYPE | All 0 | R/W | When the address of an outbound TLP is matched to this region, then the TYPE field of the TLP is changed to the value in this register. |

### 104.2.260 ATU Capabilities Registers [1+*i**18] (ATUCAP[1+*i**18]) (*i* = 0 to 15)

**Common to Header TYPE00/01**

- ATU Region Control 2 Register for outbound

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | REGION_EN | _ | INVERT_ | CFG_SHI | DMA_BY | _ | _ | _ | HEADER | INHIBIT_ | TLP_HEA | SNP | FUNC_B | MSB2BITS_TAG | | TAG_SU |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R | R/W | R/W | R/W | R | R | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | TAG | | | | | | | | MSG_CODE | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

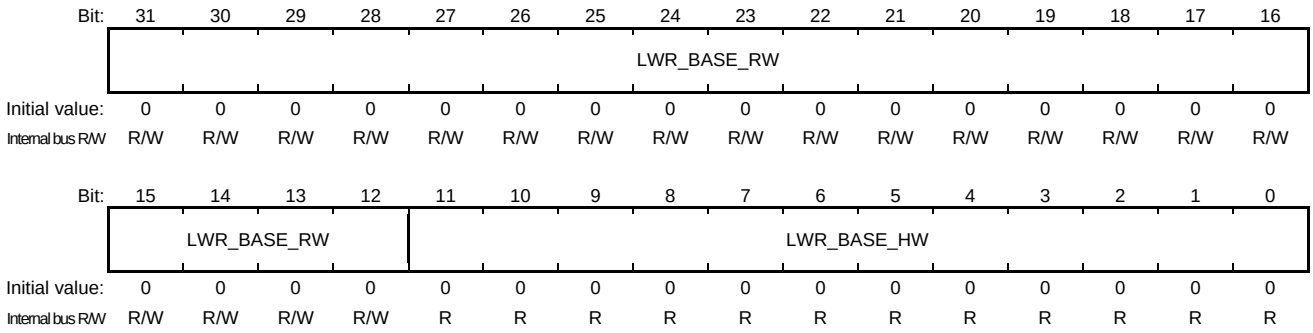
| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 | REGION_EN | 0 | R/W | Region Enable. This bit must be set to '1' for address translation to take place. |
| 30 | — | 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 29 | INVERT_MODE | 0 | R/W | Invert Mode. When set the address matching region is inverted. Therefore, an address match occurs when the untranslated address is in the region outside the defined range (Base Address to Limit Address). |
| 28 | CFG_SHIFT_MODE | 0 | R/W | CFG Shift Mode.<br>The ATU uses bits [27:12] of the untranslated address (on the AXI slave interface address) to form the BDF number of the outgoing CFG TLP.<br>This supports the Enhanced Configuration Address Mapping (ECAM) mechanism (Section 7.2.2 of the PCI Express Base 4.0 Specification, revision 1.0) by allowing all outgoing I/O and MEM TLPs (that have been translated to CFG) to be mapped from memory space into any 256 MB region of the PCIe configuration space. |
| 27 | DMA_BYPASS | 0 | R/W | DMA Bypass Mode. Allows request TLPs which are initiated by the DMA controller to pass through the ATU untranslated. |
| 26 to 24 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 23 | HEADER_SUBSTITUTE_EN | 0 | R/W | Header Substitute Enable.<br>When enabled and region address is matched, the ATU fully substitutes bytes 8-11 (for 3 DWORD header) or bytes 12-15 (for 4 DWORD header) of the outbound TLP header with the contents of the LWR_TARGET_RW field in ATU Capabilities Registers [5+i*18].<br>■ 1: LWR_TARGET_RW in the ATU Capabilities Registers [5+i*18] is used to fill bytes 8-to-11 (for 3 DWORD header) or bytes 12-to-15 (for 4 DWORD header) of the translated TLP header.<br>■ 0: LWR_TARGET_RW in the ATU Capabilities Registers [5+i*18] forms the new address of the translated region. |
| 22 | INHIBIT_PAYLOAD | 0 | R/W | Inhibit TLP Payload Data for TLP's in Matched Region;<br>assign ATU region to be TLP without data. When enabled and region address is matched, the ATU marks all TLPs as having no payload data by forcing the TLP header Fmt[1] bit =0.<br>■ 1: Fmt[1] =0 so that only TLP type without data is sent.<br>For example, a Msg instead of MsgD will be sent.<br>■ 0: Fmt[1] =0/1 so that TLPs with or without data can be sent. |
| 21 | TLP_HEADER_FIELDS_BYPASS | 0 | R/W | TLP Header Fields Translation Bypass. In this mode header fields of the translated TLP is taken from your application transmit interface. |
| 20 | SNP | 0 | R/W | Serialize Non-Posted Requests. In this mode, when the AXI Bridge is populated, same AXI ID Non-Posted Read/Write Requests are transmitted on the wire if there are no other same ID Non-Posted Requests outstanding. |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 19 | FUNC_BYPASS | 0 | R/W | Function Number Translation Bypass. In this mode, the function number of the translated TLP is taken you're your application transmit interface and not from the CTRL_1_FUNC_NUM field of the "ATU Capabilities Registers [0+i*18]". |
| 18 to 17 | MSB2BITS_TAG | All 0 | R/W | TAG.<br>Two most significant bits of the substituted TAG field in the outgoing TLP header when TAG_SUBSTITUTE_EN is set. |
| 16 | TAG_SUBSTITUTE_EN | 0 | R/W | TAG Substitute Enable.<br>When enabled and region address is matched, the ATU substitutes the TAG field of the outbound TLP header with the contents of the TAG field in this register. The expected usage scenario is translation from AXI MWr to Vendor Defined Msg/MsgD. |
| 15 to 8 | TAG | All 0 | R/W | TAG.<br>The substituted TAG field (byte 6) in the outgoing TLP header when TAG_SUBSTITUTE_EN is set. |
| 7 to 0 | MSG_CODE | All 0 | R/W | MSG TLPs (Message Code). When the address of an outbound TLP is matched to this region, and the translated TLP TYPE field is Msg or MsgD; then the message field of the TLP is changed to the value in this register. |

### 104.2.261 ATU Capabilities Registers [2+*i**18] (ATUCAP[2+*i**18]) (*i* = 0 to 15)

### Common to Header TYPE00/01

- ATU Lower Base Address Register for outbound

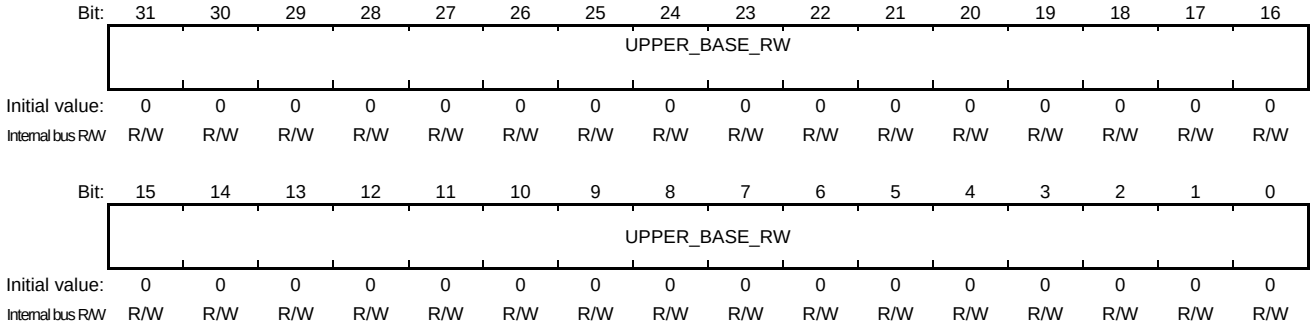


| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 12 | LWR_BASE_RW | All 0 | R/W | Forms bits [31:12] of the start address of the address region to be translated. |
| 11 to 0 | LWR_BASE_HW | All 0 | R | Forms bits [11:0] of the start address of the address region to be translated. The start address must be aligned to a 4 kB boundary, so these bits are always 0. A write to this location is ignored by the PCIe controller. |

### 104.2.262 ATU Capabilities Registers [3+*i**18] (ATUCAP[3+*i**18]) (*i* = 0 to 15)

**Common to Header TYPE00/01**

- ATU Upper Base Address Register for outbound

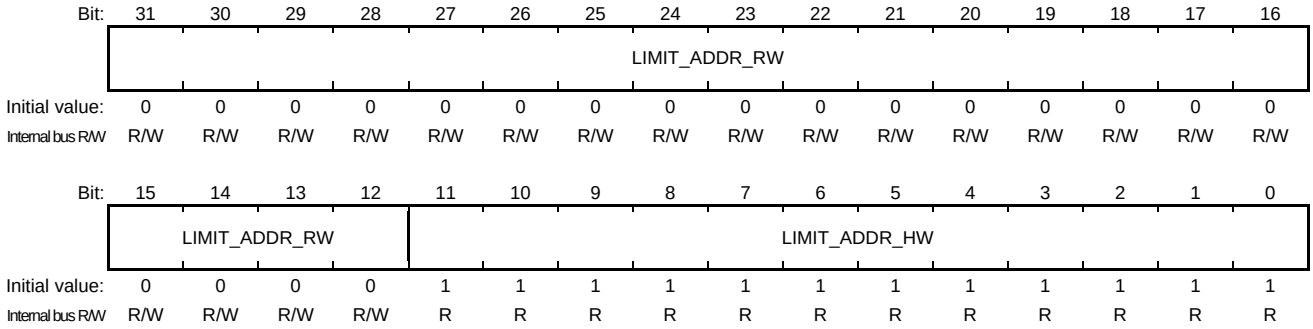


| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | UPPER_BASE_RW | All 0 | R/W | Forms bits [63:32] of the start (and end) address of the address region to be translated. In systems with a 32-bit address space, this register is not used and therefore writing to this register has no effect. |

### 104.2.263 ATU Capabilities Registers [4+*i**18] (ATUCAP[4+*i**18]) (*i* = 0 to 15)

**Common to Header TYPE00/01**

- ATU Limit Address Register for outbound

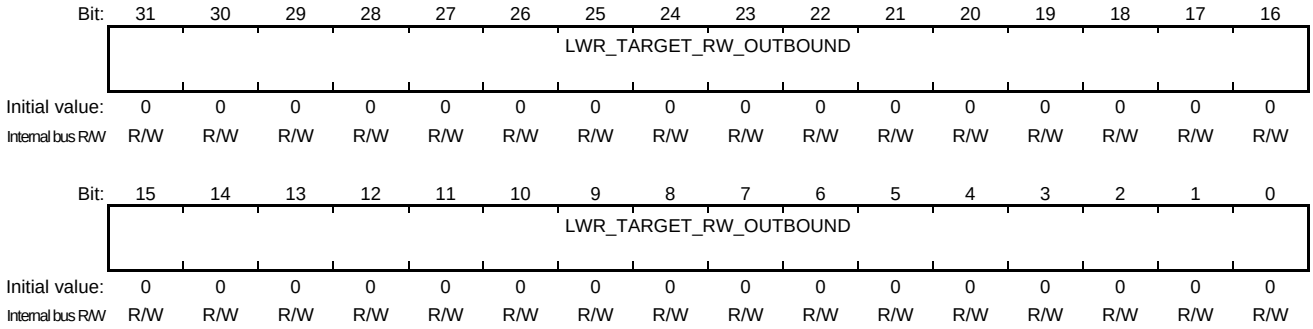


| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 12 | LIMIT_ADDR_RW | All 0 | R/W | Forms upper bits of the end address of the address region to be translated. |
| 11 to 0 | LIMIT_ADDR_HW | All H'FFF | R | Forms lower bits of the end address of the address region to be translated. The end address must be aligned to a 4 kB boundary, so these bits are always all ones. A write to this location is ignored by the PCIEC. |

### 104.2.264 ATU Capabilities Registers [5+*i**18] (ATUCAP[5+*i**18]) (*i* = 0 to 15)

**Common to Header TYPE00/01**

- ATU Lower Target Address Register for outbound

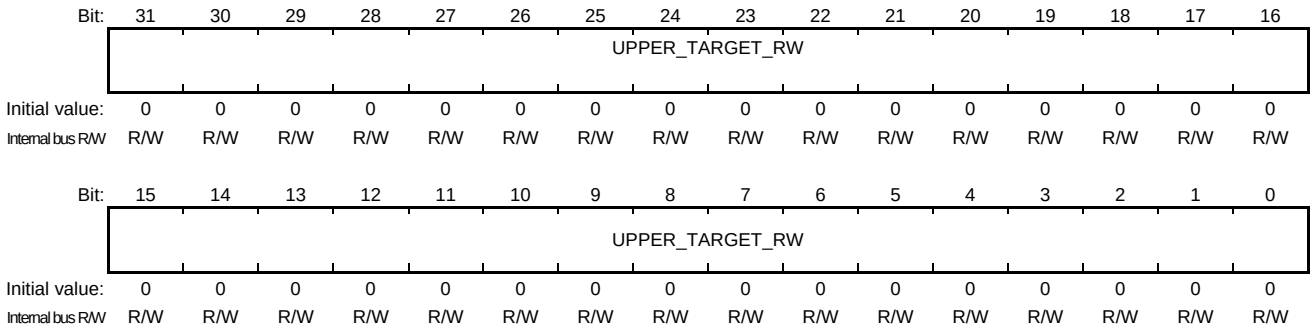


| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | LWR_TARGET_RW_OUTBOUND | All 0 | R/W | When HEADER_SUBSTITUTE_EN in ATU Capabilities Registers [1+i*18] is '0 (normal operation):<br>■ LWR_TARGET_RW[31:12] forms MSB's of the Lower Target part of the new address of the translated region;<br>■ LWR_TARGET_RW[11:0] are not used. (The start address must be aligned to a 4 kB boundary, so the lower bits of the start address of the new address of the translated region (bits 11:0) are always '0').<br>When HEADER_SUBSTITUTE_EN in ATU Capabilities Registers [1+i*18] is '1':<br>■ LWR_TARGET_RW[31:0] forms bytes 8-11 (for 3 DWORD header) or bytes 12-15 (for 4 DWORD header) of the outbound TLP header. Usage scenarios include the transmission of Vendor Defined Messages where the controller determines the content of bytes 12 to 15 of the TLP header. |

### 104.2.265 ATU Capabilities Registers [6+*i**18] (ATUCAP[6+*i**18]) (*i* = 0 to 15)

**Common to Header TYPE00/01**

- ATU Upper Target Address Register for outbound



| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | UPPER_TARGET_RW | All 0 | R/W | Forms bits [63:32] of the start address (Upper Target part) of the new address of the translated region. |

### 104.2.266 ATU Capabilities Registers [7+*i**18] (ATUCAP[7+*i**18]) (*i* = 0 to 15)

**Common to Header TYPE00/01**

- ATU Region Control 3 Register for outbound (setting for virtual function)

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |

### 104.2.267 ATU Capabilities Registers [8+*i**18] (ATUCAP[8+*i**18]) (*i* = 0 to 15)

**Common to Header TYPE00/01**

- ATU Upper Limit Address Register for outbound

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | UPPR_LIMIT_ADDR_HW | | | | | | | | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

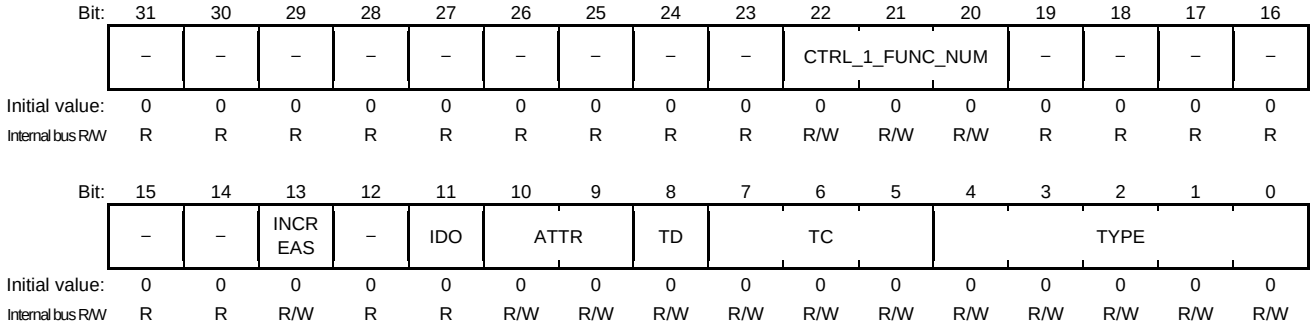
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | UPPR_LIMIT_ADDR_HW | | | | | | | | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | UPPR_LIMIT_ADDR_HW | All 0 | R | Forms MSB's of the Upper Limit part of the region "end address" to be translated. Only applies to 64-bit systems and when the INCREASE_REGION_SIZE field in ATU Capabilities Registers [0+i*18] is '1'. These bits are always '0'. |

### 104.2.268 ATU Capabilities Registers [9+*i**18] (ATUCAP[9+*i**18]) (*i* = 0 to 15)

**Common to Header TYPE00/01**

- ATU Region Control 1 Register for inbound



| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 23 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 22 to 20 | CTRL_1_FUNC_NUM | All 0 | R/W | Function Number.<br>■ MEM-I/O: When the Address and BAR matching logic in the controller indicate that a MEM-I/O transaction matches a BAR in the function corresponding to this value, then address translation proceeds. This check is only performed if the "Function Number Match Enable" bit of the "ATU Capabilities Registers [10+i*18]" is set.<br>■ CFG0/CFG1: When the destination function number as specified in the routing ID of the TLP header matches the function, then address translation proceeds. This check is only performed if the "Function Number Match Enable" bit of the "ATU Capabilities Registers [10+i*18]" is set. |
| 19 to 14 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 13 | INCREASE_REGION_SIZE | 0 | R/W | Increase the maximum ATU Region size. When set, the maximum ATU Region size is determined by CX_ATU_MAX_REGION_SIZE. When clear, the maximum ATU Region size is 4 GB (default). |
| 12 | — | 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 11 | IDO | 0 | R/W | When the IDO field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "ATTR Match Enable" bit of the "ATU Capabilities Registers [10+i*18]" is set.<br>Note: This function is not supported. |
| 10 to 9 | ATTR | All 0 | R/W | When the ATTR field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "ATTR Match Enable" bit of the "ATU Capabilities Registers [10+i*18]" is set. |
| 8 | TD | 0 | R/W | When the TD field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "TD Match Enable" bit of the "ATU Capabilities Registers [10+i*18]" is set. |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 7 to 5 | TC | All 0 | R/W | When the TC field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "TC Match Enable" bit of the "ATU Capabilities Registers [10+i*18]" is set. |
| 4 to 0 | TYPE | All 0 | R/W | When the TYPE field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). |

### 104.2.269 ATU Capabilities Registers [10+*i**18] (ATUCAP[10+*i**18]) (*i* = 0 to 15)

### Common to Header TYPE00/01

- ATU Region Control 2 Register for inbound

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | REGION_EN | MATCH_MODE | INVERT_MODE | CFG_SHIFT_MODE | FUZZY_TYPE_MATCH_CODE | – | RESPONSE_CODE | | SINGLE_ADDR_LOC_TRANS_EN | – | MSG_CODE_MATCH_EN | – | FUNC_NUM_MATCH_EN | – | – | ATTR_MATCH_EN |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R | R/W | R/W | R/W | R | R/W | R | R/W | R | R | R/W |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | TD_MATCH_EN | TC_MATCH_EN | MSG_TYPE_MATCH_MODE | – | – | BAR_NUM | | | MSG_CODE | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 | REGION_EN | 0 | R/W | Region Enable. This bit must be set to '1' for address translation to take place. |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 30 | MATCH_MODE | 0 | R/W | Match Mode. Determines Inbound matching mode for TLPs.<br>The mode depends on the type of TLP that is received as follows:<br>For MEM-I/O TLPs, this field is interpreted as follows:<br>■ 0: Address Match Mode. The ATU operates using addresses as in the outbound direction. The Region Base and Limit Registers must be setup.<br>■ 1:BAR Match Mode. BAR matching is used. The "BAR Number" field is relevant. Not used for RC.<br>For CFG0 TLPs, this field is interpreted as follows:<br>■ 0: Routing ID Match Mode. The ATU interprets the Routing ID (Bytes 8 to 11 of TLP header) as an address.<br>This corresponds to the upper 16 bits of the address in MEM-I/O transactions. The Routing ID of the TLP must be within the base and limit of the ATU region for matching to proceed.<br>■ 1: Accept Mode. The ATU accepts all CFG0 transactions as address matches. The routing ID in the CFG0 TLP is ignored. This is useful as all received CFG0 TLPs should be processed regardless of the Bus number.<br>For MSG/MSGD TLPs, this field is interpreted as follows:<br>■ 0: Address Match Mode. The ATU treats the third DWORD and fourth DWORD of the inbound MSG/MSGD TLP as an address and it is matched against the Region Base and Limit Registers.<br>■ 1: Vendor ID Match Mode. This mode is relevant for ID routed Vendor Defined Messages. The ATU ignores the Routing ID (Bus, Device, Function) in bits [31:16] of the third DWORD of the TLP header, but matches against the Vendor ID in bits [15:0] of the third DWORD of the TLP header. Bits [15:0] of the Region Upper Base register should be programmed with the required Vendor ID. The lower Base and Limit Register should be programmed to translate TLPs based on vendor specific information in the fourth DWORD of the TLP header.<br>-If SINGLE_ADDRESS_LOCATION_TRANSLATE_EN = 1<br>AND MSG_TYPE_MATCH_MODE = 1, then Match Mode is ignored. |
| 29 | INVERT_MODE | 0 | R/W | Invert Mode. When set the address matching region is inverted. Therefore, an address match occurs when the untranslated address is in the region outside the defined range (Base Address to Limit Address). |
| 28 | CFG_SHIFT_MODE | 0 | R/W | CFG Shift Mode. This is useful for CFG transactions where the PCIe configuration mechanism maps bits [27:12] of the address to the bus/device and function number. This allows a CFG configuration space to be located in any 256MB window of your application memory space using a 28-bit effective address. Shifts bits [31:16] of the untranslated address to form bits [27:12] of the translated address. |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 27 | FUZZY_TYPE_MATCH_CODE | 0 | R/W | Fuzzy Type Match Mode. When enabled, the ATU relaxes the matching of the TLP TYPE field against the expected TYPE field so that<br>■ CfgRd0 and CfgRd1 TLPs are seen as identical. Similarly with CfgWr0 and CfgWr1.<br>■ MWr, MRd and MRdLk TLPs are seen as identical<br>■ The Routing field of Msg/MsgD TLPs is ignored<br>■ FetchAdd, Swap and CAS are seen as identical.<br>For example, CFG0 in the TYPE field in the "ATU Capabilities Registers [9+i*18]" matches against an inbound CfgRd0, CfgRd1, CfgWr0 or CfgWr1 TLP. |
| 26 | — | All 0 | R | Reserved<br>This bit is always read as 0. The write value should always be 0. |
| 25 to 24 | RESPONSE_CODE | All 0 | R/W | Response Code. Defines the type of response to give for accesses matching this region. This overrides the normal RADM filter response. Note that this feature is not available for any region where Single Address Location Translate is enabled. |
| 23 | SINGLE_ADDR_LOC_TRANS_EN | 0 | R/W | Single Address Location Translate Enable.<br>When enabled, Rx TLPs can be translated to a single address location as determined by the target address register of the ATU region. The main usage scenario is translation of Messages (such as Vendor Defined or ATS Messages) to MWr TLPs. |
| 22 | — | 0 | R | Reserved<br>This bit is always read as 0. The write value should always be 0. |

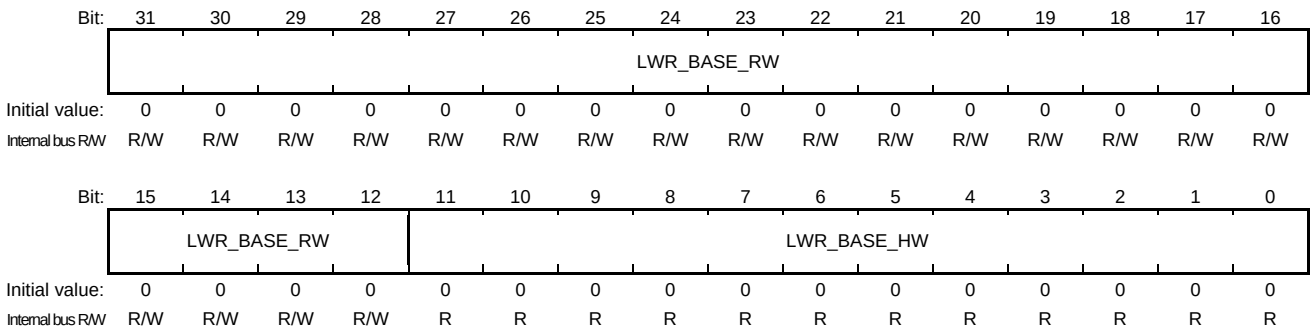
| | | | | |
|---|---|---|---|---|
| 21 | MSG_CODE_MATCH_EN | 0 | R/W | Message Code Match Enable (Msg TLPS). Ensures that a successful message Code TLP field comparison match (see Message Code field of the "ATU Capabilities Registers [10+i*18]") occurs (in MSG transactions) for address translation to proceed. |
| 20 | — | 0 | R | Reserved<br>This bit is always read as 0. The write value should always be 0. |
| 19 | FUNC_NUM_MATCH_EN | 0 | R/W | Function Number Match Enable. Ensures that a successful Function Number TLP field comparison match (see Function Number field of the "ATU Capabilities Registers [9+i*18]") occurs (in MEM-I/O and CFG0/CFG1 transactions) for address translation to proceed. |
| 18 to 17 | — | All 0 | R | Reserved<br>This bit is always read as 0. The write value should always be 0. |
| 16 | ATTR_MATCH_EN | 0 | R/W | ATTR Match Enable. Ensures that a successful ATTR TLP field comparison match (see ATTR field of the "ATU Capabilities Registers [9+i*18]") occurs for address translation to proceed. |
| 15 | TD_MATCH_EN | 0 | R/W | TD Match Enable. Ensures that a successful TD TLP field comparison match (see TD field of the "ATU Capabilities Registers [9+i*18]") occurs for address translation to proceed. |

| | | | | |
|---|---|---|---|---|
| 14 | TC_MATCH_EN | 0 | R/W | TC Match Enable. Ensures that a successful TC TLP field comparison match (see TC field of the "ATU Capabilities Registers [9+i*18]") occurs for address translation to proceed. |
| 13 | MSG_TYPE_MATCH_ MODE | 0 | R/W | Message Type Match Mode.<br>When enabled, and if single address location translate enable is set, then inbound TLPs of type MSG/MSGd which match the type field of the ATU Capabilities Registers [9+i*18] register (=>TYPE[4:3]=2'b10) will be translated. Message type match mode overrides any value of MATCH_MODE field in this register. Usage scenarios for this are translation of VDM. |
| 12 to 11 | — | All 0 | R | Reserved<br>This bit is always read as 0. The write value should always be 0. |
| 10 to 8 | BAR_NUM | 0 | R/W | BAR Number. When the BAR number of an inbound MEM or IO TLP " that is matched by the normal internal BAR address matching mechanism " is the same as this field, address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "Match Mode" bit of the "ATU Capabilities Registers [10+i*18]" is set.<br>■ 000b - BAR0<br>■ 001b - BAR1<br>■ 010b - BAR2<br>■ 011b - BAR3<br>■ 100b - BAR4<br>■ 101b - BAR5<br>■ 110b - ROM<br>■ 111b - reserved<br>■ IO translation would require either 00100b or 00101b in the inbound TLP TYPE; the BAR Number set in the range 000b - 101b and that BAR configured as an IO BAR. |
| 7 to 0 | MSG_CODE | 0 | R/W | MSG TLPs: (Message Code). When the TYPE field of an inbound Msg/MsgD TLP is matched to this value, then address translation proceeds (when all other enabled fieldmatches are successful). This check is only performed if the "Message Code Match Enable" bit of the "ATU Capabilities Registers [10+i*18]" is set. |

### 104.2.270 ATU Capabilities Registers [11+*i**18] (ATUCAP[11+*i**18]) (*i* = 0 to 15)

### Common to Header TYPE00/01

- ATU Lower Base Address Register for inbound



| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 12 | LWR_BASE_RW | All 0 | R/W | Forms bits [31:12] of the start address of the address region to be translated. |
| 11 to 0 | LWR_BASE_HW | All 0 | R | Forms bits [11:0] of the start address of the address region to be translated. The start address must be aligned to a 4 kB boundary, so these bits are always 0. A write to this location is ignored by the PCIEC. |

### 104.2.271 ATU Capabilities Registers [12+*i**18] (ATUCAP[12+*i**18]) (*i* = 0 to 15)

**Common to Header TYPE00/01**

- ATU Upper Base Address Register for inbound

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | UPPER_BASE_RW | | | | | | | | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | UPPER_BASE_RW | | | | | | | | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | UPPER_BASE_RW | All 0 | R/W | Forms bits [63:32] of the start (and end) address of the address region to be translated. |

### 104.2.272 ATU Capabilities Registers [13+*i**18] (ATUCAP[13+*i**18]) (*i* = 0 to 15)

**Common to Header TYPE00/01**

- ATU Limit Address Register for inbound

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | LIMIT_ADDR_RW | | | | | | | | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

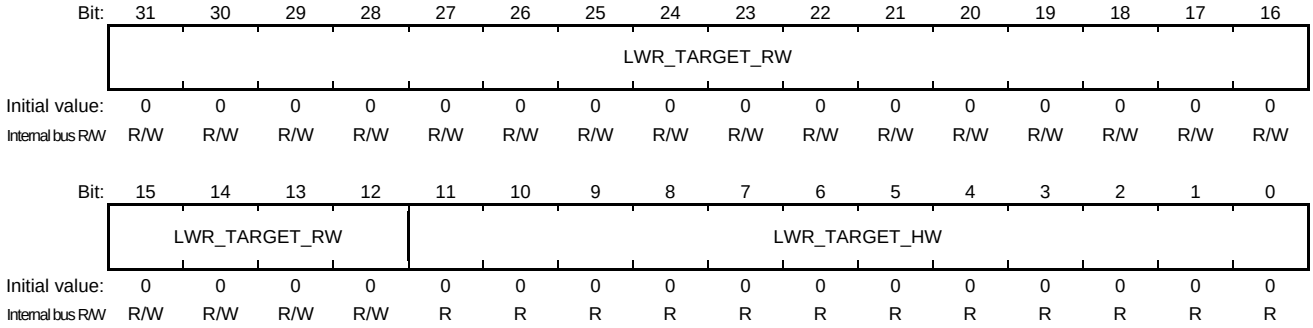
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | LIMIT_ADDR_RW | | | | LIMIT_ADDR_HW | | | | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 12 | LIMIT_ADDR_RW | All 0 | R/W | Forms upper bits of the end address of the address region to be translated. |
| 11 to 0 | LIMIT_ADDR_HW | H'FFF | R | Forms lower bits of the end address of the address region to be translated. The end address must be aligned to a 4 kB boundary, so these bits are always all ones. A write to this location is ignored by the PCIEC. |

### 104.2.273 ATU Capabilities Registers [14+*i**18] (ATUCAP[14+*i**18]) (*i* = 0 to 15)

**Common to Header TYPE00/01**

- ATU Lower Target Address Register for inbound

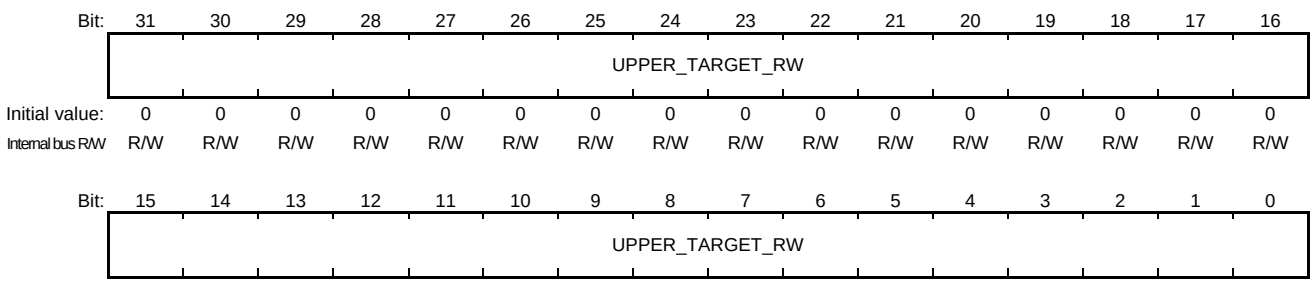


| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 12 | LWR_TARGET_RW | All 0 | R/W | Forms MSB's of the Lower Target part of the new address of the translated region. These bits are always '0'. |
| 11 to 0 | LWR_TARGET_HW | All 0 | R | Forms the LSB's of the Lower Target part of the new address of the translated region. The start address must be aligned to a 4 kB boundary (in address match mode); and to the Bar size boundary (in BAR match mode) so that these bits are always '0'. If the BAR is smaller than the ATU region size, then the ATU target address must align to the ATU region size; otherwise it must align to the BAR size.<br>A write to this location is ignored by the PCIEC. |

### 104.2.274 ATU Capabilities Registers [15+*i**18] (ATUCAP[15+*i**18]) (*i* = 0 to 15)

**Common to Header TYPE00/01**

- ATU Upper Target Address Register for inbound



| | | | | | | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | UPPER_TARGET_RW | All 0 | R/W | Forms bits [63:32] of the start address (Upper Target part) of the new address of the translated region. In systems with a 32-bit address space, this register is not used and therefore writing to this register has no effect. |

### 104.2.275 ATU Capabilities Registers [16+*i**18] (ATUCAP[16+*i**18]) (*i* = 0 to 15)

**Common to Header TYPE00/01**

- ATU Region Control 3 Register for inbound (Setting for VF)

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | | | | | | | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | | | | | | | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |

### 104.2.276 ATU Capabilities Registers [17+*i**18] (ATUCAP[17+*i**18]) (*i* = 0 to 15)

**Common to Header TYPE00/01**

- ATU Upper Limit Address Register for inbound

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | UPPR_LIMIT_ADDR_HW | | | | | | | | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | UPPR_LIMIT_ADDR_HW | | | | | | | | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | UPPR_LIMIT_ADDR_HW | 0 | R | Forms MSB's of the Upper Limit part of the region "end address" to be translated. Only applies to 64-bit systems and when the INCREASE_REGION_SIZE field in ATU Capabilities Registers 9 is '1'. These bits are always '0'. |

### 104.2.277 DMA Capabilities Registers 0 (DMACAP0)

**Common to Header TYPE00/01**

- DMA Arbitration Scheme for TRGT1 Interface
- This register is used to control traffic priorities among various sources that are delivered to internal bus where H’0 represents the highest priority. Concurrent traffic from channels with same priority are sorted according to Round-Robin arbitration rules. The arbitration priority defaults to Non-DMA requests (highest), Write Channel MRd, Read Channel MRd, Read Channel MWr.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | RDBUFF_TRGT_WEIGHT | | | RD_CTRL_TRGT_WEIGHT | | | WR_CTRL_TRGT_WEIGHT | | | RTRGT1_WEIGHT | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 0 | 1 | 0 | 0 | 0 | 1 | 0 | 0 | 0 |
| Internal bus R/W | R | R | R | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

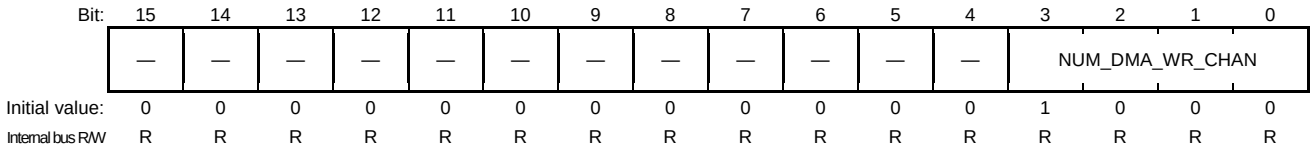
| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 12 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 11 to 9 | RDBUFF_TRGT_WEIGHT | H’3 | R/W | DMA Read Channel MWr Requests. |
| 8 to 6 | RD_CTRL_TRGT_WEIGHT | H’2 | R/W | DMA Read Channel MRd Requests. For LL element/descriptor access. |
| 5 to 3 | WR_CTRL_TRGT_WEIGHT | H’1 | R/W | DMA Write Channel MRd Requests. For DMA data requests and LL element/descriptor access. |
| 2 to 0 | RTRGT1_WEIGHT | All 0 | R/W | Non-DMA Rx Requests. |

### 104.2.278 DMA Capabilities Registers 1 (DMACAP1)

**Common to Header TYPE00/01**

- DMA Number of Channels Register

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | DIS_C2W_CACHE_RD | DIS_C2W_CACHE_WR | — | — | — | — | NUM_DMA_RD_CHAN | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 |
| Internal bus R/W | R | R | R | R | R | R | R/W | R/W | R | R | R | R | R | R | R | R |

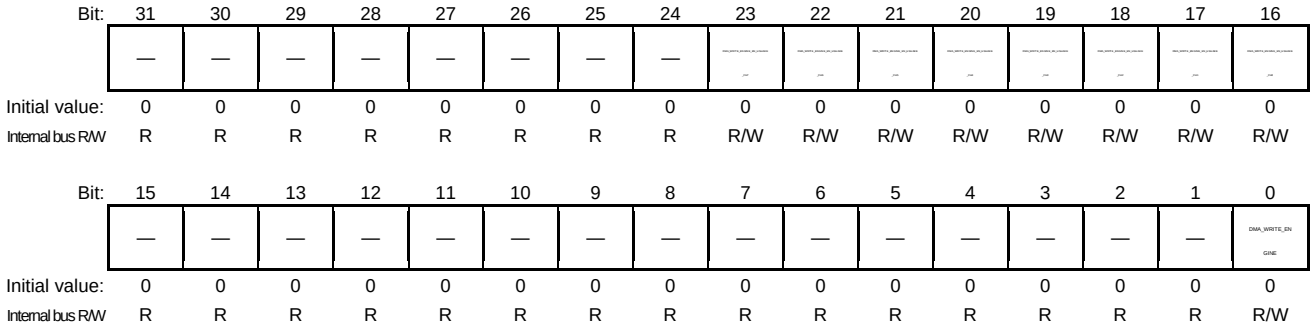


| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 26 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 25 | DIS_C2W_CACHE_RD | 0 | R/W | Disable DMA Read Channels "completion to memory write" context cache pre-fetch function.<br>Note: For internal debugging only. |
| 24 | DIS_C2W_CACHE_WR | 0 | R/W | Disable DMA Write Channels "completion to memory write" context cache pre-fetch function.<br>Note: For internal debugging only. |
| 23 to 20 | — | All 0 | R | Reserved<br>This bit is always read as 0. The write value should always be 0. |
| 19 to 16 | NUM_DMA_RD_CHAN | H'8 | R | Number of Read Channels. You can read this register to determine the number of read channels the DMA controller has been configured to support. |
| 15 to 4 | — | All 0 | R | Reserved<br>This bit is always read as 0. The write value should always be 0. |
| 3 to 0 | NUM_DMA_WR_CHAN | H'8 | R | Number of Write Channels. You can read this register to determine the number of write channels the DMA controller has been configured to support. |

### 104.2.279 DMA Capabilities Registers 2 (DMACAP2)

### Common to Header TYPE00/01

- DMA Write Engine Enable Register



| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 24 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 23 | DMA_WRITE_ENGINE_EN_HSHAKE_CH7 | 0 | R/W | Enable Handshake for DMA Write Engine Channel 7. |
| 22 | DMA_WRITE_ENGINE_EN_HSHAKE_CH6 | 0 | R/W | Enable Handshake for DMA Write Engine Channel 6. |
| 21 | DMA_WRITE_ENGINE_EN_HSHAKE_CH5 | 0 | R/W | Enable Handshake for DMA Write Engine Channel 5. |
| 20 | DMA_WRITE_ENGINE_EN_HSHAKE_CH4 | 0 | R/W | Enable Handshake for DMA Write Engine Channel 4. |
| 19 | DMA_WRITE_ENGINE_EN_HSHAKE_CH3 | 0 | R/W | Enable Handshake for DMA Write Engine Channel 3. |
| 18 | DMA_WRITE_ENGINE_EN_HSHAKE_CH2 | 0 | R/W | Enable Handshake for DMA Write Engine Channel 2. |
| 17 | DMA_WRITE_ENGINE_EN_HSHAKE_CH1 | 0 | R/W | Enable Handshake for DMA Write Engine Channel 1. |
| 16 | DMA_WRITE_ENGINE_EN_HSHAKE_CH0 | 0 | R/W | Enable Handshake for DMA Write Engine Channel 0. |
| 15 to 1 | — | 0 | R | Reserved<br>This bit is always read as 0. The write value should always be 0. |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 0 | DMA_WRITE_ENGINE | 0 | R/W | DMA Write Engine Enable.<br>■ 1: Enable<br>■ 0: Disable (Soft Reset)<br>For normal operation, you must initially set this bit to "1", before any other software setup actions. You do not need to toggle or rewrite to this bit during normal operation. You should set this bit to "0" when you want to "Soft Reset" the DMA controller write logic. There are three possible reasons for resetting the DMA controller write logic:<br>■ The "Abort Interrupt Status" bit is set in the "DMA Capabilities Registers 10" (DMACAP10), and any of the bits is in the " DMA Capabilities Registers 13" (DMACAP13) are set. Resetting the DMA controller write logic re-initializes the control logic ensuring that the next DMA write transfer is executed successfully.<br>■ You have executed the procedure outlined in "Stop Bit", after which, the "Abort Interrupt Status" bit is set and the Channel Status field (CS) of the DMA write "DMA Capabilities Registers [37+i*16]" (DMACAP[37+i*16]) is set to "Stopped." Resetting the DMA controller write logic reinitializes the control logic ensuring that the next DMA write transfer is executed successfully.<br>■ During software development, when you incorrectly program the DMA write engine.<br>To "Soft Reset" the DMA controller write logic, you must:<br>■ De-assert the DMA write engine enable bit.<br>■ Wait for the DMA to complete any in-progress TLP transfer, by waiting until a read on the DMA write engine enable bit returns a "0".<br>■ Assert the DMA write engine enable bit.<br>This "Soft Reset" does not clear the DMA configuration registers. The DMA write transfer does not start until you write to the " DMA Capabilities Registers 3" (DMACAP3). |

### 104.2.280 DMA Capabilities Registers 3 (DMACAP3)

### Common to Header TYPE00/01

- DMA Write Doorbell Register

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | WR_STOP | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

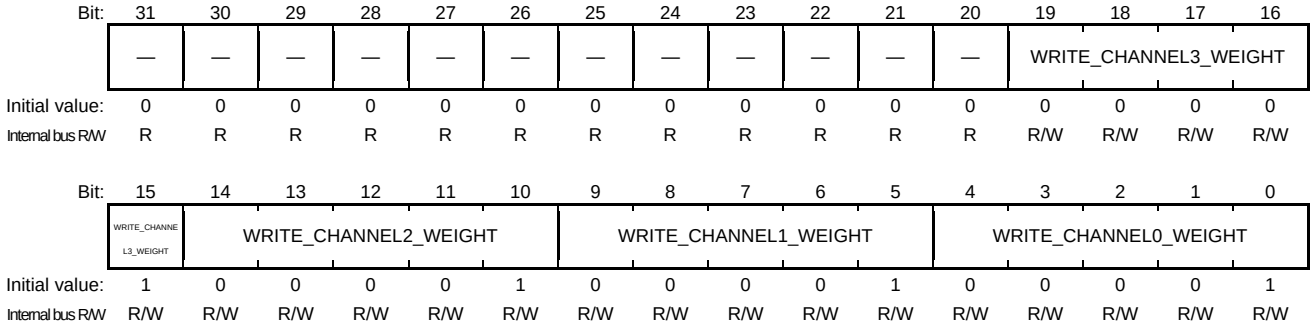
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | WR_DOORBELL_NUM | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 | WR_STOP | 0 | R/W | Stop. Set in conjunction with the Doorbell Number field. The DMA write channel stops issuing requests, sets the channel status to "Stopped", and asserts the "Abort" interrupt if it is enabled. Before setting the Stop bit, you must read the channel Status field (CS) of the " DMA Capabilities Registers 59" (DMACAP59) to ensure that the write channel is "Running" (transferring data). For more information, see "Stopping the DMA Transfer (Software Stop)." |
| 30 to 3 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 2 to 0 | WR_DOORBELL_NUM | All 0 | R/W | Doorbell Number. You must write the channel number to this register to start the DMA write transfer for that channel. The DMA detects a write to this register field even if the value of this field does not change. You do not need to toggle or write any other value to this register to start a new transfer. The range of this field is 0x0 to 0x7, and 0x0 corresponds to channel 0. Also note that a write to this field triggers the controller to exit L1 substates. |

### 104.2.281 DMA Capabilities Registers 4 (DMACAP4)

### Common to Header TYPE00/01

- DMA Write Engine Channel Arbitration Weight Low Register



| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 20 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 19 to 15 | WRITE_CHANNEL3_WEIGHT | H'1 | R/W | Channel 3 Weight. The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel write request. A value of '0' means that one TLP is issued before moving to the next channel. |
| 14 to 10 | WRITE_CHANNEL2_WEIGHT | H'1 | R/W | Channel 2 Weight. The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel write request. A value of '0' means that one TLP is issued before moving to the next channel. |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 9 to 5 | WRITE_CHANNEL1_WEIGHT | H'1 | R/W | Channel 1 Weight. The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel write request. A value of '0' means that one TLP is issued before moving to the next channel. |
| 4 to 0 | WRITE_CHANNEL0_WEIGHT | H'1 | R/W | Channel 0 Weight. The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel write request. A value of '0' means that one TLP is issued before moving to the next channel. |

### 104.2.282 DMA Capabilities Registers 5 (DMACAP5)

### Common to Header TYPE00/01

- DMA Write Engine Channel Arbitration Weight High Register

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R | R | R | R | R | R | R | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | DMA_READ_ENGINE |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R/W |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 24 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 23 | DMA_READ_ENGINE_EN_HSHAKE_CH7 | 0 | R/W | Enable Handshake for DMA Read Engine Channel 7. |
| 22 | DMA_READ_ENGINE_EN_HSHAKE_CH6 | 0 | R/W | Enable Handshake for DMA Read Engine Channel 6. |
| 21 | DMA_READ_ENGINE_EN_HSHAKE_CH5 | 0 | R/W | Enable Handshake for DMA Read Engine Channel 5. |
| 20 | DMA_READ_ENGINE_EN_HSHAKE_CH4 | 0 | R/W | Enable Handshake for DMA Read Engine Channel 4. |
| 19 | DMA_READ_ENGINE_EN_HSHAKE_CH3 | 0 | R/W | Enable Handshake for DMA Read Engine Channel 3. |
| 18 | DMA_READ_ENGINE_EN_HSHAKE_CH2 | 0 | R/W | Enable Handshake for DMA Read Engine Channel 2. |
| 17 | DMA_READ_ENGINE_EN_HSHAKE_CH1 | 0 | R/W | Enable Handshake for DMA Read Engine Channel 1. |
| 16 | DMA_READ_ENGINE_EN_HSHAKE_CH0 | 0 | R/W | Enable Handshake for DMA Read Engine Channel 0. |
| 15 to 1 | — | All 0 | R | Reserved<br>This bit is always read as 0. The write value should always be 0. |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 0 | DMA_READ_ENGINE | 0 | R/W | DMA Read Engine Enable.<br>■ 1: Enable<br>■ 0: Disable (Soft Reset)<br>For normal operation, you must initially set this bit to "1", before any other software setup actions. You do not need to toggle or rewrite to this bit during normal operation. You should set this field to "0" when you want to "Soft Reset" the DMA controller read logic. There are three possible reasons for resetting the DMA controller read logic:<br>■ The "Abort Interrupt Status" bit is set (in the "DMA Capabilities Registers 23" (DMACAP23), and any of the bits in the ""DMA Capabilities Registers 26" (DMACAP26) is set. Resetting the DMA controller read logic re-initializes the control logic, ensuring that the next DMA read transfer is executed successfully.<br>■ You have executed the procedure outlined in "Stop Bit", after which, the "Abort Interrupt Status" bit is set and the channel Status field (CS) of the DMA read "DMA Capabilities Registers [45+i*16]" (DMACAP[45+i*16]) is set to "Stopped". Resetting the DMA controller read logic reinitializes the control logic ensuring that the next DMA read transfer is executed successfully.<br>■ During software development, when you incorrectly program the DMA read engine. To "Soft Reset" the DMA controller read logic, you must:<br>■ De-assert the DMA read engine enable bit.<br>■ Wait for the DMA to complete any in-progress TLP transfer, by waiting until a read on the DMA read engine enable bit returns a "0".<br>■ Assert the DMA read engine enable bit. This "Soft Reset" does not clear the DMA configuration registers. The DMA read transfer does not start until you write to the " DMA Capabilities Registers 7" (DMACAP7). |

### 104.2.284 DMA Capabilities Registers 7 (DMACAP7)

### Common to Header TYPE00/01

- DMA Read Doorbell Register

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | RD_STOP | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

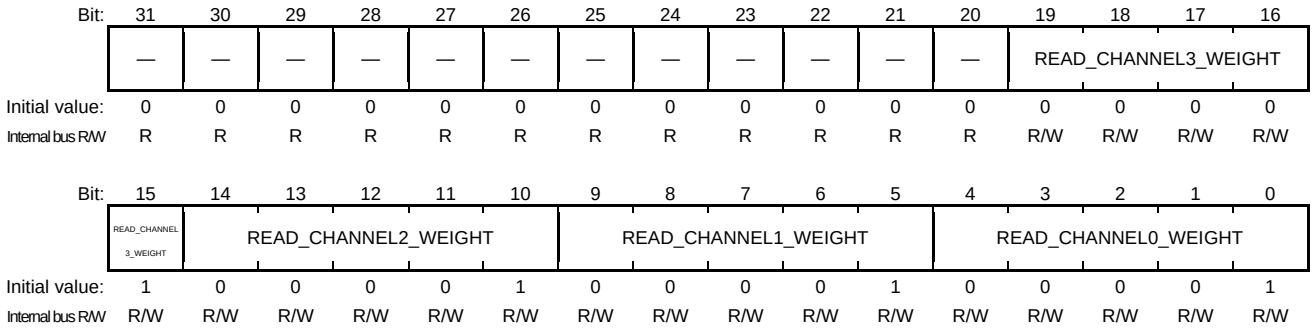
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | RD_DOORBELL_NUM | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 | RD_STOP | 0 | R/W | Stop. Set in conjunction with the Doorbell Number field. The DMA read channel stops issuing requests, sets the channel status to "Stopped", and asserts the "Abort" interrupt if it is enabled. Before setting the Stop bit, you must read the channel Status field (CS) of the "DMA Capabilities Registers 68" (DMACAP68) to ensure that the read channel is "Running" (transferring data).<br>For more information, see "Stopping the DMA Transfer (Software Stop)". |
| 30 to 3 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 2 to 0 | RD_DOORBELL_NUM | All 0 | R/W | Doorbell Number. You must write 0x0 to this register to start the DMA read transfer for that channel. The DMA detects a write to this register field even if the value of this field does not change. The range of this field is 0x0 to 0x7, and 0x0 corresponds to channel 0. Also note that a write to this field triggers the controller to exit L1 substates. |

### 104.2.285 DMA Capabilities Registers 8 (DMACAP8)

### Common to Header TYPE00/01

- Description: DMA Read Engine Channel Arbitration Weight Low Register



| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 20 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 19 to 15 | READ_CHANNEL3_WEIGHT | H'1 | R/W | Channel 3 Weight. The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. |
| 14 to 10 | READ_CHANNEL2_WEIGHT | H'1 | R/W | Channel 2 Weight. The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. |
| 9 to 5 | READ_CHANNEL1_WEIGHT | H'1 | R/W | Channel 1 Weight. The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 4 to 0 | READ_CHANNEL0_WEIGHT | H'1 | R/W | Channel 0 Weight. The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. |

### 104.2.286 DMA Capabilities Registers 9 (DMACAP9)

**Common to Header TYPE00/01**

- DMA Read Engine Channel Arbitration Weight High Register

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | — | READ_CHANNEL7_WEIGHT | | | |

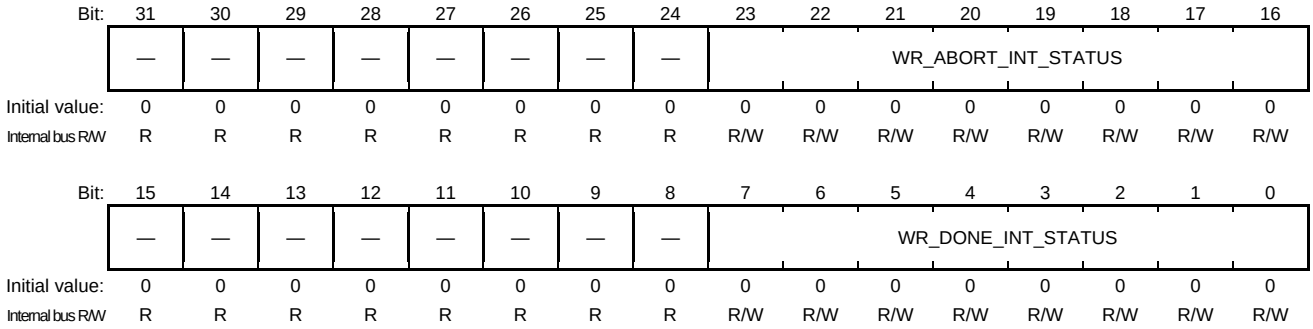
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | READ_CHANNEL7_WEIGHT | READ_CHANNEL6_WEIGHT | | | | | READ_CHANNEL5_WEIGHT | | | | | READ_CHANNEL4_WEIGHT | | | | |
| Initial value: | 1 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 1 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 20 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 19 to 15 | READ_CHANNEL7_WEIGHT | H'1 | R/W | Channel 7 Weight. The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. |
| 14 to 10 | READ_CHANNEL6_WEIGHT | H'1 | R/W | Channel 6 Weight. The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. |
| 9 to 5 | READ_CHANNEL5_WEIGHT | H'1 | R/W | Channel 5 Weight. The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. |
| 4 to 0 | READ_CHANNEL4_WEIGHT | H'1 | R/W | Channel 4 Weight. The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. |

### 104.2.287 DMA Capabilities Registers 10 (DMACAP10)

**Common to Header TYPE00/01**

- DMA Write Interrupt Status Register



| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 24 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 23 to 16 | WR_ABORT_INT_STATUS | All 0 | R/W | Abort Interrupt Status. The DMA write channel has detected an error, or you manually stopped the transfer as described in "Error Handling Assistance by Remote Software". Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0.<br>■ Enabling: For details, see "Interrupts and Error Handling".<br>■ Masking: The DMA write interrupt Mask register has no effect on this register.<br>■ Clearing: You must write a 1'b1 to the corresponding channel bit in the DMA write interrupt Clear register to clear this interrupt bit.<br>Note: You can write to this register to emulate interrupt generation, during software or hardware testing. A write to the address triggers an interrupt, but the DMA does not set the Done or Abort bits in this register. |
| 15 to 8 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 7 to 0 | WR_DONE_INT_STATUS | All 0 | R/W | Done Interrupt Status. The DMA write channel has successfully completed the DMA transfer. For more details, see "Interrupts and Error Handling". Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0.<br>■ Enabling: For details, see "Interrupts and Error Handling".<br>■ Masking: The DMA write interrupt Mask register has no effect on this register.<br>■ Clearing: You must write a 1'b1 to the corresponding channel bit in the DMA write interrupt Clear register to clear this interrupt bit.<br>Note: You can write to this register to emulate interrupt generation, during software or hardware testing. A write to the address triggers an interrupt, but the DMA does not set the Done or Abort bits in this register. |

### 104.2.288 DMA Capabilities Registers 11 (DMACAP11)

**Common to Header TYPE00/01**

- DMA Write Interrupt Mask Register

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | WR_ABORT_INT_MASK | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |
| Internal bus R/W | R | R | R | R | R | R | R | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | WR_DONE_INT_MASK | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |
| Internal bus R/W | R | R | R | R | R | R | R | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 24 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 23 to 16 | WR_ABORT_INT_MASK | H'FF | R/W | Abort Interrupt Mask. Prevents the Abort interrupt status field in the DMA write interrupt status register from asserting the intreq_pci*m*_dma_p output. Each bit corresponds to a DMA channel. (*m* = 0, 1, 2, 3)<br>Bit [0] corresponds to channel 0. |
| 15 to 8 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 7 to 0 | WR_DONE_INT_MASK | H'FF | R/W | Done Interrupt Mask. Prevents the Done interrupt status field in the DMA write interrupt status register from asserting the intreq_pci*m*_dma_p output. Each bit corresponds to a DMA channel. (*m* = 0, 1, 2, 3)<br>Bit [0] corresponds to channel 0. |

### 104.2.289 DMA Capabilities Registers 12 (DMACAP12)

**Common to Header TYPE00/01**

- DMA Write Interrupt Clear Register

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | WR_ABORT_INT_CLEAR | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R | R | R | R | R | R | R | R | W | W | W | W | W | W | W | W |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | WR_DONE_INT_CLEAR | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R | R | R | R | R | R | R | R | W | W | W | W | W | W | W | W |

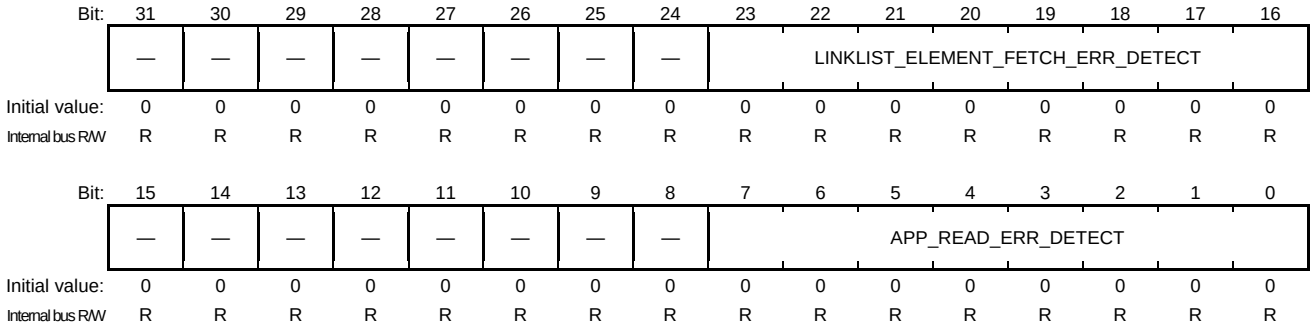
| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 24 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 23 to 16 | WR_ABORT_INT_CLEAR | All 0 | W | Abort Interrupt Clear. You must write a 1'b1 to clear the corresponding bit in the Abort interrupt status field of the DMA write interrupt status register. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0.<br>Note: Reading from this self-clearing register field always returns a "0". |
| 15 to 8 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 7 to 0 | WR_DONE_INT_CLEAR | All 0 | W | Done Interrupt Clear. You must write a 1'b1 to clear the corresponding bit in the Done interrupt status field of the DMA write interrupt status register. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0.<br>Note: Reading from this self-clearing register field always returns a "0". |

### 104.2.290 DMA Capabilities Registers 13 (DMACAP13)

### Common to Header TYPE00/01

- DMA Write Error Status Register



| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 24 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 23 to 16 | LINKLIST_ELEMENT_FETCH_ERR_DETECT | All 0 | R | Linked List Element Fetch Error Detected. The DMA write channel has received an error response from the AXI bus while reading a linked list element from local memory. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0.<br>■ Enabling: For details, see "Interrupts and Error Handling".<br>■ Masking: The DMA write interrupt Mask register has no effect on this register.<br>■ Clearing: You must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the "DMA Capabilities Registers 12" (DMACAP12) to clear this error bit. |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 15 to 8 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 7 to 0 | APP_READ_ERR_DETECT | All 0 | R | Application Read Error Detected. The DMA write channel has received an error response from the AXI bus while reading data from it. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0.<br>■ Enabling: For details, see "Interrupts and Error Handling".<br>■ Masking: The DMA write interrupt Mask register has no effect on this register.<br>■ Clearing: You must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the "DMA Capabilities Registers 12" (DMACAP12) to clear this error bit. |

### 104.2.291 DMA Capabilities Registers 14 (DMACAP14)

**Common to Header TYPE00/01**

- DMA Write Done IMWr Address Low Register

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | DMA_WRITE_DONE_LOW_REG | | | | | | | | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | DMA_WRITE_DONE_LOW_REG | | | | | | | | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | DMA_WRITE_DONE_LOW_REG | All 0 | R/W | The DMA uses this field to generate bits [31:0] of the address field for the Done IMWr TLP. Bits [1:0] must be "00" as this address must be DWORD aligned. |

### 104.2.292 DMA Capabilities Registers 15 (DMACAP15)

**Common to Header TYPE00/01**

- DMA Write Done IMWr Interrupt Address High Register

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | DMA_WRITE_DONE_HIGH_REG | | | | | | | | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | DMA_WRITE_DONE_HIGH_REG | | | | | | | | | | | | | | | |

| | | | | | | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | DMA_WRITE_DONE_HIGH_REG | All 0 | R/W | The DMA uses this field to generate bits [63:32] of the address field for the Done IMWr TLP. |

### 104.2.293 DMA Capabilities Registers 16 (DMACAP16)

**Common to Header TYPE00/01**

- DMA Write Abort IMWr Address Low Register

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | DMA_WRITE_ABORT_LOW_REG | | | | | | | | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | DMA_WRITE_ABORT_LOW_REG | | | | | | | | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | DMA_WRITE_ABORT_LOW_REG | All 0 | R/W | The DMA uses this field to generate bits [31:0] of the address field for the Abort IMWr TLP it generates. Bit [1:0] must be "00" as this address must be DWORD aligned. |

### 104.2.294 DMA Capabilities Registers 17 (DMACAP17)

**Common to Header TYPE00/01**

- DMA Write Abort IMWr Address High Register

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | DMA_WRITE_ABORT_HIGH_REG | | | | | | | | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

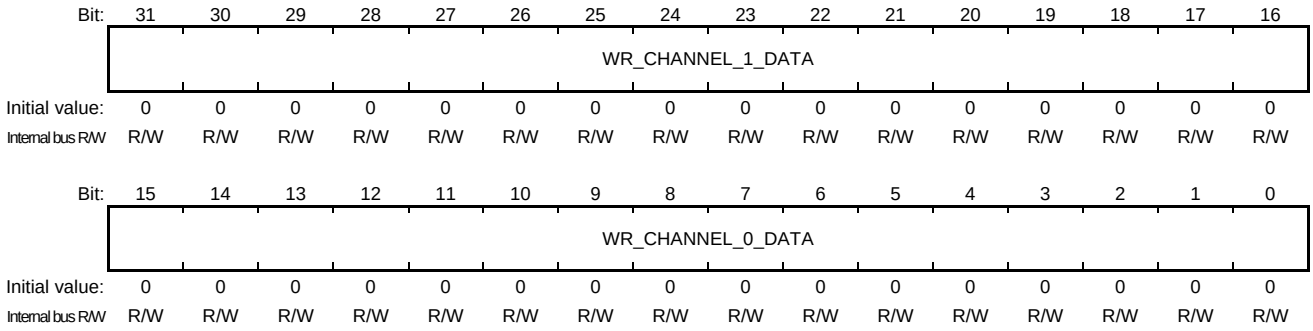
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | DMA_WRITE_ABORT_HIGH_REG | | | | | | | | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | DMA_WRITE_ABORT_HIGH_REG | All 0 | R/W | The DMA uses this field to generate bits [63:32] of the address field for the Abort IMWr TLP. |

### 104.2.295 DMA Capabilities Registers 18 (DMACAP18)

**Common to Header TYPE00/01**

- DMA Write Channel 1 and 0 IMWr Data Register

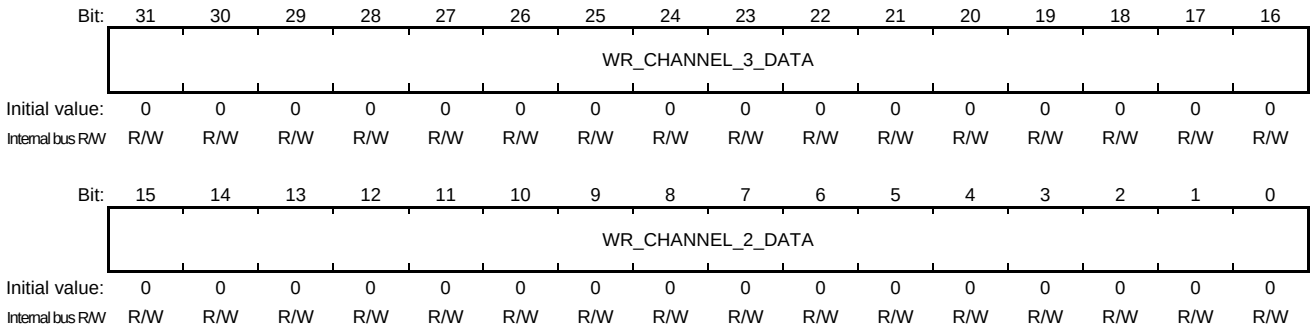


| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 16 | WR_CHANNEL_1_DATA | All 0 | R/W | The DMA uses this field to generate the data field for the Done or Abort IMWr TLPs it generates for write channel 1. |
| 15 to 0 | WR_CHANNEL_0_DATA | All 0 | R/W | The DMA uses this field to generate the data field for the Done or Abort IMWr TLPs it generates for write channel 0. |

### 104.2.296 DMA Capabilities Registers 19 (DMACAP19)

**Common to Header TYPE00/01**

- DMA Write Channel 3 and 2 IMWr Data Register



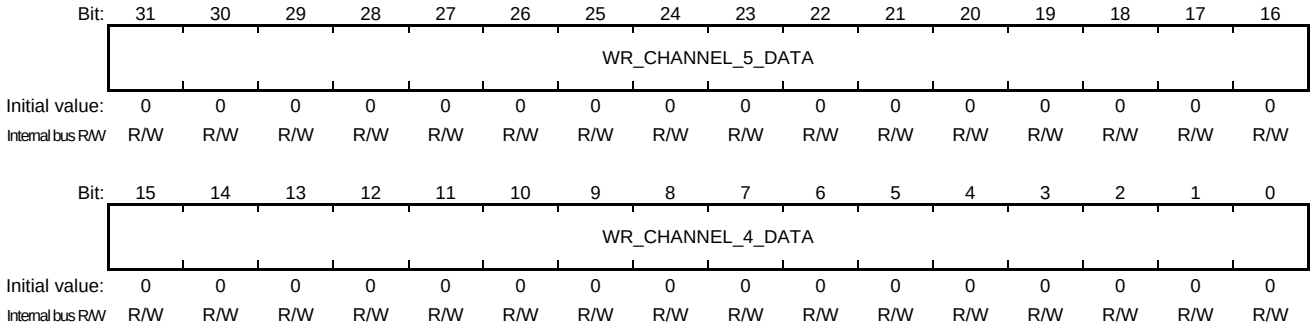
| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 16 | WR_CHANNEL_3_DATA | All 0 | R/W | The DMA uses this field to generate the data field for the Done or Abort IMWr TLPs it generates for write channel 3. |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 15 to 0 | WR_CHANNEL_2_DATA | All 0 | R/W | The DMA uses this field to generate the data field for the Done or Abort IMWr TLPs it generates for write channel 2. |

### 104.2.297 DMA Capabilities Registers 20 (DMACAP20)

**Common to Header TYPE00/01**

- DMA Write Channel 5 and 4 IMWr Data Register

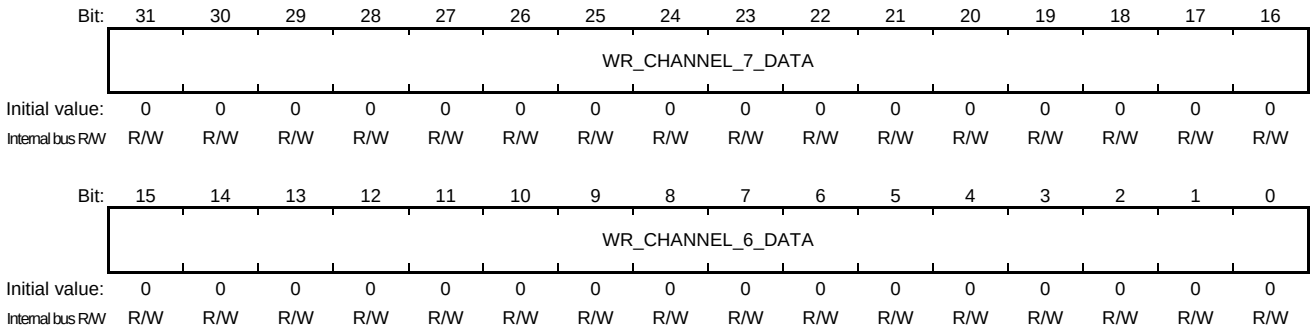


| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 16 | WR_CHANNEL_5_DATA | All 0 | R/W | The DMA uses this field to generate the data field for the Done or Abort IMWr TLPs it generates for write channel 5. |
| 15 to 0 | WR_CHANNEL_4_DATA | All 0 | R/W | The DMA uses this field to generate the data field for the Done or Abort IMWr TLPs it generates for write channel 4. |

### 104.2.298 DMA Capabilities Registers 21 (DMACAP21)

**Common to Header TYPE00/01**

- DMA Write Channel 7 and 6 IMWr Data Register



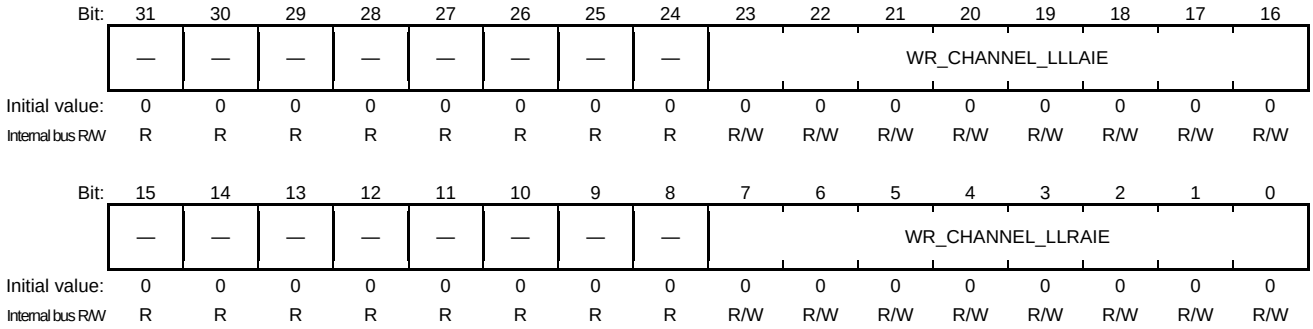
| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 16 | WR_CHANNEL_7_DATA | All 0 | R/W | The DMA uses this field to generate the data field for the Done or Abort IMWr TLPs it generates for write channel 7. |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 15 to 0 | WR_CHANNEL_6_DATA | All 0 | R/W | The DMA uses this field to generate the data field for the Done or Abort IMWr TLPs it generates for write channel 6. |

### 104.2.299 DMA Capabilities Registers 22 (DMACAP22)

**Common to Header TYPE00/01**

- DMA Write Linked List Error Enable Register

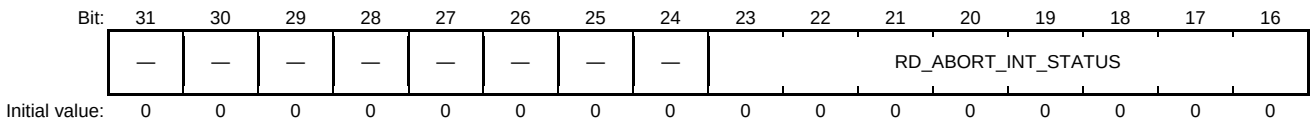


| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 24 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 23 to 16 | WR_CHANNEL_LLLAIE | All 0 | R/W | Write Channel LL Local Abort Interrupt Enable (LLLAIE).<br>You enable the write channel local abort interrupt through this bit. The LIE and RIE bits in the LL element enable the write channel done interrupts. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. Used in linked list mode only. For more details, see "Interrupt Handling". |
| 15 to 8 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 7 to 0 | WR_CHANNEL_LLRAIE | All 0 | R/W | Write Channel LL Remote Abort Interrupt Enable (LLRAIE).<br>You enable the write channel remote abort interrupt through this bit. The LIE and RIE bits in the LL element enable the write channel done interrupts. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. Used in linked list mode only. For more details, see "Interrupt Handling". |

### 104.2.300 DMA Capabilities Registers 23 (DMACAP23)

**Common to Header TYPE00/01**

- DMA Read Interrupt Status Register



| | | | | | | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Internal bus R/W | R | R | R | R | R | R | R | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | — | — | — | — | — | — | — | — | RD_DONE_INT_STATUS | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R | R | R | R | R | R | R | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 24 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 23 to 16 | RD_ABORT_INT_STATUS | All 0 | R/W | Abort Interrupt Status. The DMA read channel has detected an error, or you manually stopped the transfer as described in "Stopping the DMA Transfer (Software Stop)". Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. You can read the "DMA Capabilities Registers 26" (DMACAP26) and "DMA Capabilities Registers 27" (DMACAP27) to determine the source of the error.<br>■ Enabling: For details, see "Interrupts and Error Handling".<br>■ Masking: The DMA read interrupt Mask register has no effect on this register.<br>■ Clearing: You must write a 1'b1 to the corresponding channel bit in the DMA read interrupt Clear register to clear this interrupt bit.<br>Note: You can write to this register to emulate interrupt generation, during software or hardware testing. A write to the address triggers an interrupt, but the DMA does not set the Done or Abort bits in this register. |
| 15 to 8 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 7 to 0 | RD_DONE_INT_STATUS | All 0 | R/W | Done Interrupt Status. The DMA read channel has successfully completed the DMA read transfer. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0.<br>■ Enabling: For details, see "Interrupts and Error Handling".<br>■ Masking: The DMA read interrupt Mask register has no effect on this register.<br>■ Clearing: You must write a 1'b1 to the corresponding channel bit in the DMA read interrupt Clear register to clear this interrupt bit.<br>Note: You can write to this register to emulate interrupt generation, during software or hardware testing. A write to the address triggers an interrupt, but the DMA does not set the Done or Abort bits in this register. |

### 104.2.301 DMA Capabilities Registers 24 (DMACAP24)

#### Common to Header TYPE00/01

- DMA Read Interrupt Mask Register

| | | | | | | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | — | — | — | — | — | — | — | RD_ABORT_INT_MASK | | | | | | | |

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | RD_ABORT_INT_CLEAR | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R | R | R | R | R | R | R | R | W | W | W | W | W | W | W | W |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | RD_DONE_INT_CLEAR | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R | R | R | R | R | R | R | R | W | W | W | W | W | W | W | W |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 24 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 23 to 16 | RD_ABORT_INT_CLEAR | H'FF | R/W | Abort Interrupt Clear. Clears the Abort interrupt status field in the DMA read interrupt status register. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. (*m* = 0, 1, 2, 3)<br>0: Clear the Abort interrupt status field<br>1: Ignored |
| 15 to 8 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 7 to 0 | RD_DONE_INT_CLEAR | H'FF | R/W | Done Interrupt Clear. Clears the Done interrupt status field in the DMA read interrupt status register. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. (*m* = 0, 1, 2, 3)<br>0: Clear the Done interrupt status field<br>1: Ignored |

### 104.2.302 DMA Capabilities Registers 25 (DMACAP25)

### Common to Header TYPE00/01

- DMA Read Interrupt Clear Register

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | RD_ABORT_INT_CLEAR | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R | R | R | R | R | R | R | R | W | W | W | W | W | W | W | W |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | RD_DONE_INT_CLEAR | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R | R | R | R | R | R | R | R | W | W | W | W | W | W | W | W |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 24 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 23 to 16 | RD_ABORT_INT_CLEAR | All 0 | W | Abort Interrupt Clear. You must write a 1'b1 to clear the corresponding bit in the Abort interrupt status field of the DMA read interrupt status register. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0.<br>Note: Reading from this self-clearing register field always returns a "0". |
| 15 to 8 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 7 to 0 | RD_DONE_INT_CLEAR | All 0 | W | Done Interrupt Clear. You must write a 1'b1 to clear the corresponding bit in the Done interrupt status field of the DMA read interrupt status register. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0.<br>Note: Reading from this self-clearing register field always returns a "0". |

### 104.2.303 DMA Capabilities Registers 26 (DMACAP26)

**Common to Header TYPE00/01**

- DMA Read Error Status Low Register

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | LINK_LIST_ELEMENT_FETCH_ERR_DETECT | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | APP_WR_ERR_DETECT | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

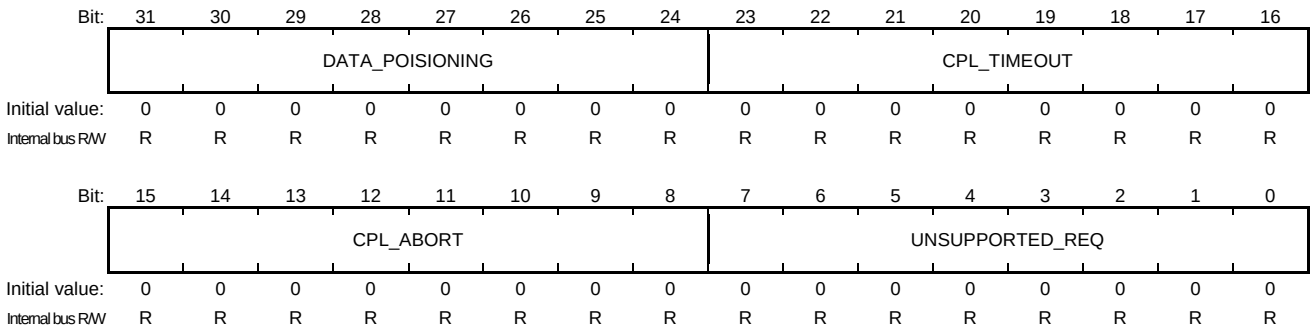
| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 24 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 23 to 16 | LINK_LIST_ELEMENT_FETCH_ERR_DETECT | All 0 | R | Linked List Element Fetch Error Detected.<br>■ The DMA read channel has received an error response from the AXI bus while reading a linked list element from local memory. Each bit corresponds to a DMA channel.<br>Bit [0] corresponds to channel 0.<br>■ Enabling: For details, see "Interrupts and Error Handling".<br>■ Masking: The DMA read interrupt Mask register has no effect on this register.<br>■ Clearing: You must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the "DMA Capabilities Registers 25" (DMACAP25) to clear this error bit.<br>Note, this clears all bits in this register, and also the DMA Capabilities Registers 27 (DMACAP27). |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 15 to 8 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 7 to 0 | APP_WR_ERR_DETECT | All 0 | R | Application Write Error Detected. The DMA read channel has received an error response from the AXI bus (or TRGT1 interface when the AXI Bridge is not used) while writing data to it. This error is fatal. You must restart the transfer from the beginning, as the channel context is corrupted, and the transfer is not rolled back. For more details, see "Linked List Mode". Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0.<br>■ Enabling: For details, see "Interrupts and Error Handling".<br>■ Masking: The DMA read interrupt Mask register has no effect on this register.<br>■ Clearing: You must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the "DMA Capabilities Registers 25" (DMACAP25) to clear this error bit.<br>Note, this clears all bits in this register, and also the DMA Capabilities Registers 27 (DMACAP27). |

### 104.2.304 DMA Capabilities Registers 27 (DMACAP27)

### Common to Header TYPE00/01

- DMA Read Error Status High Register



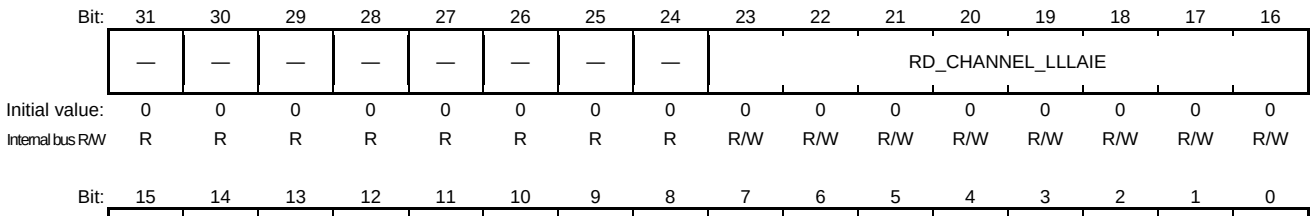
| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 24 | DATA_POISIONING | All 0 | R | Data Poisoning. The DMA read channel has detected data poisoning in the completion from the remote device (in response to the MRd request). The DMA read channel will drop the completion and then be halted. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0.<br>■ Enabling: For details, see "Interrupts and Error Handling".<br>■ Masking: The DMA read interrupt Mask register has no effect on this register.<br>■ Clearing: You must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the "DMA Capabilities Registers 25" (DMACAP25) to clear this error bit.<br>Note, this also clears the other error bits for the same channel in this register and in the DMA Capabilities Registers 26. |

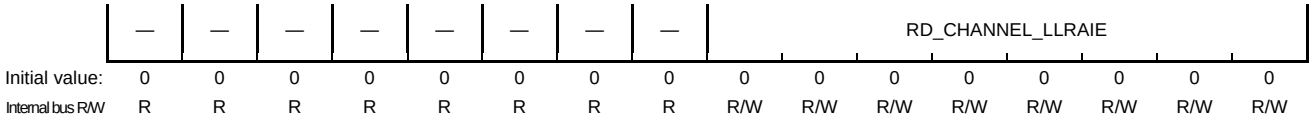
| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 23 to 16 | CPL_TIMEOUT | All 0 | R | Completion Time Out. The DMA read channel has timed-out while waiting for the remote device to respond to the MRd request, or a malformed CplD has been received. For more details, see "Linked List Mode". Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0.<br>■ Enabling: For details, see "Interrupts and Error Handling".<br>■ Masking: The DMA read interrupt Mask register has no effect on this register.<br>■ Clearing: You must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the "DMA Capabilities Registers 25" (DMACAP25) to clear this error bit.<br>Note, this also clears the other error bits for the same channel in this register and in the DMA Capabilities Registers 26. |
| 15 to 8 | CPL_ABORT | All 0 | R | Completer Abort. The DMA read channel has received a PCIe completer abort completion status from the remote device in response to the MRd request. For more details, see "Linked List Mode". Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0.<br>■ Enabling: For details, see "Interrupts and Error Handling".<br>■ Masking: The DMA read interrupt Mask register has no effect on this register.<br>■ Clearing: You must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the " DMA Capabilities Registers 25" (DMACAP25) to clear this error bit.<br>Note, this also clears the other error bits for the same channel in this register and in the DMA Capabilities Registers 26. |
| 7 to 0 | UNSUPPORTED_REQ | All 0 | R | Unsupported Request. The DMA read channel has received a PCIe unsupported request completion status from the remote device in response to the MRd request. For more details, see "Linked List Mode". Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0.<br>■ Enabling: For details, see "Interrupts and Error Handling".<br>■ Masking: The DMA read interrupt Mask register has no effect on this register.<br>■ Clearing: You must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the "DMA Capabilities Registers 25" (DMACAP25) to clear this error bit.<br>Note, this also clears the other error bits for the same channel in this register and in the DMA Capabilities Registers 26. |

### 104.2.305 DMA Capabilities Registers 28 (DMACAP28)

### Common to Header TYPE00/01

- DMA Read Linked List Error Enable Register



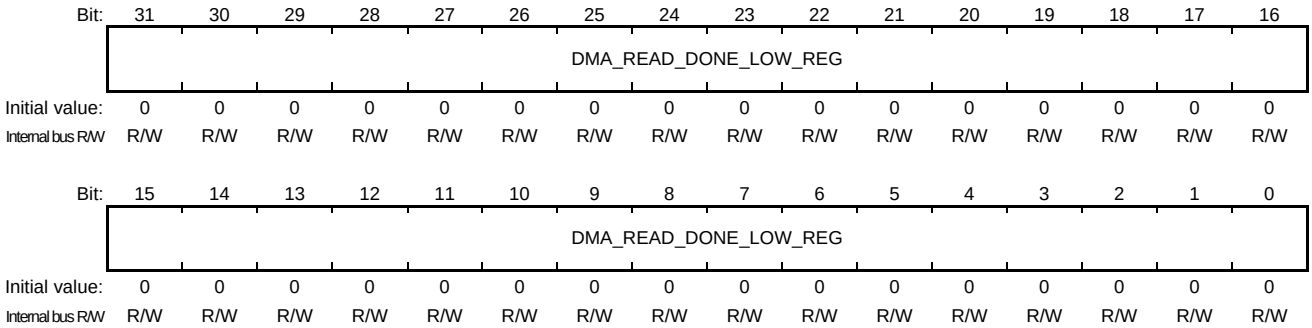


| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 24 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 23 to 16 | RD_CHANNEL_LLLAIE | All 0 | R/W | Read Channel LL Local Abort Interrupt Enable (LLLAIE). You enable the read channel Local Abort interrupt through this bit. The LIE and RIE bits in the LL element enable the read channel done interrupts. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. Used in linked list mode only. For more details, see "Interrupt Handling". |
| 15 to 8 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 7 to 0 | RD_CHANNEL_LLRAIE | All 0 | * R/W | Read Channel LL Remote Abort Interrupt Enable (LLRAIE). You enable the read channel Remote Abort interrupt through this bit. The LIE and RIE bits in the LL element enable the read channel done interrupts. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. Used in linked list mode only. For more details, see "Interrupt Handling". |

### 104.2.306 DMA Capabilities Registers 29 (DMACAP29)

**Common to Header TYPE00/01**

- DMA Read Done IMWr Address Low Register

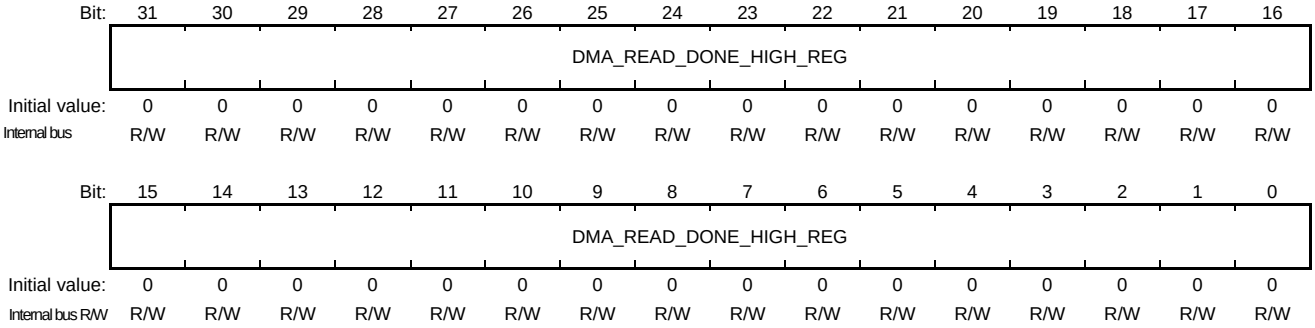


| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | DMA_READ_DONE_LOW_REG | All 0 | R/W | The DMA uses this field to generate bits [31:0] of the address field for the Done IMWr TLP. Bits [1:0] must be "00" as this address must be DWORD aligned. |

### 104.2.307 DMA Capabilities Registers 30 (DMACAP30)

**Common to Header TYPE00/01**

- DMA Read Done IMWr Address High Register

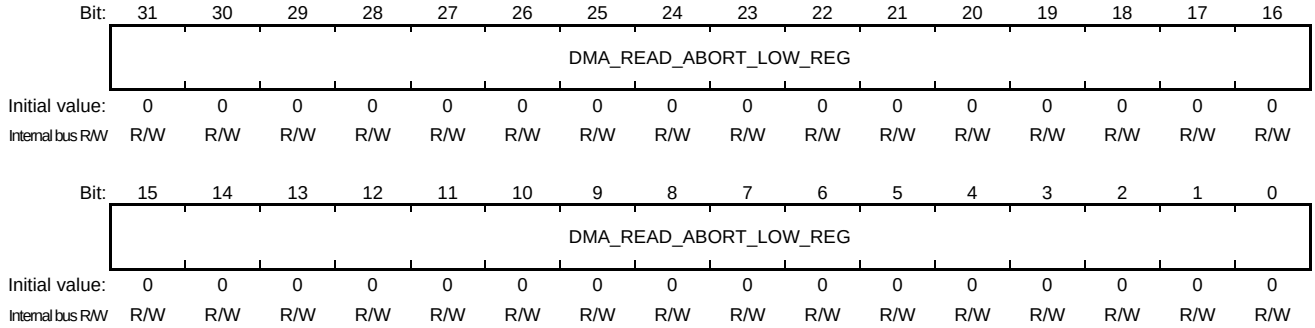


| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | DMA_READ_DONE_HIGH_REG | All 0 | R/W | The DMA uses this field to generate bits [63:32] of the address field for the Done IMWr TLP. |

### 104.2.308 DMA Capabilities Registers 31 (DMACAP31)

**Common to Header TYPE00/01**

- DMA Read Abort IMWr Address Low Register

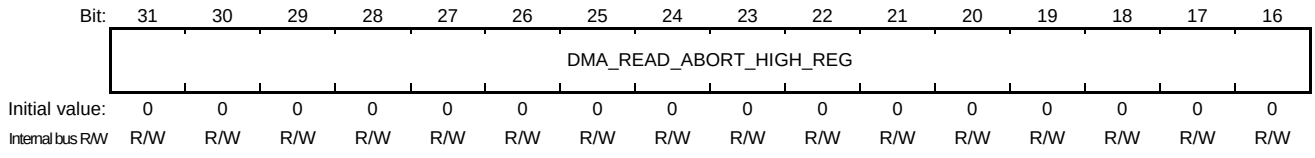


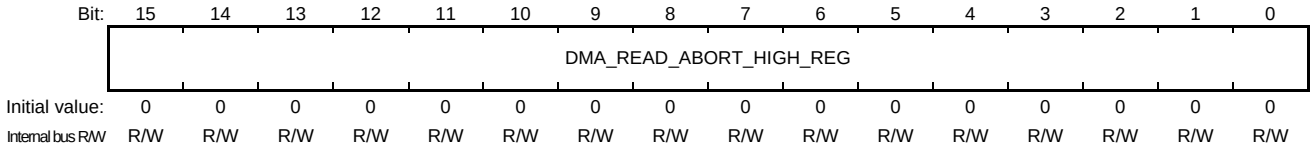
| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | DMA_READ_ABORT_LOW_REG | All 0 | R/W | The DMA uses this field to generate bits [31:0] of the address field for the Abort IMWr TLP. Bits [1:0] must be "00" as this address must be DWORD aligned. |

### 104.2.309 DMA Capabilities Registers 32 (DMACAP32)

**Common to Header TYPE00/01**

- DMA Read Abort IMWr Address High Register



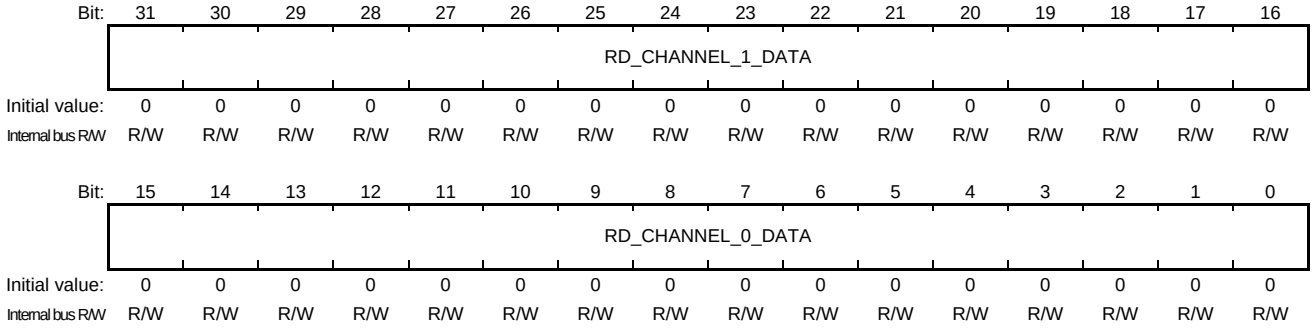


| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | DMA_READ_ABORT_ HIGH_REG | All 0 | R/W | The DMA uses this field to generate bits [63:32] of the address field for the Abort IMWr TLP. |

### 104.2.310 DMA Capabilities Registers 33 (DMACAP33)

**Common to Header TYPE00/01**

- DMA Read Channel 1 and 0 IMWr Data Register

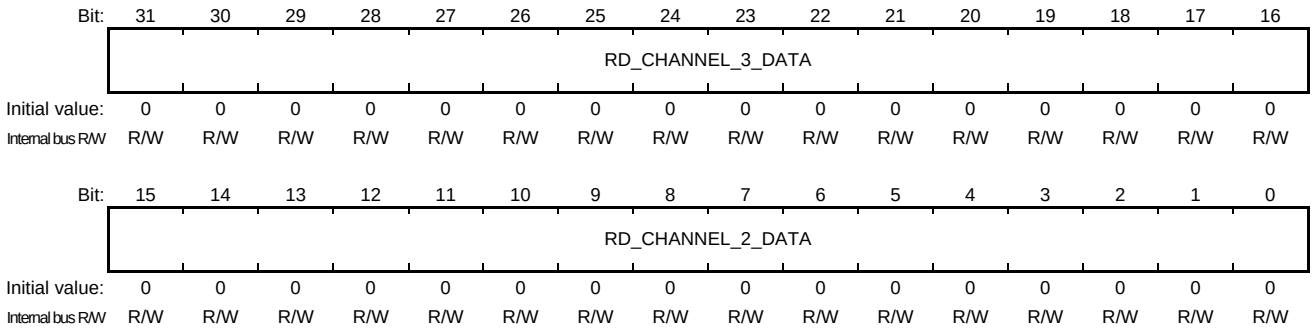


| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 16 | RD_CHANNEL_1_DAT A | All 0 | R/W | The DMA uses this field to generate the data field for the Done or Abort IMWr TLPs it generates for read channel 1. |
| 15 to 0 | RD_CHANNEL_0_DAT A | All 0 | R/W | The DMA uses this field to generate the data field for the Done or Abort IMWr TLPs it generates for read channel 0. |

### 104.2.311 DMA Capabilities Registers 34 (DMACAP34)

**Common to Header TYPE00/01**

- DMA Read Channel 3 and 2 IMWr Data Register

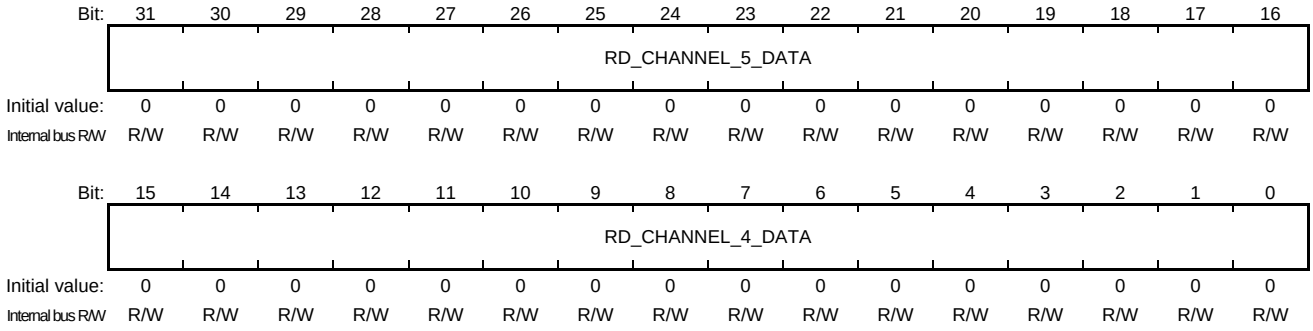


| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 16 | RD_CHANNEL_3_DATA | All 0 | R/W | The DMA uses this field to generate the data field for the Done or Abort IMWr TLPs it generates for read channel 3. |
| 15 to 0 | RD_CHANNEL_2_DATA | All 0 | R/W | The DMA uses this field to generate the data field for the Done or Abort IMWr TLPs it generates for read channel 2. |

### 104.2.312 DMA Capabilities Registers 35 (DMACAP35)

**Common to Header TYPE00/01**

- DMA Read Channel 5 and 4 IMWr Data Register

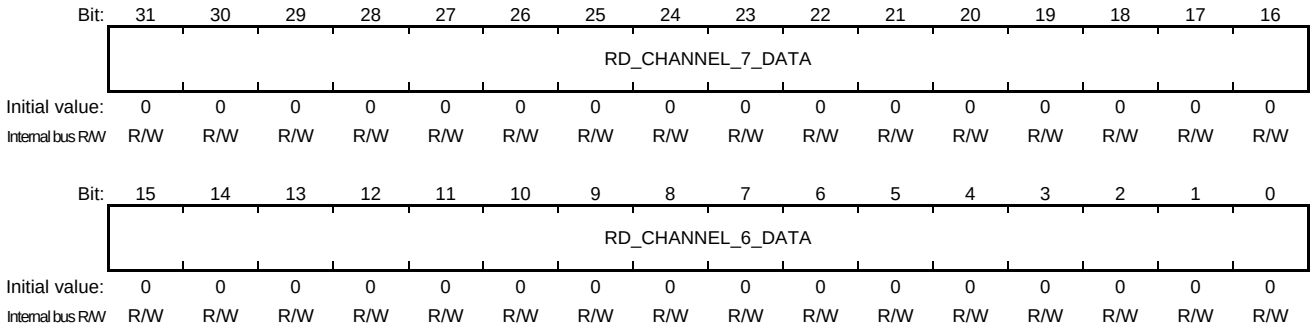


| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 16 | RD_CHANNEL_5_DATA | All 0 | R/W | The DMA uses this field to generate the data field for the Done or Abort IMWr TLPs it generates for read channel 5. |
| 15 to 0 | RD_CHANNEL_4_DATA | All 0 | R/W | The DMA uses this field to generate the data field for the Done or Abort IMWr TLPs it generates for read channel 4. |

### 104.2.313 DMA Capabilities Registers 36 (DMACAP36)

**Common to Header TYPE00/01**

- DMA Read Channel 7 and 6 IMWr Data Register



| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 16 | RD_CHANNEL_7_DATA | All 0 | R/W | The DMA uses this field to generate the data field for the Done or Abort IMWr TLPs it generates for read channel 7. |
| 15 to 0 | RD_CHANNEL_6_DATA | All 0 | R/W | The DMA uses this field to generate the data field for the Done or Abort IMWr TLPs it generates for read channel 6. |

### 104.2.314 DMA Capabilities Registers [37+*i**16] (DMACAP[37+*i**16]) (*i* = 0 to 7)

**Common to Header TYPE00/01**

- DMA Write Channel Control 1 Register

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | DMA_AT | | DMA_TC | | | — | DMA_RO | DMA_NS_SRC | DMA_NS_DST | DMA_ME | — | — | — | — | — | DMA_FUNC_NUM |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R | R/W | R/W | R/W | R/W | R | R | R | R | R | R/W |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | DMA_FUNC_NUM | | | | — | — | LLE | CCS | — | CS | | RIE | LIE | LLP | TCB | CB |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R | R | R/W | R/W | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 30 | DMA_AT | All 0 | R/W | Address Translation TLP Header Bit (AT)<br>The DMA uses this TLP header field when generating MRd/MWr (not IMWr) TLPs. |
| 29 to 27 | DMA_TC | All 0 | R/W | Traffic Class TLP Header Bit (TC)<br>The DMA uses this TLP header field when generating MRd/MWr (not IMWr) TLPs. |
| 26 | — | 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 25 | DMA_RO | 0 | R/W | Relaxed Ordering TLP Header Bit (RO)<br>The DMA uses this TLP header field when generating MRd/MWr (not IMWr) TLPs. |
| 24 | DMA_NS_SRC | 0 | R/W | Source No Snoop TLP Header Bit (DMA_NS_SRC).<br>The DMA uses this TLP header field when generating MRd (SAR addressing space) (not IMWr) TLPs. |
| 23 | DMA_NS_DST | 0 | R/W | Destination No Snoop TLP Header Bit (DMA_NS_DST).<br>The DMA uses this TLP header field when generating MWr (DAR addressing space) (not IMWr) TLPs. |
| 22 | DMA_MEM_TYPE | 0 | R/W | Master AXI ACE-Lite Cache Coherency Control. This field sets the DMA channel memory type of the address space of the data transfer as follows:<br>■ 0x0:peripheral type<br>■ 0x1:memory type |

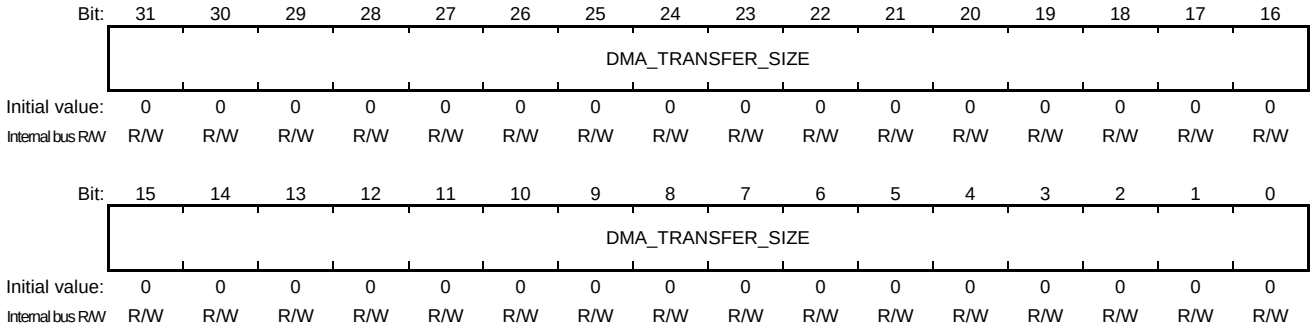
| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 21 to 17 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 16 to 12 | DMA_FUNC_NUM | All 0 | R/W | DMA Channel Physical Function Number. This field indicates the physical function associated with the DMA channel. The controller uses this field to form the requester ID of the generated MRd/MWr DMA TLPs. |
| 11 to 10 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 9 | LLE | 0 | R/W | Linked List Enable (LLE).<br>■ 0: Disable linked list operation<br>■ 1: Enable linked list operation |
| 8 | CCS | 0 | R/W | Consumer Cycle State (CCS). Used in linked list mode only.<br>It is used to synchronize the producer (software) and the consumer (DMA). For more details, see "PCS-CCS-CB-TCB Producer-Consumer Synchronization". You must initialize this bit. The DMA updates this bit during linked list operation. |
| 7 | — | 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 6 to 5 | CS | All 0 | R | Channel Status (CS). The channel status bits identify the current operational state of the DMA channel. The operation state encoding for each DMA channel is a s follows:<br>■ 00: Reserved<br>■ 01: Running. This channel is active and transferring data.<br>■ 10: Halted. An error condition has been detected, and the DMA has stopped this channel.<br>■ 11: Stopped. The DMA has transferred all data for this channel, or you have prematurely stopped this channel by writing to the Stop field of the "DMA Capabilities Registers 3" (DMACAP3) or "DMA Capabilities Registers 7" (DMACAP7). |
| 4 | RIE | 0 | R/W | Remote Interrupt Enable (RIE). You must set this bit to enable the generation of the Done or Abort Remote interrupts. For more details, see "Interrupts and Error Handling". In LL mode, the DMA overwrites this with the RIE of the LL element. The RIE bit in a LL element only enables the Done interrupt. In non-LL mode, the RIE bit enables the Done and Abort interrupts.<br>This field is not defined in a link LL element. |
| 3 | LIE | 0 | R/W | Local Interrupt Enable (LIE). You must set this bit to enable the generation of the Done or Abort Local interrupts. For more details, see "Interrupts and Error Handling". In LL mode, the DMA overwrites this with the LIE of the LL element. The LIE bit in a LL element only enables the Done interrupt. In non-LL mode, the LIE bit enables the Done and Abort interrupts.<br>This field is not defined in a link LL element. |
| 2 | LLP | 0 | R/W | Load Link Pointer (LLP). Used in linked list mode only.<br>Indicates that this linked list element is a link element, and its LL element pointer dwords are pointing to the next (noncontiguous) element. The DMA loads this field with the LLP of the linked list element. |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 1 | TCB | 0 | R/W | Toggle Cycle Bit (TCB). Indicates to the DMA to toggle its interpretation of the CB. Used in linked list mode only. It is used to synchronize the producer (software) and the consumer (DMA). For more details, see "PCS-CCS-CB-TCB Producer-Consumer Synchronization". The DMA loads this field with the TCB of the linked list element. this field is not defined in a data LL element. |
| 0 | CB | 0 | R/W | Cycle Bit (CB). Used in linked list mode only. It is used to synchronize the producer (software) and the consumer (DMA). For more details, see "PCS-CCS-CB-TCB Producer-Consumer Synchronization". The DMA loads this field with the CB of the linked list element. |

### 104.2.315 DMA Capabilities Registers [38+*i**16] (DMACAP[38+*i**16]) (*i* = 0 to 7)

**Common to Header TYPE00/01**

- DMA Write Transfer Size Register

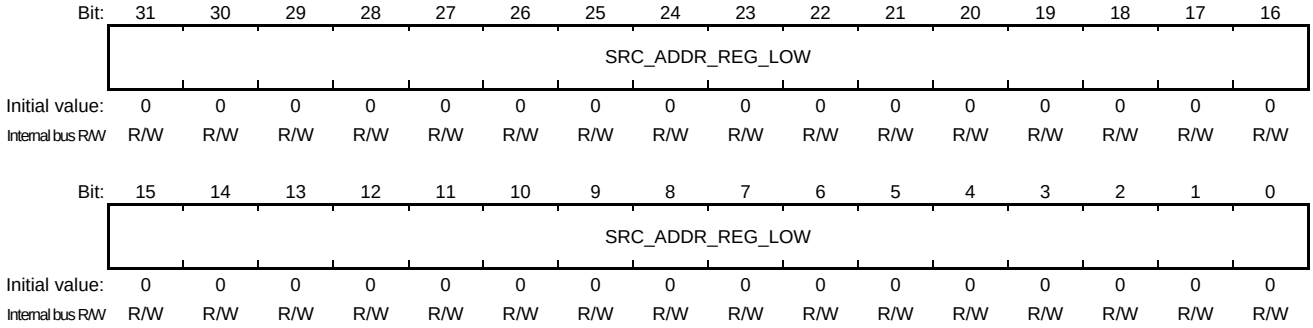


| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | DMA_TRANSFER_SIZE | 0 | R/W | DMA Transfer Size. You program this register with the size of the DMA transfer. The maximum DMA transfer size is 4Gbytes. The minimum transfer size is one byte (0x1). This field is automatically decremented by the DMA as the DMA write channel transfer progresses. This field indicates the number bytes remaining to be transferred. When all bytes are successfully transferred the current transfer size is zero. In LL mode, the DMA overwrites this register with the corresponding dword of the LL element. You can read this register to monitor the transfer progress, however in some scenarios this register is updated after a delay. For example, when less than 3 channels are doorbelled, this register is updated only after a descriptor finishes (linked list mode), or the transfer ends (non-linked list mode). |

### 104.2.316 DMA Capabilities Registers [39+*i**16] (DMACAP[39+*i**16]) (*i* = 0 to 7)

**Common to Header TYPE00/01**

- DMA Write SAR Low Register

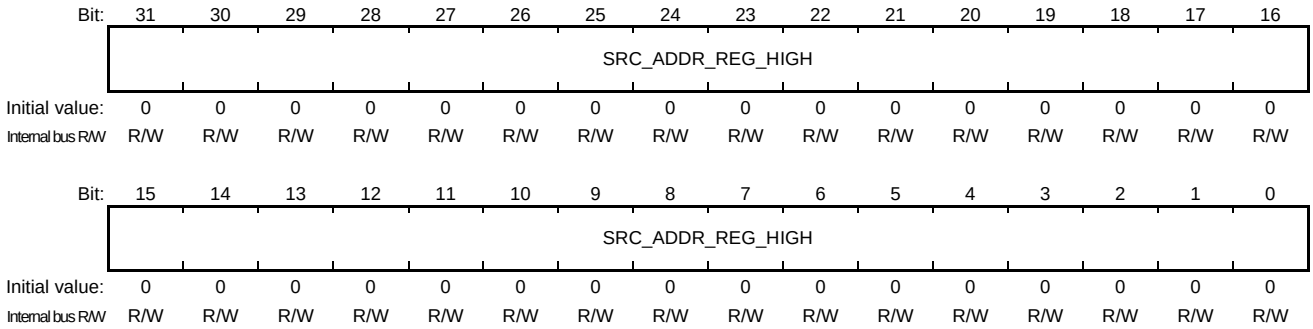


| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | SRC_ADDR_REG_LOW | 0 | R/W | Source Address Register (Lower 32 bits). Indicates the next address to be read from. The DMA increments the SAR as the DMA transfer progresses. In LL mode, the DMA overwrites this with the corresponding DWORD of the LL element.<br>■ DMA Read: The SAR is the address of the remote memory.<br>■ DMA Write: The SAR is the address of the local memory. |

### 104.2.317 DMA Capabilities Registers [40+*i**16] (DMACAP[40+*i**16]) (*i* = 0 to 7)

**Common to Header TYPE00/01**

- DMA Write SAR High Register

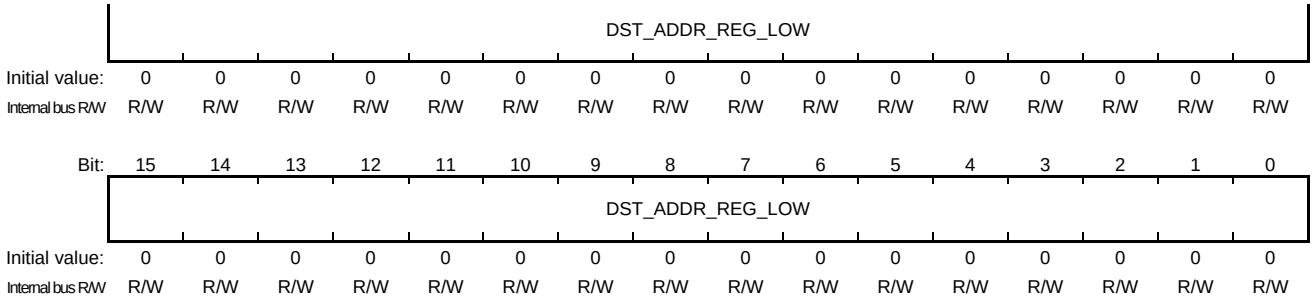


| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | SRC_ADDR_REG_HIGH | All 0 | R/W | Source Address Register (Higher 32 bits). In LL mode, the DMA overwrites this with the corresponding DWORD of the LL element. |

### 104.2.318 DMA Capabilities Registers [41+*i**16] (DMACAP[41+*i**16]) (*i* = 0 to 7)

**Common to Header TYPE00/01**

- DMA Write DAR Low Register

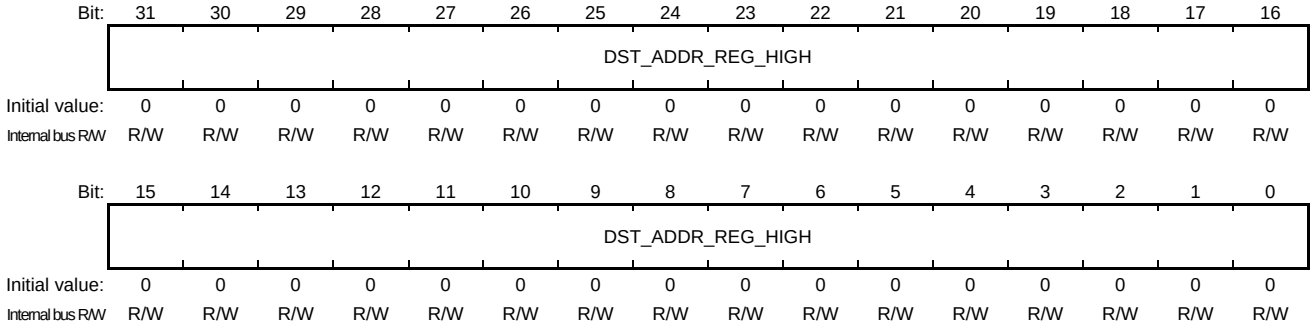


| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | DST_ADDR_REG_LOW | All 0 | R/W | Destination Address Register (Lower 32 bits). Indicates the next address to be written to. The DMA increments the DAR as the DMA transfer progresses. In LL mode, the DMA overwrites this with the corresponding dword of the LL element.<br>■ DMA Read: The DAR is the address of the local memory.<br>■ DMA Write: The DAR is the address of the remote memory. |

### 104.2.319 DMA Capabilities Registers [42+*i**16] (DMACAP[42+*i**16]) (*i* = 0 to 7)

**Common to Header TYPE00/01**

- DMA Write DAR High Register

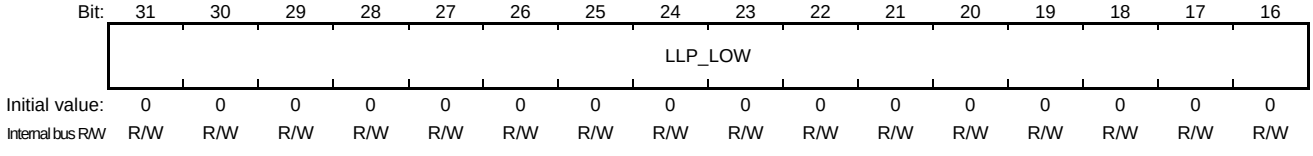


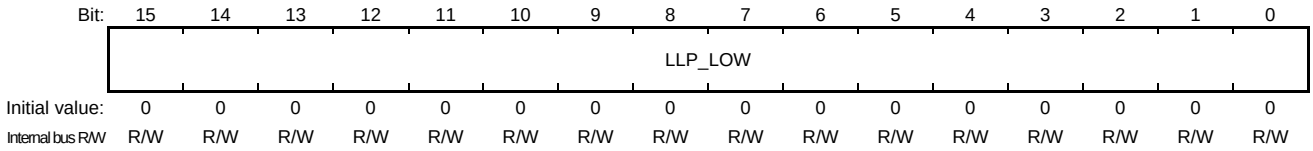
| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | DST_ADDR_REG_HIGH | All 0 | R/W | Destination Address Register (Higher 32 bits). In LL mode, the DMA overwrites this with the corresponding DWORD of the LL element. |

### 104.2.320 DMA Capabilities Registers [43+*i**16] (DMACAP[43+*i**16]) (*i* = 0 to 7)

**Common to Header TYPE00/01**

- DMA Write Linked List Pointer Low Register



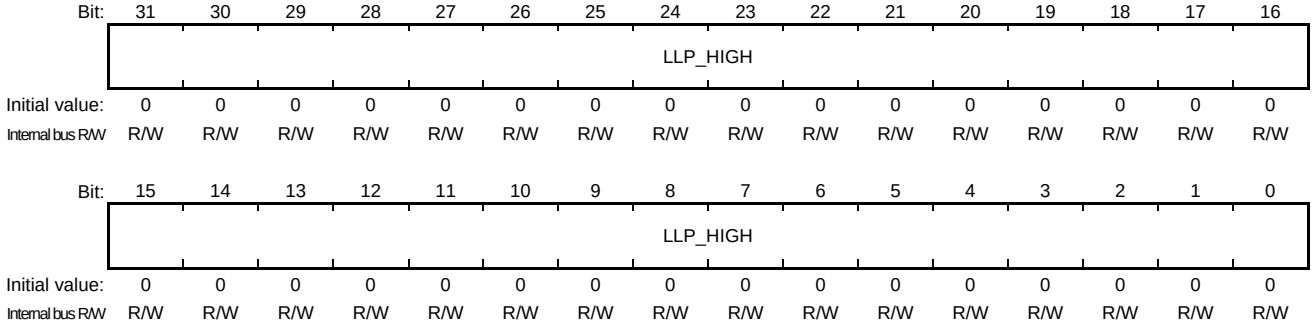


| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | LLP_LOW | All 0 | R/W | Lower bits of the address of the linked list transfer list in local memory. Used in linked list mode only. Updated by the DMA to point to the next element in the transfer list after the previous element is consumed.<br>■ When the current element is a data element; this field is incremented by 6 DWORDS.<br>■ When the current element is a link element; this field is overwritten by the LL Element Pointer of the element. |

### 104.2.321 DMA Capabilities Registers [44+*i**16] (DMACAP[44+*i**16]) (*i* = 0 to 7)

**Common to Header TYPE00/01**

- DMA Write Linked List Pointer High Register

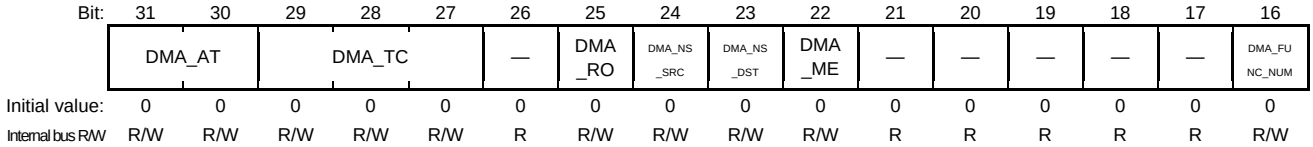


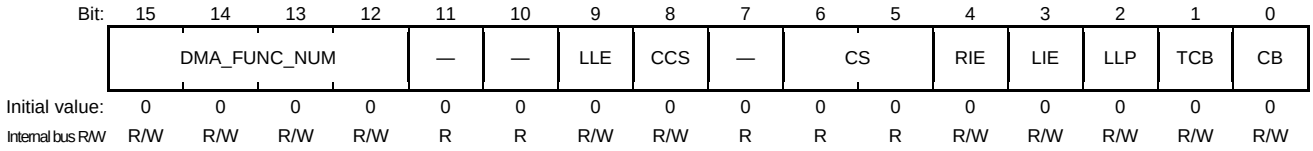
| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | LLP_HIGH | All 0 | R/W | Upper 32 bits of the address of the linked list transfer list in local memory. Used in linked list mode only. Updated by the DMA to point to the next element in the transfer list as elements are consumed. |

### 104.2.322 DMA Capabilities Registers [45+*i**16] (DMACAP[45+*i**16]) (*i* = 0 to 7)

**Common to Header TYPE00/01**

- DMA Read Channel Control 1 Register





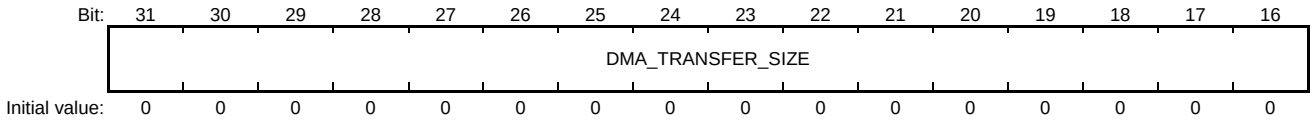
| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 30 | DMA_AT | All 0 | R/W | Address Translation TLP Header Bit (AT)<br>The DMA uses this TLP header field when generating MRd/MWr (not IMWr) TLPs. |
| 29 to 27 | DMA_TC | All 0 | R/W | Traffic Class TLP Header Bit (TC)<br>The DMA uses this TLP header field when generating MRd/MWr (not IMWr) TLPs. |
| 26 | — | 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 25 | DMA_RO | 0 | R/W | Relaxed Ordering TLP Header Bit (RO)<br>The DMA uses this TLP header field when generating MRd/MWr (not IMWr) TLPs. |
| 24 | DMA_NS_SRC | 0 | R/W | Source No Snoop TLP Header Bit (DMA_NS_SRC).<br>The DMA uses this TLP header field when generating MRd (SAR addressing space) (not IMWr) TLPs. |
| 23 | DMA_NS_DST | 0 | R/W | Destination No Snoop TLP Header Bit (DMA_NS_DST).<br>The DMA uses this TLP header field when generating MWr (DAR addressing space) (not IMWr) TLPs. |
| 22 | DMA_MEM_TYPE | 0 | R/W | Master AXI ACE-Lite Cache Coherency Control. This field sets the DMA channel memory type of the address space of the data transfer as follows:<br>■ 0x0:peripheral type<br>■ 0x1:memory type |
| 21 to 17 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 16 to 12 | DMA_FUNC_NUM | All 0 | R/W | DMA Channel Physical Function Number. This field indicates the physical function associated with the DMA channel. The controller uses this field to form the requester ID of the generated MRd/MWr DMA TLPs. |
| 11 to 10 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 9 | LLE | 0 | R/W | Linked List Enable (LLE).<br>■ 0: Disable linked list operation<br>■ 1: Enable linked list operation |
| 8 | CCS | 0 | R/W | Consumer Cycle State (CCS). Used in linked list mode only.<br>It is used to synchronize the producer (software) and the consumer (DMA). For more details, see "PCS-CCS-CB-TCB Producer-Consumer Synchronization". You must initialize this bit. The DMA updates this bit during linked list operation. |
| 7 | — | 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |

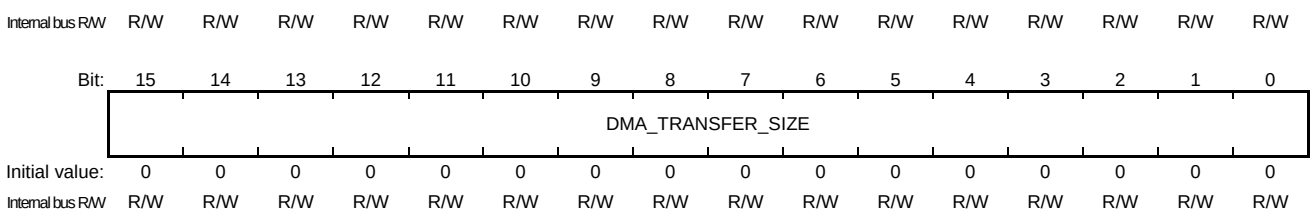
| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 6 to 5 | CS | 0 | R | Channel Status (CS). The channel status bits identify the current operational state of the DMA channel. The operation state encoding for each DMA channel is a s follows:<br>■ 00: Reserved<br>■ 01: Running. This channel is active and transferring data.<br>■ 10: Halted. An error condition has been detected, and the DMA has stopped this channel.<br>■ 11: Stopped. The DMA has transferred all data for this channel, or you have prematurely stopped this channel by writing to the Stop field of the "DMA Capabilities Registers 3" (DMACAP3) or "DMA Capabilities Registers 7" (DMACAP7). |
| 4 | RIE | 0 | R/W | Remote Interrupt Enable (RIE). You must set this bit to enable the generation of the Done or Abort Remote interrupts. For more details, see "Interrupts and Error Handling". In LL mode, the DMA overwrites this with the RIE of the LL element. The RIE bit in a LL element only enables the Done interrupt. In non-LL mode, the RIE bit enables the Done and Abort interrupts. This field is not defined in a link LL element. |
| 3 | LIE | 0 | R/W | Local Interrupt Enable (LIE). You must set this bit to enable the generation of the Done or Abort Local interrupts. For more details, see "Interrupts and Error Handling". In LL mode, the DMA overwrites this with the LIE of the LL element. The LIE bit in a LL element only enables the Done interrupt. In non-LL mode, the LIE bit enables the Done and Abort interrupts. This field is not defined in a link LL element. |
| 2 | LLP | 0 | R/W | Load Link Pointer (LLP). Used in linked list mode only. Indicates that this linked list element is a link element, and its LL element pointer DWORDs are pointing to the next (noncontiguous) element. The DMA loads this field with the LLP of the linked list element. |
| 1 | TCB | 0 | R/W | Toggle Cycle Bit (TCB). Indicates to the DMA to toggle its interpretation of the CB. Used in linked list mode only. It is used to synchronize the producer (software) and the consumer (DMA). For more details, see "PCS-CCS-CB-TCB Producer-Consumer Synchronization". The DMA loads this field with the TCB of the linked list element. this field is not defined in a data LL element. |
| 0 | CB | 0 | R/W | Cycle Bit (CB). Used in linked list mode only. It is used to synchronize the producer (software) and the consumer (DMA). For more details, see "PCS-CCS-CB-TCB Producer-Consumer Synchronization". The DMA loads this field with the CB of the linked list element. |

### 104.2.323 DMA Capabilities Registers [46+*i**16] (DMACAP[46+*i**16]) (*i* = 0 to 7)

**Common to Header TYPE00/01**

- DMA Read Transfer Size Register



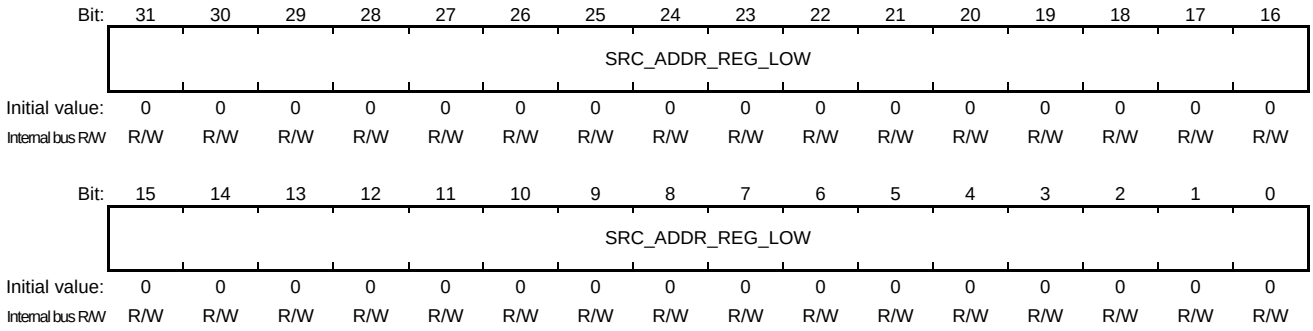


| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | DMA_TRANSFER_SIZE | All 0 | R/W | DMA Transfer Size. You program this register with the size of the DMA transfer. The maximum DMA transfer size is 4Gbytes. The minimum transfer size is one byte (0x1). This field is automatically decremented by the DMA as the DMA read channel transfer progresses. This field indicates the number bytes remaining to be transferred. When all bytes are successfully transferred the current transfer size is zero. In LL mode, the DMA overwrites this register with the corresponding DWORD of the LL element. You can read this register to monitor the transfer progress, however in some scenarios this register is updated after a delay. For example, when less than 3 channels are doorbelled, this register is updated only after a descriptor finishes (linked list mode), or the transfer ends (non-linked list mode). |

### 104.2.324 DMA Capabilities Registers [47+*i**16] (DMACAP[47+*i**16]) (*i* = 0 to 7)

**Common to Header TYPE00/01**

- DMA Read SAR Low Register

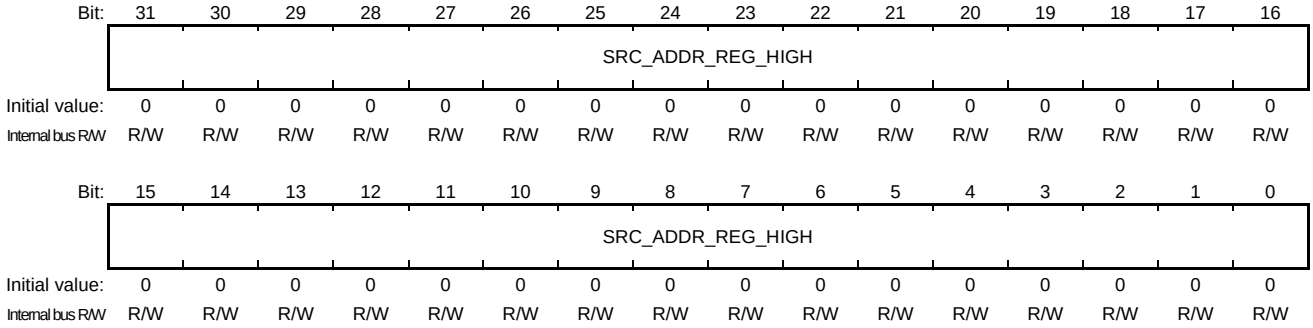


| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | SRC_ADDR_REG_LOW | All 0 | R/W | Source Address Register (Lower 32 bits). Indicates the next address to be read from. The DMA increments the SAR as the DMA transfer progresses. In LL mode, the DMA overwrites this with the corresponding DWORD of the LL element.<br>■ DMA Read: The SAR is the address of the remote memory.<br>■ DMA Read: The SAR is the address of the local memory. |

### 104.2.325 DMA Capabilities Registers [48+*i**16] (DMACAP[48+*i**16]) (*i* = 0 to 7)

**Common to Header TYPE00/01**

- DMA Read DAR Low Register

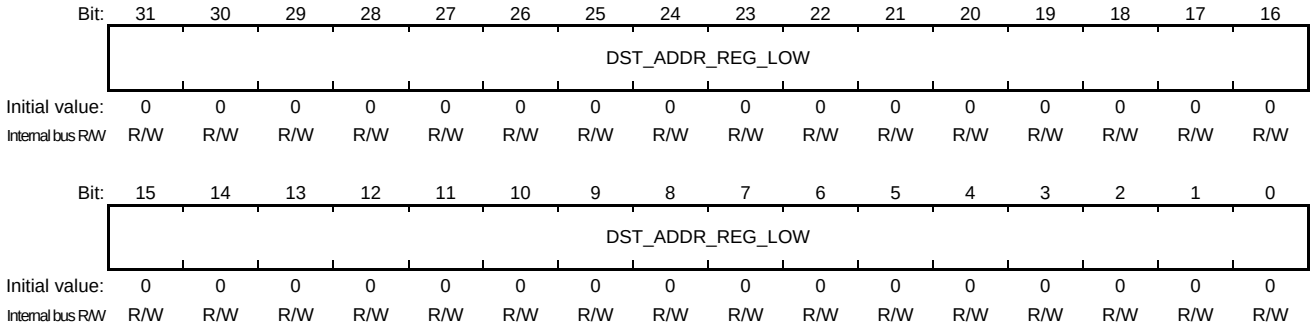


| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | SRC_ADDR_REG_HIGH | All 0 | R/W | Source Address Register (Higher 32 bits). In LL mode, the DMA overwrites this with the corresponding dword of the LL element. |

### 104.2.326 DMA Capabilities Registers [49+*i**16] (DMACAP[49+*i**16]) (*i* = 0 to 7)

**Common to Header TYPE00/01**

- DMA Read DAR Low Register

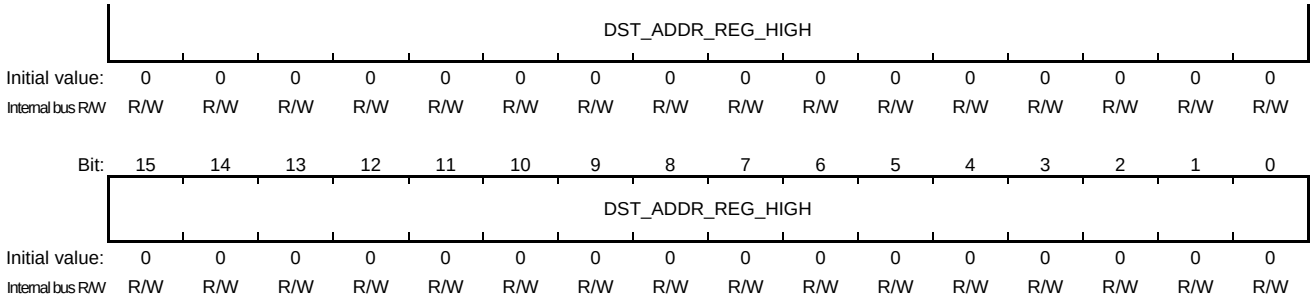


| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | DST_ADDR_REG_LOW | All 0 | R/W | Destination Address Register (Lower 32 bits). Indicates the next address to be written to. The DMA increments the DAR as the DMA transfer progresses. In LL mode, the DMA overwrites this with the corresponding DWORD of the LL element.<br>■ DMA Read: The DAR is the address of the local memory.<br>■ DMA Read: The DAR is the address of the remote memory. |

### 104.2.327 DMA Capabilities Registers [50+*i**16] (DMACAP[50+*i**16]) (*i* = 0 to 7)

**Common to Header TYPE00/01**

- DMA Read DAR High Register

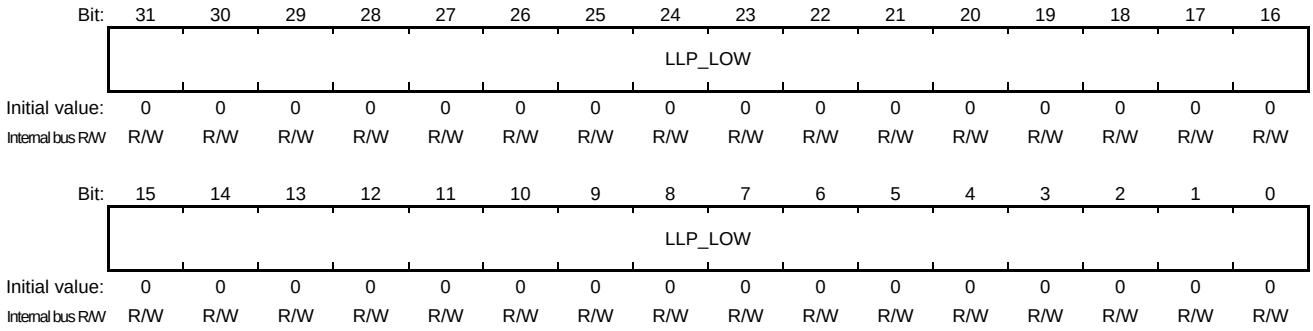


| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | DST_ADDR_REG_HIGH | All 0 | R/W | Destination Address Register (Higher 32 bits). In LL mode, the DMA overwrites this with the corresponding DWORD of the LL element. |

### 104.2.328 DMA Capabilities Registers [51+*i**16] (DMACAP[51+*i**16]) (*i* = 0 to 7)

**Common to Header TYPE00/01**

- DMA Read Linked List Pointer Low Register

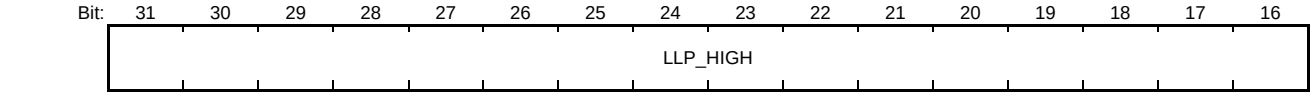


| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | LLP_LOW | All 0 | R/W | Lower bits of the address of the linked list transfer list in local memory. Used in linked list mode only. Updated by the DMA to point to the next element in the transfer list after the previous element is consumed.<br>■ When the current element is a data element; this field is incremented by 6 DWORDS.<br>■ When the current element is a link element; this field is overwritten by the LL Element Pointer of the element. |

### 104.2.329 DMA Capabilities Registers [52+*i**16] (DMACAP[52+*i**16]) (*i* = 0 to 7)

**Common to Header TYPE00/01**

- DMA Read Linked List Pointer High Register



| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | LLP_HIGH | | | | | | | | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | LLP_HIGH | | | | | | | | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | LLP_HIGH | All 0 | R/W | Upper 32 bits of the address of the linked list transfer list in local memory. Used in linked list mode only. Updated by the DMA to point to the next element in the transfer list as elements are consumed. |

### 104.2.330 PCIe Mode Setting Register 0 (PCIEMSR0)

**Common to Header TYPE00/01**

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | ELBI_MODE | | app_sris_ | device_type | | | | BFRCTNST | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 9 | Reserved | All 0 | R/W | These bits are read as 0. The write value must be 0. |
| 8 to 7 | ELBI_MODE | H'0 | R/W | Handshake between lbc_ext_cs and ext_lbc_ack<br>0: return an error response (per bit)<br>1: do not return an error response (per bit) |
| 6 | app_sris_mode | H'0 | R/W | SRIS operating mode.<br>0: non-SRIS mode<br>1: SRIS mode |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 5 to 2 | device_type | H'0 | R/W | Device/port type.<br>Indicates the specific type of this PCI Express function.<br>It is also used to set the 'Device/Port Type' field of the 'PCI Express Capabilities Register'. The controller uses this input to determine the operating mode of the controller at run time.<br>4'b0000: PCI Express endpoint<br>4'b0001: Legacy PCI Express endpoint<br>4'b0100: Root port of PCI Express root complex<br>Others: Setting prohibited<br>Note: Set device_type before deasserting software reset by CPG SRSTCLR6[24]. |
| 1 to 0 | BFRCTNST | H'0 | R/W | Bifurcation mode setting.<br>00: 1x Quad lane mode (Bifurcation off)<br>01: 2x Dual lanes mode (Bifurcation on)<br>Others: Setting prohibited |

### 104.2.331 PCIe Mode Setting Register 1 (PCIEMSR1)

**Common to Header TYPE00/01**

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | tx_lane_flip_en | rx_lane_flip_en |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 2 | Reserved | All 0 | R/W | These bits are read as 0. The write value must be 0. |
| 1 | tx_lane_flip_en | H'0 | R/W | Performs manual lane reversal for transmit lanes.<br>For use when automatic lane reversal does not occur because lane 0 is not detected. In most cases, tx_lane_flip_en should be wired to a static value at the chip level. For more details, see 'Lane Reversal and Broken Lanes'. This signal is only used in Conventional PCIe mode. When in M-PCIe mode, mpcie_tx_lane_flip_en is used. |
| 0 | rx_lane_flip_en | H'0 | R/W | Performs manual lane reversal for receive lanes.<br>For use when automatic lane reversal does not occur because lane 0 is not detected. In most cases, rx_lane_flip_en should be wired to a static value at the chip level. For more details, see 'Lane Reversal and Broken Lanes'. This signal is only used in Conventional PCIe mode. When in M-PCIe mode, mpcie_rx_lane_flip_en is used. |

### 104.2.332 PCIe Mode Setting Register 2 (PCIEMSR2)

**Common to Header TYPE00/01**

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | app_dbi_ro_wr_dis | app_req_retry_en |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 2 | Reserved | All 0 | R/W | These bits are read as 0. The write value must be 0. |
| 1 | app_dbi_ro_wr_disable | H'0 | R/W | DBI Read-only Write Disable.<br>0: PRTLGC58.DBI_RO_WR_EN register field is read-write<br>1: PRTLGC58.DBI_RO_WR_EN register field is forced to 0 and is read-only. |
| 0 | app_req_retry_en | H'0 | R/W | Provides a capability to defer incoming configuration requests until initialization is complete.<br>When app_req_retry_en is asserted, the controller completes incoming configuration requests with a configuration request retry status. Other incoming requests complete normally. When the Readiness Notification mechanism is supported, DRS messaging is blocked when app_req_retry_en=1. When app_req_retry_en=0 and app_drs_ready=1, the controller autonomously transmits a DRS message when the link transitions from DL_Down to DL_Up. |

### 104.2.333 PCIe Mode Setting Register 3 (PCIEMSR3)

**Common to Header TYPE00/01**

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|

| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 25 | Reserved | All 0 | R | These bits are read as 0. The write value must be 0. |
| 24 | refclk_share_prop_en | H'0 | R/W | pcie_clkreq_dis_in propagation enable.<br>0: Disable<br>1: Enable |
| 23 to 17 | Reserved | All 0 | R | These bits are read as 0. The write value must be 0. |
| 16 | perst_n | H'1 | R/W | Indicates when the main power supply is within its tolerated voltage range and is stable.<br>This signal is syncronized using aux_clk and can be driven/supplied<br>asynchronously to the controller in certain low-power modes |
| 15 to 9 | Reserved | All 0 | R | These bits are read as 0. The write value must be 0. |
| 8 | refclk_share | H'0 | R/W | Reference clock share bit.<br>When shared, previous CLKREQ# is invalid<br>0: Not Shared<br>1: Shared |
| 7 to 0 | Reserved | All 0 | R | These bits are read as 0. The write value must be 0. |

### 104.2.335 PCIe Reset Control Register 1 (PCIERSTCTRL1)

**Common to Header TYPE00/01**

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | app_hold_phy_rst |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | app_ltssm_enable |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 17 | Reserved | All 0 | R/W | These bits are read as 0. The write value must be 0. |
| 16 | app_hold_phy_rst | H'1 | R/W | Set this signal to 1 during the power on reset sequence to hold the PHY in reset while the PHY is configured through the PHY viewport. |
| 15 to 1 | Reserved | All 0 | R/W | These bits are read as 0. The write value must be 0. |
| 0 | app_ltssm_enable | H'0 | R/W | To do otherwise (that is, de-assert it outside of the Detect LTSSM state) causes the controller to be reset and the LTSSM moves immediately back to the Detect state. This transition is outside of the PCIe Specification and it might cause a PIPE protocol violation. |

### 104.2.336 PCIe Reset Control Register 2 (PCIERSTCTRL2)

**Common to Header TYPE00/01**

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | app_init_rst |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 1 | Reserved | All 0 | R/W | These bits are read as 0. The write value must be 0. |
| 0 | app_init_rst | H'0 | R/W | Request from your application to send a hot reset to the upstream port.<br>The hot reset request is sent when a single cycle pulse is applied to this<br>pin. In an upstream port, you should set this input to '0'.<br>Note: This signal is not used by the controller to set the SBR field in the<br>PCICONF15F*i* register. During the transition from DL_Active to DL_inactive, assertion of app_init_rst signal indicates a Surprise Down Error, but setting of SBR field in the PCICONF15F*i* register through DBI does not trigger a Surprise Down Error. |

### 104.2.337 PCIe Reset Control Register 3 (PCIERSTCTRL3)

**Common to Header TYPE00/01**

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | app_flr_pf_done | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 2 | Reserved | All 0 | R/W | These bits are read as 0. The write value must be 0. |
| 1 to 0 | app_flr_pf_done | H'0 | R/W | Assert 1 when your application has stopped / reset the PFx application to initiate FLR of PFx.<br>After PCIERSTSTS.cfg_flr_pf_active is cleared, this bit is automatically cleared to 0.<br>Note : After writting 1 during the PCIERSTSTS.cfg_flr_pf_active =1, do not write "0" until it changes to "0" by the automatic clear. |

### 104.2.338 PCIe Reset Status Register (PCIERSTSTS)

**Common to Header TYPE00/01**

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | cfg_flr_pf_ | training_r | smlh_req | link_re | link_req_rs | cfg_2nd_reset |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 6 | Reserved | All 0 | R | These bits are read as 0. The write value must be 0. |
| 5 to 4 | cfg_flr_pf_active | H'0 | R | Set when the software initiates FLR a physical function by writing to the "Initiate FLR" register bit of that function. This signal is held asserted until reset of both the application and controller logic has been completed. |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 3 | training_rst_n | H'0 | R | Hot reset from upstream component.<br>When the controller LTSSM receives two consecutive TS1 ordered sets with the hot_reset bit asserted, it asserts training_rst_n for one clock cycle. This signal is only kept for legacy purposes. You should use the link_req_rst_not signal to reset the controller after a 'hot reset' request. |
| 2 | smlh_req_rst_not | H'0 | R | Early version of the link_req_rst_not signal.<br>A low level indicates that the controller is requesting external logic to reset the controller because the PHY link is down. When the AXI bridge module is enabled the link reset request is delayed until all pending AXI transfers have completed. When the AXI Bridge module is not enabled the link reset request is sent immediately. |
| 1 | link_req_rst_not | H'0 | R | Reset request because the link has gone down or the controller received a hot-reset request.<br>A low level indicates that the controller is requesting external logic to reset the controller because the PHY link is down. When the AXI bridge module is enabled the link reset request is delayed until all pending AXI transfers have completed. When the AXI Bridge module is not enabled the link reset request is sent immediately. |
| 0 | cfg_2nd_reset | H'0 | R | Secondary Bus Reset.<br>Indicates that your application has requested this downstream port to start Link hot reset. This signal is asserted when your application writes to the Secondary Bus Reset field (bit 6) of the Bridge Control Register (Offset 0x3E) in the Type 1 Configuration Space header. Setting this bit triggers a hot reset the corresponding PCI Express port. |

### 104.2.339 MSI Control Register 0 (MSICTRL0)

**Common to Header TYPE00/01**

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | ven_msi_req |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | cfg_msi_pending_hi | All 0 | R/W | Upper bits [63:32]. Indication from application about which functions have a pending associated message<br>Used to determine the value of the Vector Interrupt Pending register in the MSI Capability structure. |

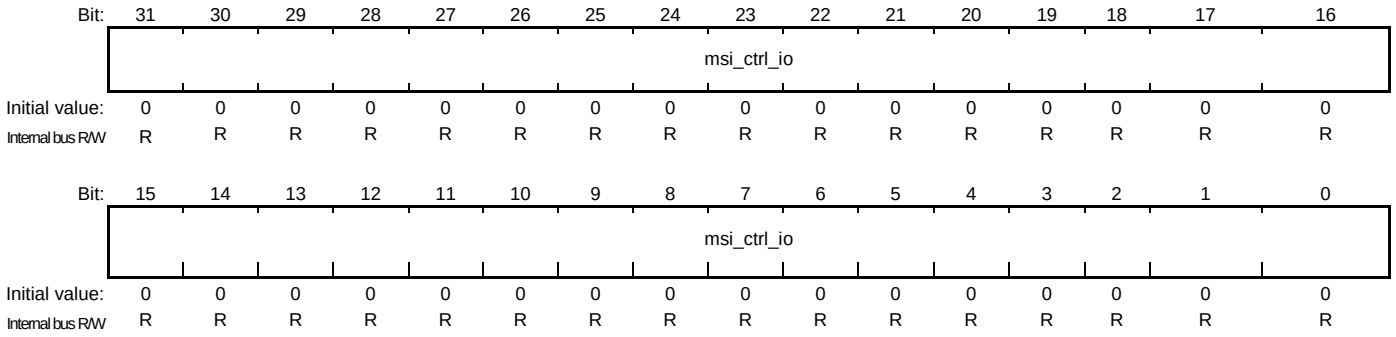
### 104.2.343 MSI Control Register 4 (MSICTRL4)

**Common to Header TYPE00/01**

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 26 | Reserved | All 0 | R | These bits are read as 0. The write value must be 0. |
| 25 to 24 | cfg_msi_en | H'0 | R | Indicates that MSI is enabled (INTx message is not sent), one bit per configured function. |
| 23 to 16 | msi_ctrl_int_vec | H'0 | R | DSP AXI MSI Interrupt Vector.<br>Asserted when an MSI interrupt is pending. De-asserted when there is no MSI interrupt pending. |
| 15 to 1 | Reserved | All 0 | R | These bits are read as 0. The write value must be 0. |
| 0 | ven_msi_grant | H'0 | R | Indicates that the controller has accepted the request to send an MSI.<br>After asserting ven_msi_grant for one cycle, the controller does not wait for ven_msi_req to be de-asserted then reasserted to generate another MSI. When ven_msi_req remains asserted after the controller asserts ven_msi_grant for one cycle, the controller generates another MSI. |

### 104.2.344 MSI Control Register 5 (MSICTRL5)

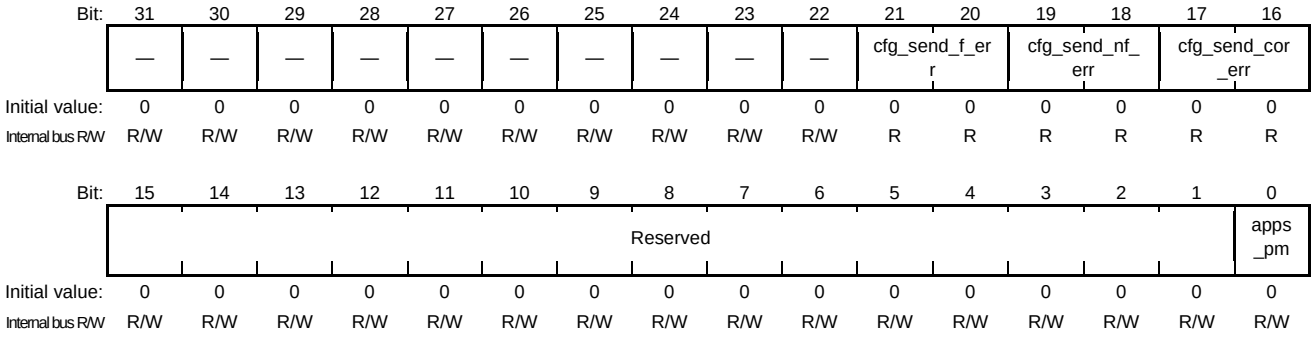
**Common to Header TYPE00/01**



| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | msi_ctrl_io | All 0 | R | DSP AXI iMRM: Integrated MSI Reception Module GPIO.<br>General purpose IO driven by the MSI interrupt controller GPIO register |

### 104.2.345 PCIe Message Transmission (PCIEMSGTX)

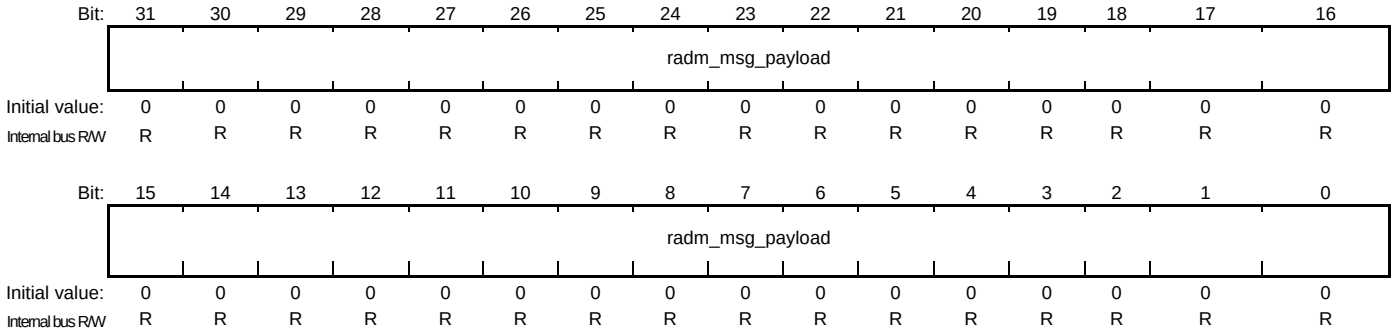
**Common to Header TYPE00/01**



| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 22 | Reserved | All 0 | R/W | These bits are read as 0. The write value must be 0. |
| 21 to 20 | cfg_send_f_err | H'0 | R | Sent Fatal Error.<br>Core has sent a message towards the Root Complex indicating that an Rx TLP that contained a fatal error, and that cannot be corrected, was received by the EndPoint |
| 19 to 18 | cfg_send_nf_err | H'0 | R | Sent Non-Fatal Error.<br>Core has sent a message towards the Root Complex indicating that an Rx TLP that contained an non-fatal error, and that cannot be corrected, was received by the EndPoint |
| 17 to 16 | cfg_send_cor_err | H'0 | R | Sent Correctable Error.<br>Core has sent a message towards the Root Complex indicating that an Rx TLP that contained an error, and that can be corrected, was received by the EndPoint |
| 15 to 1 | Reserved | H'0 | R/W | These bits are read as 0. The write value must be 0. |
| 0 | apps_pm_xmt_turnoff | H'0 | R/W | Request from your application to generate a PM_Turn_Off message.<br>You must assert this signal for one clock cycle. The controller does not<br>return an acknowledgment or grant signal. You must not pulse the same<br>signal again, until the previous message has been transmitted. |

### 104.2.346 PCIe Message Reception 0 (PCIEMSGRX0)

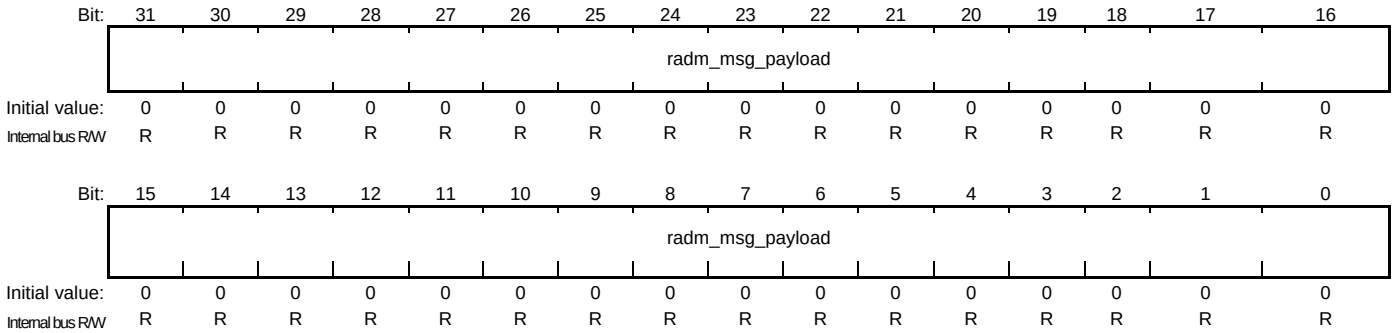
**Common to Header TYPE00/01**



| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | radm_msg_payload | All 0 | R | Lower bits [31:0].<br>Received message header information.<br>When a vendor-defined or ltr message is received (radm_vendor_msg=1 or radm_ltr_msg=1), the controller maps radm_msg_payload to the Rx TLP header dwords as follows:<br>■ [31:0] = bytes 12-15 (4th dword), where [7:0] =byte 15<br>■ [63:32] = bytes 8-11 (3rd dword)<br>When any other type of message is received, the controller maps<br>radm_msg_payload to the Rx TLP header dwords as follows:<br>■ [31:0] = DW Data of Message<br>■ [63:32] = '0' |

### 104.2.347 PCIe Message Reception 1 (PCIEMSGRX1)

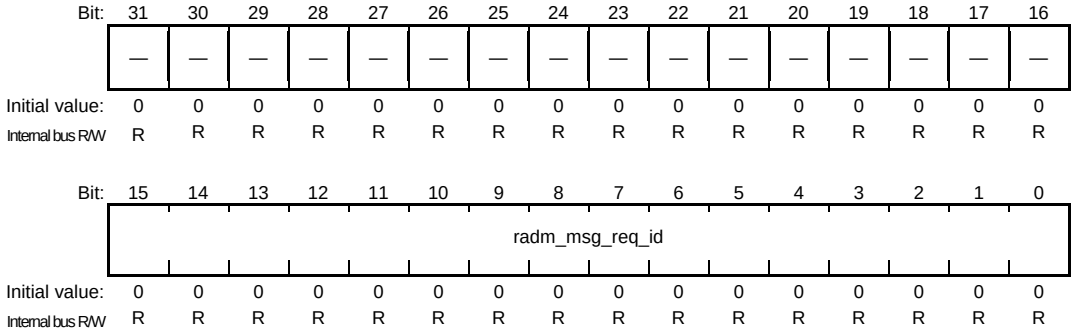
**Common to Header TYPE00/01**



| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | radm_msg_payload | All 0 | R | Upper bits [63:32].<br>Received message header information.Received message header information.<br>When a vendor-defined or ltr message is received<br>(radm_vendor_msg=1 or radm_ltr_msg=1), the controller maps<br>radm_msg_payload to the Rx TLP header dwords as follows:<br>■ [31:0] = bytes 12-15 (4th dword), where [7:0] =byte 15<br>■ [63:32] = bytes 8-11 (3rd dword)<br>When any other type of message is received, the controller maps<br>radm_msg_payload to the Rx TLP header dwords as follows:<br>■ [31:0] = DW Data of Message<br>■ [63:32] = '0' |

### 104.2.348 PCIe Message Reception 2 (PCIEMSGRX2)

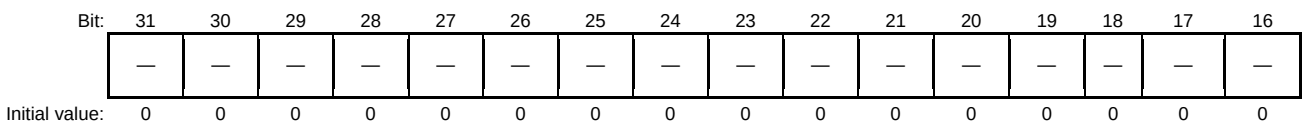
**Common to Header TYPE00/01**



| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 16 | Reserved | All 0 | R | These bits are read as 0. The write value must be 0. |
| 15 to 0 | radm_msg_req_id | H'0 | R | The requester ID of the received Message.<br>■ [15:8]: Bus number<br>■ [7:3]: Device number<br>■ [2:0]: Function number |

### 104.2.349 PCIe Message Reception Status (PCIEMSGRCPSTS)

**Common to Header TYPE00/01**



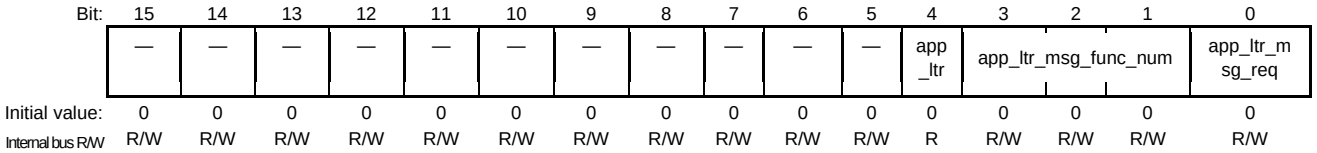
| Internal bus R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | — | — | — | — | — | — | — | radm_msg | radm_ven | radm_pm | radm_pm | radm_pm | radm_fatal | radm_ | radm_correc | radm_ms |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 9 | Reserved | All 0 | R | These bits are read as 0. The write value must be 0. |
| 8 | radm_msg_unlock | H'0 | R | Indicates that the controller received an Unlock message.<br>When two messages of the same type are received in the same clock cycle (back-to-back), then no separate indication is given for the second message. |
| 7 | radm_vendor_msg | H'0 | R | Indicates the controller received a vendor-defined message.<br>The controller makes the message header available the radm_msg_payload output. When FX_TLP > 1 and when two messages<br>of the same type are received in the same clock cycle (back-to-back),<br>then both bits are asserted. |
| 6 | radm_pm_turnoff | H'0 | R | Indicates that the controller received a PME Turnoff message.<br>When two messages of the same type are received in the same clock cycle (back-to-back), then no indication is given for the second message. |
| 5 | radm_pm_to_ack | H'0 | R | Indicates that the controller received a PME_TO_Ack message. Upstream port: Reserved. |
| 4 | radm_pm_pme | H'0 | R | Indicates that the controller received a PM_PME message |
| 3 | radm_fatal_err | H'0 | R | Indicates that the controller received an ERR_FATAL message |
| 2 | radm_nonfatal_err | H'0 | R | Indicates that the controller received an ERR_NONFATAL message |
| 1 | radm_correctable_err | H'0 | R | Indicates that the controller received an ERR_COR message.<br>The controller makes the message header available the radm_msg_payload output. |
| 0 | radm_msg_ltr | H'0 | R | Indicates that the controller received an LTR message.<br>The controller makes the message header available the radm_msg_payload output. It is also available the app_ltr_latency<br>output. When two messages of the same type are received in the same clock cycle (back-to-back), then no separate indication is given for the second message. |

### 104.2.350 PCIe LTR Message Control 0 (PCIELTRMSGCTRL0)

**Common to Header TYPE00/01**

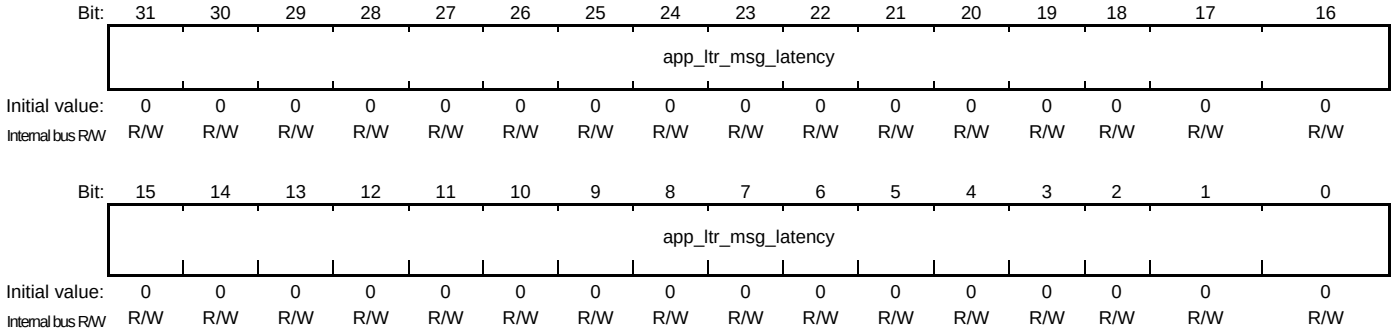
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |



| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 5 | Reserved | All 0 | R/W | These bits are read as 0. The write value must be 0. |
| 4 | app_ltr_msg_grant | H'0 | R | Indicates that the controller has accepted your request to send an LTR message. |
| 3 to 1 | app_ltr_msg_func_num | H'0 | R/W | Function number in your application that is requesting to send an LTR<br>message.<br>Function numbering starts at '0'. |
| 0 | app_ltr_msg_req | H'0 | R/W | Indicates that your application is requesting to send an LTR message.<br>Once asserted, app_ltr_msg_req must remain asserted until the controller asserts app_ltr_msg_grant |

### 104.2.351 PCIe LTR Message Control 1 (PCIELTRMSGCTRL1)

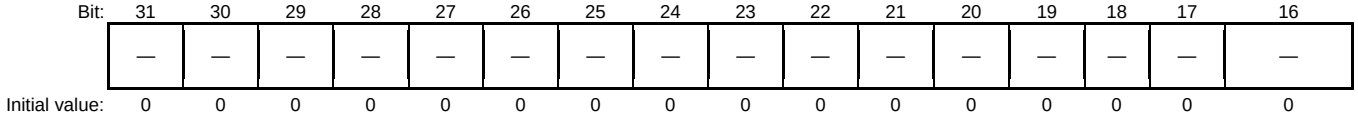
**Common to Header TYPE00/01**

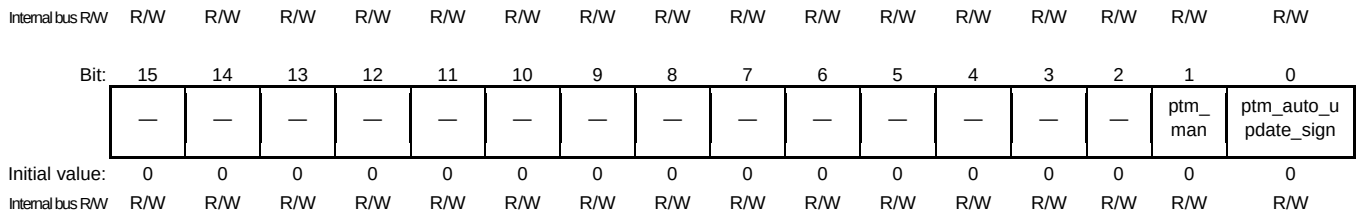


| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | app_ltr_msg_latency | All 0 | R/W | LTR message that your application is requesting to send.<br>The message format is defined in the PCI Express Specification. |

### 104.2.352 PCIe PTM Control (PCIEPTMCTRL)

**Common to Header TYPE00/01**

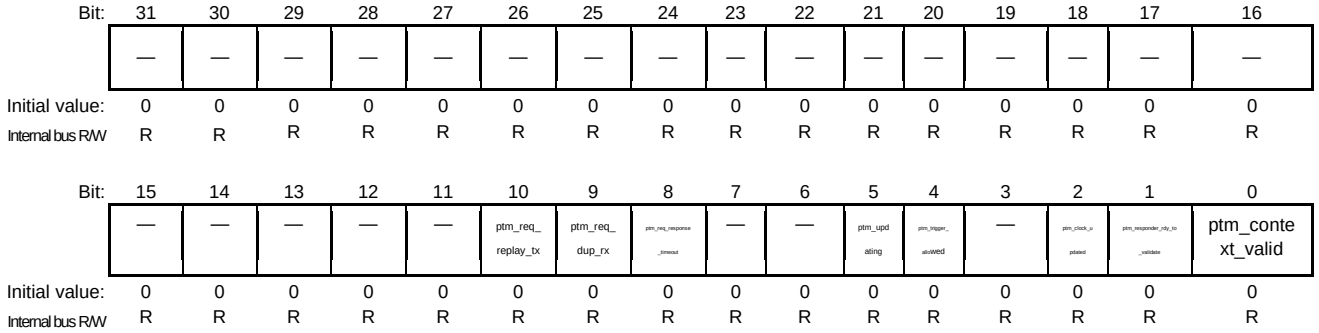




| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 2 | Reserved | All 0 | R/W | These bits are read as 0. The write value must be 0. |
| 1 | ptm_manual_update_pulse | H'0 | R/W | Indicates that the controller should update the PTM Requester Context and Clock now. |
| 0 | ptm_auto_update_signal | H'0 | R/W | Indicates that the controller should update the PTM Requester Context and Clock automatically every 10ms. |

### 104.2.353 PCIe PTM Status 0 (PCIEPTMSTS0)

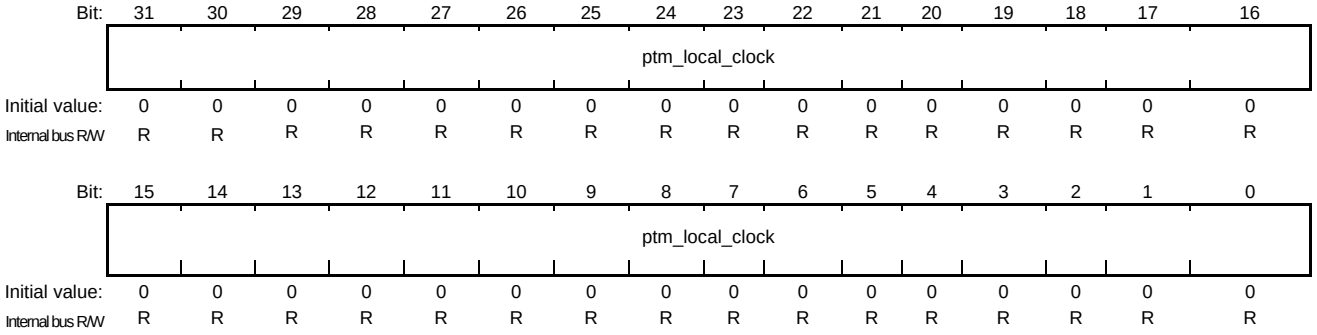
**Common to Header TYPE00/01**



| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 11 | Reserved | All 0 | R | These bits are read as 0. The write value must be 0. |
| 10 | ptm_req_replay_tx | H'0 | R | PTM Requester Replay Sent. |
| 9 | ptm_req_dup_rx | H'0 | R | PTM Requester Duplicate Received. |
| 8 | ptm_req_response_timeout | H'0 | R | PTM Requester Response Timeout. |
| 7 to 6 | Reserved | All 0 | R | These bits are read as 0. The write value is ignored. |
| 5 | ptm_updating | H'0 | R | Indicates that a PTM update is in progress |
| 4 | ptm_trigger_allowed | H'0 | R | Indicates that a PTM Requester manual update trigger is allowed |
| 3 | Reserved | H'0 | R | These bits are read as 0. The write value is ignored. |
| 2 | ptm_clock_updated | H'0 | R | Indicates that the controller has updated the Local Clock. |
| 1 | ptm_responder_rdy_to_validate | H'0 | R | PTM Responder Ready to Validate. |
| 0 | ptm_context_valid | H'0 | R | Context Valid |

### 104.2.354 PCIe PTM Status 1 (PCIEPTMSTS1)

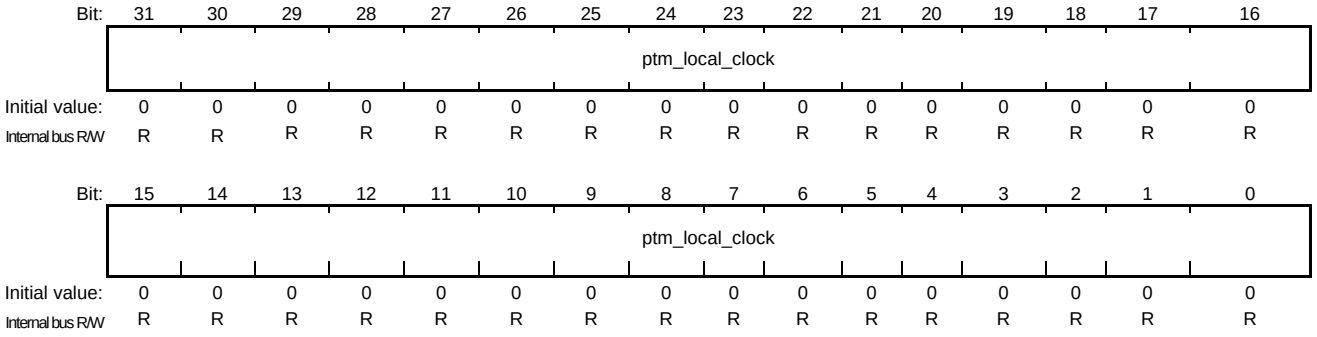
**Common to Header TYPE00/01**



| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | ptm_local_clock | All 0 | R | Lower bits [31:0]<br>Local Clock value |

### 104.2.355 PCIe PTM Status 2 (PCIEPTMSTS2)

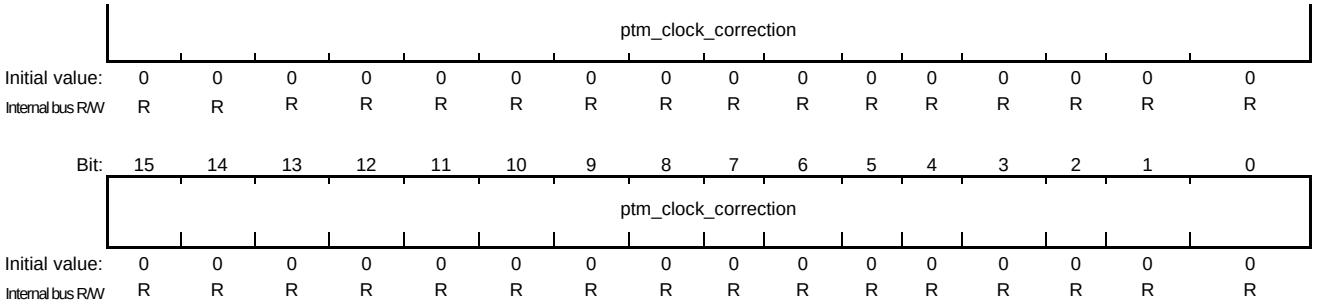
**Common to Header TYPE00/01**



| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | ptm_local_clock | All 0 | R | Upper bits [63:32]<br>Local Clock value |

### 104.2.356 PCIe PTM Status 3 (PCIEPTMSTS3)

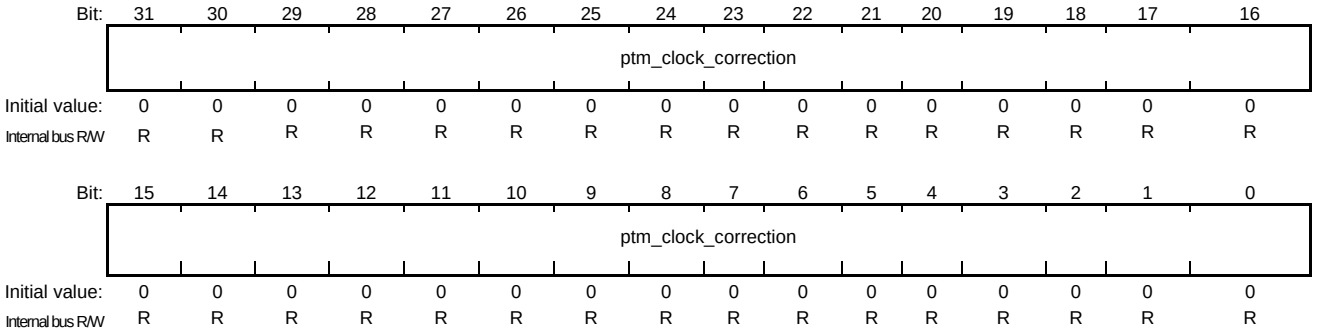
**Common to Header TYPE00/01**



| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | ptm_clock_correction | All 0 | R | Lower bits [31:0]<br>Amount by which Local Clock has been corrected. |

### 104.2.357 PCIe PTM Status 4 (PCIEPTMSTS4)

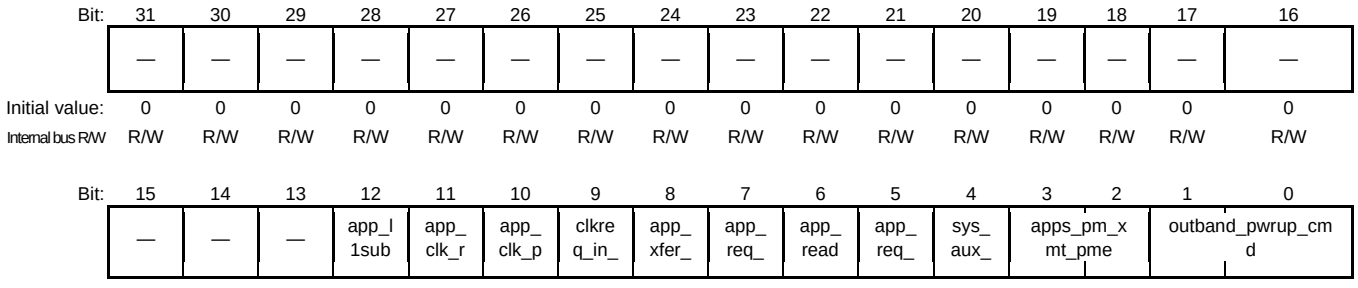
**Common to Header TYPE00/01**



| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 0 | ptm_clock_correction | All 0 | R | Upper bits [63:32]<br>Amount by which Local Clock has been corrected. |

### 104.2.358 PCIe Power Management Control (PCIEPWRMNGCTRL)

**Common to Header TYPE00/01**



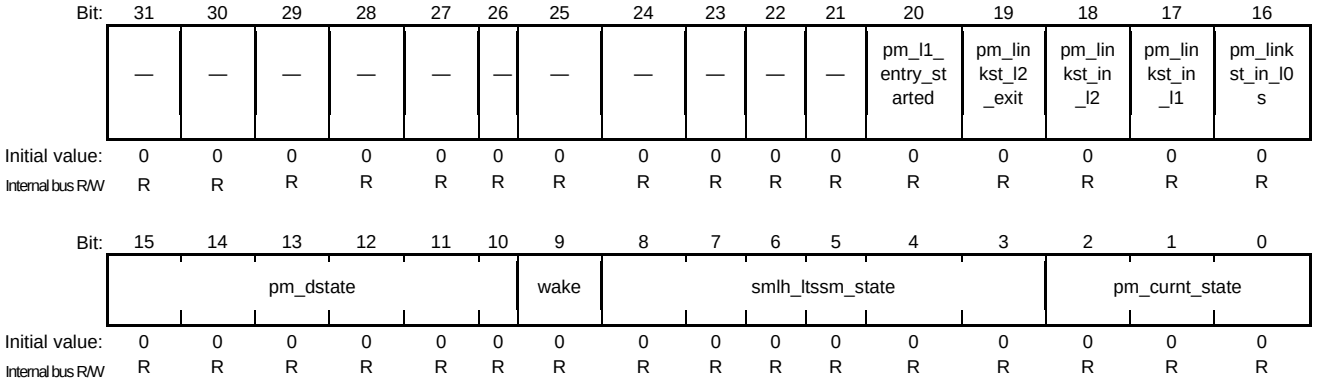
| | | | | | | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 13 | Reserved | All 0 | R/W | These bits are read as 0. The write value must be 0. |
| 12 | app_l1sub_disable | H'0 | R/W | The application can set this input to 1'b1 to prevent entry to L1<br>Sub-states.<br>This pin is used to gate the L1 sub-state enable bits from the L1 PM Substates Control 1 Register |
| 11 | app_clk_req_n | H'0 | R/W | Indicates that the application logic is ready to have reference clock removed<br>In designs which support reference clock removal through either L1 PM Sub-states or L1 CPM, the application should set this signal to 1'b when it is ready to have reference clock removed. If the application does not want to remove reference clock it should set this signal to 1'b0. |
| 10 | app_clk_pm_en | H'0 | R/W | Clock PM feature enabled by application.<br>Used to inhibit the programming of the Clock PM in Link Control Register |
| 9 | clkreq_in_n | H'0 | R/W | Status of the CLKREQ# bidirectional CMOS board-level signal.<br>Used by the controller to determine when to enter and exit L1 Substates when using the CLKREQ#-based mechanism. |
| 8 | app_xfer_pending | H'0 | R/W | Indicates that your application has transfers pending and prevents the controller from entering L1.<br>This is a level signal used to inform the controller about the state of external queues and pipeline stages that contain transactions to be transmitted by the controller. The controller uses this information to determine when to enter/exit L1. When this signal is asserted, it indicates that there are transactions outside the controller that the controller needs to transmit. When de-asserted, it indicates that there are no transactions outside the controller. The controller responds to an assertion on this signal as follows:<br>■ Upstream Ports: Prevents generation of requests to enter L1. Triggers<br>exit if already in L1.<br>■ Downstream Ports: Triggers exit if already in L1.<br>You can instruct the controller to exit L1 by asserting either or both of<br>app_xfer_pending and app_req_exit_l1. The controller only samples<br>app_req_exit_l1 when the controller is already in the L1 state. |
| 7 | app_req_exit_l1 | H'0 | R/W | Application request to Exit L1.<br>Request from your application to exit L1. It is only effective when L1 is enabled |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 6 | app_ready_entr_l23 | H'0 | R/W | Application Ready to Enter L23.<br>Indication from your application that it is ready to enter the L23 state. The app_ready_entr_l23 signal is provided for applications that must control L23 entry (in case certain tasks must be performed before going into L23). The controller delays sending PM_Enter_L23 (in response to PM_Turn_Off) until this signal becomes active. When this signal has been asserted by the application, it must be kept asserted until L2 entry has completed. Hardwire to 1 for applications that do not require this feature.<br>Note: The controller ignores this input in RC mode. |
| 5 | app_req_entr_l1 | H'0 | R/W | Application request to Enter L1 ASPM state.<br>The app_req_entr_l1 signal is for use by applications that need to control L1 entry instead of using the L1 entry timer as defined in the PCI Express Specification. It is only effective when L1 is enabled. The controller latches this request when in L0 or L0s; to be acted upon later.<br>Note: The controller ignores this input in RC mode. |
| 4 | sys_aux_pwr_det | H'1 | R/W | Auxiliary Power Detected.<br>Used to report to the host software that auxiliary power (Vaux) is present.<br>For a configuration where the auxiliary power is not available (sys_aux_pwr_det =0), the controller cannot exit from L23 Ready with beacon or PERST# de-assertion when main power is not removed. |
| 3 to 2 | apps_pm_xmt_pme | H'0 | R/W | Wake Up.<br>If PME is enabled and PME support is configured for current<br>PMCSR D-state asserting this signal will cause the controller to wake<br>from either L1 or L2 state. When the controller has transitioned back to<br>the L0 state it will transmit a PME message and set the PME_Status.<br>Upon receiving the PME message the root complex should clear the<br>PME_Status and change the D-state back to D0. |
| 1 to 0 | outband_pwrup_cmd | H'0 | R/W | Wake Up.<br>If PME is enabled and PME support is configured for current PMCSR D-state asserting this signal will cause the controller to wake<br>from either L1 or L2 state. When the controller has transitioned back to<br>the L0 state it will transmit a PME message and set the PME_Status.<br>There is a separate outband_pwrup_cmd input bit for each function in<br>your controller configuration. This port is functionally identical to apps_pm_xmt_pme. Upon receiving the PME message the root complex should clear the PME_Status and change the D-state back to D0. |

### 104.2.359 PCIe Power Management Status 0 (PCIEPWRMNGSTS0)

**Common to Header TYPE00/01**



| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 21 | Reserved | All 0 | R | These bits are read as 0. The write value must be 0. |
| 20 | pm_l1_entry_started | H'0 | R | L1 entry process is in progress |
| 19 | pm_linkst_l2_exit | H'0 | R | Power management is exiting L2 state |
| 18 | pm_linkst_in_l2 | H'0 | R | Power management is in L2 state |
| 17 | pm_linkst_in_l1 | H'0 | R | Power management is in L1 state |
| 16 | pm_linkst_in_l0s | H'0 | R | Power management is in L0s state |
| 15 to 10 | pm_dstate | H'0 | R | The current power management D-state of the function.<br>■ 000b: D0<br>■ 001b: D1<br>■ 010b: D2 (not support D2 Power Management State, Read/write value B'10 always read as 0. The write value should always be 0.)<br>■ 011b: D3<br>■ 100b: Uninitialized<br>■ Other values: Not applicable<br>There are 3 bits of pm_dstate for each configured function. |
| 9 | wake | H'0 | R | Wake Up.<br>Wake up from power management unit. The controller generates wake to request the system to restore power and clock when a wakeup event has been detected such as apps_pm_xmt_pme, apps_pm_vf_xmt_pme, or outband_pwrup_cmd. The wake signal is an active high signal and its rising edge should be detected to drive the WAKE# the connector. Assertion of wake could be for a single clock cycle or multiple clock cycles. Not used in RC mode. |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 8 to 3 | smlh_ltssm_state | H'0 | R | Current state of the LTSSM.<br>Encoding is defined as follows:<br>■ 6'h00: S_DETECT_QUIET<br>■ 6'h01: S_DETECT_ACT<br>■ 6'h02: S_POLL_ACTIVE<br>■ 6'h03: S_POLL_COMPLIANCE<br>■ 6'h04: S_POLL_CONFIG<br>■ 6'h05: S_PRE_DETECT_QUIET<br>■ 6'h06: S_DETECT_WAIT<br>■ 6'h07: S_CFG_LINKWD_START<br>■ 6'h08: S_CFG_LINKWD_ACEPT<br>■ 6'h09: S_CFG_LANENUM_WAI<br>■ 6'h0A: S_CFG_LANENUM_ACEPT<br>■ 6'h0B: S_CFG_COMPLETE<br>■ 6'h0C: S_CFG_IDLE<br>■ 6'h0D: S_RCVRY_LOCK<br>■ 6'h0E: S_RCVRY_SPEED<br>■ 6'h0F: S_RCVRY_RCVRCFG<br>■ 6'h10: S_RCVRY_IDLE<br>■ 6'h11: S_L0<br>■ 6'h12: S_L0S<br>■ 6'h13: S_L123_SEND_EIDLE<br>■ 6'h14: S_L1_IDLE<br>■ 6'h15: S_L2_IDLE<br>■ 6'h16: S_L2_WAKE<br>■ 6'h17: S_DISABLED_ENTRY<br>■ 6'h18: S_DISABLED_IDLE<br>■ 6'h19: S_DISABLED<br>■ 6'h1A: S_LPBK_ENTRY<br>■ 6'h1B: S_LPBK_ACTIVE<br>■ 6'h1C: S_LPBK_EXIT<br>■ 6'h1D: S_LPBK_EXIT_TIMEOUT<br>■ 6'h1E: S_HOT_RESET_ENTRY<br>■ 6'h1F: S_HOT_RESET<br>■ 6'h20: S_RCVRY_EQ0<br>■ 6'h21: S_RCVRY_EQ1<br>■ 6'h22: S_RCVRY_EQ2<br>■ 6'h23: S_RCVRY_EQ3 |
| 2 to 0 | pm_curnt_state | H'0 | R | Indicates the current power state.<br>The pm_curnt_state output is intended for debugging purposes, not for system operation. |

### 104.2.360 PCIe Power Management Status 1 (PCIEPWRMNGSTS1)

**Common to Header TYPE00/01**

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

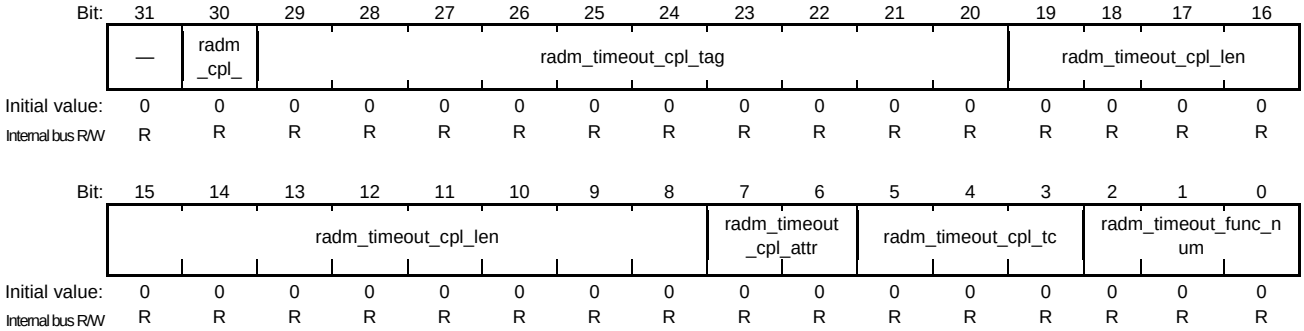
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | cdm_reg_ch | cdm_reg |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R | R/W |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 2 | Reserved | All 0 | R/W | These bits are read as 0. The write value must be 0. |
| 1 | cdm_reg_chk_cmplt | H'0 | R | Signal to indicate that a Register Checking Sequence has Completed. |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 0 | cdm_reg_chk_test_en | H'0 | R/W | Signal to enter test mode in the Register Checking Logic. u_cdm_b will not be written to when this signal is high. Allows a value to be written to u_cdm to compare against the previous value in u_cdm_b |

### 104.2.367 PCIe Receive CPL Timeout Status (PCIERCVCPLTOSTS)

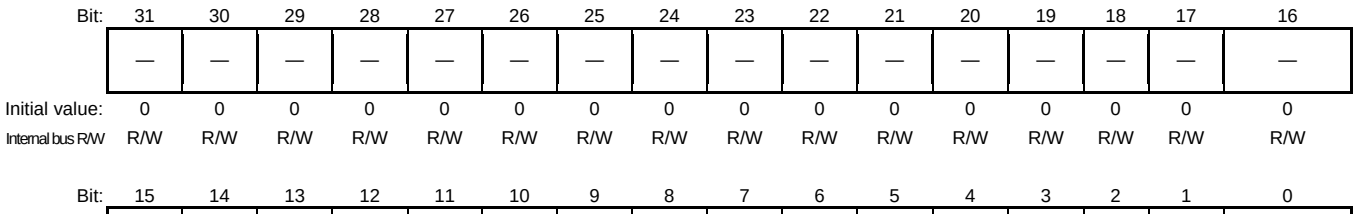
**Common to Header TYPE00/01**



| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 | Reserved | All 0 | R | These bits are read as 0. The write value must be 0. |
| 30 | radm_cpl_timeout | H'0 | R | Indicates that the completion TLP for a request has not been received within the expected time window. |
| 29 to 20 | radm_timeout_cpl_tag | H'0 | R | The Tag field of the timed out completion |
| 19 to 8 | radm_timeout_cpl_len | H'0 | R | Length (in bytes) of the timed out completion.<br>For a split completion, it indicates the number of bytes remaining to be delivered when the completion timed out. |
| 7 to 6 | radm_timeout_cpl_attr | H'0 | R | The Attributes field of the timed out completion |
| 5 to 3 | radm_timeout_cpl_tc | H'0 | R | The Traffic Class of the timed out completion |
| 2 to 0 | radm_timeout_func_num | H'0 | R | The function Number of the timed out completion. Function numbering starts at '0'. |

### 104.2.368 PCIe Transmit Control 0 (PCIETXCNTRL0)

**Common to Header TYPE00/01**



| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | app_hdr_valid |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 1 | Reserved | All 0 | R/W | These bits are read as 0. The write value must be 0. |
| 0 | app_hdr_valid | H'0 | R/W | Indicates that the data app_hdr_log, app_err_bus, app_err_func_num, and app_tlp_prfx_log is valid. |

### 104.2.369 PCIe Transmit Control 1 (PCIETXCNTRL1)

**Common to Header TYPE00/01**

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | app_err_func_num |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

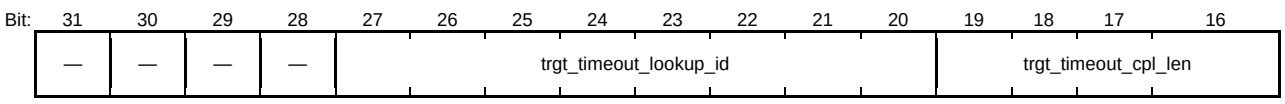
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | app_err_func_num | | app_err_a | app_err_bus | | | | | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 17 | Reserved | All 0 | R/W | These bits are read as 0. The write value must be 0. |
| 16 to 14 | app_err_func_num | H'0 | R/W | The number of the function that is reporting the error indicated app_err_bus, valid when app_hdr_valid is asserted.<br>Correctable and Uncorrected Internal errors (app_err_bus[10:9]) are not function specific, and are recorded for all physical functions, regardless of the value this bus. Function numbering starts at '0'. |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 13 | app_err_advisory | H'0 | R/W | Indicates that your application error is an advisory error..<br>Your application should assert app_err_advisory under either of the following conditions:<br>■ The controller is configured to mask completion timeout errors, your<br>application is reporting a completion timeout error app_err_bus, and<br>your application intends to resend the request. In such cases the<br>error is an advisory error, as described in PCI Express Specification.<br>When your application does not intend to resend the request, then<br>your application must keep app_err_advisory de-asserted when<br>reporting a completion timeout error.<br>■ The controller is configured to forward poisoned TLPs to your application<br>and your application is going to treat the poisoned TLP as a normal TLP, as described in PCI Express Specification. Upon receipt of a poisoned TLP, your application must report the error app_err_bus, and either assert app_err_advisory (to indicate an advisory error) or de-assert app_err_advisory (to indicate that your application is dropping the TLP). |
| 12 to 0 | app_err_bus | H'0 | R/W | The type of error that your application detected.<br>The controller combines the values the app_err_bus bits with the internally-detected error signals to set the corresponding bit in the Uncorrectable or Correctable Error<br>Status Registers:<br>■ app_err_bus[0]: Malformed TLP<br>■ app_err_bus[1]: Receiver Overflow<br>■ app_err_bus[2]: Unexpected completion<br>■ app_err_bus[3]: Completer abort<br>■ app_err_bus[4]: Completion Timeout<br>■ app_err_bus[5]: Unsupported request<br>■ app_err_bus[6]: ECRC Check Failed<br>■ app_err_bus[7]: Poisoned TLP received<br>■ app_err_bus[8]: AtomicOp Egress Blocked: only valid when CX_ATOMIC_ROUTING_EN =1<br>■ app_err_bus[9]: Uncorrectable Internal Error<br>■ app_err_bus[10]: Corrected Internal Error<br>■ app_err_bus[11]: TLP Prefix Blocked Error Status: only valid for RC<br>and when CX_NPRFX >0<br>■ app_err_bus[12]: ACS Violation: only valid when CX_ACS_ENABLE<br>=1 |

### 104.2.370 PCIe Target Completion LUT 0 (PCIETRGTCMPLUT0)

**Common to Header TYPE00/01**



| | | | | | | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 10 | Reserved | All 0 | R | These bits are read as 0. The write value must be 0. |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 9 | trgt_lookup_empty | H'0 | R | When this signal is asserted with radm_trgt1_hv, it indicates that the target completion LUT is not full.<br>The application can use this signal to determine a back-pressure mechanism to the controller so that there is not an overflow condition when the number of outstanding non-posted transactions received is more than expected. Your application logic must drive trgt1_radm_halt with the logical OR of your application halt signal and the inverse of this output. |
| 8 | trgt_cpl_timeout | H'0 | R | Indicates that the application has not generated a completion for an incoming request within the required time interval.<br>Information about the timed out completion is available the trgt_timeout_* outputs listed later. When a completion timeout occurs, the controller does not clear the corresponding entry from the completion lookup table. The default completion timeout value is approximately 10 ms. |
| 7 to 0 | trgt_lookup_id | H'0 | R | The target completion LUT lookup ID for the incoming request TLP.<br>When using the optional target completion lookup table feature, the<br>application must save the lookup ID and assert the same lookup ID<br>client0/1/2_cpl_lookup_id when generating a completion for the request. |

### 104.2.372 PCIe Mode Information (PCIEMODEINFO)

**Common to Header TYPE00/01**

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

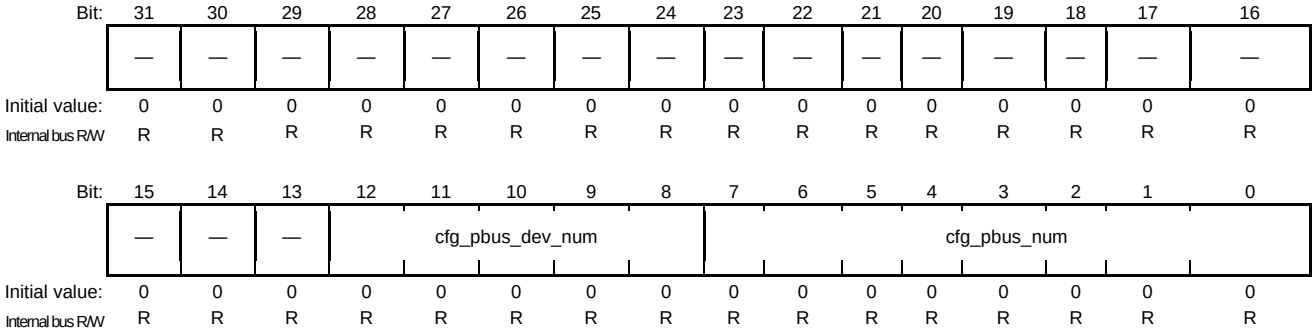
| 31 to 2 | Reserved | All 0 | R | These bits are read as 0. The write value must be 0. |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 1 | slv_rasdp_err_mode | H'0 | R | Indication (slv_aclk version) from the controller that it has entered RASDP error mode.<br>The controller enters RASDP error mode (if the ERROR_MODE_EN register field =1) upon detection of the first uncorrectable error. During this mode:<br>■ Core sets mstr_rasdp_error_mode=1<br>■ Core sets slv_rasdp_error_mode=1<br>■ Rx TLPs that are forwarded to your application are not guaranteed<br>to be correct; you must discard them. |
| 0 | mstr_rasdp_err_mode | H'0 | R | Indication (mstr_aclk version) from the controller that it has entered<br>RASDP error mode.<br>The controller enters RASDP error mode (if the ERROR_MODE_EN register field =1) upon detection of the first uncorrectable error. During this mode:<br>■ Core sets slv_rasdp_err_mode=1<br>■ Core sets mstr_rasdp_err_mode=1<br>■ Rx TLPs that are forwarded to your application are not guaranteed<br>to be correct; you must discard them. |

### 104.2.373 PCIe Configuration Information 0 (PCIECNFGINFO0)

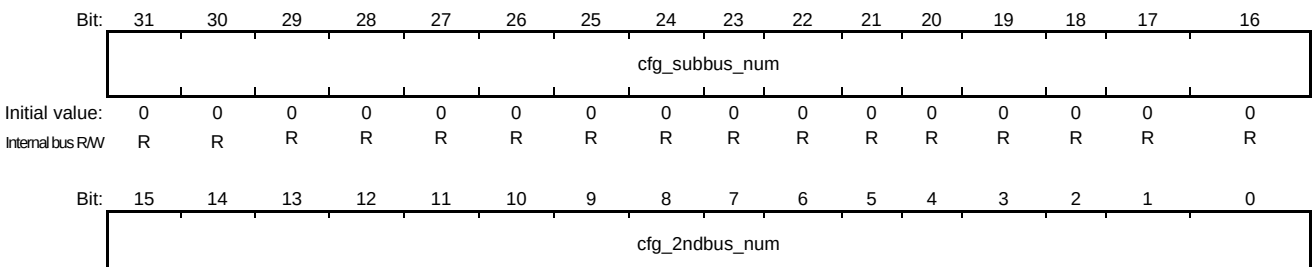
**Common to Header TYPE00/01**



| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 13 | Reserved | All 0 | R | These bits are read as 0. The write value must be 0. |
| 12 to 8 | cfg_pbus_dev_num | H'0 | R | The device number assigned to the function.<br>The number of bits depends the value of MULTI_DEVICE_AND_BUS_PER_FUNC_EN:<br>■ If MULTI_DEVICE_AND_BUS_PER_FUNC_EN =0, there are five<br>bits of cfg_pbus_dev_num ([4:0]), regardless of the number of functions.<br>■ If MULTI_DEVICE_AND_BUS_PER_FUNC_EN =1, there are five<br>bits of cfg_pbus_dev_num for each configured function. |
| 7 to 0 | cfg_pbus_num | H'0 | R | The primary bus number assigned to the function.<br>The number of bits depends the value of MULTI_DEVICE_AND_BUS_PER_FUNC_EN:<br>■ If MULTI_DEVICE_AND_BUS_PER_FUNC_EN =0, there are eight<br>bits of cfg_pbus_num ([7:0]), regardless of the number of functions.<br>■ If MULTI_DEVICE_AND_BUS_PER_FUNC_EN =1, there are eight<br>bits of cfg_pbus_num for each configured function. |

### 104.2.374 PCIe Configuration Information 1 (PCIECNFGINFO1)

**Common to Header TYPE00/01**



| | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Internal bus R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | Internal Bus R/W | Description |
|---|---|---|---|---|
| 31 to 16 | cfg_subbus_num | H'0 | R | Configured Subordinate Bus Number.<br>When the switch controller receives a configuration request from the upstream port, it must see the secondary and subordinate bus number fields from the downstream ports to route the request. |
| 15 to 0 | cfg_2ndbus_num | H'0 | R | Configured Secondary Bus Number.<br>The secondary bus number assigned to the device. When the host software detects the upstream switch port, it assigns a secondary bus number. This bus number is then used in configuration requests to detect the downstream ports. The switch controller must see this so that it can route configuration requests. |

### 104.2.375 PCIe Margining Control (PCIEMARGINGCTRL)

**Common to Header TYPE00/01**

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| 2 | phy1_ref_use_pad | H'0 | R/W | Select reference clock connected to ref_pad_clk_p/ref_pad_clk_m |
| 1 to 0 | — | H'0 | R | Reserved<br><br>These bits are read as 0. The write value must be 0. |

## 104.3 Operation

The following describes the operation of this module.

Note: The following operation flowcharts are each divided in two parts and described. One part covers the H/W, hardware operation of this module and the other covers the S/W, software operation to control this module. The arrows originating from the outside of the figure frame indicate that the event arises from the user program.

In the explanation of the operation flows, interrupt sources are described in the H/W part. The S/W should first verify a given interrupt flag and then clear it.

If generation of interrupt sources is expected, enable each of the interrupt sources referring to Figure 104.41, Figure 104.42, Figure 104.43 and Figure 104.44.

### 104.3.1 Clocks

The following describes the clocks specification for PCIEC.

#### 104.3.1.1 Overview

PCIEC uses the clocks outlined in Table 104.7.

**Table 104.7 Clocks list in PCIEC**

| Clock Name | Frequency[MHz] | Descrition |
|---|---|---|
| S0D2_HSCφ | Refer to section 8(CPG) | This clock is used for AXI bus I/F. |
| S0D4_HSCφ | Refer to section 8(CPG) | This clock is used for APB bus I/F. |
| core_clk@ Gen{1,2,3,4} | {62.5, 125, 250, 500} | This clock is the primary clock for the PCIe Controller module |
| PCIE*m*_CLK_P/M<br>(*m* = 0) | 100 | Reference clock for the PLL incorporated in the PCIe Controller module (differential inputs). |

#### 104.3.1.2 Reference Clock

PCIEC physical unit is able to repeat the input reference clocks. A reference clock repeater is provided to propagate the reference clock through PCIEC physical unit pins. This is called reference clock repeat mode.

Figure 104.2 shows connection of reference repeat mode.

Reference clock repeat mode is enabled by setting PCIEC0 Local register REFCLKCTRLP0. phy0_ref_use_pad = 1 and REFCLKCTRLP0. phy0_ref_repeat_clk_en = 1, PCIEC1 Local register REFCLKCTRLP*i*. phy*i*_ref_use_pad = 0 and REFCLKCTRLP0. phy*i*_ref_repeat_clk_en= 1 (*i* = 0,1). Starting point of reference clock is only PCIE0_CLK_P/M supported.

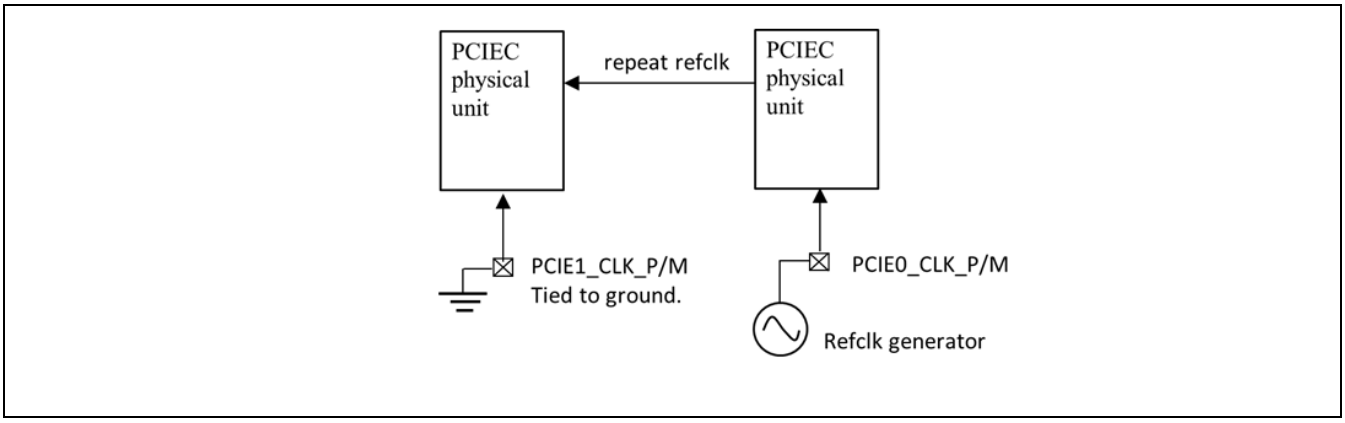

**Figure 104.2 Connection of reference repeat mode**

PCIEC supports the Separate Reference clock with Independent Spread Spectrum Clocking (SRIS) feature as defined by the PCI-SIG. SRIS is enabled by setting PCIEMSR0. app_sris_mode = 1. When SRIS is enabled, then L0s is not supported and must not be advertised in the ASPM Support Capability Registers.

### 104.3.2 Resets

The following describes the resets specification for PCIEC.

PCIEC uses the resets outlined in Table 104.8. These resets are implemented per link.

Cold-reset (power_up_rst_n) is controlled by CPG registers, Warm-reset (perst_n) and Hot-reset (app_init_rst) are controlled by PCIEC control register (PCIERSTCTRL0 / PCIERSTCTRL2) in PCIEC module.

**Table 104.8 Resets list in PCIEC**

| Reset level | Description |
|---|---|
| Cold-reset | power_up_rst_n. This reset is used as PCIEC fundamental reset.<br><br>Assertion of this reset resets all registers in PCIEC. |
| Warm-reset | PCIERSTCTRL0.perst_n. This reset is used as same as PERST#.<br><br>Assertion of this reset resets registers except PCIEC control registers partial. |
| Hot-reset | PCIERSTCTRL2.app_init_rst. This reset is used as Hot-reset.<br><br>Assertion of this reset resets non-sticky registers. |

### 104.3.3 Endian

The ordering of AXI/APB address and data is a little endian.

### 104.3.4 Initialization

#### (1) Standby State Cancellation

- After canceling a reset, cancel the module standby state. For the module standby state, refer to section “8A. Module Standby and Software Reset”. This module is in the module standby state after a power-on reset is canceled.

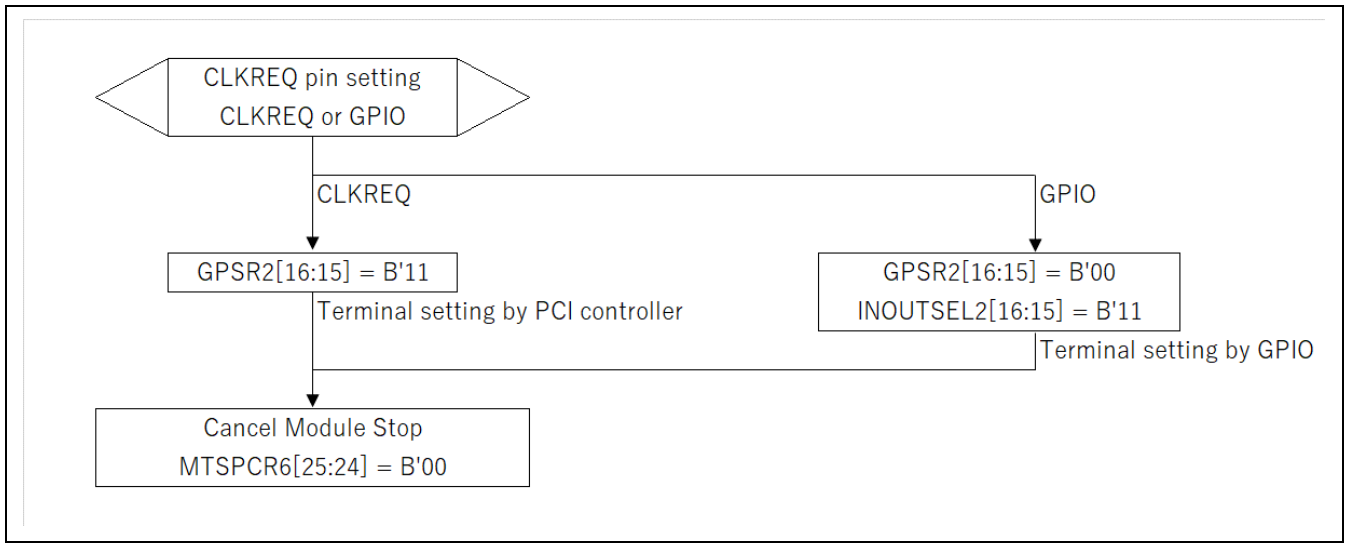

**Figure 104.3a Initial Setting of PCIEC**

### (2) Initial Setting of PCI Express

- Figure 104.3 shows the PCIEC operation in initial setting example.
- After start-up processing for the PCIe control register access is completed, the initial setting is executed to start operation as a PCI Express. Until the initial setting is completed, this module cannot work correctly as a PCI Express device. Therefore, a link is not established immediately after a reset is canceled. When the initial setting is completed, set the PCIERSTCTRL1.app_ltssm_enable=1 and PCIERSTCTRL1. app_hold_phy_rst =0 to start operation.
- Set the bits in the configuration registers as directed in the related register description, if there is a direction on initialization.
- When a register is used with the default setting, setting the register is not required.
- Set PRTLGC5.LANE_CONFIG =H'00_0040.

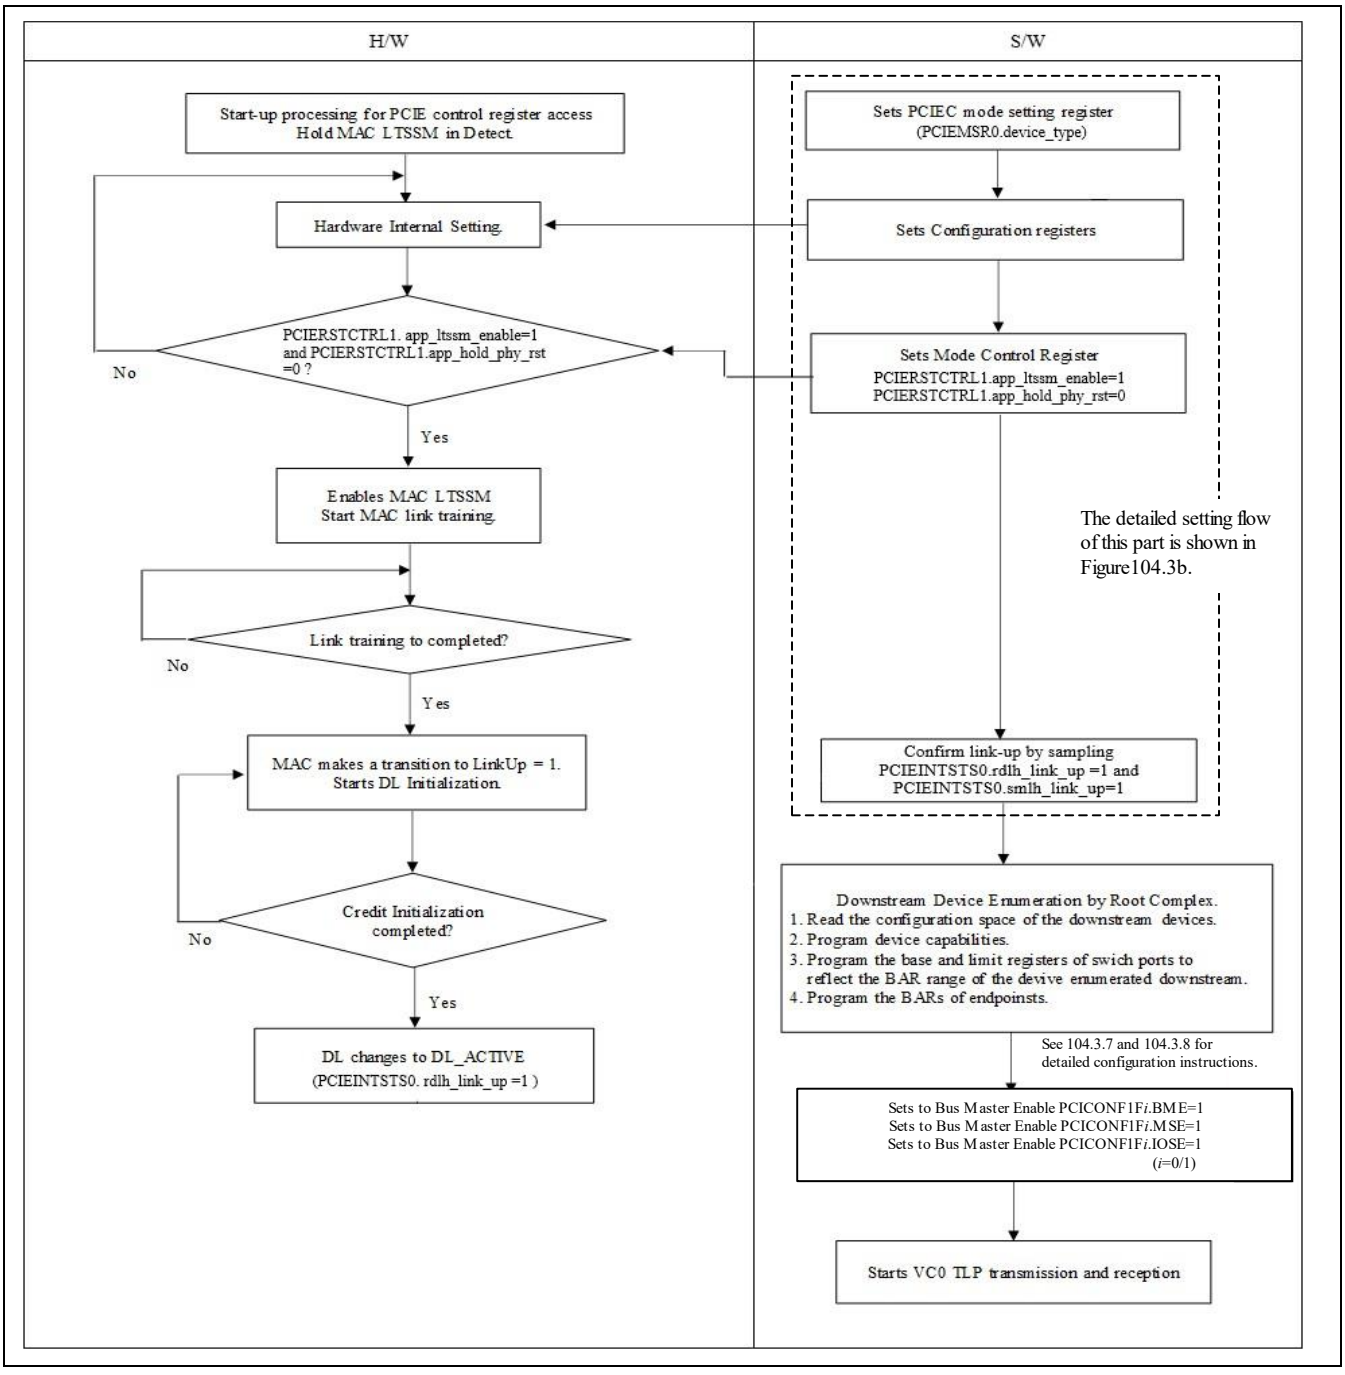

**Figure 104.3 Initial Setting of PCIEC(example)**

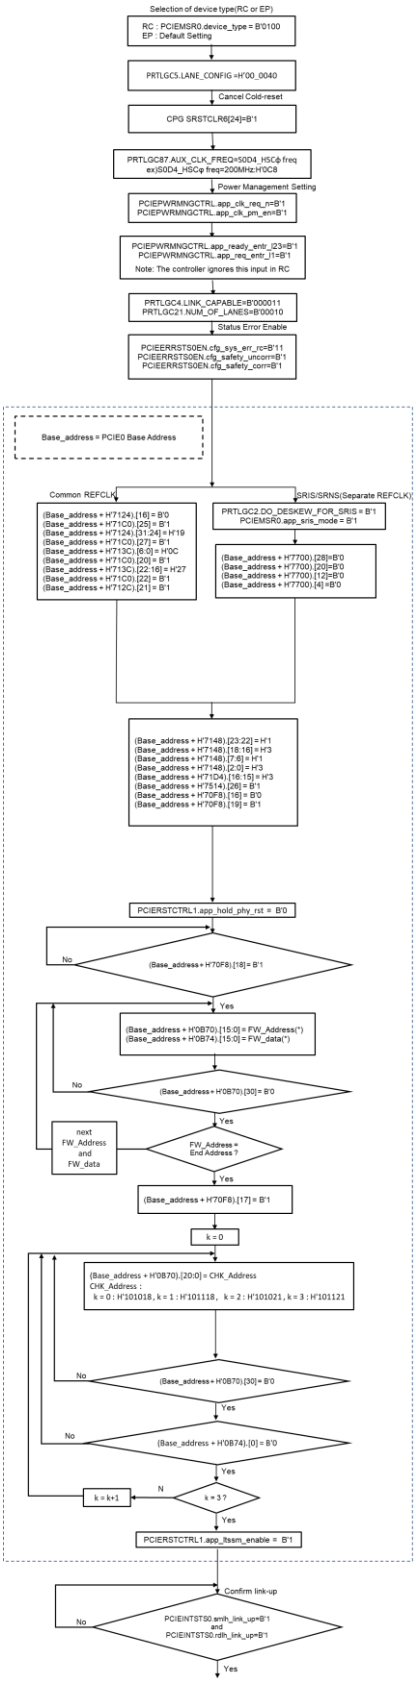

(*): FW_Address(ADDR) and FW_data(DATA) refer to attachment File "104_PCIe_fw_addr_data_ver1.05.txt"

**Figure 104.3b Initial Setting of PCIEC(example)**

### (3) DL_Down Operation

Figure 104.4 shows the operation when a link goes down (LinkUP = 0) in the state where a link is established, thus causing DL_Down. When DL_Down is caused, PCIERSTCTRL1.app_ltssm_enable is set to 0. Since the current data is invalidated, all the resources of the data transmitter/receiver of this module are initialized.

- Upon DL_Down, a write to the transmission buffer is disabled thus stopping transmission.
- Upon DL_Down, the receive buffer is forcibly cleared.
- If a link goes down, transmission and reception are suspended; therefore, data before and after DL_Down becomes illegal. Since the specific process here differs depending on the application, the operation is simply indicated as “Processes errors.” in the flowchart shown in Figure 104.4.

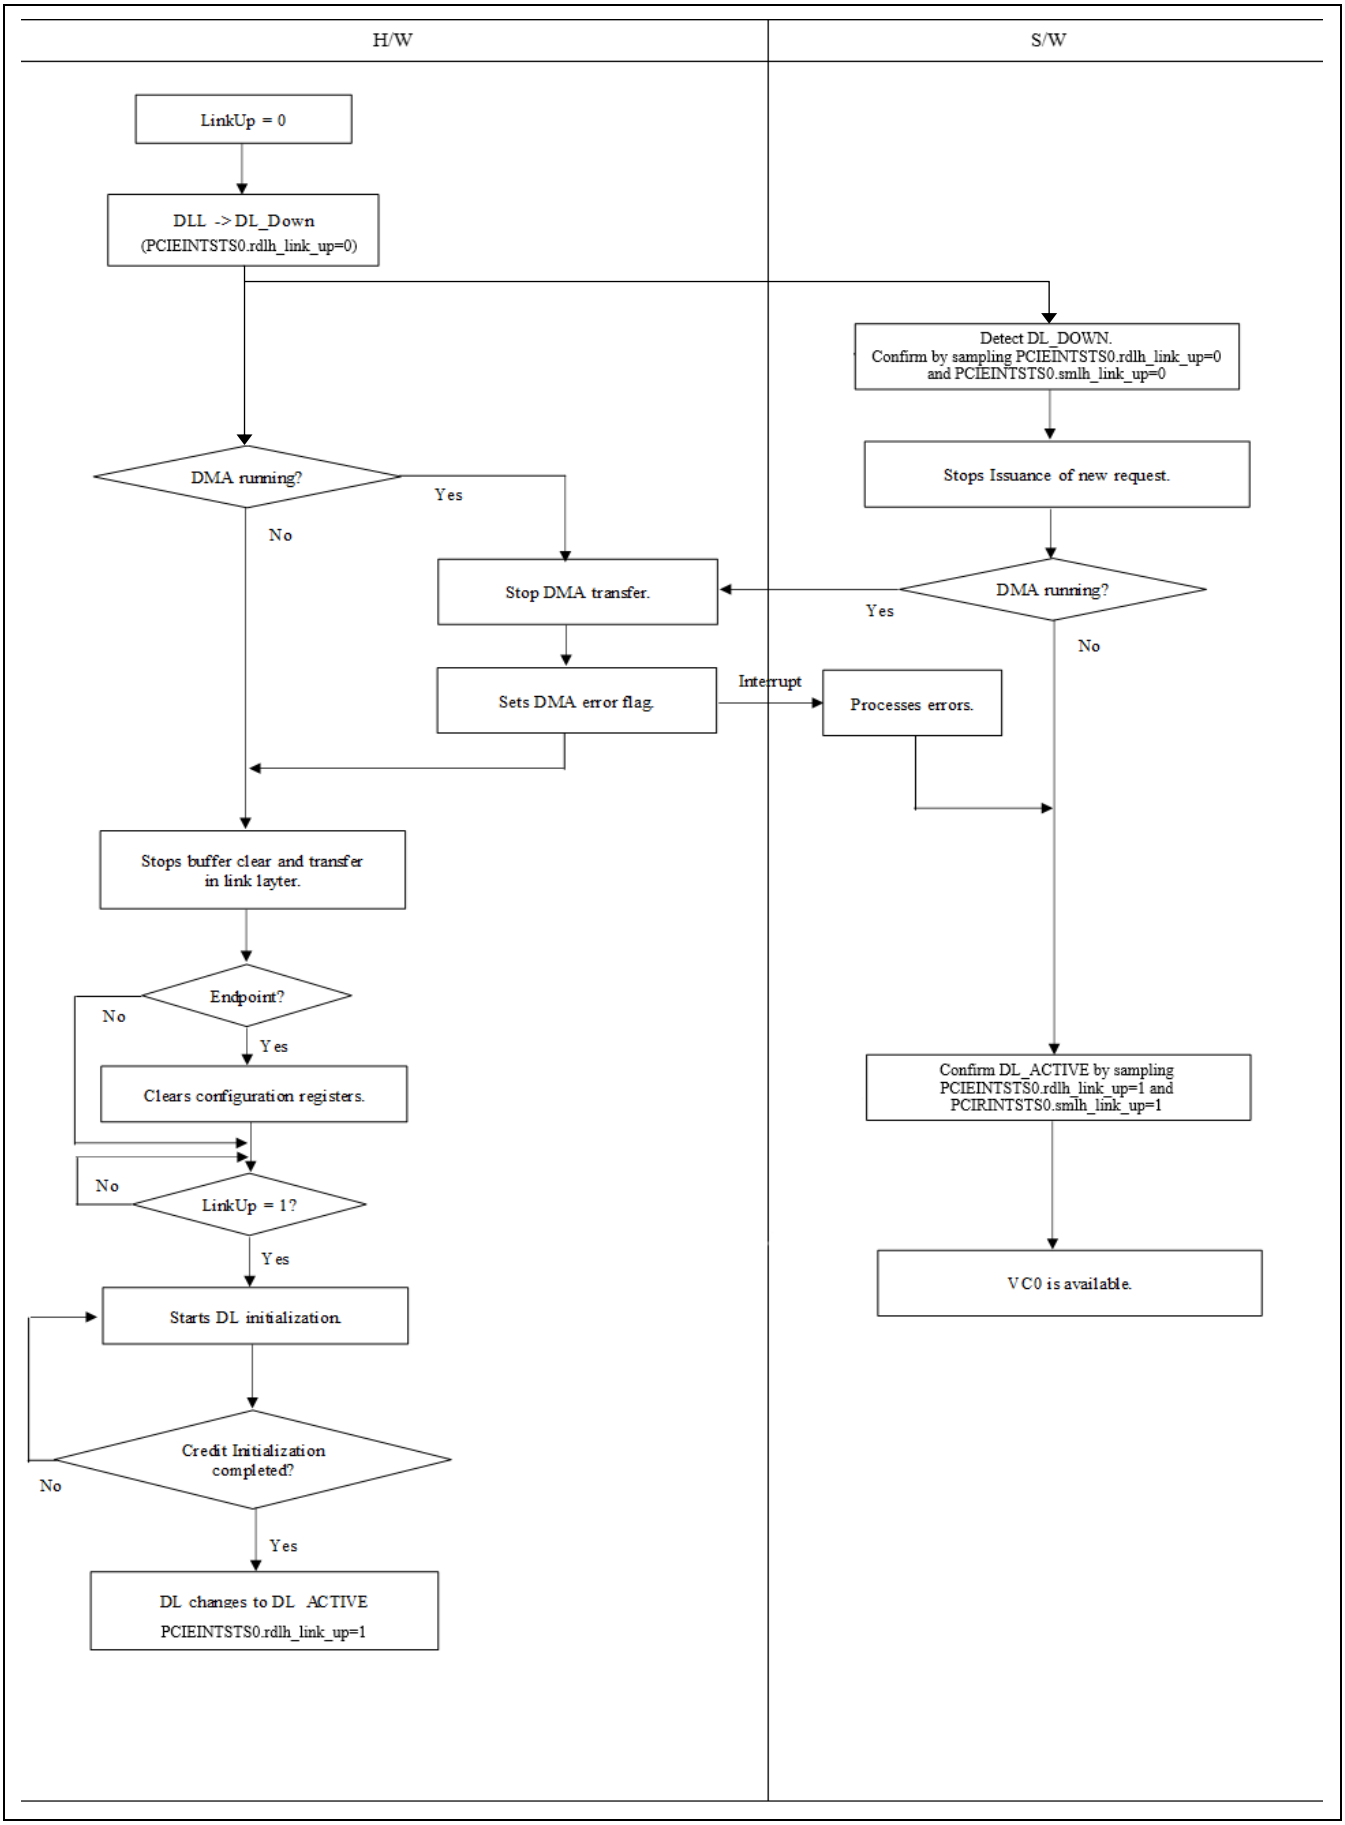

**Figure 104.4 DL_Down Operation**

#### (4) Hot Reset Operation

##### (a) Hot Reset Transmission

In Root Port mode, to send a hot reset to a downstream port, write 1 to the secondary bus reset bit in the configuration register. Before issuing a hot reset, confirm that this module has completed transfer.

##### (b) Hot Reset Reception

In Endpoint mode, when a hot reset is received from a downstream port, the LTSSM on the link layer makes a transition to the hot reset state. This causes LinkUp = 0 and then DL_Down = 1. After this, the same operation is performed as the operation upon the DL_Down.

### 104.3.5 Configuration Cycle

When using this module as a Root Port, a configuration cycle must be generated to configure the connection-target device. A configuration cycle refers to the process of checking the status of the configuration register of the connection-target Endpoint, switch, or bridge through the use of configuration access, and assigning values to the configuration registers of the Root Port itself and the Endpoint according to the result of the checking. When the Root Port accesses its own configuration register, such access is normally made through the internal bus.

This section describes the transmission (write) and reception (read) operations of the configuration access, and the items to be specified during a configuration cycle.

When this module is used as an Endpoint, it receives a configuration access from a Root Port, and accepts the initialization processing.

#### (1) Initialization of PCIEC in Root Port Mode

In Root Port mode, set all the Endpoints (indicated as system in the flow chart) connected to the PCIEC after link establishment.Figure 104.5 shows a sample setting flowchart.

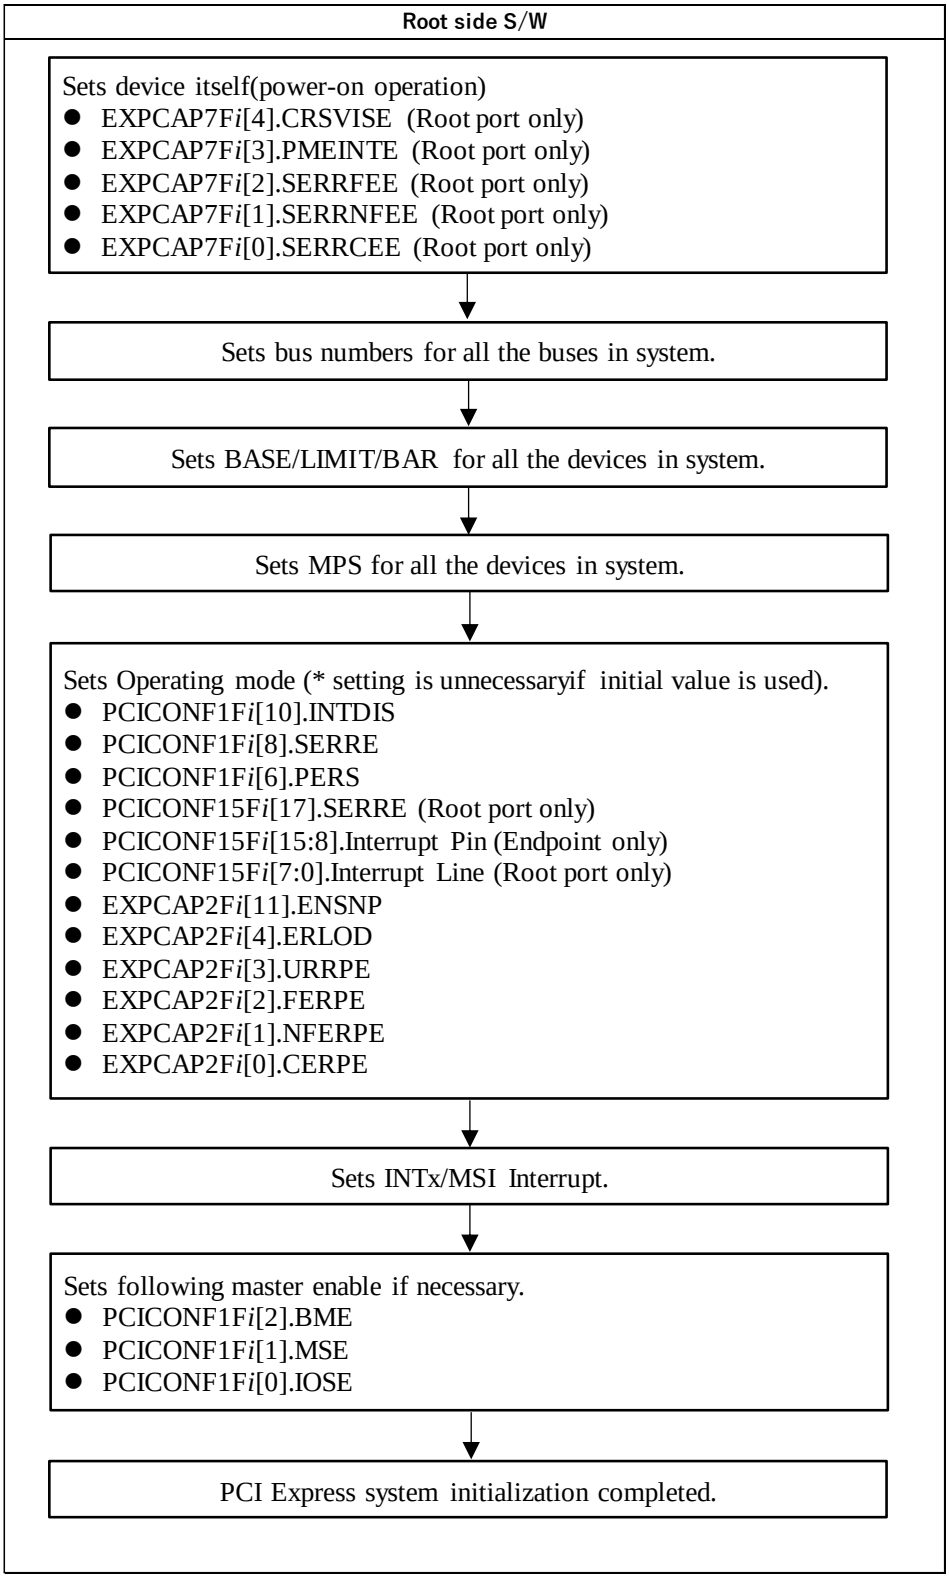

**Figure 104.5 PCIEC Initialization in Root Port Mode**

### 104.3.6 Overview of Transmission and Reception

PCI Express transfers are classified into two types of requests and one type of completion.

The following three methods are provided for PCI Express transactions. For details on each transfer, refer to the following sections.

1. Outbound: A request is issued from the internal bus side to a device on the PCI Express.
2. Inbound: A request is received by the internal bus side from the PCI Express.
3. DMA transfer: A great quantity of data is automatically written and read between the PCI Express and the internal bus without intervention of the CPU.

Table 104.9 shows the relationship between two types of requests and PCI Express transactions and shows the transaction issuance methods with this module.

**Table 104.9 Relationship between Posted/Non-Posted Requests and PCI Express Transactions**

| Transaction Type | Transfer Type | Completion | Device Type that can Issue Transaction | Transaction Issuance Method with This Module | Operation |
|---|---|---|---|---|---|
| Memory Write | Posted | Not provided | Root Port &Endpoint | PIO, DMA, (MSI Endpoint only) | Data is written to the memory of the communication peer. 1 byte to 4 Kbytes of data not exceeding MPS*1 can be written. |
| Memory Read | Non-Posted | Provided | Root Port &Endpoint | PIO, DMA | A quantity of data not exceeding MRRS*2 is read from the memory of the communication peer. The read data is returned with a completion separately from this request; no data is included in this request. |
| I/O Write | Non-Posted | Provided | Root Port only | PIO | Data is written to I/O. Data size is 1 DW. A completion is necessary that indicates whether this request has succeeded. |
| I/O Read | Non-Posted | Provided | Root Port only | PIO | Data is read from I/O. No data is included. The read data and a completion that indicates whether this request has succeeded are necessary. |
| Configuration Write | Non-Posted | Provided | Root Port only | PCI Express transfer control register | Configuration write is performed. Data size is 1 DW. A completion is necessary that indicates whether this request has succeeded. |
| Configuration Read | Non-Posted | Provided | Root Port only | PCI Express transfer control register | Configuration read is performed. No data is included. The read data and a completion that indicates whether this request has succeeded are necessary. |
| Message | Posted | Not provided | Root Port & Endpoint | Issued by this IP, message transmit register, message transmit module | A message request is transmitted. This is used for power management and interrupt control. |

Notes: 1. MPS: Max Payload Size
2. MRRS: Max Read Request Size

In Table 104.9, the transactions for which “Provided” is indicated in the “Completion” column, make a response with a completion. The data returned with a completion differs depending on the transaction. Table 104.10 shows the particulars of the completion contents returned. Specifically, the table shows whether

completion data for each type of transactions is included or not, the devices that can issue the transaction, and some other related information.

**Table 104.10 Relationship between Completion and PCI Express Transactions**

| Transaction Type | Completion Data | Device Type that can Issue Transaction | Transaction Issuance Method with This Module | Operation |
|---|---|---|---|---|
| Memory Read | Included | Root Port & Endpoint | Automatically issued by this module. | Data requested by memory read request and status are returned. |
| I/O Write | Not included | Root Port only | Automatically issued by this module. | No data is included. Status in response to I/O write is returned. |
| I/O Read | Included | Root Port only | Automatically issued by this module. | Data size is 1 DW. The read data and a completion that indicates whether this request has succeeded are returned. |
| Configuration Write | Not included | Root Port only | Automatically issued by this module. | No data is included. Status in response to configuration write is returned. |
| Configuration Read | Included | Root Port only | Automatically issued by this module. | Data size is 1 DW. The read data and a completion that indicates whether this request has succeeded are returned. |

### 104.3.7 Outbound (Data Transfer from Internal Bus → PCIEC → External Device)

This section describes Outbound. Outbound here refers to the transfer method to create a PCI Express packet by accessing the memory space assigned to the PCI Express via the internal bus.

#### (1) Outbound Features

Number of Outbound Address Translation Regions is 16.

Address translation is used for mapping different address ranges to different memory spaces supported by your application. A typical example maps your application memory space to PCI memory space. The iATU also supports type translation. Without address translation, your application address is passed unmodified to the TLPs directly through the Tx application interface. You can program the iATU to implement your own outbound address translation scheme without external logic.

**Outbound Features:**

- Address Match mode operation for MEM and I/O, CFG, and MSG TLPs. No translation for completions.
- Supports type translation through TLP type header field replacement for MEM or I/O types to MSG/CFG types.
  - Includes posted to non-posted translation (for example, MWr to CfgWr0)
  - No translation from completions.
- Programmable TLP header field replacement.
  - TYPE/TC/AT/ATTR/MSG-Code.
  - Function Number
- Multiple (up to 256) address regions programmable for location and size.
- Programmable enable/disable per region.
- Automatic FMT field translation between three DWORDs and four DWORDs for 64-bit addresses.

■ Invert Address Matching mode to translate accesses outside of a successful address match.

■ Configuration Shift mode. Optimizes the memory footprint of CFG accesses destined for the Rx application interface in a multifunction device.

■ Response code which defines the completion status to return for accesses matching a region.

■ Supports regions from 4 KB to 16 ZB in size.The minimum and maximum region sizes are determined by CX_ATU_MIN_REGION_SIZE and CX_ATU_MAX_REGION_SIZE. Smaller region sizes consume extra decode logic.

For AXI, this feature is applicable only when SLAVE_BUS_ADDR_WIDTH = 64; If SLAVE_BUS_ADDR_WIDTH < 64, CX_ATU_MAX_REGION_SIZE is restricted to 4GB. For AHB, this features is not applicable.

■ Payload Inhibit marks all TLPs as having no payload data.

■ Header Substitution replaces bytes 8 to 11 (for 3 DWORD header) or bytes 12 to 15 (for 4 DWORD header), inclusive, of the outbound TLP header.

■ Tag Substitution of the outbound TLP tag field.

■ Function number bypass mode to allow function number information to be supplied from your application transmit interface while translating the address and other attributes of the TLP.

■ DMA bypass mode to allow TLPs which are initiated by the embedded DMA engine, to pass through the iATU untranslated.

■ TLP Header fields bypass mode to allow header information to be supplied from your application transmit interface or, if AMBA is configured, from the AMBA sideband bus while translating the address and Type of the TLP.

***Note:** The default behavior of the ATU when there is no address match in the outbound direction or no TLP attribute match in the inbound direction, is to pass the transaction through.

### (2) Outbound Limitations

■ Generation of ATS requests and messages not supported (no facility to insert NW and iTAG fields).

### (3) Outbound Basic Operation (Address Match Mode)

The address field of each request MEM and I/O TLP is checked to see if it falls into any of the enabled address regions defined by the Start and End addresses as defined in Figure 104.6. When an address match is found, then the TLP address field is modified as follows:

*Translated Address = Original Address - Base Address + Target Address*

and the TYPE, TC, AT, TH, PH, ST, Function Number, and ATTR header fields are replaced with the corresponding fields in the ATUCAP[0+i*18] register. When your application (XALI0/1/2) address field matches more than one of the CX_ATU_NUM_OUTBOUND_REGIONS address regions, then the first (lowest of the numbers from 0 to CX_ATU_NUM_OUTBOUND_REGIONS-1) enabled region to be matched is used. For details on what happens when there is no address match, see “No Address Match Result”. This operational mode (called Address Match Mode) is always used for outbound translation. Figure 104.6 to Figure 104.7 provide more details on this translation process.

***Note:** The iATU does not translate DBI requests.

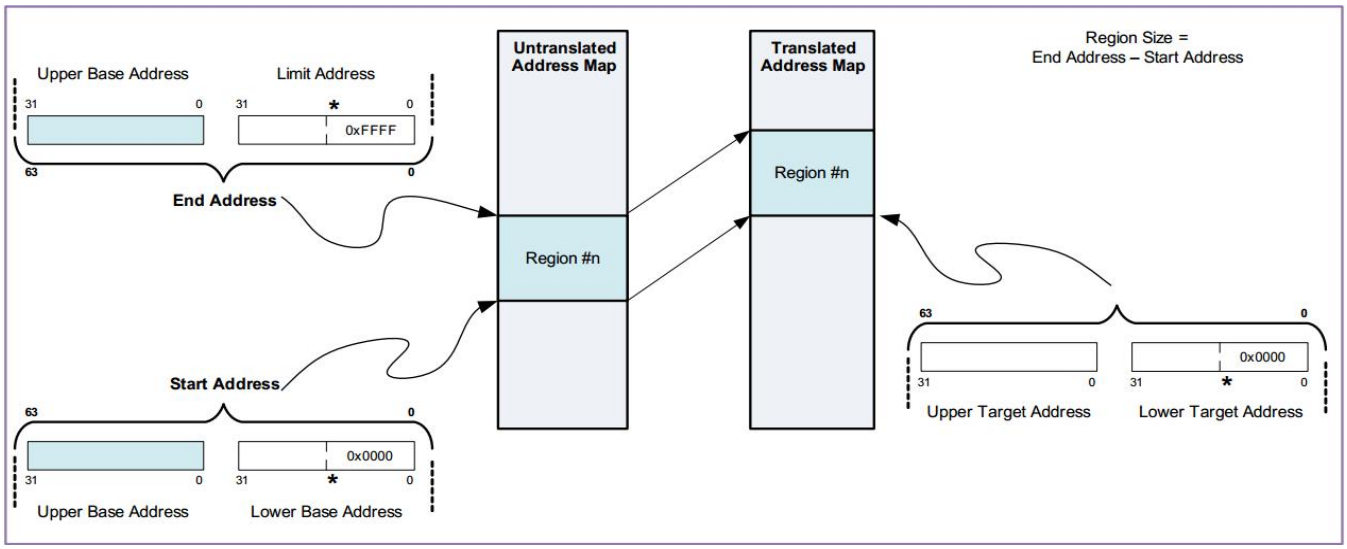

**Figure 104.6 64-bit Region Mapping: Outbound and Inbound (Address Match Mode); INCREASE_REGION_SIZE=0**

**Note:** * is log2(CX_ATU_MIN_REGION_SIZE)

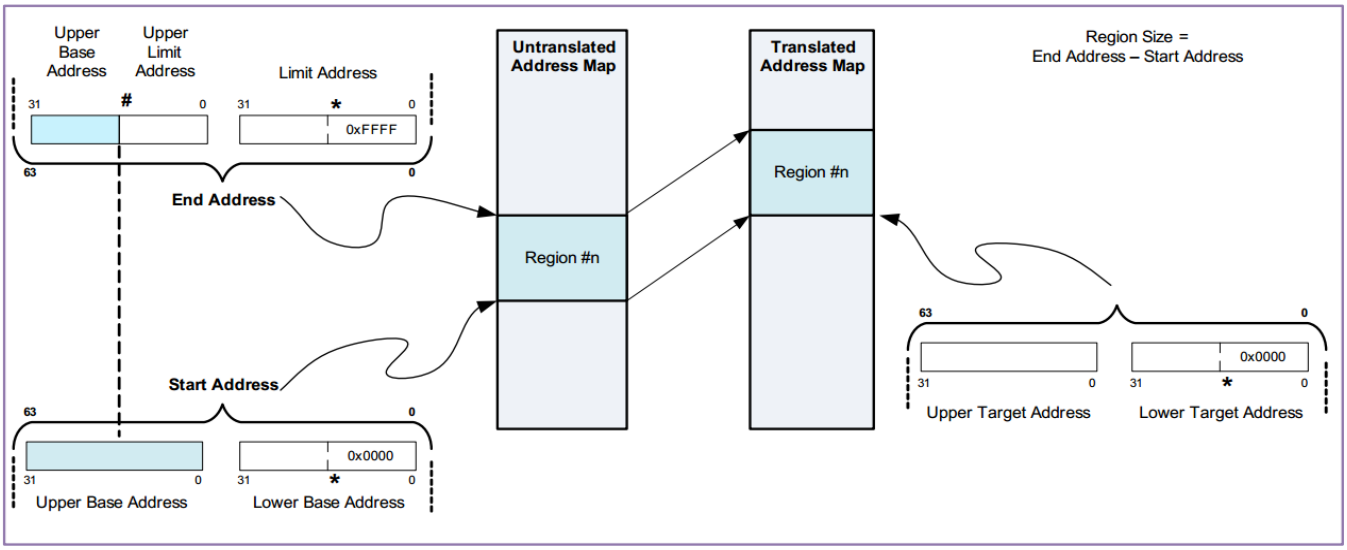

**Figure 104.7 64-bit Region Mapping: Outbound and Inbound (Address Match Mode); INCREASE_REGION_SIZE=1**

**Note:** * is log2(CX_ATU_MIN_REGION_SIZE)

The CX_ATU_MIN_REGION_SIZE configuration parameter (4 kB - 64 kB) specifies the minimum size of an address translation region. For example, when set to 64 kB, the lower 16 bits of the Base and Target registers are zero, the lower 16 bits of the Limit register is 0xFFFF, and all address regions are aligned on 64 kB boundaries. More precisely, the lower log2(CX_ATU_MIN_REGION_SIZE) bits are zero. In Figure 104.8, # is CX_ATU_MAX_REGION_SIZE; if =0, Upper Limit Address register does not exist.
The INCREASE_REGION_SIZE field in ATUCAP[0+i*18] determines if the maximum region size is 4 GB or is set by the CX_ATU_MAX_REGION_SIZE configuration parameter. This only applies to 64-bit addressing.

***Caution**: *The combination of region size and number of regions must not consume the maximum space that is addressable with your 32-bit or 64-bit system address*.*

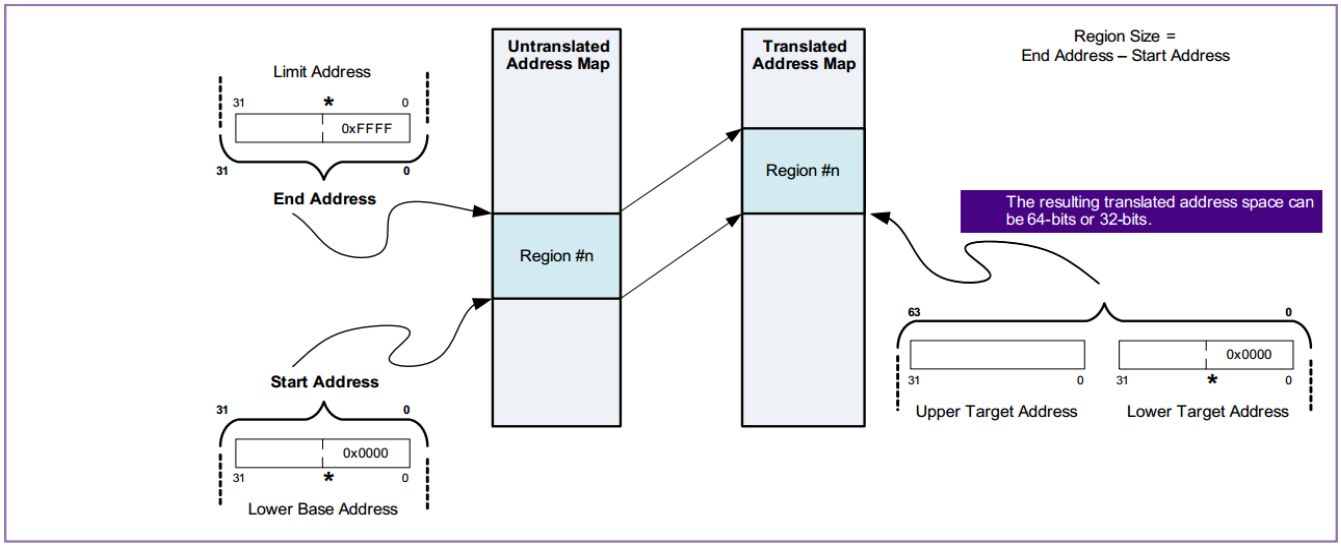

**Figure 104.8 32-bit Region Mapping: Outbound and Inbound (Address Match Mode)**

**Note:** * is log2(CX_ATU_MIN_REGION_SIZE)

### (4) Outbound Detailed Operation

The following advanced topics are discussed:

**Default Operation:**

- RID BDF Number Replacement.
- IO/MEM to Msg/MsgD Type Translation.
- IO/MEM to CFG Type Translation.
- FMT Translation.
- Writing to a MRdLk Region.
- No Address Match Result

**Optional Features:**

- CFG Shift.
- Address Match Invert.
- General Bypass.
- DMA Bypass.
- Function Number Translation Bypass.
- TLP Header Field Translation Bypass.
- Payload Inhibit.

- Header Substitution.
- Tag Substitution.

**(a) RID BDF Number Replacement:**

**Overview:** When there is a successful address match on an outbound TLP, then the function number used in generating the function part of the requester ID field of the TLP is taken from the 3-bit Function Number field of the ATUCAP[0+i*18] register. The value in this field must be 0x0 unless multifunction operation in the controller is enabled. To override this behavior, use the “Function Number Translation Bypass”.

**(b) IO/MEM to Msg/MsgD Type Translation:**

**Overview:** The iATU supports TYPE translation/conversion of MEM and I/O TLPs to Msg/MsgD TLPs.
When there is a successful address match on an outbound MEM TLP, and the translated TLP type field is MSG (that is, the type field of the ATUCAP[0+i*18] register is 10xxx), then the message code field of the TLP is set to the value in the Message Code field of the
ATUCAP[1+i*18] register. A MWr with an effective length of ‘0’ is converted to Msg and all other MWr TLPs are converted to MsgD. For more information on generating messages, see “Message Generation”.

***Caution:** *The iATU does not translate outbound messages.*

**Usage Scenario:** This is useful for applications that are unable to generate Msg/MsgD TLPs.

**(c) IO/MEM to CFG Type Translation:**

**Overview:** The iATU supports translation of I/O and MEM TLPs to CFG TLPs. The 16-bit BDF is located at bits [31:16] of the translated address where:

*Translated Address = Original Address - Base Address + Target Address*

As an example

*Original Address[31:16] = {13h0,function_no[2:0]}*

*Base Address[31:16] = 16h0*

*Target Address[31:16] = {bus_no[7:0],device_no[4:0],3h0}*

Then

*Translated Address[31:16] = BDF ={bus_no[7:0],device_no[4:0],function_no[2:0]}*

To handle eight functions (as the previous example indicates), you should use a 19-bit wide region size.
For CFG transactions created directly by your application (as opposed to the iATU), you must ensure that the BDF field does not match any programmed iATU address region or else unintentional type translation could occur.
**Usage Scenario:** This is useful for applications that are unable to generate CFG TLPs.

**(d) FMT Translation:**

**Overview:** The iATU automatically sets the TLP format field for three DWORDs when it detects all zeros in the upper 32 bits of the translated address. Otherwise, it sets it to four DWORDs when it detects a 64-bit address (that is, when there is a ‘1’ in the upper 32 bits of the translated address). When the original address and the translated address are of different format, the iATU ensures that the TLP header size matches the translated address format.

**(e) Writing to a MRdLk Region:**

**Overview:** When there is a successful address match for an outbound write and the type header field in the ATUCAP[0+i*18]_i register is “00001” indicating a locked MEM transfer, then the controller sets the type field to “00000” (MEM).

**(f) No Address Match Result:**

**Overview:** When there is no address match then the address is untranslated but the TLP header information (for fields that are programmable) comes from the relevant fields on the application transmit interface XALI* or AXI slave.

**(g) CFG Shift:**

**Overview:** The iATU uses bits [27:12] of the original address to form bits [31:16] (BDF location) of the outgoing CFG TLP. This supports the Enhanced Configuration Address Mapping (ECAM) mechanism (Section 7.2.2 of the *PCI Express Base Specification, Revision 4.0, Version 1.0*) by allowing all outgoing I/O and MEM TLPs (that have been translated to CFG) to be mapped from memory space into any 256 MB region of the PCIe configuration space.
**Usage Scenario:** This is useful for applications that implement Enhanced Configuration Address Mapping (ECAM) mechanism (Section 7.2.2 of the *PCI Express Base Specification, Revision 4.0, Version 1.0*).
**Feature Configuration:** To enable CFG shift feature, set the CFG_SHIFT_MODE field of the ATUCAP[1+i*18] register to ‘1’.

**(h) Address Match Invert:**

**Overview:** In normal operation an address match on an outbound TLP occurs when the untranslated address is in the region bounded by the base address and limit address. When the invert feature is enabled, an address match occurs when the untranslated address is not in the region bounded by the base address and limit address.
**Feature Configuration:** To enable Invert feature, set the INVERT_MODE field of the ATUCAP[1+i*18] register to ‘1’.

**(i) General Bypass:**

**Not supported.**

**(j) DMA Bypass:**

**Overview:** When you do not want the iATU to translate outbound requests that are generated by the DMA, you must implement one of the following approaches:

■ Ensure that the combination of DMA channel address programming and iATU control register programming causes no translation of DMA traffic to be done in the iATU, or (see below)

■ Enable the DMA bypass mode to allow request TLPs which are initiated by the embedded DMA controller to pass through the iATU untranslated.
**Feature Configuration:** To enable DMA bypass, set the DMA_BYPASS field of the ATUCAP[1+*i**18] register to '1'.

**(k) Function Number Translation Bypass**:

**Overview:** When function number translation bypass is enabled and region address is matched, the function number of the translated TLP is taken from your application transmit interface and not from the CTRL_1_FUNC_NUM field of the ATUCAP[0+*i**18] register.

**Feature Configuration:** To enable function number translation bypass, set the FUNC_BYPASS field of the ATUCAP[1+*i**18] register to '1'.

**(l) TLP Header Field Translation Bypass:**

**Overview:** When TLP header field bypass is enabled and region address is matched, header fields of the translated TLP are taken from your application transmit interface or, if AMBA is configured, from the AMBA sideband bus and not from the corresponding fields of the ATUCAP[0+*i**18] or ATUCAP[1+*i**18] registers. The header fields are TC, ATTR *(RO and NS)* fields.
**Feature Configuration:** To enable TLP header field bypass, set the TLP_HEADER_FIELDS_BYPASS field of the ATUCAP[1+*i**18] register to '1'.

**(m) Payload Inhibit:**

**Overview:** When payload inhibit is enabled and region address is matched, the iATU converts transactions with data payload to TLPs without payload data by forcing the TLP header Fmt[1] bit =0, regardless of the application inputs.
***Note**:* This feature is not supported for MemWr/IOWr with data payload greater than 1DW.

***Caution:** This feature must not be used for outbound transactions with data poisoning, because the EP bit will be set for TLPs without data payload, this is a violation of data poisoning rules defined in section "2.7.2.2. Rules For Use of Data Poisoning" of the PCI Express Base Specification.

**Usage Scenario:** This is useful for Vendor Defined Msg (without data); your application sends a MWr over the AXI interface but does not set the byte write enables to 0.
**Feature Configuration:** To enable payload inhibit, set the the INHIBIT_PAYLOAD field of ATUCAP[1+*i**18] _i to '1'.

**(n) Header Substitution:**

**Overview:** When header substitution is enabled and region address is matched, the iATU fully substitutes bytes 8-11 (for 3 DWORD header) or bytes 12-15 (for 4 DWORD header) of the outbound TLP header with the contents of the of LWR_TARGET_RW_OUTBOUND field in ATUCAP[5+*i**18].
***Note:** For a Vendor Defined Msg/MsgD having 4 DWORD header, when HEADER_SUBSTITUTE_EN =1, the 4th DWORD (bytes 12-15) is replaced with the contents of LWR_TARGET_RW_OUTBOUND field in the ATUCAP[5+*i**18] register. But regardless of the value of HEADER_SUBSTITUTE_EN, the 3rd DWORD is replaced with the contents of UPPER_TARGET_RW field in the ATUCAP[6+*i**18] register. So for a Vendor Defined Msg, BDF (or reserved) and Vendor ID must be programmed in UPPER_TARGET_RW.
**Usage Scenario:** This is useful for Vendor Defined Msg/MsgD and ATS transactions over the AXI bridge which is normally inefficient requiring a very large iATU region.

**Feature Configuration:** To enable header substitution, set the HEADER_SUBSTITUTE_EN field in ATUCAP[1+*i**18] register to '1'.

**(o) Tag Substitution:**

**Overview:** When tag substitution is enabled and region address is matched, the iATU substitutes the TAG field of the outbound TLP header with the contents of the TAG field in ATUCAP[1+*i**18].
ST substitution can still take place using the MSG_CODE field in ATUCAP[1+*i**18]. Your application must not attempt to perform TAG substitution for outgoing non-posted TLPs.
**Usage Scenario:** This is useful for translation from AXI MWr to Vendor Defined Msg/MsgD.
**Feature Configuration:** To enable tag substitution, set the TAG_SUBSTITUTE_EN field of the ATUCAP[1+*i**18] register to '1'.

### (5) Outbound Programming

This section discusses the register programming interface and provides details of programming examples.

**(a) iATU Outbound Programming Overview**

You can access the iATU registers through the DBI interface or through BAR Matched Mem/IO requests.
The following registers are used for programming the iATU.

Table 104.11 iATU Register Map

| Address | Label (i = 0 to CX_ATU_NUM_OUTBOUND_REGIONS-1) | Description |
|---|---|---|
| **0x000** | ATUCAP[0+*i**18] | Region Control 1 |
| **0x004** | ATUCAP[1+*i**18] | Region Control 2 |
| **0x008** | ATUCAP[2+*i**18] | Lower Base Address |
| **0x00C** | ATUCAP[3+*i**18] | Upper Base Address |
| **0x010** | ATUCAP[4+*i**18] | Limit Address |
| **0x014** | ATUCAP[5+*i**18] | Lower Target Address |
| **0x018** | ATUCAP[6+*i**18] | Upper Target Address |
| **0x01C** | ATUCAP[7+*i**18] | Region Control 3 |
| **0x020** | ATUCAP[8+*i**18] | Upper Limit Address |

**Table 104.12 iATU Register Address Bus Layout**

| Register Bit | 31-20 | 19 | 18-17 | 16-9 | 8 | 7-2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Value | Not used | 0 | Reserved | Region | Inbound/Outbound | Register Address | 0 | 1 |

**Table 104.13 Example: Address Table for Accessing iATU Outbound Region 1 Configuration Register**

| Address | Register | Register Bit Value | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| | | **31-20** | **19** | **18-17** | **16-9** | **8** | **7-2** | **1** | **0** |

| | | | | | | |
|---|---|---|---|---|---|---|
| 0x200 | Region Control 1 | 0 | 0 | 0 | 1 | 001 |
| 0x204 | Region Control 2 | 0 | 0 | 0 | 1 | 005 |
| 0x208 | Lower Base Address | 0 | 0 | 0 | 1 | 009 |
| 0x20C | Upper Base Address | 0 | 0 | 0 | 1 | 00D |
| 0x210 | Limit Address | 0 | 0 | 0 | 1 | 011 |
| 0x214 | Lower Target Address | 0 | 0 | 0 | 1 | 015 |
| 0x218 | Upper Target Address | 0 | 0 | 0 | 1 | 019 |

**(b) Outbound iATU Programming Example**

Define Outbound Region 1 as:
64 kB I/O region from 0x80000000_d0000000 to 0x80000000_d000ffff, to be mapped to 0x00010000 in the PCIe I/O space.

1. Setup the Region Base and Limit Address Registers.
   Write 0xd0000000 to Address {0x208} to set the Lower Base Address.
   Write 0x80000000 to Address {0x20C} to set the Upper Base Address.
   Write 0xd000ffff to Address {0x210} to set the Limit Address.
2. Setup the Target Address Registers.
   Write 0x00010000 to Address {0x214} to set the Lower Target Address.
   Write 0x00000000 to Address {0x218} to set the Upper Target Address.
3. Configure the region through the Region Control 1 Register.
   Write 0x00000002 to Address {0x200} to define the type of the region to be I/O.
4. Enable the region.
   Write 0x80000000 to Address {0x204} to enable the region.

### 104.3.8 Inbound (Data Transfer from External Device → PCIEC → Internal Bus)

This section describes Inbound. With Inbound, the device on the PCI Express accesses the device on the internal bus of this module through a PCI Express request packet.

#### (1) Inbound Features

Number of Inbound Address Translation Regions is 16.

Address translation is used for mapping different address ranges to different memory spaces supported by your application. A typical example maps your application memory space to PCI memory space. The iATU supports type translation. Without address translation, your application address is passed from the TLPs directly through the TRGT1 application interface. You can program the iATU to implement your own inbound address translation scheme without external logic.

- ■ Programmable Match mode operation for MEM, I/O, CFG, and MSG TLPs. No translation for completions.
- ■ Selectable BAR Match mode operation for I/O and MEM TLPs.
  - ❑ TLPs destined for the internal CDM (or ELBI) in an upstream port are not translated.
  - ❑ TLPs that are not error-free (ECRC, malformed and so on) are not translated.
- ■ Selectable VF BAR Match mode operation for I/O and MEM TLPs which target VF BARs.
  - ❑ The VF BAR match mode enables all VFs in a PF which match a BAR to be matched with a single ATU region instead of an ATU region per VF.
- ■ Programmable TLP header field matching.
  - ❑ TYPE/TD/TC/AT/ATTR/MSG-Code.
  - ❑ Function Number.
- ■ Multiple (up to 256) address regions programmable for location and size.
- ■ Programmable enable/disable per region.
- ■ Automatic FMT field translation between three DWORDs and four DWORDs for 64-bit addresses.
- ■ Invert Address Matching mode to translate accesses outside of a successful address match.
- ■ ECAM Configuration Shift mode to allow a 256 MB CFG1 space to be located anywhere in the 64-bit address space.
- ■ Supports regions from 4 KB to 16 ZB in size. The minimum and maximum region sizes are determined by CX_ATU_MIN_REGION_SIZE and CX_ATU_MAX_REGION_SIZE. Smaller region sizes consume extra decode logic.
  For AXI, this feature is applicable only when SLAVE_BUS_ADDR_WIDTH =64; If SLAVE_BUS_ADDR_WIDTH <64, CX_ATU_MAX_REGION_SIZE is restricted to 4GB.
- ■ Single Address Location to allow all TLPs to be translated to a single address location.
- ■ Msg Type Match Mode to allow matching of any TLP of type Message.

***Note:** The default behavior of the ATU when there is no address match in the outbound direction or no TLP attribute match in the inbound direction, is to pass the transaction through.

#### (2) Inbound Limitations

■ Generation of ATS requests and messages not supported (no facility to insert NW and iTAG fields).

#### (3) Inbound Basic Operation

This section discusses how the iATU processes inbound requests. The topics are:

■ “Overview”

■ “I/O and MEM Match Modes”.

**(a) Overview**

***Note:** ■ The main difference between inbound and outbound iATU operation is that the TLP type is never changed in the inbound direction. Instead, the type field is used for more precise matching. Other fields can also be optionally used to further refine the matching process.

■ Another difference is that for MEM and I/O TLPs, you can select between address matching (as used in outbound operation) or BAR matching. Normally, an endpoint uses BAR match mode, and a root complex uses address mode as a root complex normally does not implement BARs.

The following translation rules and limitations apply:

■ When there is no match, then the address is untranslated. In addition

■ TLPs destined for the internal CDM or ELBI in an upstream port are not translated.

■ TLPs that are not error-free (ECRC, malformed and so on) are not translated.

■ Address translation of all TLP types (MEM, I/O, CFG, and MSG) except completion is supported in Address Match mode. In BAR Match mode, only translation of I/O and MEM is supported.

The setting of the MATCH_MODE field in ATUCAP[10+I*18] determines how iATU inbound matching is done for each TLP type.

**Table 104.14 Determination of Match Mode**

| TLP Type | MATCH_MODE=0 | MATCH_MODE=1 |
|---|---|---|
| MEM or I/O | Address Match Mode | BAR Match Mode |
| CFG0 | Routing ID Match Mode | Accept Mode |
| MSG/MSGD | Address Match Mode | Vendor ID Match Mode |

**(b) I/O and MEM Match Modes**

Inbound address translation for I/O and MEM TLPs operates in one of two matching modes as determined by the “Inbound Match Mode” field in the ATUCAP[10+I*18] register.

**Address Match Mode**: The operation is similar to “Outbound Basic Operation (Address Match Mode)”. The address field of each request TLP is checked to see if it falls into any of the enabled address regions as shown in Figure 104.9. When an address match is found then the TLP address field is modified as follows:

Address = Address - Base Address + Target Address

When the TLP address field matches more than one of the CX_ATU_NUM_INBOUND_REGIONS address regions, then the first (lowest of the numbers from 0 to CX_ATU_NUM_INBOUND_REGIONS -1)enabled region to be matched is used.

**BAR Match Mode**

Looking for an address match is a two-step process.

1. The standard internal PCI Express BAR Matching Mechanism checks if the address field of any MEM and I/O request TLP falls into any address region defined by the enabled BAR addresses and masks.

2. When a matched BAR is found, then the iATU compares the BAR ID to the BAR Number field in the ATUCAP[10+I*18] register for all enabled regions. Figure 104.9 and Figure 104.10 below provide more details on inbound translation in BAR Match Mode.

****Attention:** BAR Match Mode can only be used for MEM and I/O transactions.*

When the PCIe controller is operating with 64-bit BARs, the operation is defined as in Figure 104.9 on where * is log2(BAR_MASK+1).

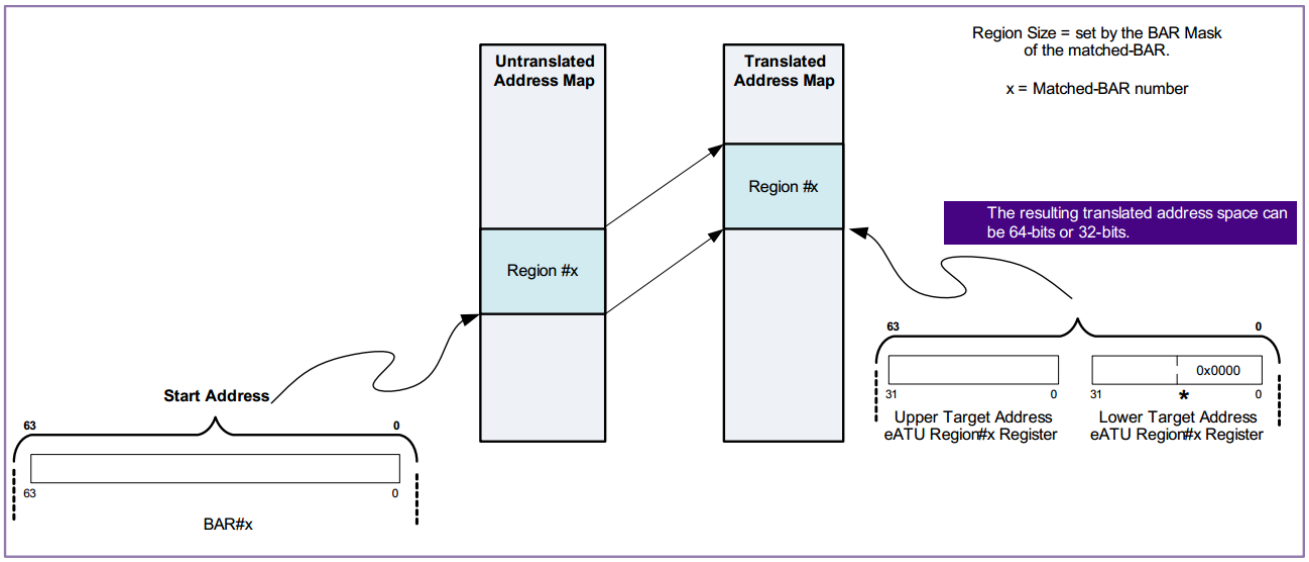

**Figure 104.9 iATU Address Region Mapping: Inbound (BAR Match Mode), 64-bit BAR**

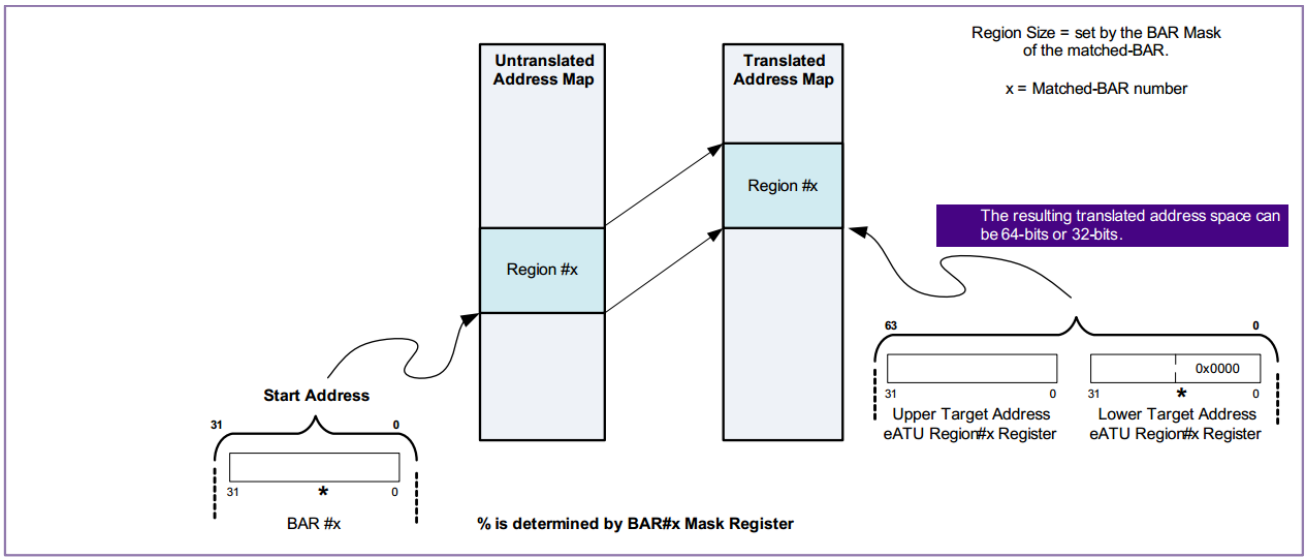
In address match mode, when the address range does not match one of its BAR ranges in an upstream port, then the device rejects the request with unsupported request (UR) completion status and no translation occurs. When the PCIe controller is operating with 32-bit BARs, the operation is defined as in Figure 104.10

**Figure 104.10 iATU Address Region Mapping: Inbound (BAR Match Mode), 32-bit BAR**



### (4) Inbound Detailed Operation

The following advanced topics are discussed:

- “Single Address Location”.
- “CFG Handling (Upstream Port)”.
- “Optional Matching Fields”.
- “Response Code Feature”.
- “iATU Inbound MSG Handling”.

- “Msg Type Match Mode”.
- “Fuzzy Type Match Mode”.
- “FMT Translation”.
- “Invert Feature”.

**(a) Single Address Location**

When enabled and region address is matched, the TLPs can be translated to a single address location as determined by the target address register of the iATU region. This feature can be enabled using the SINGLE_ADDR_LOC_TRANS_EN field in ATUCAP[10+i*18]. This feature is useful for translating messages when AXI bridge is enabled.

**Received Message TLP Header Bytes 8 - 15 at TRGT1 Interface**

Bytes 8 to 15 of the received TLPs header destined for TRGT1 are made available on radm_trgt1_hdr_uppr_bytes irrespective of TLP translation. When radm_trgt1_hdr_uppr_bytes_valid is asserted your application should use radm_trgt1_hdr_uppr_bytes along with radm_trgt1_data.The radm_trgt1_hdr_uppr_bytes_valid is set only when an ATU match occurs for Single Address Location enabled region.
For example, if a received MsgD matches a Single Address Location enabled ATU region, bytes 8 to 15 of the MsgD header are available on radm_trgt1_hdr_uppr_bytes when radm_trgt1_hdr_uppr_bytes_valid is asserted, and radm_trgt1_hv is true. The available radm_trgt1_hdr_uppr_bytes can be concatenated with radm_trgt1_data and used by your application.

*Note: The width of radm_trgt1_ hdr_uppr_bytes is FLT_Q_ADDR_WIDTH bits. For radm_trgt1_hdr_uppr_bytes[63:32] to exist FLT_Q_ADDR_WIDTH must be 64. If 32 < FLT_Q_ADDR_WIDTH < 64, radm_trgt1_hdr_uppr_bytes[FLT_Q_ADDR_WIDTH-1:32] = 0.

**(b) CFG Handling (Upstream Port)**

The controller normally routes CFG TLPs (to the internal CDM or ELBI) without translation. The iATU only translates CFG0 TLPs that the controller has routed to the TRGT1. Inbound address translation for CFG0 TLPs operates in one of two matching modes as determined by the Inbound CFG0 MATCH_MODE field in the ATUCAP[10+i*18] register.

**Accept Mode**

The controller always accepts CFG0 TLPs even when the CFG bus number does not match the current bus number of the device. This mode follows that behavior. The routing ID of received CFG0 TLPs are ignored when determining a match.

**Routing ID Match Mode**

The operation is similar to “Outbound Basic Operation (Address Match Mode)”. The routing ID of the inbound CFG0 TLP must fall within the Base and Limit of the defined iATU region for matching to proceed. The iATU interprets the routing ID (Bytes1 8-11 of TLP header) as an address. This corresponds to the upper 16 bits of the address in MEM and I/O transactions.

**CFG Shift Feature**

Inbound CFG transactions routed to the Rx application interface can exist anywhere in address space, because the PCIe controller filter processes the routing ID (BDF) as bits [31:16] of an address. This BDF changes according on the PCIe bus topology. A compressor feature (CFG Shift Feature) can be enabled by setting the CFG Shift bit in the ATUCAP[10+i*18] register. Bits [15:12] of the third DWORD1 of CFG TLPs are reserved. The compressor feature uses this fact to reduce the memory requirement. This shifts/maps the BDF (bits [31:16] of the third header DWORD, which would be matched against the Base and Limit addresses) of the incoming CfgRd0/CfgWr0 down

to bits[27:12]of the translated address.

**CFG1 Transactions**
For CfgRd1/CfgWr1 transactions, the base and limit addresses could enclose the entire 32-bit 4GB memory space with the routing ID forming the upper 16 bits. The target address maps these CFG transactions to anywhere in application address space.

**(c) Optional Matching Fields**
In address and BAR match modes, a successful address/BAR match can be optionally gated by successful matching of the following programmable TLP header fields (per region):

- TD/TC/AT/ATTR/TH/PH/ST.
- MSG Code (MSG TLPs only).
- Function number (MEM, I/O, or CFG TLPs only).
- Virtual function number (MEM or I/O TLPs only).

For each of the previous fields in the ATUCAP[9+i*18] register, there is an associated Match Enable bit in the ATUCAP[10+i*18] register. Address translation only proceeds when compares on all enabled field are successful.

**(d) Response Code Feature**
When the Response Code field of the ATUCAP[10+i*18] register is set to a value other than 00, the controller uses it to determine the completion status field of completion TLPs sent in response to successfully matched non-posted TLPs. This can be set to unsupported request (UR) or completer abort (CA). When the error response field is set to 2b00, then the normal receive filter response for this TLP is used.

***Note:** Response Code feature is not available in regions where Single Address Location Enable is set.

**(e) iATU Inbound MSG Handling**
Inbound message (Msg/MsgD) transactions can use one of two matching modes:

- **Address Match Mode**
  The third and fourth header DWORDs are treated as an address and are compared against the iATU Region Base and Limit Address registers. For vendor defined messages this allows specific messages to be filtered into memory at the target address. The Upper Base address should be set to Bus Device Function (BDF) and Vendor ID. The Lower Base address can be used as a filter for specific messages.
- **Vendor ID Match Mode**
  This mode is relevant for ID-routed vendor defined messages. The iATU ignores the routing ID (BDF) in bits [31:16] of the third DWORD of the TLP header1, but compares it against the vendor ID in bits [15:0] of the third DWORD of the TLP header (bytes1 10 and 11). This allows vendor defined messages to be filtered against specific vendor IDs without needing to know the BDF number which might vary depending on the PCI topology. Bits [15:0] of the Region Upper Base register should be programmed with the required vendor ID as follows:
  Region Upper Base[15:8] =byte 10
  Region Upper Base[7:0] =byte 11
  The lower base and limit register should be programmed to translate TLPs based on vendor-specific information in the fourth DWORD of the TLP header.

■ For a proper understanding of messages, you should be familiar with Section 2.2.8, Message Request Rules of the PCI Express Base Specification.

**(f) Msg Type Match Mode**

Inbound message (Msg/MsgD) transactions can also use Msg Type matching mode. When this mode is enabled and “Single Address Location” is enabled, the iATU matches Msg TLP Type field with TYPE field of ATUCAP[9+i*18] register.
If “Fuzzy Type Match Mode” is also enabled, then any Msg received is matched (that is, Msg Type's sub-field r[2:0], which specifies the Message routing mechanism, is ignored).

****Caution:** The Message should be consumed by your application before the next message arrives as all messages go to the same address.

***Note:** If SINGLE_ADDR_LOC_TRANS_EN is set for any region, then you must ensure that the same TLP cannot be matched in any other region where SINGLE_ADDR_LOC_TRANS_EN is not set. If this *happens radm_trgt1_hdr_uppr_bytes* could have incorrect data.

**(g) Fuzzy Type Match Mode**

When enabled, the iATU relaxes the matching of the TLP type field against the expected type field so that:

- CfgRd0 and CfgRd1 TLPs are seen as identical. Similarly with CfgWr0 and CfgWr1.
- MWr, MRd and MRdLk TLPs are seen as identical.
- The routing field of MsgD TLPs is ignored.
- Atomic Ops TLPs - FetchAdd, Swap, and CAS are seen as identical.

For example, CFG0 in the type field in ATUCAP[9+*i**18] register matches against an inbound CfgRd0, CfgRd1, CfgWr0, or CfgWr1 TLP. To enable this feature, set the Fuzzy Type Match Mode bit of the ATUCAP[10+i*18] register.

**(h) FMT Translation**

The iATU automatically sets the TLP format field for three DWORDs when it detects all zeroed in the upper 32 bits of the translated address. Otherwise it sets it to four DWORDs when it detects a 64-bit address (when there is a 1 in the upper 32 bits of the translated address). When the original address and the translated address are of a different format then the iATU ensures that the TLP header size matches the translated address format.

**(i) Invert Feature**

Normally an address match on an inbound TLP occurs when the untranslated address is in the region bounded by the Base address and Limit address. When the Invert feature is activated, an address match occurs when the untranslated address is not in the region bounded by the Base address and Limit address. This feature is activated by setting the INVERT_MODE field of the ATUCAP[10+i*18] register.

## (5) Inbound Programming

This section discusses the register programming interface and provides details of programming examples.

**(a) iATU Inbound Programming Overview**

You can access the iATU registers through the DBI interface or through BAR Matched Mem/IO requests.
The following registers are used for programming the iATU.

**Table 104.15 iATU Register Map**

| Address | Label (i=0 to CX_ATU_NUM_INBOUND_REGIONS-1) | Description |
|---|---|---|
| 0x100 | ATUCAP[9+*i**18] | Region Control 1 |
| 0x104 | ATUCAP[10+*i**18] | Region Control 2 |
| 0x108 | ATUCAP[11+*i**18] | Lower Base Address |
| 0x10c | ATUCAP[12+*i**18] | Upper Base Address |
| 0x110 | ATUCAP[13+*i**18] | Limit Address |
| 0x114 | ATUCAP[14+*i**18] | Lower Target Address |
| 0x118 | ATUCAP[15+*i**18] | Upper Target Address |
| 0x11C | ATUCAP[16+*i**18] | Region Control 3 |
| 0x120 | ATUCAP[17+*i**18] | Upper Limit Address |

**Table 104.16 iATU Register Address Bus Layout**

| **Register** | **31-20** | **19** | **18-17** | **16-9** | **8** | **7-2** | **1** | **0** |
|---|---|---|---|---|---|---|---|---|
| Value | Not used | 0 | Reserved | Region | Inbound/Outbound | Register Address | 0 | 1 |

**Table 104.17 Example: Address Table for Accessing iATU Inbound Region 1 Configuration Registers**

| **Address** | **Register** | **Register Bit Value** | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| | | **31-20** | **19** | **18-17** | **16-9** | **8** | **7-2** | **1** | **0** |
| 0x300 | Region Control 1 | 0 | 0 | 0 | 1 | 101 | | | |
| 0x304 | Region Control 2 | 0 | 0 | 0 | 1 | 105 | | | |
| 0x308 | Lower Base Address | 0 | 0 | 0 | 1 | 109 | | | |
| 0x30C | Upper Base Address | 0 | 0 | 0 | 1 | 10D | | | |
| 0x310 | Limit Address | 0 | 0 | 0 | 1 | 111 | | | |
| 0x314 | Lower Target Address | 0 | 0 | 0 | 1 | 115 | | | |
| 0x318 | Upper Target Address | 0 | 0 | 0 | 1 | 119 | | | |
| 0x31C | Region Control 3 | 0 | 0 | 0 | 1 | 11D | | | |
| 0x320 | Upper Limit Address | 0 | 0 | 0 | 1 | 121 | | | |

**(b) Inbound Programming Examples**

*Address Match Mode Example*

Define Inbound Region 0 as, MEM region matching TLPs with addresses in the range 0x00010000 to 0x0005ffff mapped to 0x1000_0000_2000_0000 - 0x1000_0000_2004_ffff in your application memory space.

1. Setup the Region Base and Limit Address Registers.
   Write 0x00010000 to Address {0x108} to set the Lower Base Address.
   Write 0x00000000 to Address {0x10C} to set the Upper Base Address.
   Write 0x0005ffff to Address {0x110} to set the Limit Address
2. Setup the Target Address Registers.
   Write 0x20000000 to Address {0x114} to set the Lower Target Address.
   Write 0x10000000 to Address {0x118} to set the Upper Target Address.
3. Configure the region through the Region Control 1 Register.
   Write 0x00000000 to Address {0x100} to define the type of the region to be MEM.
4. Enable the region.
   Write 0x80000000 to Address {0x104} to enable the region in address match mode.

*BAR Match Mode Example*

Define Inbound Region 2 as MEM region matching BAR4 (BAR match mode) mapping to 0x8000_0000_2000_0000 in your application memory space.

1. Setup the Target Address Registers.
   Write 0x20000000 to Address {0x514} to set the Lower Target Address.
   Write 0x80000000 to Address {0x518} to set the Upper Target Address.

2. Configure the region through the Region Control 1 Register.
   Write 0x00000000 to Address {0x500} to define the type of the region to be MEM.

3. Enable the region for BAR Match Mode.
   Write 0xC0000400 to Address {0x504} to enable the region for BAR match mode for BAR#4.

**Note**: Default number of inbound regions is 2 (CX_ATU_NUM_INBOUND_REGIONS), so region 2 is not accessible by default.

****Attention:* EP port**: Defined MEM or I/O regions must be inside an enabled BAR range.
**RC port**: Defined MEM or I/O regions must either match a BAR or be outside of the base and limit ranges defined for the port in the Type 1 configuration header.

### 104.3.9 DMA Transfer

This section describes the DMA transfer using the DMAC (PCIEC-DMAC) incorporated in this module.

#### (1) Overview of DMA Transfer

The RC system CPU, or the EP application CPU, can offload the transferring of large blocks of data to the embedded DMA controller, leaving the CPU free to perform other tasks. You can configure the DMA to have one to eight read channels and one to eight write channels. It can simultaneously perform the following types of memory transactions (as shown in Figure 104.12):

- **DMA write**
  Transfer (copy) of a block of data from local (application) memory to remote (link partner) memory.

- **DMA read**
  Transfer (copy) of a block of data from remote (link partner) memory to local (application) memory.

Therefore the DMA supports full duplex operation, processing read and write transfers at the same time, and in parallel with normal (non-DMA) traffic. Upon completion of a DMA transfer or an error, the DMA optionally interrupts the local CPU or sends an interrupt MWr (IMWr) to the remote CPU. The DMA is highly configurable and you can program it using the local DBI or over the PCIe wire.

In linked list mode, the DMA fetches the transfer control information (called channel context) for each transfer (block), from a list of DMA elements that you have constructed in local memory.

Table 104.18 identifies the limitations when using the DMA module.

PCIEC-DMAC has features shown in Table 104.18.

**Table 104.18 DMA Module Features**

| No | DMA Module Feature | Support | Note |
|---|---|---|---|
| 1 | Number of Read Channels | 8 ch | |
| 2 | Number of Write Channels | 8 ch | |
| 3 | AXI Support | Y | |
| 4 | Native Controller Support (no AXI) | N | Not support |

| 32 | Automatic Flushing of Slave (AXI Configurations) When Link is Not Up | Y | Independent on implementation setting. |

**Table 104.19 DMA Module Limitations**

| Limitation | Note |
|---|---|
| Memory DMA Traffic Only | I/O and Type 0 or Type 1 configuration DMA transfers are not supported. |

### (2) Architecture Overview

A DMA write and read channel operate independently to maximize the performance of the DMA read and write data transfers over the PCIe link. When you configure the DMA with multiple read channels, then it uses a weighted round robin (WRR) arbitration scheme to select the next read channel to be serviced. The same applies when you have multiple write channels.

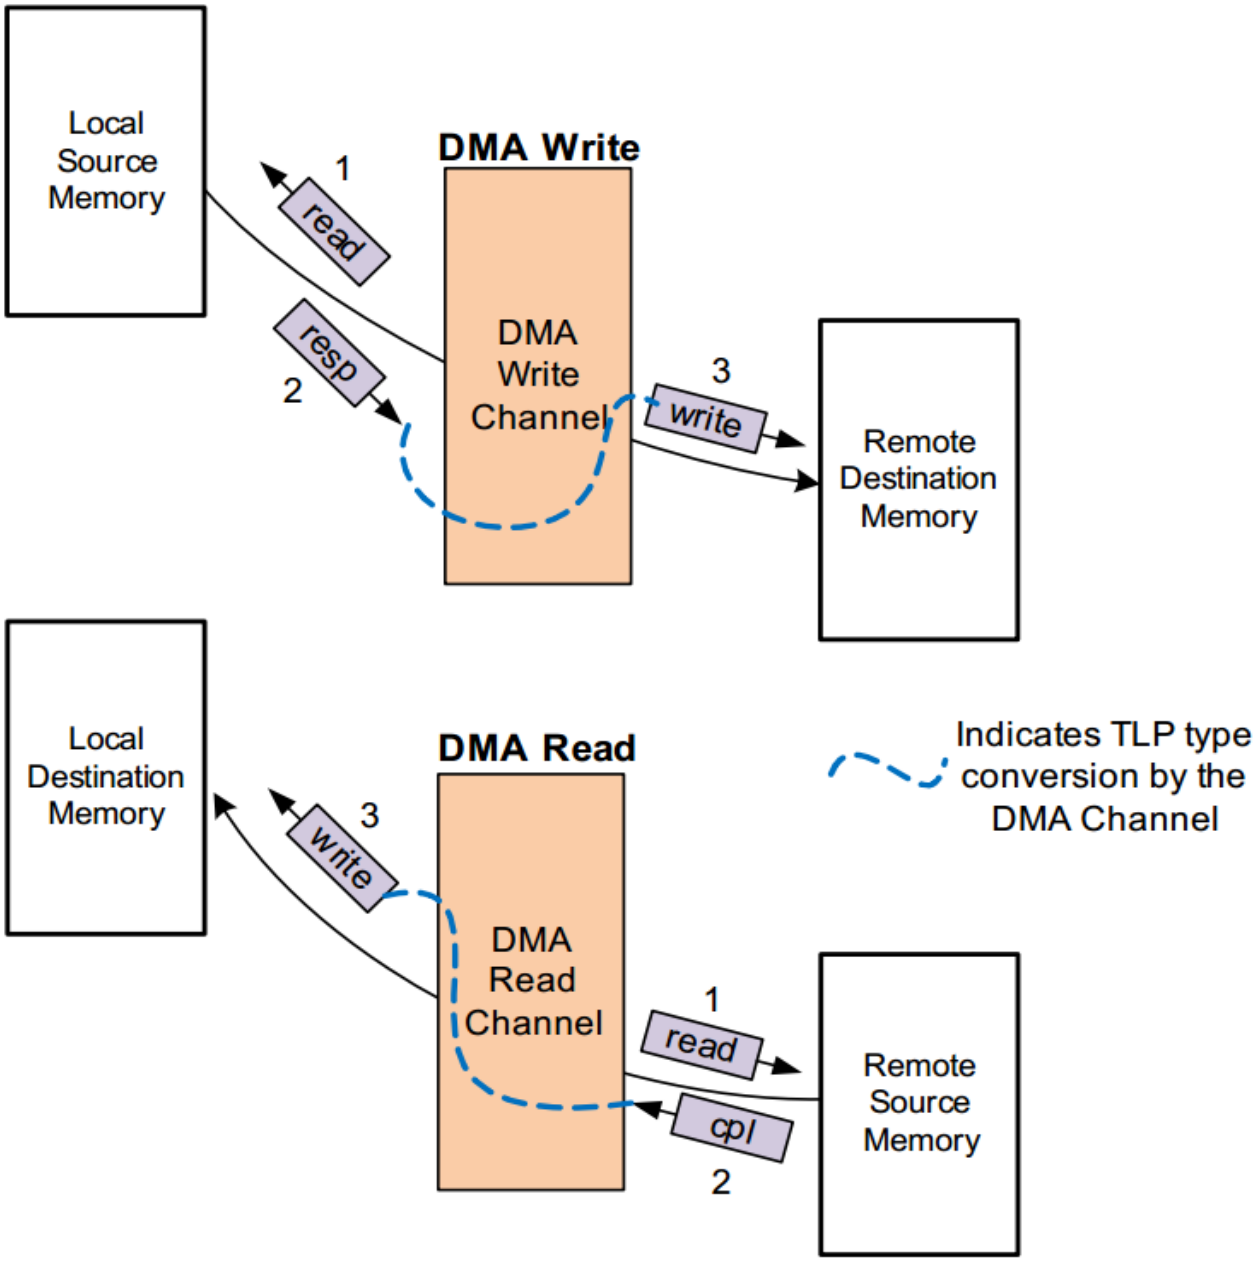

**Figure 104.12 System Level View of DMA**

**DMA Write Transfer**

The DMA injects multiple MRd requests of size less than or equal to Max_Payload_Size into the inbound request path, directed toward the local application. The DMA converts the read responses into MWr TLPs that it then transmits to the remote link partner. When the DMA data transfer is complete the CPU is notified. For more details, see “Interrupts and Error Handling”. For a write transfer, the SAR is the address of the local memory, and the DAR is the address of the remote memory.

**DMA Read Transfer**

The DMA injects multiple MRd requests of size less than or equal to the minimum of {Max_Read_Request_Size, Max_Payload_Size} into the outbound request path, directed toward the remote link partner. The DMA converts the read responses into write requests that it then transmits to the local application. When the DMA data transfer is complete, the CPU is notified. For more details, see “Interrupts and Error Handling”. For a read transfer, the SAR is the address of the remote memory, and the DAR is the address of the local memory.

**RAM Requirements**

The DMA requires two RAMs.

**Registers and Context Memory**

You program each DMA transfer (channel) using the registers described in “DMA Software Register Map”. The registers that are specific to each channel are called the channel context registers. As the transfer progresses, the DMA updates these registers. You program the channel context information and other DMA control registers directly with the local CPU through the DBI or remotely over the PCIe link.

Some of the registers are implemented in a high-speed wide interface context RAM. If you implement your RAMs external to the PCIe controller, you must connect this RAM through the external RAM interfaces.

### (3) Interrupts and Error Handling

The registers referenced in Figure 104.13 and Figure 104.14 that are related to error and interrupt handling are described in “DMA Software Register Map”.
The DMA generates two interrupts per channel:

- **Done**: The DMA successfully completes the transfer.
- **Abort**: The DMA fails to complete the transfer, or an error occurs during the transfer.

The interrupts are signaled to the software on your CPU, using one or both of the following mechanisms:

- Locally through the edma_int[CC_NUM_DMA_RD_CHAN+CC_NUM_DMA_WR_CHAN-1:0] bus.
- Remotely using a posted memory write (IMWr), which can be interpreted as an MSI when directed toward the RC.
  - There are two programmable IMWr addresses per channel, one each for the done and abort interrupts. For MSI, you must program all IMWRr address registers with the same MSI address, as PCIe only supports a single MSI address per function.
  - A single IMWr data register is used for both types of interrupts, so you must read DMACAP23 (or DMACAP10) to identify the interrupt type.
- The relaxed ordering (RO) bit is automatically set to zero in the TLP header of all IMWr’s so that subsequent MWr TLPs do not arrive at the remote device before the IMWr.

The interrupt handling mechanism is different for linked list (LL) mode (than non LL mode), and there are also some differences between the read and write channels.

**Non Linked List Mode Interrupt Handling**

You enable the local and remote interrupts through the local and remote interrupt enable (LIE and RIE) bits: DMACAP[37+i*16].LIE and DMACAP[37+i*16].RIE.

In the write channel, there is only one error condition that results in an abort interrupt. For more details, see “Linked List Mode”. You mask, clear, and read the status of each of the two interrupts (done and abort) through the DMA interrupt registers as indicated in Figure 104.13.
In the read channel, there are five error conditions that results in an abort interrupt. For more details, see “Linked List Mode”. You mask and clear each of the two interrupts (done and abort) through the DMA interrupt registers as indicated in Figure 104.14. However, you can read the status of each of the five abort errors (that contribute to the abort interrupt) through DMACAP26 and DMACAP27.

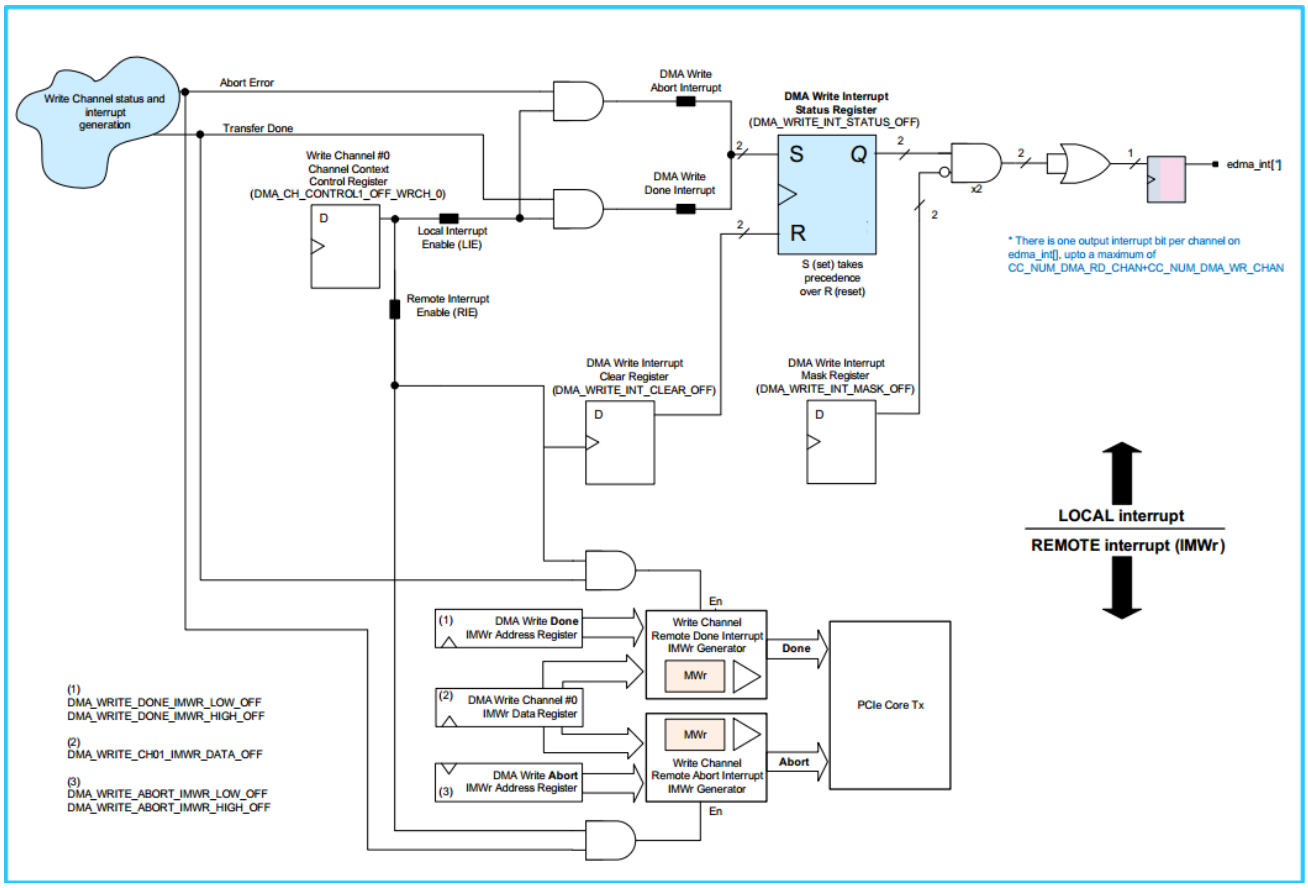

**Figure 104.13 Write Interrupt Generation - Non Linked List Mode - Shown For Write Channel #0**

****Hint:** If you want a remote interrupt and not a local interrupt then:

- Set LIE and RIE
- Mask the local interrupt using the mask register

This allows you to poll the status register to distinguish a DONE from an ABORT.

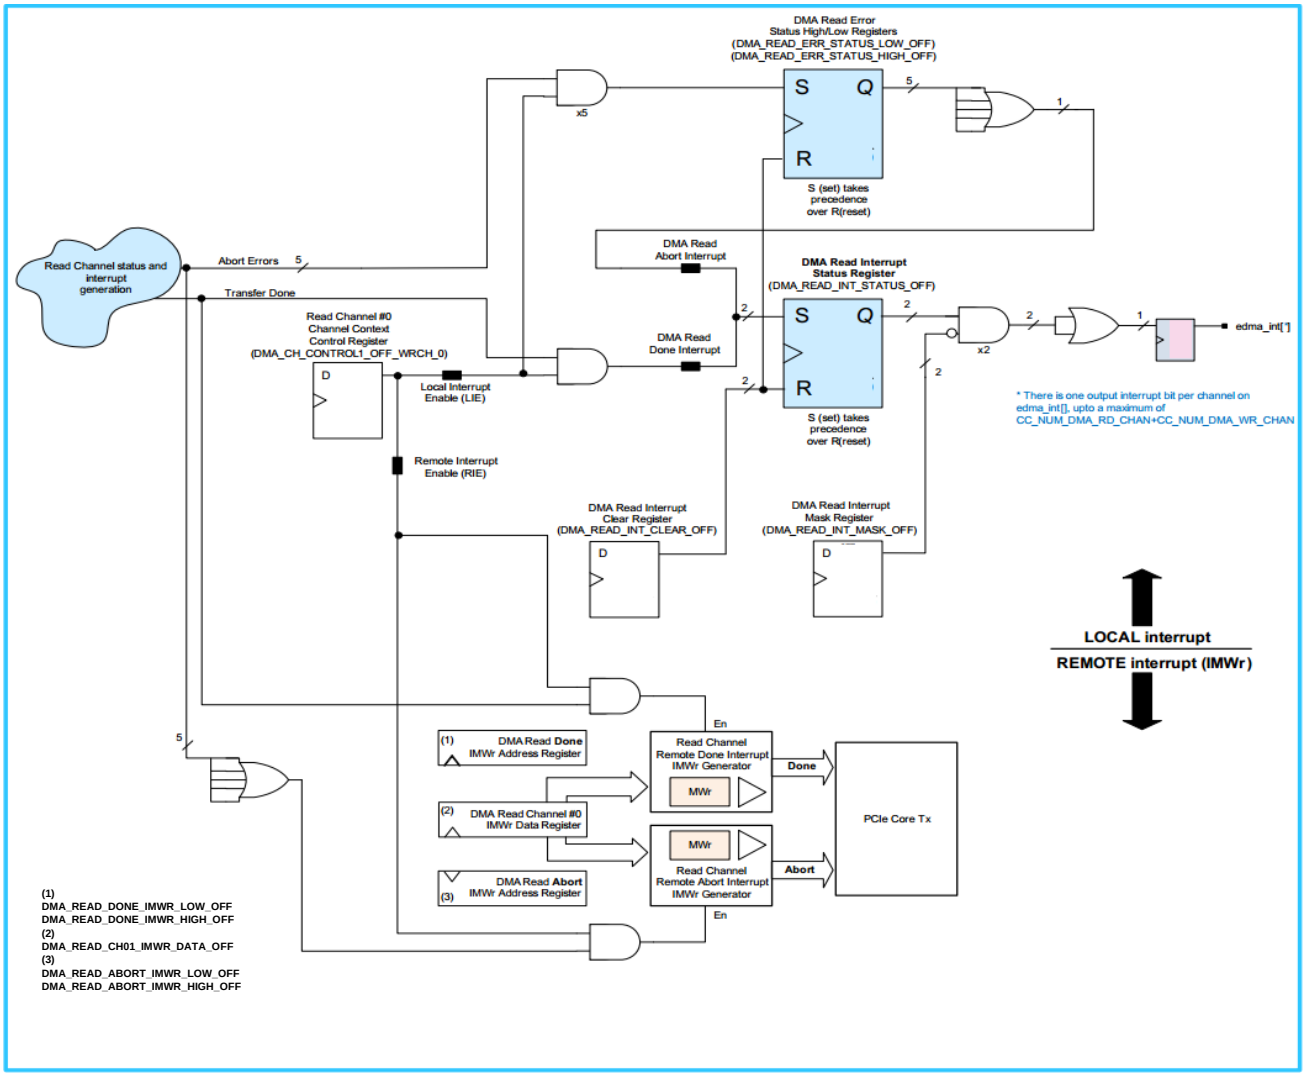

**Figure 104.14 Read Interrupt Generation - Non Linked List Mode - Shown For Read Channel #0**

### Linked List Mode Interrupt Handling

The LIE and RIE bits in the LL element enable the channel done interrupts (local and remote). The LLLAIE and LLRAIE bits of the DMACAP22/ DMACAP28 registers enable the channel abort interrupts (local and remote). In the write channel, there are two error conditions that results in an abort interrupt. For more details, see “Linked List Mode”. You mask and clear each of the two interrupts (done and abort) through the DMA interrupt registers as indicated in Figure 104.15. You can read the status of each of the two abort errors (that contribute to the abort interrupt) through the DMACAP13 register.

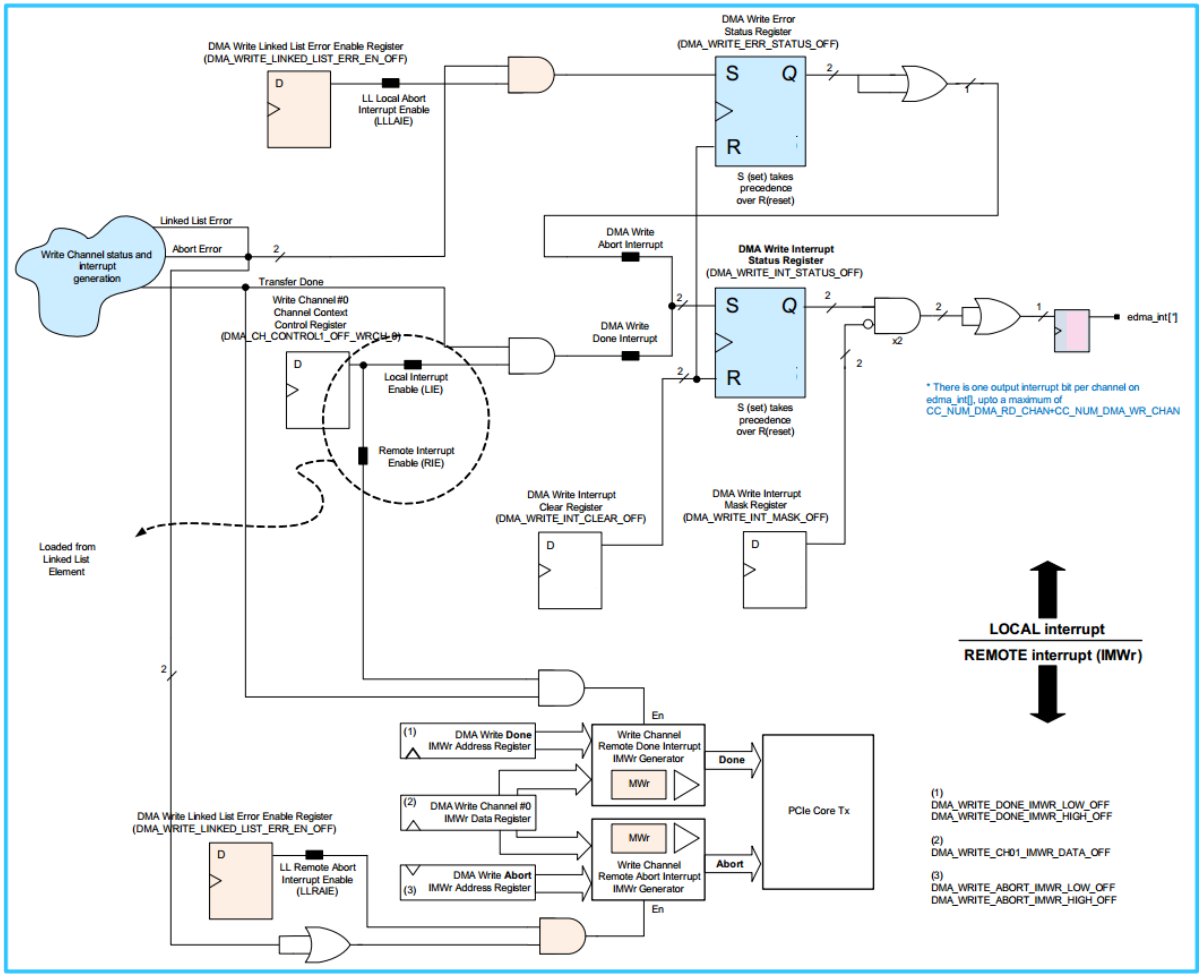

**Figure 104.15 Write Interrupt Generation - Linked List Mode - Shown For Write Channel #0**

In the read channel, there are six error conditions that results in an abort interrupt. For more details, see “Linked List Mode. You mask and clear each of the two interrupts (done and abort) through the DMA interrupt registers as indicated in Figure 104.16. You can read the status of each of the six abort errors (that contribute to the abort interrupt) through the DMACAP26 and DMACAP27 registers.

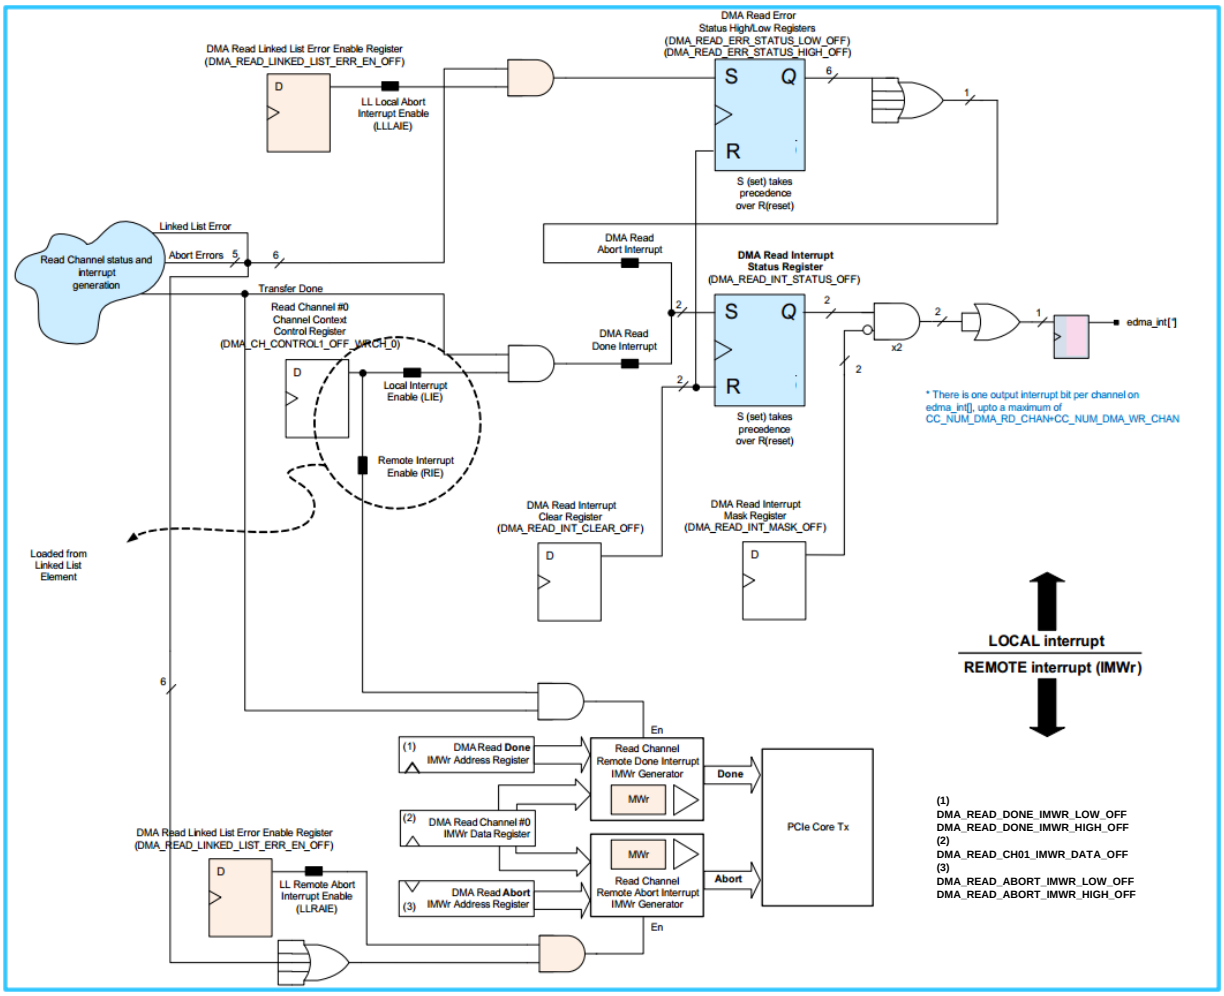

**Figure 104.16 Read Interrupt Generation - Linked List Mode - Shown For Read Channel #0**

***Note:** In non-linked list mode, LIE acts as a global switch. However when in linked list mode, LIE is just local to the current linked list element and the global switch is LLLAIE.

****Attention: Software Programming of an Endpoints LIE and RIE Bits for Linked List Transfers.** If the DMA driver is running on the host and the interrupt service routine is reading local interrupts to determine if the transfer is successful, then you must set LIE and RIE in the same element and you should mask or ignore the local interrupt pin. Setting RIE and LIE in element A followed by RIE (only) in element B is not a verified usage scenario.

### (4) Linked List Mode

The DMA provides a linked list (LL) mode to efficiently move data from source to destination with minimal intervention from the local CPU. This mode provides an alternative to programming the DMA multiple times to transfer multiple blocks of data. The programming information (address, size, and so on) for each block of memory is pre-programmed by your software into a LL element (also known as a descriptor) in local memory. Each element (called a data element) in the LL structure (called a transfer list) can transfer up to 4GB of data.

You enable LL operation for a channel, by setting the LLE field of the DMACAP[37+*i**16] register to 1. You can enable LL mode independently for each channel. When you enable LL for more than one channel, then you must have a separate LL structure in local memory for each channel. Your application must produce the LL element structure in local memory as shown in Figure 104.17. Normally, all of the elements are contiguous (one after the other) in memory, and each element has six DWORDs containing the information about the block of data to be transferred. You program the channel context

registers (DMACAP[43+i*16] and DMACAP[44+i*16]) with the location of where you have placed the LL element structure in local memory.

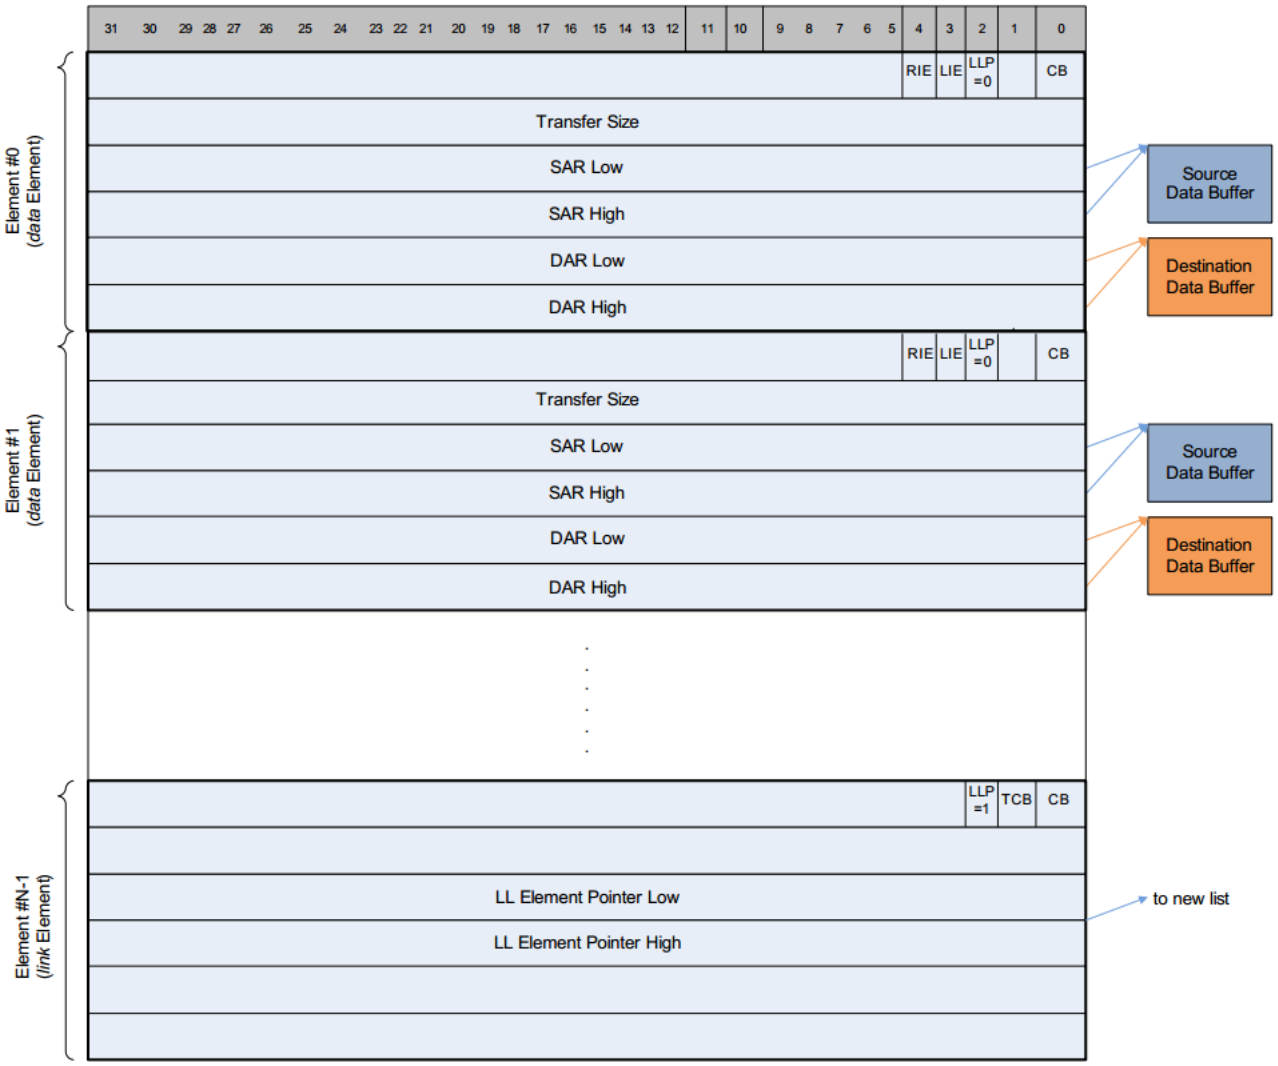

**Figure 104.17 Linked List Element/Descriptor Structure in Local Memory with N Elements.**

When you start the DMA transfer (by writing to the DMA Write Doorbell Register DMACAP3 or DMA Read Doorbell Register DMACAP7), the DMA read (consumes) each element from local memory, and loads the information (SAR, DAR, size, and so on) from that element into the channel context registers in the DMA. These channel context registers determine the operation of the channel that the DMA controller is currently servicing. The DMA then proceeds to transfer the block of data (as defined by the element), and when it is finished, reads the next element from local memory. Normally, all of the elements are contiguous (one after the other) in memory, with the starting address defined in the channel context DMA Linked List Pointer Low Register DMACAP[43+i*16].

When you want to jump in local memory to another element list (or recycle the consumed elements), then you set the LLP bit in the element (for example, link element #N-1 in Figure 104.17), specify the location of the next element structure using the LL Element Pointer DWORDs (as indicated in Figure 104.17), and, set TCB to 1 (for recycling) or to 0 (to jump to another list).

**Relationship Between Element DWORDs and Channel Context Registers**

Notice the similarity between a data element and the DMA Channel Context registers for each channel. Each element has six DWORDs as in Figure 104.17. There are eight channel context registers (DWORDs) for a channel. The DMA loads the six element DWORDs into the following channel context:

- CB, LLP, LIE, and RIE fields of the DMA Channel Control 1 register.

- DMA Transfer Size.
- DMA SAR Low and DMA SAR High.
- DMA DAR Low and DMA DAR High

The definitions of the element DWORD bit fields are the same as the DMA Channel Context registers described in the “DMA Software Register Map”, with the exception of the LIE and RIE bits. The LIE and RIE bits in a LL element, only enable the done interrupt. In non-LL mode, the RIE and LIE bits (in the channel context registers) enable the done and abort interrupts.

When the LLP field of the first DWORD in the element is set to 1, the element is a link element. The DMA only loads the following information into the channel context registers:

- CB, TCB, and LLP bits of the first DWORD. The LIE and RIE bits are not defined in a link element.
- LL Element Pointer (3rd and 4th DWORDs) into the DMA Linked List Pointer registers (DMACAP[43+i*16] and DMACAP[44+i*16]).

***Caution:* Linked List Operation**

When you enable linked list operation (DMACAP[37+i*16].LLE=1’b1), the DMA overwrites the following DMA channel context registers with information from linked list data elements:

- ☐ The CB, LLP, LIE, and RIE fields of the DMA Channel Control 1 register.
- ☐ DMA Transfer Size.
- ☐ DMA SAR Low & High.
- ☐ DMA DAR Low & High

The structure of a link element is different to that of the data element. A data element has no TCB field. A link element has no LIE or RIE fields. It has no SAR, DAR, or Transfer Size DWORDs, but has LL Element Pointer DWORDs instead of the SAR DWORDs.
The LIE and RIE bits in a LL element, only enable the done interrupt. In non-LL mode, the RIE and LIE bits enable the done and abort interrupts. For more information, see “Interrupts and Error Handling”.

**Descriptor Early Fetch (AXI Bridge Configuration)**

In AXI bridge configuration, the DMA serializes the next descriptor fetch with the previous descriptor’s last data fetch. This allows the next descriptor to be loaded into DMA’s context memory just in time. Early descriptor fetch reduces the number of idle cycles between subsequent descriptor fetches introduced because of high round-trip read-to-completion latencies in scenarios where the descriptor’s transfer size is small.

The descriptor is fetched and loaded into AXI Bridge’s master completion buffer. While the previous descriptor’s CPL and MWr transactions are in progress, DMA back-pressures the descriptor loaded in the master completion buffer. It is recommended to have the configuration respecting the following relationship to avoid any potential performance issues:

CC_MAX_MSTR_TAGS_AXI > (CC_NUM_DMA_RD_CHAN + CC_NUM_DMA_WR_CHAN)

The early fetched descriptor completes concurrently with previous descriptor’s data completion. If previous descriptor transfer aborts due to an error in any data completion, the early-fetched descriptor is flushed. Figure 104.18 and Figure 104.19 describe Read/Write channel operation example for a scenario where each descriptor transfer size is 1 TLP.

***Note:** You can revert to legacy descriptor fetch by setting the hidden parameter CC_DMA_EFETCH_EN to 0.

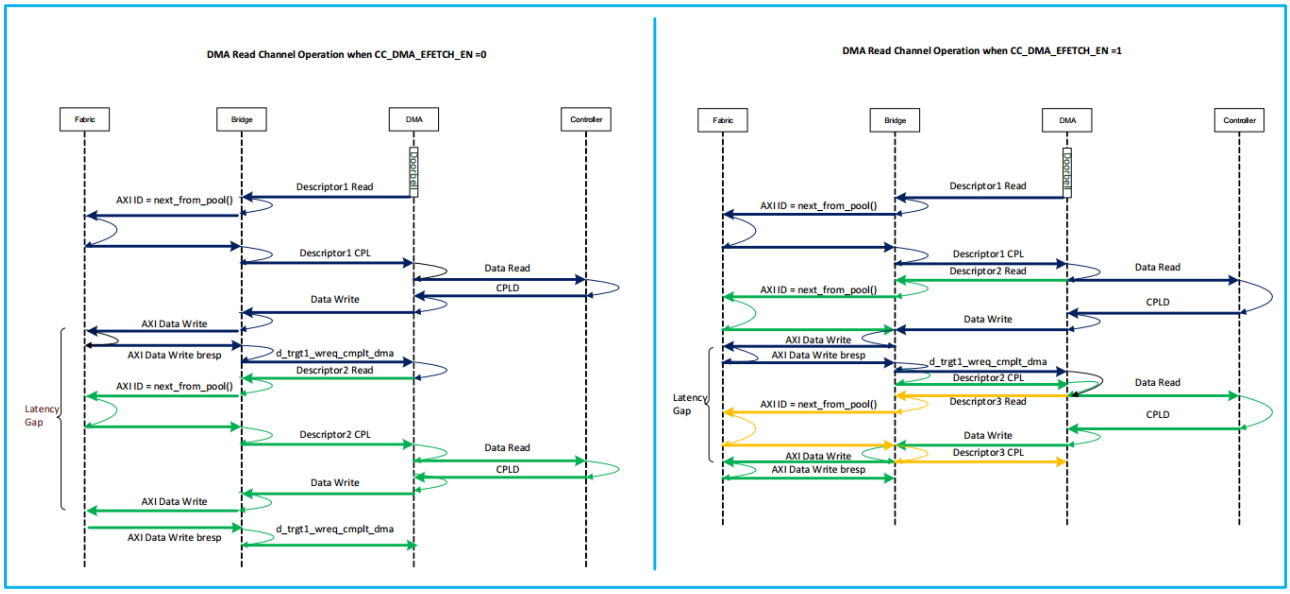

**Figure 104.18 Read Channel Operation Example: Before and After Early Fetch Optimization**

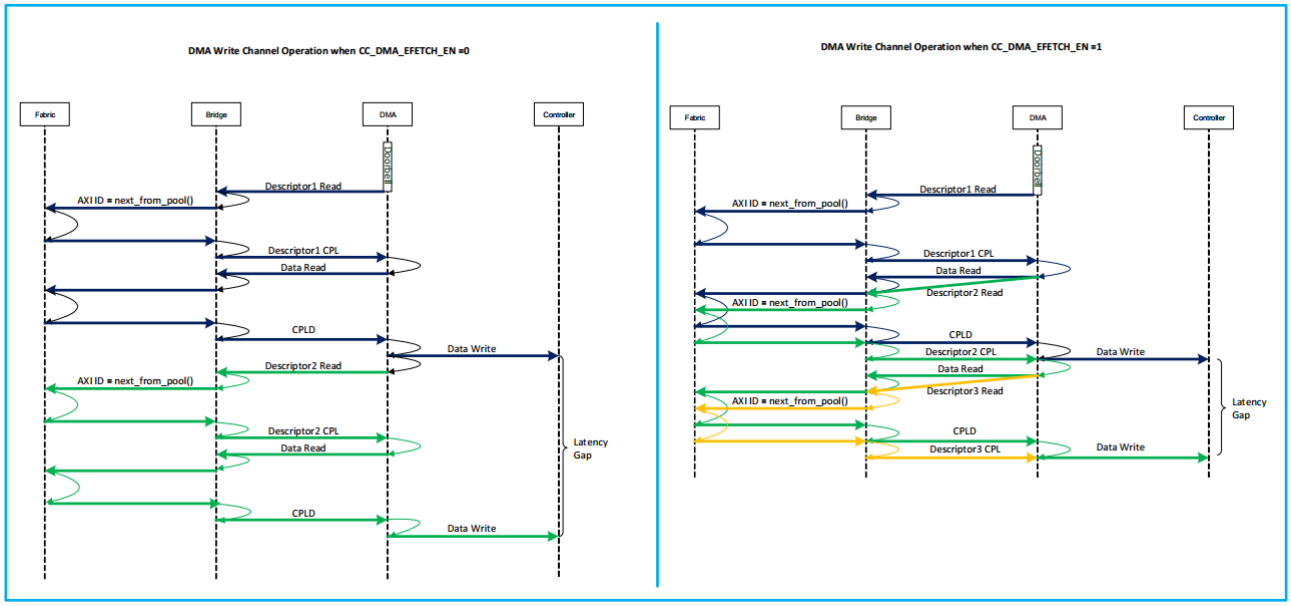

**Figure 104.19 Write Channel Operation Example: Before and After Early Fetch Optimization**

### (5) Using the DMA

This section describes how to use the DMA. The topics for this section are:

- "Source and Destination Address Registers (SAR, DAR)".
- "DMA Transfer Size Register".
- "Starting The DMA Transfer".
- "Detecting the End of The DMA Transfer".
- "Stopping the DMA Transfer (Software Stop)".

- "TLP Generator Header Control".
- "DMA Software Register Map".
- "Programming Examples".

You can configure the DMA to have from one to eight read channels and one to eight write channels. It can simultaneously perform the following types of memory transactions:

- DMA write
  Transfer (copy) of a block of data from local memory to remote memory.
- DMA read
  Transfer (copy) of a block of data from remote memory to local memory.

The DMA supports full duplex operation, processing read and write transfers at the same time, and in parallel with normal (non-DMA) traffic. Upon completion of a DMA transfer or an error, the DMA optionally interrupts the local CPU or sends an interrupt MWr (IMWr) to the remote CPU. The DMA is highly configurable and you can program it using the local DBI, or over the PCIe wire.
The channels are named read channel 7…0 and write channel 7...0. Each channel is programmed using a number of registers.

**(a) Source and Destination Address Registers (SAR, DAR)**

The DMA channel context SAR and DAR registers (DMACAP[39+*i**16]/ DMACAP[40+*i**16]/ DMACAP[41+*i**16]/ DMACAP[42+*i**16]) provide support for remote-to-local, and local-to-remote PCIe address mapping. You program the start of the local and remote data buffers using these registers, and the DMA increments the SAR and DAR as the DMA transfer progresses. For a write transfer, the SAR is the address of the local memory, and the DAR is the address of the remote memory, as shown in Figure 104.20.

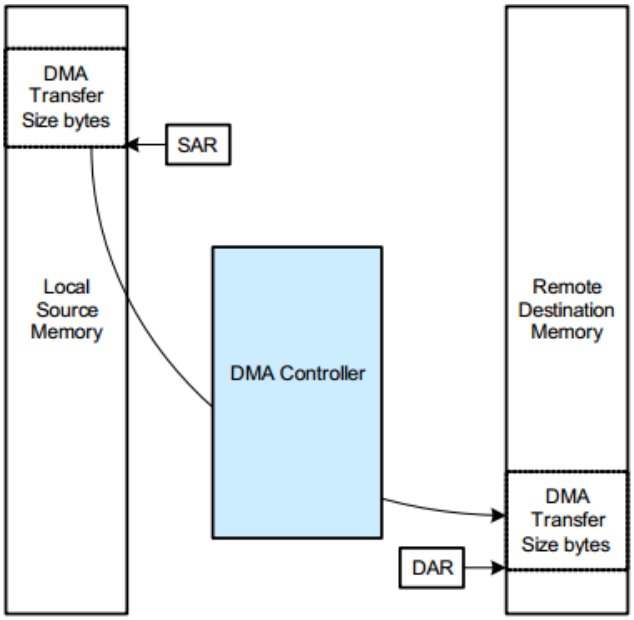

**Figure 104.20 Write Transfer: SAR and DAR for Write Channel 0**

For a read transfer, the SAR is the address of the remote memory, and the DAR is the address of the local memory, as shown in Figure 104.21.

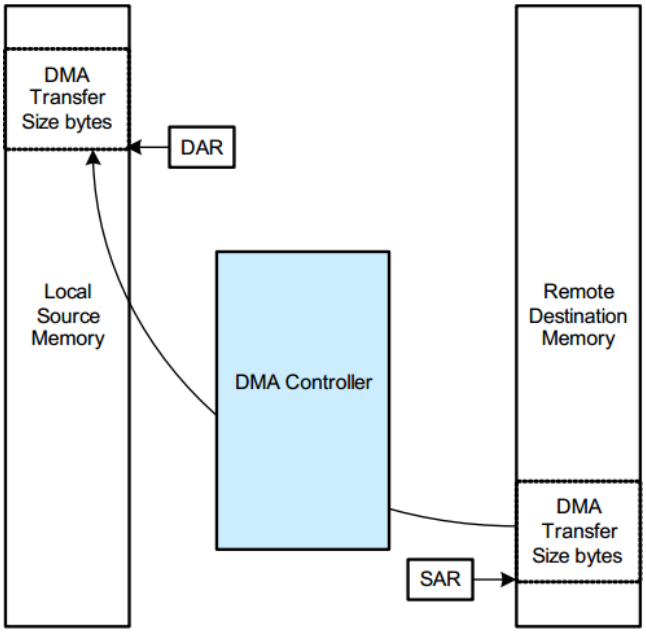

**Figure 104.21 Read Transfer: SAR and DAR for Read Channel 0**

The presence of the DMA controller does not affect:

- Normal filtering rules for inbound TLPs (for example, BAR checking in an Endpoint, as described in “Internal Address Translation Unit (iATU)”).
- The operation of any internal or external address translation, as described in “Receive Filtering”.

****Caution:** When you do not want the iATU to translate outbound requests that are generated by the internal DMA module, then you must implement one of the following approaches:

- Ensure that the combination of DMA channel programming and iATU control register programming, causes no translation of DMA traffic to be done in the iATU.
- Activate the DMA bypass mode to allow request TLPs which are initiated by the DMA controller to pass through the iATU untranslated. You can activate DMA bypass mode by setting the DMA Bypass field of the iATU Control 2 Register (ATUCAP[1+*i**18]).

### (b) DMA Transfer Size Register

You program the DMA transfer size using the DMA Transfer Size Register (DMACAP[38+*i**16] or DMACAP[46+*i**16]). The maximum DMA transfer size is 4GB, and the minimum transfer size is one byte (0x1). The DMA decrements the value in this register as the DMA transfer progresses. When all bytes are successfully transferred, the value in this register is zero. In LL mode, the DMA overwrites this register with the corresponding dword of the LL element.

You can read this register to monitor the transfer progress. However, in some scenarios there is a delay before the controller updates this register. For example, when less than three channels are doorbelled, this register is only updated after a descriptor finishes (LL mode), or the transfer ends (non-LL mode).

### (c) Starting The DMA Transfer

After you program the DMA controller registers (including writing to the DMA Read Engine Enable or DMA Write Engine Enable register), you start a DMA transfer by writing the channel number to the Doorbell Number field of the DMA Write Doorbell Register (DMACAP3) or DMA Read Doorbell Register (DMACAP7). You can program and start both a read and a write transfer at the same time. The DMA supports full duplex operation, processing read and write transfers at the same time and in parallel with normal (non-DMA) traffic. You can program and start any number of channels in the DMA controller sequentially or simultaneously.

- **Sequentially**: configure and start a channel, and then configure and start another channel
- **Simultaneously**: configure multiple channels, and then start multiple channels

****Caution:** You must not write to any of the context registers for a particular channel after you start the channel by writing the channel number to the Doorbell Number field of the DMA Write Doorbell Register (DMACAP3) or DMA Read Doorbell Register (DMACAP7)**.**

**(d) Detecting the End of The DMA Transfer**

If a DMA transfer proceeds without any errors, it stops automatically when finished.

**Detecting End of Transfer without Errors**
The normal end of a DMA transfer is detected by any of the following methods:

- Done local interrupt (pin) asserted.
- Done remote interrupt (IMWr) received.
- Channel status field of the Channel Control 1 register is stopped, and the DMA Transfer Size register is 0x0.
- Polling of the DMA Write Interrupt Status Register (DMACAP10) or DMA Read Interrupt Status Register (DMACAP23).

**Detecting End of Transfer with Errors**

The abnormal end of a DMA transfer is detected by any of the following methods:

- Abort local interrupt (pin) asserted.
- Abort remote interrupt (IMWr) received.
- Polling of the DMA Write Interrupt Status Register (DMACAP10) or DMA Read Interrupt Status Register (DMACAP23).
- Channel Status field of the Channel Control 1 register is Halted. When the DMA controller detects an error, it forces the DMA to stop issuing requests for the channel. It also sets the channel status field of the Channel Control 1 register to Halted, generates an abort interrupt (if enabled), and sends an abort IMWr (if enabled). The DMA Transfer Size register indicates the remaining number bytes to be transferred, except when there is an AXI write error during a DMA read transfer.
- Channel Status field of the Channel Control 1 register is stopped, and the DMA Transfer Size register is not 0x0. You have prematurely stopped this channel as described in “Stopping the DMA Transfer (Software Stop)”.

**(e) Stopping the DMA Transfer (Software Stop)**

You can manually abort (stop) the DMA transfer by writing the channel number to the Doorbell Number field and writing 1 to the Stop field in DMACAP3. This causes the DMA to:

- Place the channel in a Stopped state.
  The channel Status field in DMACAP[37+*i**16] is stopped and the value in DMACAP[38+*i**16]0 is not 0x0.
- Wait for all outstanding pending transactions.
- Assert the abort interrupt (if it is enabled) in DMACAP10.

You might do this as part of error handling which is described in “Error Handling Assistance by Remote Software”, which is only necessary during software development if you incorrectly program the DMA write channel DAR.

You might also do this as part of a function level reset (FLR). FLR does not directly affect the DMA transfer so you must manually stop the DMA transfer before initiating an FLR.

***Caution:* Use This Feature With Caution**
You should not use the STOP feature in operational mode. It is only a debug feature and has associated hazards.

- Before setting the Stop bit.
  - You must read the channel status field (CS) of the DMA Channel Control 1 register to ensure that the corresponding channel is running (transferring data).
  - To eliminate the possibility of a race condition between these two actions (read and write), you should confirm the presence of the abort bit in the DMA Write Interrupt Status Register (DMACAP10) or DMA Read Interrupt Status Register (DMACAP23) and check the status of any fatal error if some other event has occurred.
- After a Stop event, you cannot seamlessly resume the transfer again because the DMA does not resume operation exactly from the point it stopped. Therefore, you must setup and start the complete channel context again, including the
  - Linked list pointer.
  - Linked list structure in memory.
  - Related PCS and CCS values.
  - When operating in non-linked list mode, setup channel context registers

### (f) TLP Generator Header Control

You must program bits [31:12] of the DMA Channel Control 1 Register (DMACAP[37+*i**16]/ DMACAP[45+*i**16), so that the DMA TLP generator correctly sets the TC, RO, NS, and FN TLP header fields for any TLPs that it generates.

### (g) DMA Software Register Map

This section discusses the grouping and access methods of the DMA registers. The following registers are present when the DMA is enabled.

- DMA Global Registers: these registers control global settings

**Table 104.20 DMA Global Register**

| | Description |
|---|---|
| base address + 0x000 | DMA Arbitration Scheme for TRGT1 Interface |
| +0x008 | Number of DMA Channels |
| +0x00C | DMA Write Engine Enable |
| +0x010 | DMA Write Doorbell |
| +0x018 | DMA Write Engine Channel Arbitration Weight Low |
| +0x01C | DMA write Engine Channel Arbitration Weight High |
| +0x02C | DMA Read Engine Enable |

| | |
|---|---|
| +0x030 | DMA Read Doorbell |
| +0x038 | DMA Read Engine Channel Arbitration Weight Low |
| +0x03C | DMA Read Engine Channel Arbitration Weight High |

- DMA Interrupt Registers: these registers control the generation of local interrupts and remote IMWr. The IMWr addresses and data are stored in RAM.

**Table 104.21 DMA Interrupt Register**

| Byte Offset | Description |
|---|---|
| Base address + 0x4C | DMA Write Interrupt Status |
| +0x50 | Not Used (RsvdP) |
| +0x54 | DMA Write Interrupt Mask |
| +0x58 | DMA Write Interrupt Clear |
| +0x5C | DMA Write Error Status |
| +0x60 | DMA Write Done IMWr Address Low |
| +0x64 | DMA Write Done IMWr Address High |
| +0x68 | DMA write Abort IMWr Address Low |
| +0x6C | DMA Write Abort IMWr Address High |
| +0x70 | DMA Write Channels 1 and 0 IMWr Data |
| +0x74 | DMA Write Channels 3 and 2 IMWr Data |
| +0x78 | DMA Write Channels 5 and 4 IMWr Data |
| +0x7c | DMA Write Channels 7 and 6 IMWr Data |
| +0x90 | DMA Write Linked List Error Enable |
| Up to + 0x9C | Not Used (RsvdP) |
| +0xA0 | DMA Read Interrupt Status |
| +0xA4 | Not Used (RsvdP) |
| +0xA8 | DMA Read Interrupt Mask |
| +0xAC | DMA Read Interrupt Clear |
| +0xB0 | Not Used (RsvdP) |
| +0xB4 | DMA Read Error Status Low |
| +0xB8 | DMA Read Error Status High |

| | |
|---|---|
| Up to + 0xC0 | Not Used (RsvdP) |
| +0xC4 | DMA Read Linked List Error Enable |
| +0xc8 | Not Used (RsvdP) |
| +0xCC | DMA Read Done IMWr Address Low |
| +0xD0 | DMA Read Done IMWr Address High |
| +0xD4 | DMA Read Abort IMWr Address Low |
| +0xD8 | DMA Read Abort IMWr Address High |
| +0xDC | DMA Read Channels 1 and 0 IMWr data |
| +0xE0 | DMA Read Channels 3 and 2 IMWr data |
| +0xE4 | DMA Read Channels 5 and 4 IMWr data |
| +0xE8 | DMA Read Channels 7 and 6 IMWr data |

- DMA Channel Context Registers: these registers (which are stored in RAM) are for the control and status information that is specific to each channel. There is a set of registers for each channel. The number of channels in the DMA is configurable in each direction (write and read) from 1 to 8 using the CC_NUM_DMA_WR_CHAN and CC_NUM_DMA_RD_CHAN configuration parameters.

| **Byte Offset** | **Description** |
|---|---|
| DMA Channel Context | |
| Base Address + 0x200*(i+1) + 0x100*(WR\|RD) | DMA Channel Control 1 Register |
| +0x004*i + 0x200*(i+1) + 0x100*(WR\|RD) | DMA Channel Control 2 Register |
| +0x008*i + 0x200*(i+1) + 0x100*(WR\|RD) | DMA Transfer Size |
| +0x00C*i + 0x200*(i+1) + 0x100*(WR\|RD) | DMA SAR Low |
| +0x010*i + 0x200*(i+1) + 0x100*(WR\|RD) | DMA SAR High |
| +0x014*i + 0x200*(i+1) + 0x100*(WR\|RD) | DMA DAR Low |
| +0x018*i + 0x200*(i+1) + 0x100*(WR\|RD) | DMA DAR High |
| +0x01C*i + 0x200*(i+1) + 0x100*(WR\|RD) | DMA Linked List Pointer Low |
| +0x020*i + 0x200*(i+1) + 0x100*(WR\|RD) | DMA Linked List Pointer High |

***Caution:* Implementation of Channel Context Registers**

- The channel context registers are stored in RAM whose contents are automatically initialized after power-on.

- You must not write to any of the context registers for a particular channel after you start the channel by writing the channel number to the Doorbell Number field of the DMA Write Doorbell Register (DMACAP3) or DMA Read Doorbell Register (DMACAP7).

**Linked List Operation**
When you enable linked list operation (Linked List Enable field of DMA Channel Control 1 Register DMACAP[37+*i**16] to 1b1, the DMA overwrites the following DMA channel context registers with the following information from linked list data elements:

- The CB, LLP, LIE, and RIE fields of the DMA Channel Control 1 register.
- DMA Transfer Size.
- DMA SAR Low.
- DMA SAR High.
- DMA DAR Low.
- DMA DAR High

**Note**:

- The structure of a link element is different to that of the data element. A data element has no TCB field. A link element has no LIE or RIE fields. It has no SAR, DAR, or Transfer Size DWORDs, but has LL Element Pointer DWORDs instead of the SARDWORDs. For more details, see Relationship Between Element DWORDs and Channel Context Registers.
- The LIE and RIE bits in a LL element, only enable the Done interrupt. In non-LL mode, the RIE and LIE bits enable the Done and Abort interrupts.

### (h) Programing Examples

****Attention:** You must enable the DMA before you start a DMA channel. Therefore you must write ‘1’ to DMA Read Engine Enable or DMA Write Engine Enable register before you write ‘1’ to the DMA Read Doorbell or DMA Write Doorbell register.

**1 MB Write Transfer On Write Channel #0 Initiated by Local CPU (Non LL mode)**

In this example, the IMWr generation is disabled, as the local CPU initiates the DMA transfer. The local CPU is interrupted using the edma_int bus. The SAR is the address of the local memory, and the DAR is the address of the remote memory, as shown in Figure 104.22. Table 104.22 provides the programming details for this example transfer.

**Figure 104.22 1 MB Write DMA Transfer from 0xBEEF_BEE0 to 0xCAFE_CAF0**

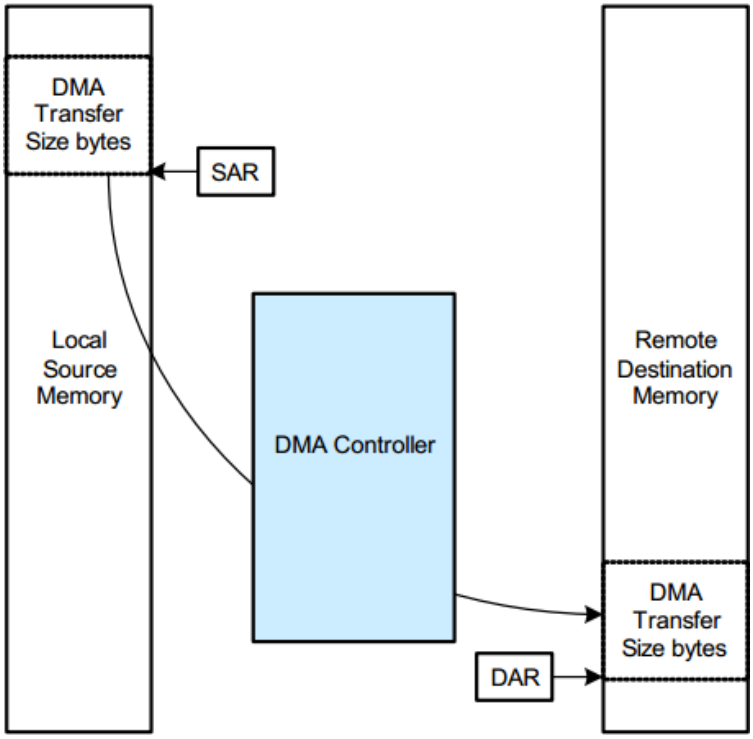

**Table 104.22 1 MB Write DMA Transfer from 0xBEEF_BEE0 to 0xCAFE_CAF0**

| Address (0x5000+) | Name | Value |
|---|---|---|
| 0x00C | DMA Write Engine Enable<br><br>You must not write 0 to this register. Even temporarily writing 0 to this register resets the DMA logic. For more detail, see DMA Write Engine Enable Register (DMACAP2). | 0x1 |
| 0x054 | DMA Write Interrupt Mask | 0x0 |
| 0x200 | DMA Channel Control 1 register<br><br>■ Local Interrupt Enable (LIE) =1<br><br>■ Remote Interrupt Enable (RIE) =0<br><br>■ RO, NS, TC, Function Number =0 | 0x04000008 |
| 0x208 | DMA Transfer Size | 0x00100000 |
| 0x20C | DMA SAR Low | 0xBEEF_BEE0 |
| 0x210 | DMA SAR High | 0x0000_0000 |
| 0x214 | DMA DAR Low | 0xCAFE_CAF0 |
| 0x218 | DMA DAR High | 0x0000_0000 |
| 0x010 | DMA Write Doorbell | 0x0 |

**1 MB Read Transfer On Read Channel #0 Initiated by Local CPU (Non LL mode)**

In this example, the IMWr generation is disabled, as the local CPU initiates the DMA transfer. The local CPU is interrupted using the edma_int bus. The SAR is the address of the remote memory, and the DAR is the address of the local memory, as shown in Figure 104.23. Table 104.23 provides the programming details for this example transfer.

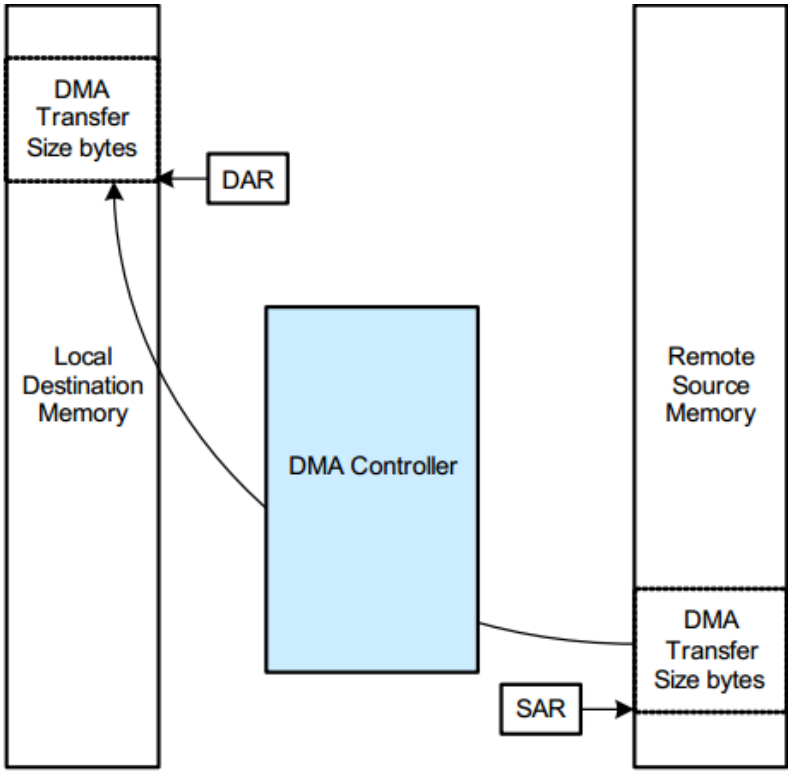

**Figure 104.23 1 MB Read DMA Transfer from 0xBEEF_BEE0 to 0xCAFE_CAF0**

**Table 104.23 DMA Register Setup**

| Address (0x5000+) | Name | Value |
|---|---|---|
| 0x02C | DMA Read Engine Enable<br><br>You must not write 0 to this register. Even temporarily writing 0 to this register resets the DMA logic. For more detail, see DMA Read Engine Enable Register (DMACAP6). | 0x1 |
| 0x0A8 | DMA Read Interrupt Mask | 0x0 |
| 0x300 | DMA Channel Control 1 register<br><br>■ Local Interrupt Enable (LIE) =1<br><br>■ Remote Interrupt Enable (RIE) =0<br><br>■ RO, NS, TC, Function Number =0 | 0x04000008 |
| 0x308 | DMA Transfer Size | 0x00100000 |
| 0x30C | DMA SAR Low | 0xBEEF_BEE0 |
| 0x310 | DMA SAR High | 0x0000_0000 |
| 0x314 | DMA DAR Low | 0xCAFE_CAF0 |

| | | |
|---|---|---|
| 0x318 | DMA DAR High | 0x0000_0000 |
| 0x030 | DMA Read Doorbell | 0x0 |

**1 MB Write Transfer On Write Channel #5 Initiated by Remote CPU (Non LL mode)**

In this example, the local interrupt generation is disabled, as the remote CPU initiates the DMA transfer. The remote CPU is interrupted using an IMWr. The SAR is the address of the local memory, and the DAR is the address of the remote memory, as shown in Figure 104.24. Table 104.24 provides the programming details for this example transfer.

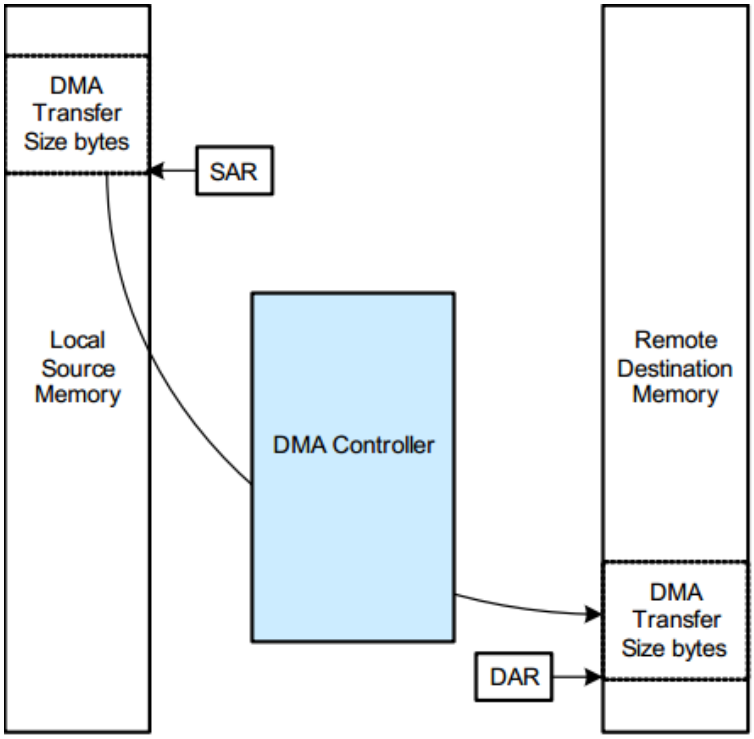

**Figure 104.24 1 MB Write DMA Transfer from 0xBEEF_BEE0 to 0xCAFE_CAF0**

**Table 104.24 DMA Register Setup**

| Address (0x5000+) | Name | Value |
|---|---|---|
| 0x00C | DMA Write Engine Enable<br><br>You must not write 0 to this register. Even temporarily writing 0 to this register resets the DMA logic. For more detail, see DMA Write Engine Enable Register (DMACAP2) | 0x1 |
| 0x060 / 0x064 | DMA Write Done IMWr Address Low and High | Your IMWr Address #1 |
| 0x068 / 0x06C | DMA Write Abort IMWr Address Low and High | Your IMWr Address #2 |
| 0x088 | DMA Write Channel 5 IMWr Data | Your IMWr Data |
| 0xC00 | DMA Channel Control 1 register<br><br>■ Local Interrupt Enable (LIE) =0 | 0x04000010 |

| | | |

| 0xD10 | DMA SAR High | 0x0000_0000 |
| 0xD14 | DMA DAR Low | 0xCAFE_CAF0 |
| 0xD18 | DMA DAR High | 0x0000_0000 |
| 0x030 | DMA Read Doorbell | 0x5 |

**Linked List Mode Programming Example (Write Channel #0)**

This write channel example with the following features:

- Recycled linked list (LL) of nine data elements and one link element.
- Transfer is initiated by local CPU.
- Each data element corresponds to a 1 MB (0x0010_0000) write transfer.
- The SARs for each element are separated by 2 MB (0x0020_0000). The DAR for each element are separated by 16 MB (0x0100_0000). The SAR is the address of the local memory, and the DAR is the address of the remote memory.
- The LL transfer list is located at address 0x0000_0200 in local memory.
- No remote interrupt is generated so the IMWr generation is disabled, as the local CPU initiates the DMA transfer. The local CPU is interrupted using the edma_int bus.
- There is a Watermark interrupt at element #5, and an Empty interrupt at element #8. Both of these interrupts are done interrupts (as opposed to abort interrupts).

You should familiarize yourself with the Linked List Flow for Producer and Consumer. These are the main steps for this process in this example:

Step 1: Create TL in local memory

- Create the 10 elements:
  - For elements 0, 1, 2, 3, 4, 6, 7: RIE, LIE, LLP, CB =0, 0, 0, 1.
  - For element 5: RIE, LIE, LLP, CB =0, 1, 0, 1.
  - For element 8: RIE, LIE, LLP, CB =0, 1, 0, 1.
  - For element 9: LLP, TCB, CB =1, 1, 0.

Step 2: Program and Start DMA

- Configure and start the DMA registers.

Step 3: Wait for done interrupt and recycle TL

****Attention: Software Programming of an Endpoints LIE and RIE Bits for Linked List Transfers.**
If the DMA driver is running on the host and the interrupt service routine is reading local interrupts to determine if the transfer is successful, then you must set LIE and RIE in the same element and you should mask or ignore the local interrupt pin. Setting RIE and LIE in element A followed by RIE (only) in element B is not a verified usage scenario.

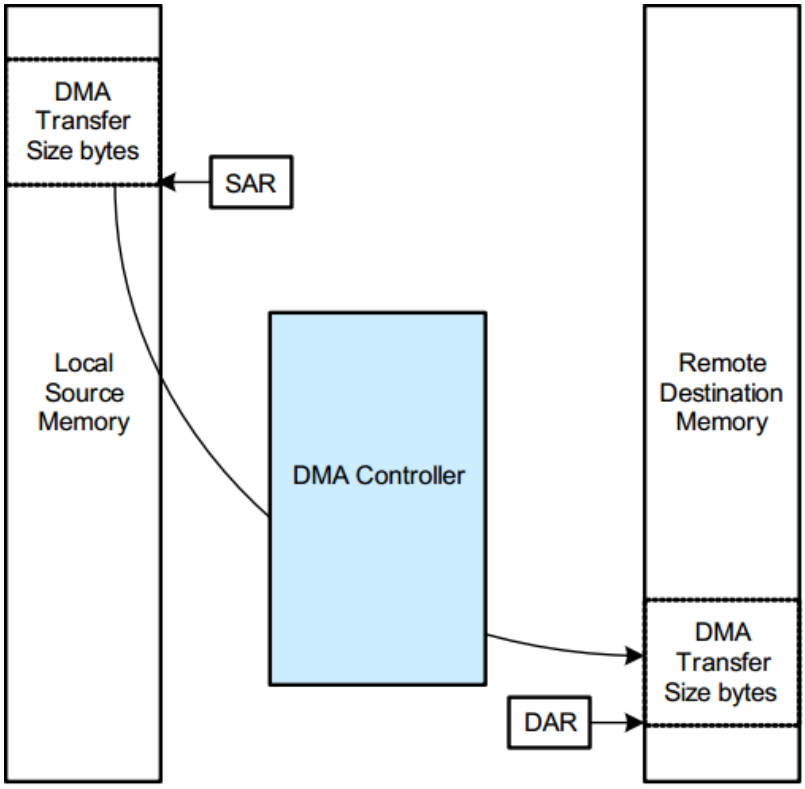

**Figure 104.26 1 MB Write DMA Transfer from SAR to DAR**

**Table 104.26 Linked List Element Initial Setup**

| Element# | Address | Data | Label |
|---|---|---|---|
| 0 | 0x0000_0200 | 0x0000_0001 | Channel Control |
| 0 | 0x0000_0204 | 0x0010_0000 | Transfer Size |
| 0 | 0x0000_0208 | 0xBEEF_BEE0 | SAR Low |
| 0 | 0x0000_020C | 0x0 | SAR High |

### 104.3.10 Peer to Peer Transfer

The PCIEC does not support the Peer-to-Peer Transfer features defined in the PCI Express Base Specification, Revision 4.0, Version 1.0. (The Peer-to-Peer in this section means that TLP is routed from one channel to another channel like PCIe switch.)

### 104.3.11 Transfer Priority

This section describes the transfer priority.

### (1) Arbitration (Transmission to PCI Express)

Accesses to transmit packets to the PCI Express include: DMA transfer, response processing to Inbound transfer, Outbound transfer, and Message transfer. The DMAC and the modules controlling Outbound transfer output posted and non-posted requests, respectively.

Arbitration between these accesses is performed according to the priority shown below Table 104.28.

**Table 104.28 TLP Arbitration Priority (1= Highest, 6= Lowest)**

| Priority | TLP Type |
|---|---|
| 1 | Completion of any TLP currently in progress |
| 2 | Retry buffer retransmissions |
| 3 | Messages generated by PCIEC (including MSI generated by register write) |
| 4 | TLPs from the transaction layer:<br>(When Root port mode) Completions generated by PCIEC for UR or CA<br>(When End port mode) Completions generated by PCIEC for Type0 configuration read and write requests (including UR responses) |
| 5 | TLPs on the internal bus |
| 6 | DMA transfer |

### (2) Arbitration (Reception from PCI Express)

The PCIEC receiver receive packets from the PCI Express and filter into three separate FIFO queues: posted, non-posted, and completion. When more than one queue has a TLP that is allowed to proceed, it uses a priority arbitration algorithm to select a transaction. This prevents that delivery rate for a particular TLP type to internal bus is unfairly reduced.

### (3) PCI Express Transmit/Receive Ordering

The following describes the transaction ordering rules of PCIEC.

Table 104.29 shows the transmit transaction ordering rules of this module.

**Table 104.29 Transmit Transaction Ordering Rules of This Module**

| Row Pass Column? | 1st Posted | 1st Non-Posted | 1st Completion |
|---|---|---|---|
| 2nd posted | No | Yes | Yes |
| 2nd non-posted | No | No | Yes |
| 2nd completion | No | Yes | No |

Note: Yes: The second transaction can pass the first transaction.
No: The second transaction cannot pass the first transaction.

Table 104.30 shows the receive transaction ordering rules of this module.

**Table 104.30 Receive Transaction Ordering Rules of This Module**

| Row Pass Column? | 1st Posted | 1st Non-Posted | 1st Completion |
|---|---|---|---|
| 2nd posted | No[a] | Yes | Yes |
| 2nd non-posted | No | No | Yes |
| 2nd completion | No | Yes | No |

Note: Yes: The second transaction can pass the first transaction.
No: The second transaction cannot pass the first transaction.
a: A non MSI P request can pass previously-received MSI P request.

PCIEC applies the ordering rules conforming to the standard to the transmission and reception sides. According to the rules, some packets cannot be passed by (to prevent an undesired influence on the order of sequential processing and such). Therefore, depending on the packet transfer order or combination, processing of a packet may be delayed until the previous packet processing is completed.

### (4) Arbitration (Bus Master Request)

Accesses to output a master request to the internal bus include: DMA transfer, Inbound transfer, and message transfer.

Arbitration between these accesses is performed according to the priority shown below.

(High priority)

- Inbound transfer (reception of memory request and IO request)
- DMA Write Channel (transmission of memory write and command read)
- DMA Read Channel (command read)
- DMA Read Channel (transmission of memory write)

(Low priority)

### 104.3.12 Link Function

The following sections describe Changing Speed, Lane Resizing and Lane Reversal and Flipping.

#### (1) Changing Speed

PCIEC supports all of the non-optional Gen1 2.5 GT/s features, Gen2 5.0 GT/s features, Gen3 8.0 GT/s features and Gen4 16.0 GT/s features defined in the PCI Express Base Specification, Revision 4.0, Version 1.0.

PCIEC initiates the speed change automatically after link up according to EXPCAP12F*i*[3:0]. cfg_target_link_speed and clears PRTLGC21. cfg_directed_speed_change bit. The default of EXPCAP12[3:0]. int_target_link_speed value is ‘B0100 (16.0 GT/s). Therefor the first link up speed is 16.0 GT/s. If you want to link up in another speed, then write a target speed value to EXPCAP12F0[3:0]. int_target_link_speed before link up.

To manually initiate the speed change then:

- Write to EXPCAP12F0[3:0]. int_target_link_speed in the local device.
- Deassert PRTLGC21. cfg_directed_speed_change in the local device.
- Assert PRTLGC21. cfg_directed_speed_change in the local device.

If you want to change speed from Gen4 rate to Gen2 or Gen3 rate,
Request speed change from Gen4 rate to Gen1 rate. Then change speed from Gen1 rate to any higher rate.

#### (2) Gen3 8.0 GT/s , Gen4 16.0 GT/s Transmitter Equalization

PCIEC performs link equalization during link training to improve signal quality by adjusting the transmitter and receiver equalization parameters for each lane on each side of the link. There are two feedback modes for determining the optional equalization settings, programmable using PRTLGC54.

- Figure of merit (FOM)
- Direction change with optional convergence support

#### (3) Gen4 Lane Margining

The controller supports all mandatory PIPE message bus interface features specified in PIPE Specification for PCI Express, Version 4.4.1, except for elastic buffer depth control and generation of read command form the controller to PHY.

#### (4) Lane Resizing

Initially, the controller tries to linkup at maximum width. You can restrict the maximum width as follows:

- Program PRTLGC4. cfg_link_capable
- Program PRTLGC21. cfg_lane_en[4:0]

The link partners can change the link width after the link is up. Resizing option are show in Table 104.31.

**Table 104.31 Link Resizing Options**

| | **Remote Partner Initiates (L0 -> Recovery -> Configuration)** | **Software Initiates Localy (L0 -> Recovery -> Configuration)** |
|---|---|---|
| Upsizing (Upconfugure) | Yes | Yes |
| Downsizing | Yes | Yes |

Resizing only occurs if both link partners advertised the Upconfigure Capability bit (except link reliability case). PCIEC has the Upconfigure Capability bit in PRTLGC59. cfg_pl_multilane_control[7] and default setting is 1.

The following steps show how you can initiate link resizing:

- Ensure the link is in the L0 LTSSM state.
- Program PRTLGC59.cfg_pl_multilane_control[5:0]
- Program PRTLGC59.cfg_pl_multilane_control[6]

Limitation:

If your system has reversed lanes in Gen3 or Gen4 speed mode, then you should perform upsizing at Gen1 or Gen2 speed only to avoid link-down caused by LFSR mismatching.

If the lanes are reversed, software must manually flip the lanes to achieve downsizing for some configuration. See 104.3.12(5) for more details.

**(5) Lane Reversal and Flipping**

PCIEC supports lane reversal, lane flipping and polarity inversion Depending on the configuration of the link partners and the topology of link between them, the controller will attempt to reverse and / or flip lanes to form a link in any of the following scenarios:

- The lanes are reversed by the physical layout of the PCIe link
- When connecting a narrower link partner into upper lanes of a wide controller
- A lane is non-operational (broken)
  - Non-operational means that a lane cannot be detected in Detect LTSSM state or it cannot receive in Polling LTSSM state.

Lane auto flip occurs in Detect when physical Lane0 cannot be detected.

Lane auto reverse occurs in Configuration and is useful to from a link when logical Lane0 receives TS Ordered Sets from the link partner with the Lane Number field different from 0.

To enable lane auto flip and lane auto reverse, set PRTLGC21[16]. cfg_lane_en[8]= 1 and PRTLGC21[15:13]. cfg_lane_en[7:5] = 0.

You can also perform lane flip manually. To enable manual lane flip, set PRTLGC21[16]. cfg_lane_en[8] =1, PCIEMSR1[1]. tx_lane_flip_en =1 for transmission lanes and set PCIEMSR1[0]. rx_lane_flip_en =1 for reception lanes.

Figure 104.27, Figure 104.28, Figure 104.29, Figure 104.30 and Figure 104.31 show Reversing and Flipping Lanes structures.

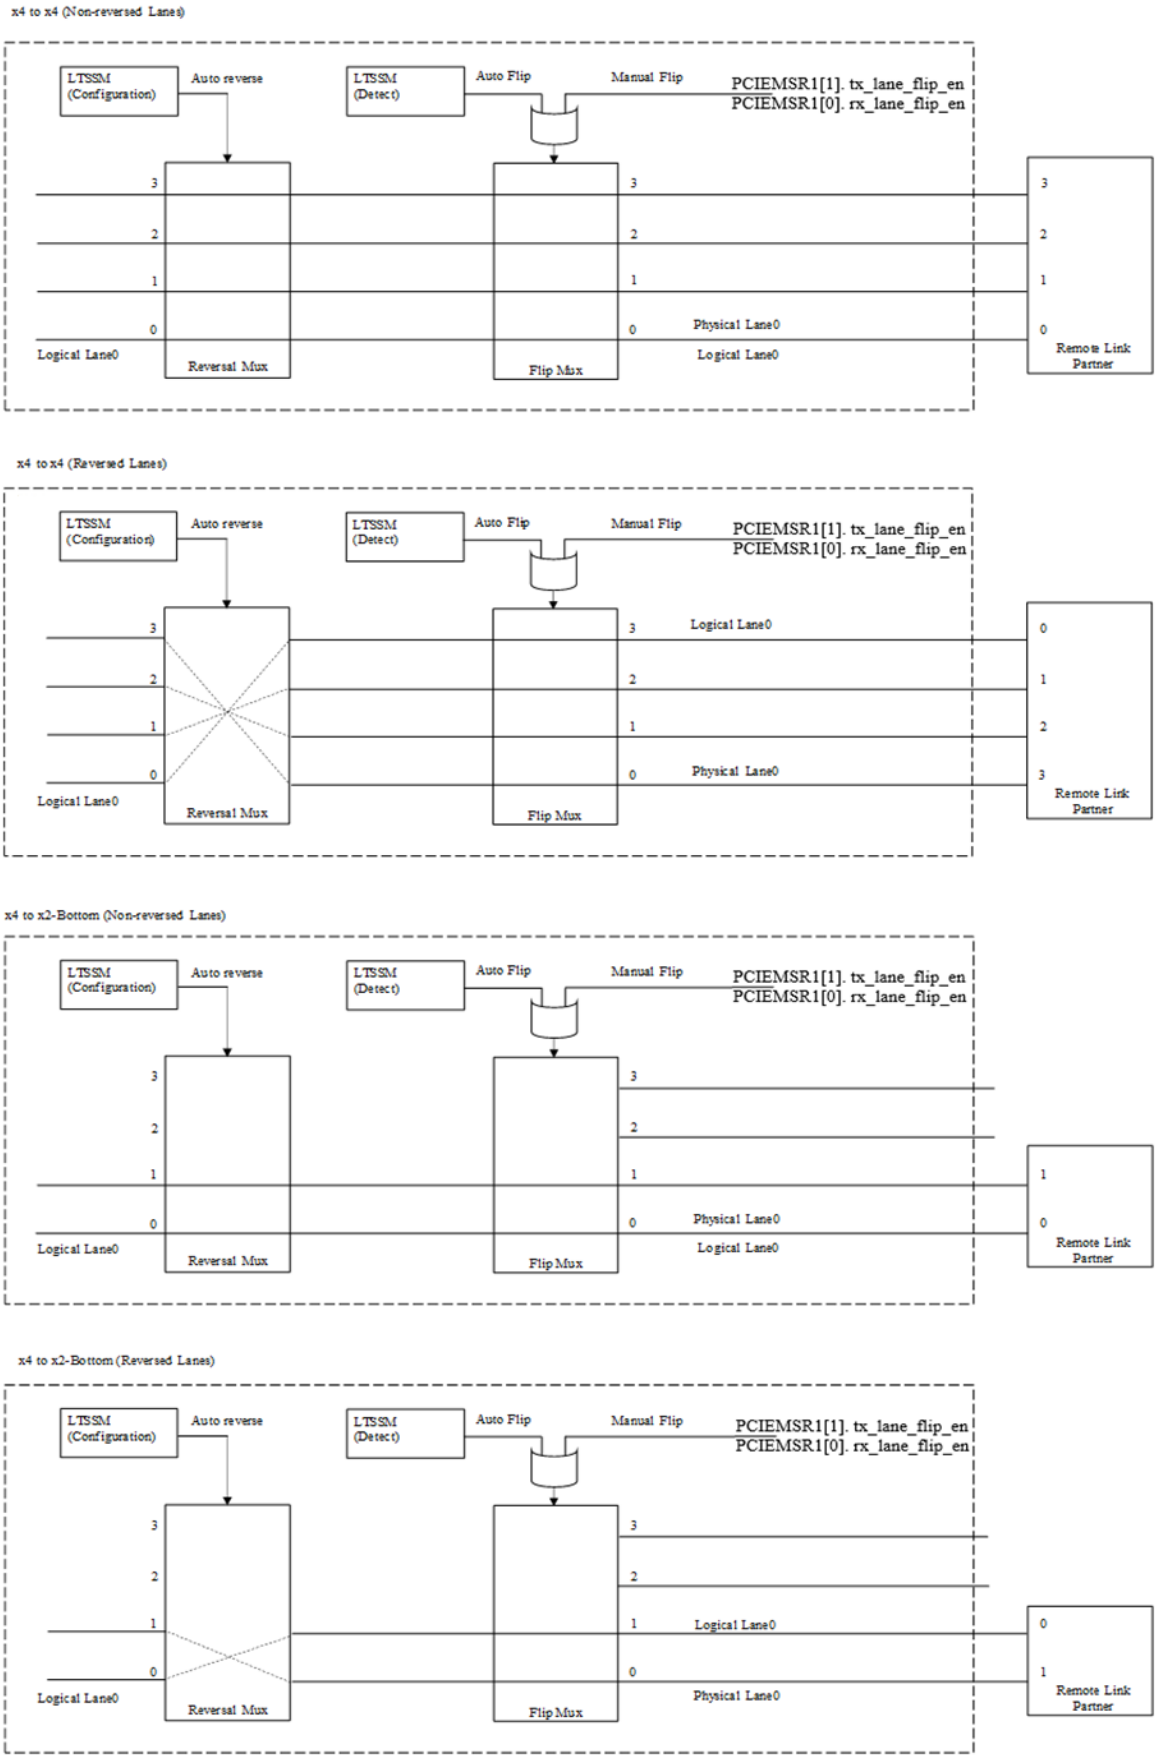

**Figure 104.27 Reversing and Flipping Lanes (1)**

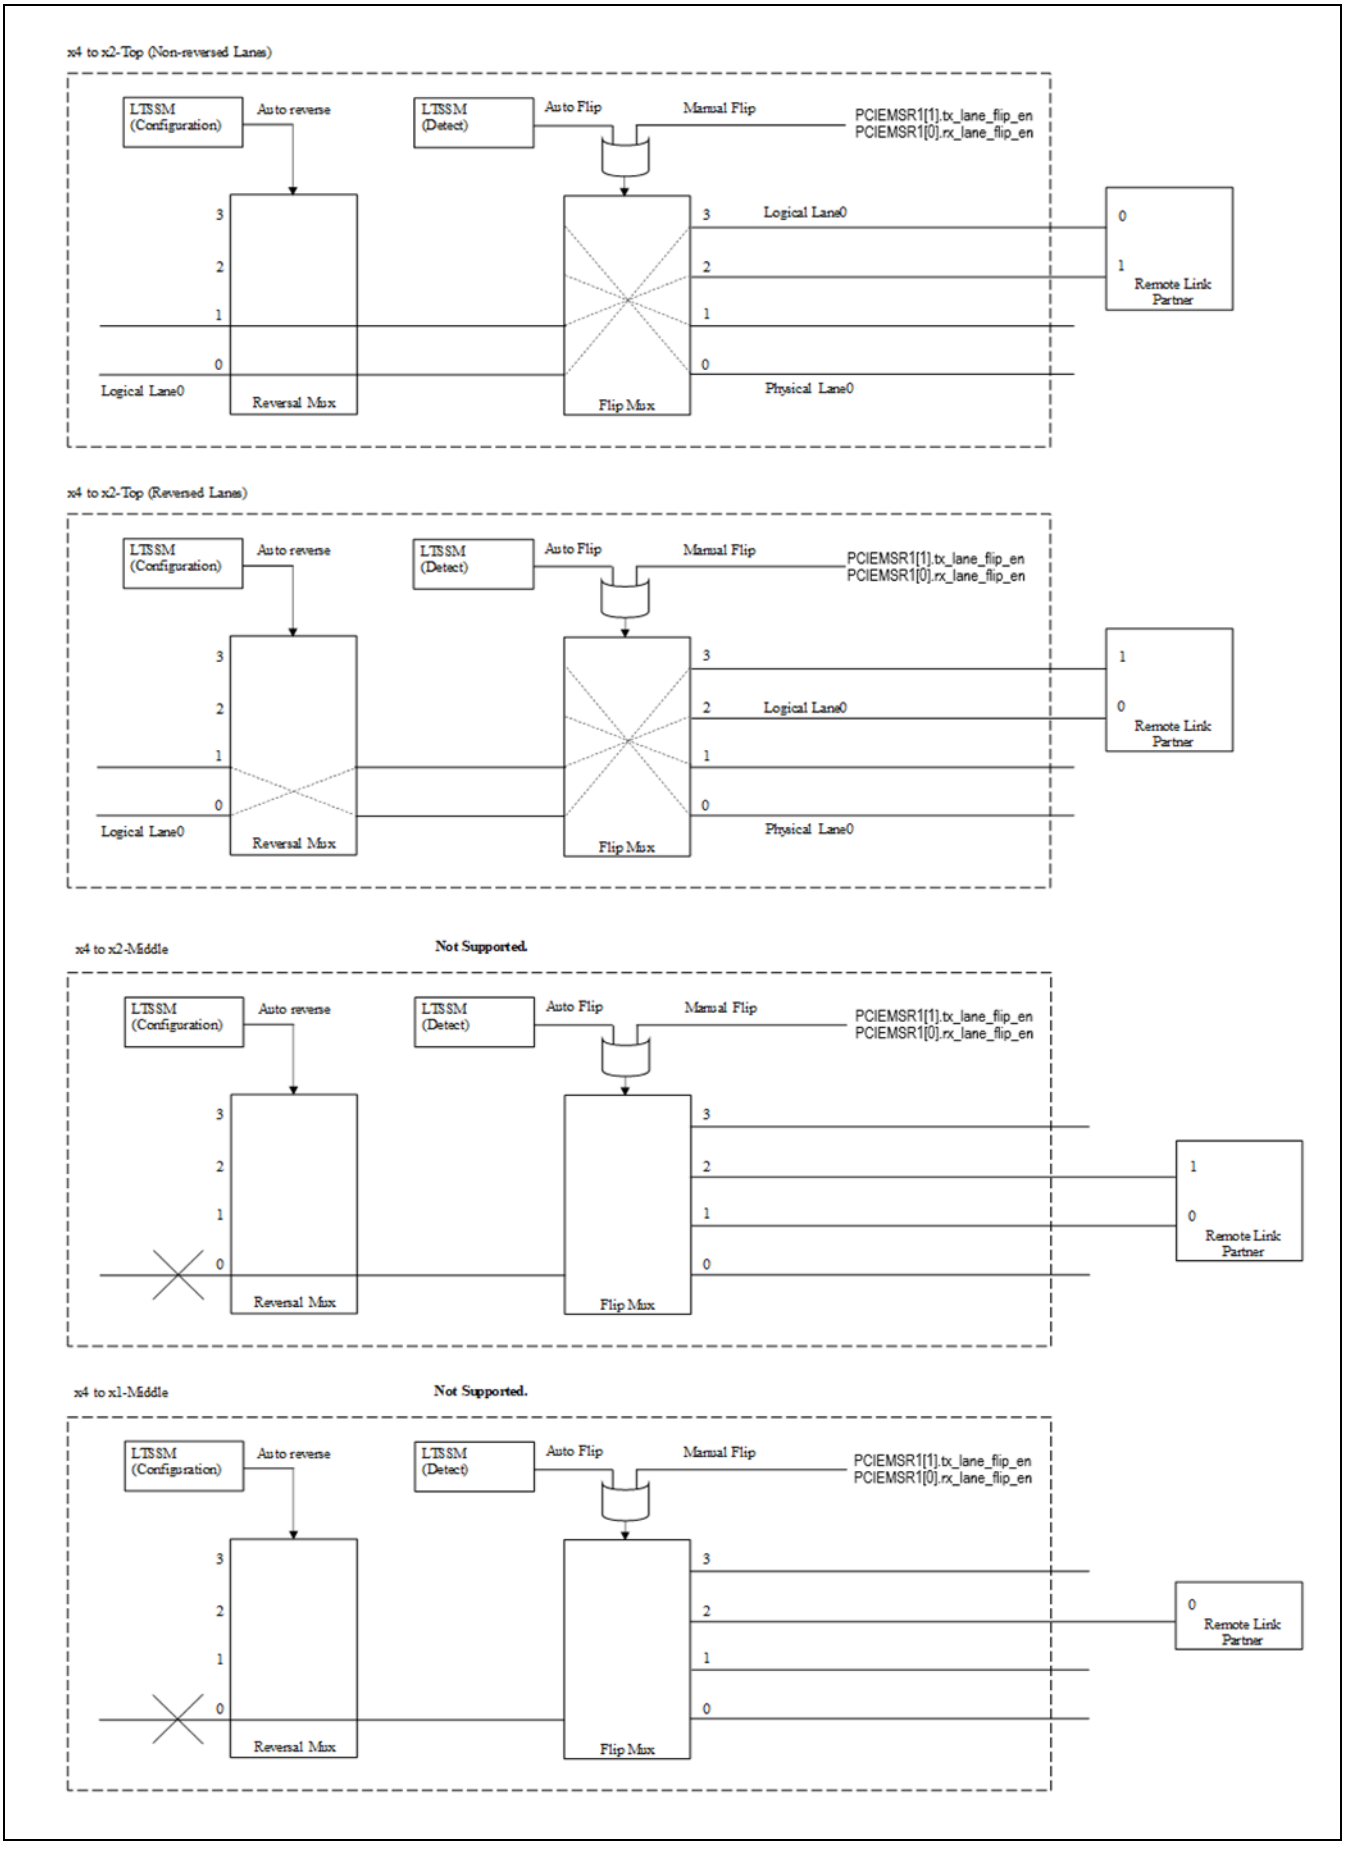

**Figure 104.28 Reversing and Flipping Lanes (2)**

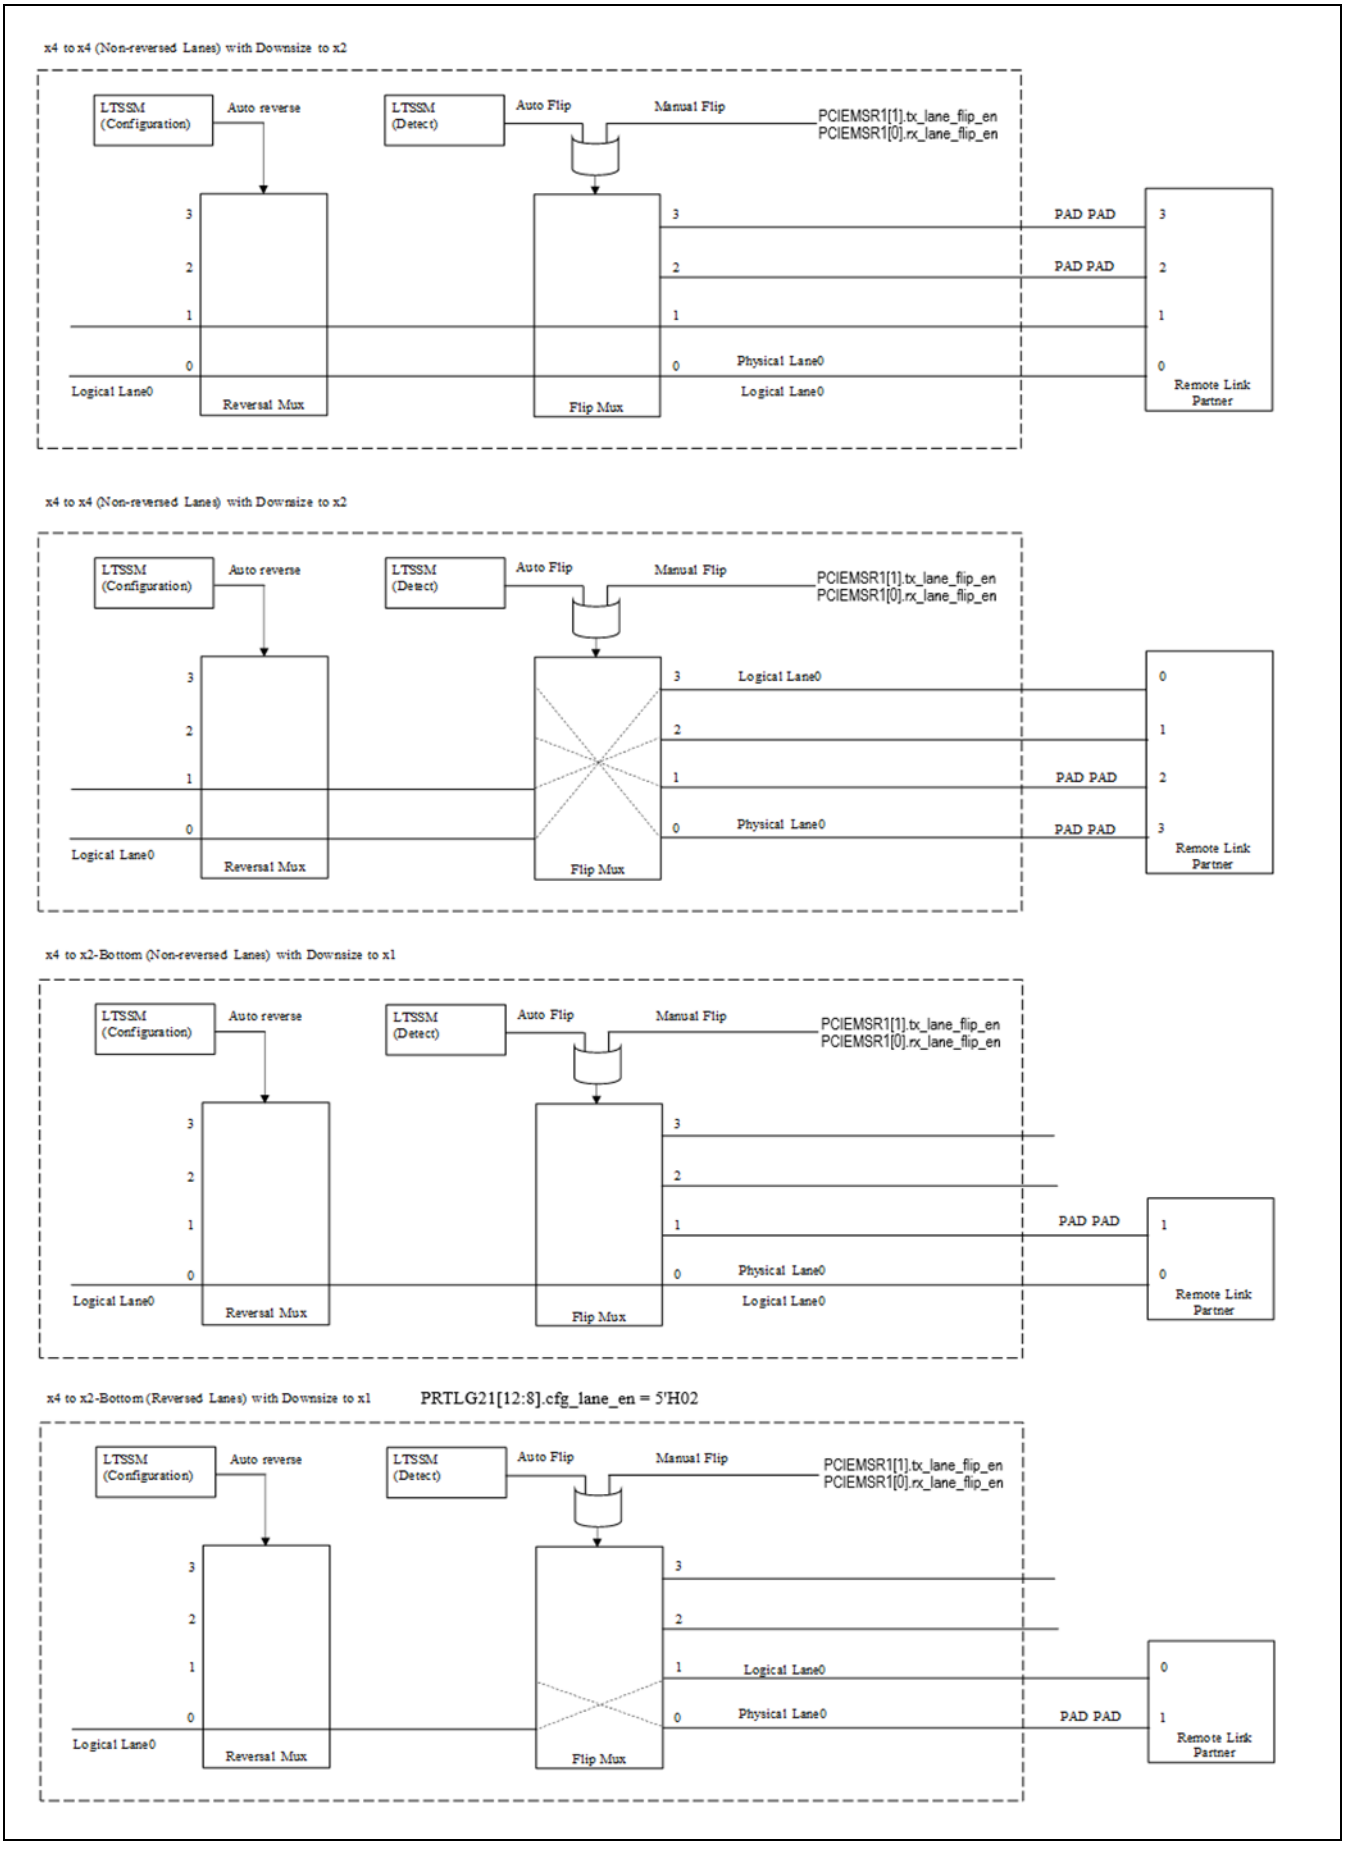

**Figure 104.29 Reversing and Flipping Lanes (3)**

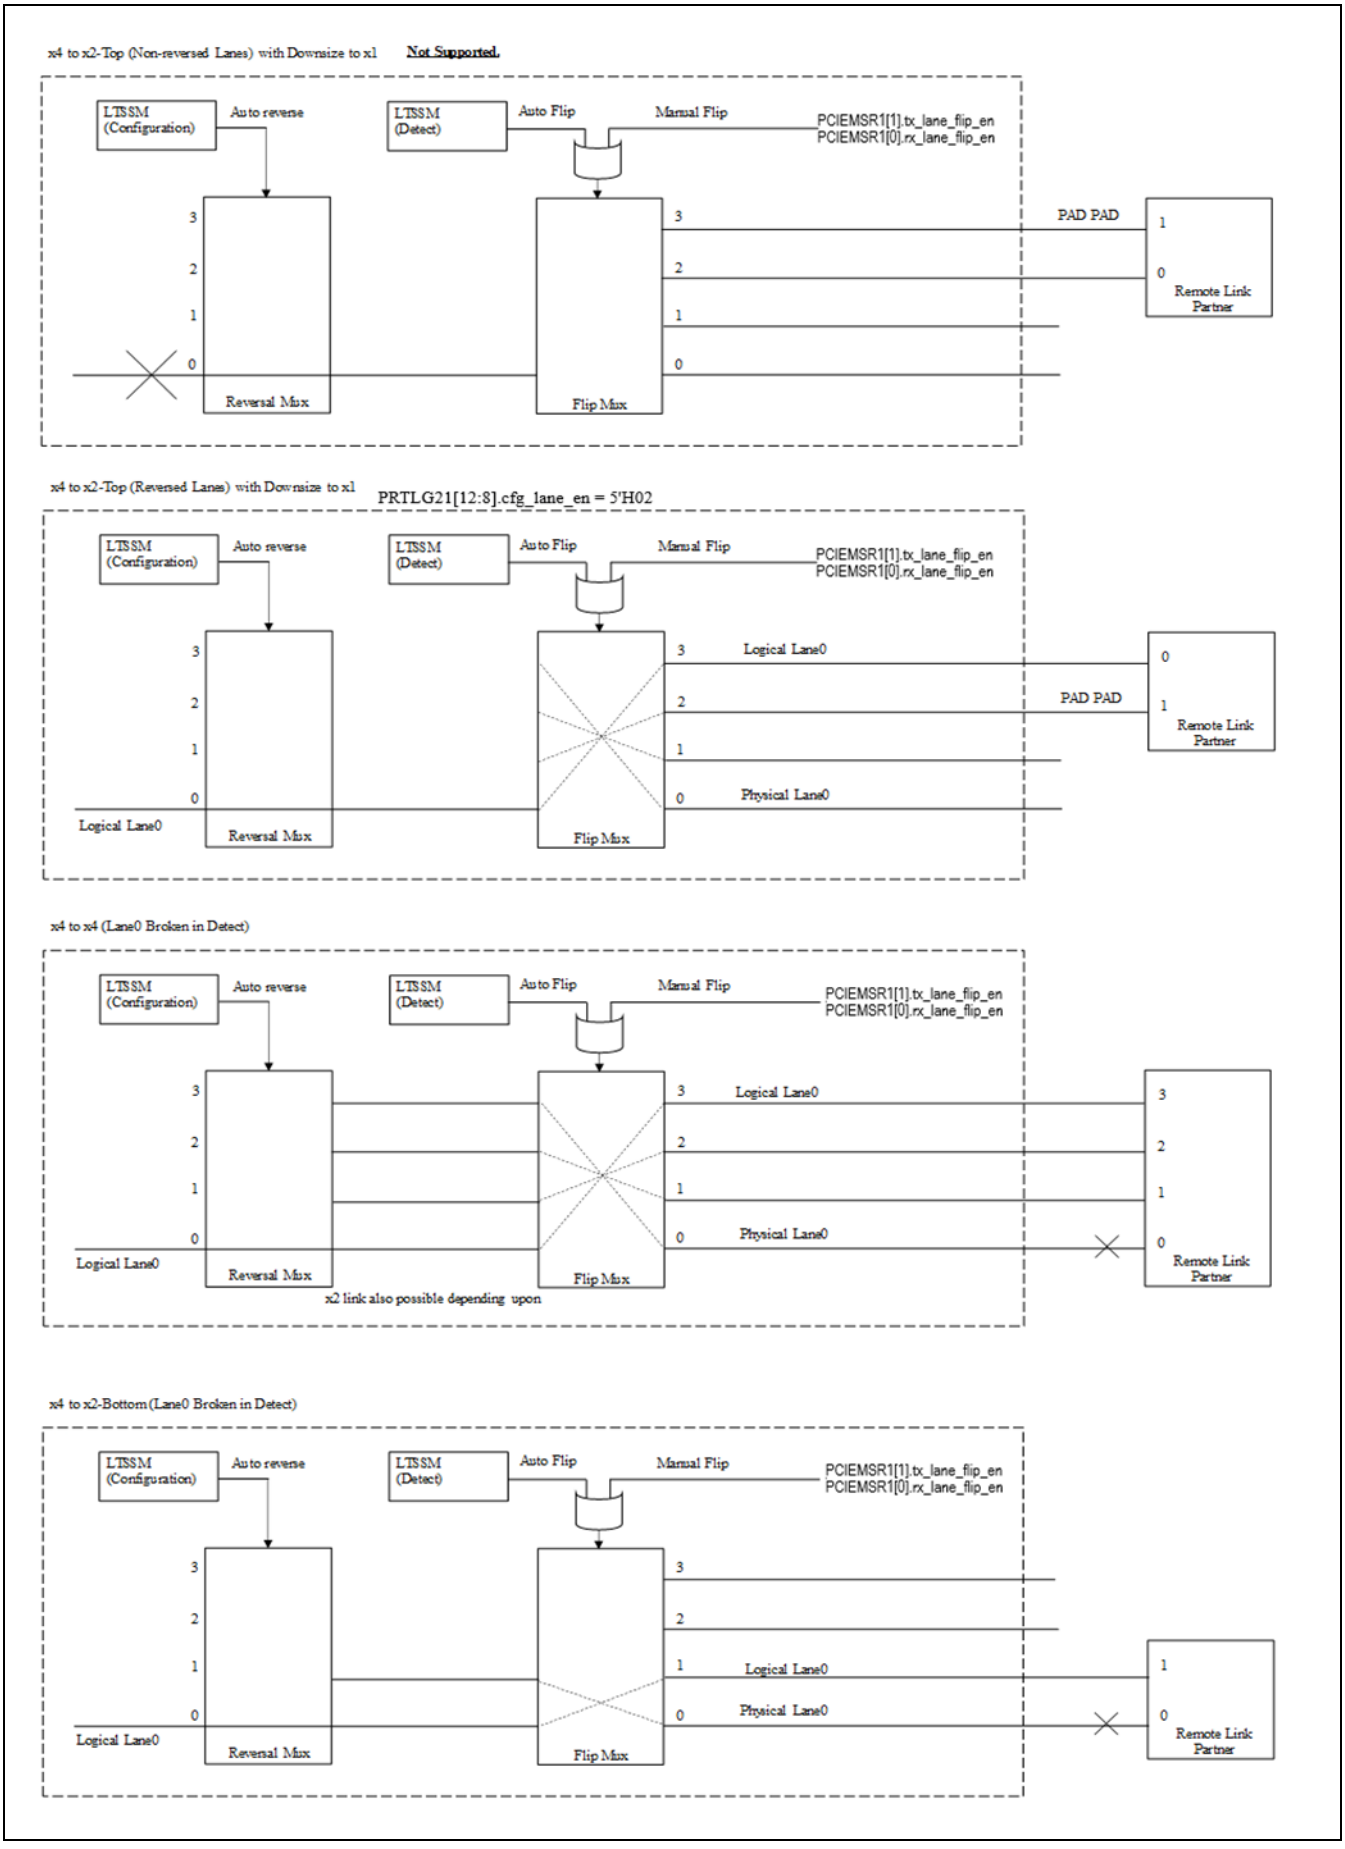

**Figure 104.30 Reversing and Flipping Lanes (4)**

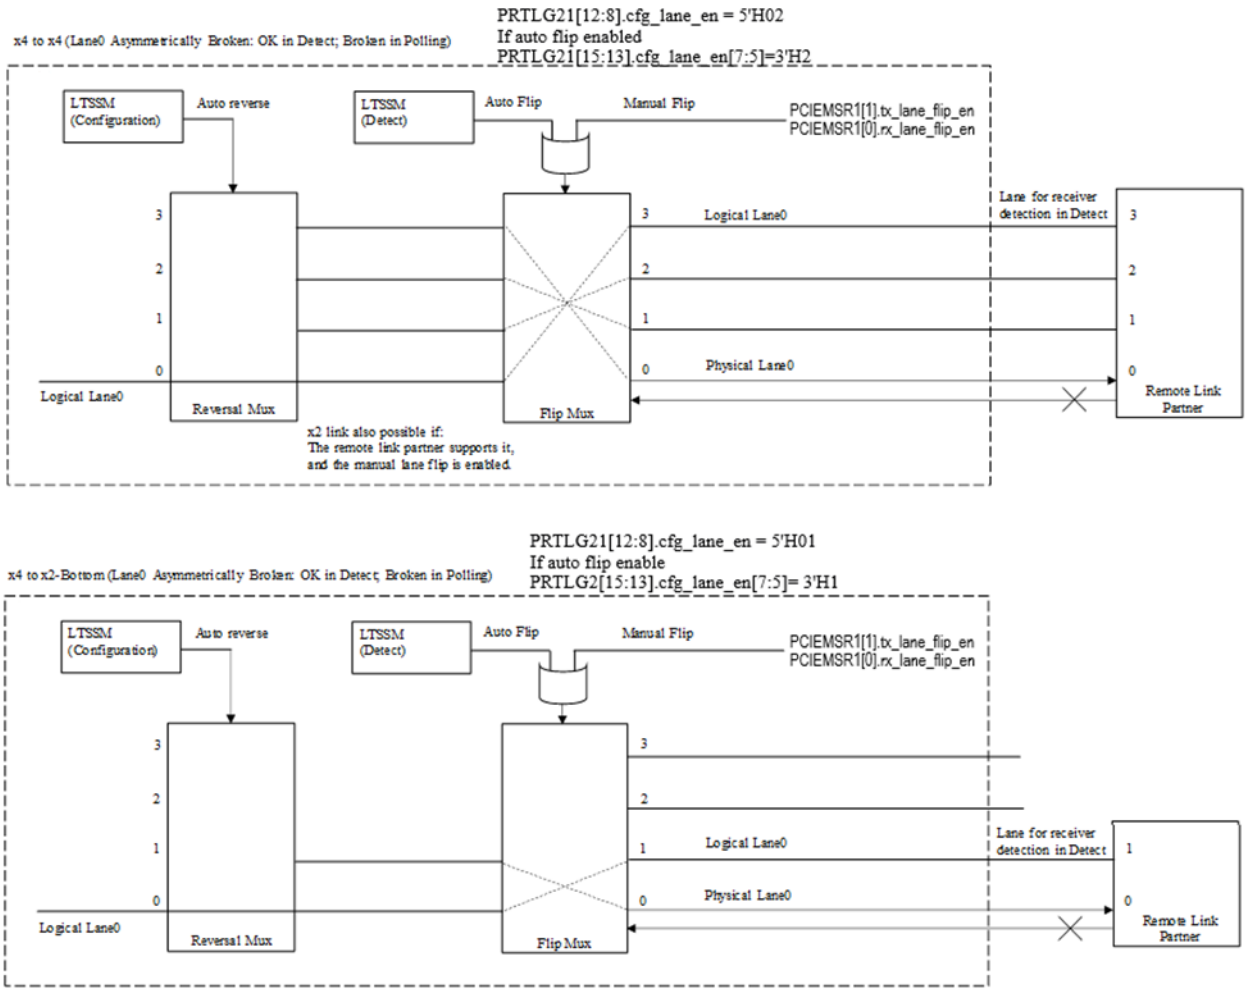

**Figure 104.31 Reversing and Flipping Lanes (5)**

### 104.3.13 Lane Bifurcation

PCIEC's channel 0 which has the quad lanes supports lane bifurcation. The channel 0 can be bifurcated to two dual lanes which are called as channel 0 and channel 1 respectively. The channel 0 and channel 1 which are bifurcated lanes have the independent link function, power management and reset architecture. Therefore, you can control each channel without effect to the other working channel.

To enable the lane bifurcation, set PCIEMSR0.BFRCTNST = H'1 before PCIEC reset de-assert. It is forbidden to change the lane bifurcation mode during PCIEC operation.

### 104.3.14 Power Management

This section discusses the power management (PM) features of the controller. For a proper understanding of PCIe power management, you should read Chapter 5, Power Management of the PCI Express Base Specification, Revision 4.0, Version 1.0. The following topics are discussed:

■ "Overview"

■ "L1 Substates"

■ "L0s Entry and Exit Conditions"

■ "L1 Operation (Non-substates)"

■ "L2 and L3 Power Down Entry and Exit Conditions (USP)"

■ "Advanced Power Management and Power Domain Gating"

#### (1) Overview

The controller supports two categories of PM operations to control the device state (D-state) and link state.

- **Software PCI Compatible PM (PCI-PM)**
  - **D-state PM of Function.** The host software can direct the function to enter any of the D1 or D3 low-power states. It does this by writing to the Power Management Control and Status Register (PMCAP1Fi) in the PCI-PM capability structure.
  - **D-state PM of Link.** Link states are not visible to PCI-PM legacy compatible software, and are derived from the power management D-states of the components connected to that link. The action of changing the D-state in the PMCAP1Fi indirectly causes a change in the link power state. The L1 state is entered whenever all functions of a USP on a link are programmed to a non-D0 state. The entry into L2 and L3 states is initiated by the DSP.
  - **Clock PM (L1 with REFCLK removal/PLL Off).** This is an optional feature that enables components on a link to further reduce idle power consumption while the link is in L1, by turning off the PLL.
- **Native PCIe PM Mechanisms**
  - **Active State PM (ASPM).** When the USP is in L0 and detects idleness on the link for a specific amount of time, it automatically transitions the link to the L0s or L1 (optional) power state.

- **L1 Substates.** This is an optional PCIe feature that enables components on a link to further reduce idle power consumption while the link is in L1, including almost complete removal of power for the high speed PHY circuits.

**Relationship Between D-state, Link State, and PHY State**

The link state and D-state determine what power and clock supplies are on or off. For implementation details of low-power clocking logic.

**Table 104.32 Power/Clock Supply Status in Low-Power States of Interest (DSP or Single Function non-ARI USP)**

| D-State | Permissible Quiescent Link States | Link State Change Trigger | Active Power Supplies | Active Clock Supplies | pipe_clk<br>core_clk | PHY State |
|---|---|---|---|---|---|---|
| $D0_{unitialize}$ | L0 | n/a | $V_{main}$<br>$V_{aux}$ | REFCLK<br>AUXCLK | ON | P0, P0s |
| $D0_{active}$ | L0 | ASPM | | | | |
| | L0s | | | | | |
| | L1 | | | | ON | P1 |
| D1, $D3_{hot}$ | L1 | PCI-PM | | | | |
| $D3_{cold}$ | L2 | PCI-PM | $V_{aux}$ | AUXCLK | OFF | P2/OFF |
| | L3 | | None | None | | |

****Note: $D0_{active}$ and $D0_{uninitialized}$**
D0 is divided into two distinct sub-states, the uninitialized sub-state and the active sub-state. When a component comes out of conventional reset or FLR, it defaults to the D0 uninitialized state. A function enters the $D0_{active}$ state whenever any of the functions Memory Space Enable, I/O Space Enable, or Bus Master Enable bits have been enabled by system software.

**Table 104.33 Link-State-Change Trigger Capabilities for Each Port Type**

| Port Type | Can Trigger L0/L0s Entry | Can Trigger L1 Entry | Can Trigger L2/L3 Entry |
|---|---|---|---|
| USP | Yes | Yes, on any of these trigger. Software program non-D0 state (PCI-PM)<br>USPs idle timer expires (ASPM)<br>Application requests the USP to Enter L1 | No |
| DSP | Yes | No | Yes |

Table below indicates the different levels of power savings (obtained by switching off circuits outside the controller) that can be expected from executing L1 in different ways. Higher exit latencies are associated with higher power savings. Power saving and latency are PHY implementation specific, and may be determined by consulting your PHY documentation.

**Table 104.34 – L1 Execution Modes and Permissible Power States of PHY Circuits**

| L1 Execution Mode | Permissible Power States for PHY Circuits | | |
|---|---|---|---|
| | **PLL/REFCLK** | **Rx Electrical Idle Detector** | **TX common mode** |
| L1 without clock PM | ON | ON | ON |
| L1 with clock PM | OFF | ON | ON |
| L1.1 | OFF | OFF | ON |
| L1.2 | OFF | OFF | OFF |

**Device State (D-state) Power Management of a Function (USP)**
The host software can direct the downstream device function to enter any of the low-power states:

- D1 (light sleep).
- D2 (deep sleep). (not support D2 Power Management State)
- $D3_{hot}$ (full of; reference clock optionally removed; $V_{main}$ normally available).
- $D3_{cold}$ (full of; reference clock removed; $V_{main}$ removed; $V_{aux}$ optionally available).

It does this by writing to the PMCAP1F*i* in the PCI-PM capability structure. This action also indirectly causes the downstream component (USP) to change the link power state. The controller negotiates with the link partner using PM TLPs and DLLPs before entering the corresponding low-power link state. The controller exits the device low-power state (and returns to D0) when it detects a CFG access to a device function, or when it detects a PME such as an event on the outband_pwrup_cmd input signal. For a function in device power states D1 and $D3_{hot}$, the controller only accepts CFG and MSG requests TLPs for that function. All other incoming request types for that function are treated as unsupported requests (UR). For more details see Section 5.3.3, “Power Management Event Mechanisms” of the *PCI Express Base Specification, Revision 4.0, Version 1.0.*

**Active State Power Management (ASPM)**

You must enable ASPM through the ASPM Control field in the Link Control register. When the USP is in L0 and detects idleness on the link for a specific amount of time (determined by the L0s Entrance Latency field in the “Ack Frequency and L0-L1 ASPM Control Register” PRTLGC3), it automatically transitions the link to the L0s power state. Each link direction (TX and RX) is processed separately. The controller exits L0s when there is traffic waiting to be sent. When the USP is in L0 or L0s and it detects idleness on the link (both directions) for a specific amount of time (determined by the L1 Entrance Latency field in PRTLGC3), it automatically transitions the link to the L1 power state. The link partners must negotiate entry into the L1 link power state using PM TLPs and DLLPs. The L1 state achieves greater power savings but the exit latency from this state is higher than from L0s. You can also instruct an USP controller (only) to enter L1 by asserting the app_req_entr_l1 input. The USP exits L1 when there is traffic waiting to be sent or when a PME (such as an event on the app_req_exit_l1 input) is received. If the ASPM exit latencies from L0s or L1 are too high for the overall PCIe system data latency requirements, then the host software can disable ASPM using the ASPM Control Field of the Link Control register. The controller reports the exit latencies using the Link Capability registers. You set these by writing to these registers or by setting the DEFAULT_L0S_EXIT_LATENCY and DEFAULT_L1_EXIT_LATENCY parameters.

**Registers Shadowed in Power Management Controller**

Table below lists the registers shadowed in the power management controller (PMC) and the reason for shadowing them.

**Table 104.35 Registers Shadowed in PMC**

| Register | Field | Description | Reason for Shadowing |
|---|---|---|---|
| Device Control Register<br>(EXPCAP2Fi) | Aux Power PM Enable<br>(aux_pm_en) | Enable aux_power support for a function | The PCI Express Base Specification, Revison4.0, Version 1.0 specifies that the value of this bit must be preserved in the $D3_{cold}$ state. In L2 when power is removed the CDM loses its context. This bits is preserved in the PM under AUX power and fed back to the CDM. |
| PMCSR<br>(PMCAP1F*i*) | PME_EN<br>(pm_pme_en) | Indicates if a function is permitted to generate a PME | PME message request, if enable, can trigger a wakeup from L2 if main power has been removed. |
| PMCSR_BSE<br>(PMCAP1F*i*) | PowerState<br>(pmstate) | Indicates the D-state of a function | Use for entry to low power states. |
| Link Capabilities Register<br>(EXPCAP3F*i*) | Clock power Management<br>(cfg_clk_pm_cap) | If set to 1 this indicates that an upstream port tolerates the removal of reference clock when the link is in L1 or L2/L3 ready | Used for the removal of reference clock in L1 or L2/L3 ready. |
| AUX_CLK_FREQ_OFF<br>(PRTLGC87) | AUX_CLK_FREQ | The frequency of the aux_clk in MHz | This field is use to scale certain timers in the power management block. It needs to be shadowed because the CDM is reset when power is removed in L2. |
| GEN3_RELATED_OFF<br>(PRTLGC53) | GEN3_ZRXDC_NONCOMPL<br>(cfg_pl_gen3_zrxdc_noncompl) | GEN3 receiver impedance zrx-dc not compliant | This bit enable a 100ms timer which can trigger exit from L1 |

Note:
Temporarily interrupt the stream of back-to-back TLPs for one or more clock cycles on the client interfaces when low power mode entry is requested. This causes performance degradation.

Implement the note 1 (if possible), or
Implement the note 2
1. The application can monitor PCIEPWRMNGSTS1.pm_master_state and PCIEPWRMNGSTS1.pm_slave_state to know when the controller is in L1 entering negotiation.
2. Disable ASPM and do not force the controller into a low power mode through PCI-PM.

### (2) L1 Substates

This section discusses the L1 link substates. The following topics are discussed:

■ “L1.1 and L1.2 Entry and Exit Conditions”

■ “L1 Exit Latency”

The L1 substates are applicable in both the ASPM and PCI-PM L1 link states. L1 substates management utilizes a per-link sideband signal called CLKREQ#. The controller supports this feature (with the additional I/O as shown in “Removing the Reference Clock” on page 69) when you set CX_L1_SUBSTATES_ENABLE =1.

**Assumptions and Limitations**

- The CLKREQ# signal is not directly controlled by the controller. You must implement external logic to do so.
- During L1 substates it is assumed that core_clk is turned off and that aux_clk is active. It is required that your application switches aux_clk to a low frequency free running clock on entry into L1.
- The controller uses aux_clk for counting time during L1 substates. You must program the frequency of this clock into the PRTLGC87 register with a value in the range 1…1000MHz to count real time. Frequencies lower than 1 MHz are possible, but with a loss of accuracy in the time counted.
- When the electrical idle detection circuitry is disabled it is assumed that the PHY holds the signal phy_mac_rxelecidle to 1.
- Access the L1 PM Substates Extended Capability register.
  System Usage Note:
  Software should not attempt to write to the mentioned fields in the L1 PM Substates Extended Capability register.

#### (a) L1.1 and L1.2 Entry and Exit Conditions

**Overview**

After the link has entered L1 through the normal L1 negotiation, the USP can initiate the sequence for entering the target L1 substate (L1.1 or L1.2) by tri-stating its CLKREQ# output buffer. The entry sequence can only proceed if the DSP is also tri-stating its CLKREQ# output buffer, resulting in the bidirectional CLKREQ# signal being pulled up to 1. Otherwise CLKREQ# remains asserted at 0 and the link state stays in L1. The exit sequence can be initiated by either ports by asserting CLKREQ# to 0. For each port there are two cases to consider, the first where the exit is initiated locally, the second where the exit is initiated remotely. The following sections provide details on the signaling that occurs between the PCIe controller as the MAC, the PHY, and the CLKREQ# output buffer, for entering and exiting L1 substates. L1 substates management utilizes a per-link sideband signal called CLKREQ#. After all of the entry conditions for a L1 substate are met, the controller asserts the mac_phy_rxelecidle_disable output. When the target L1 substate is L1.2, it also asserts the mac_phy_txcommonmode_disable output.

**L1 Substates Entry**

1. MAC transitions the PHY to P1.
2. PHY asserts phy_mac_phystatus for P1 entry.
3. Controller transitions the PHY to P1.CPM and asserts pm_sel_aux_clk to turn off core_clk.
4. PHY asserts phy_mac_phystatus for P1.CPM entry and CLK_RST asserts aux_clk_active.

5. Controller de-asserts mac_phy_pclkreq_n[1].
6. CLKREQ# output buffer tri-stated.
7. Controller waits for clkreq_in_n to de-assert.
8. Controller transitions the PHY to P1.1 (or P1.2).
9. PHY asserts phy_mac_phystatus for P1.1 (or P1.2).
10. Controller asserts mac_phy_asyncpowerchangeack.
11. PHY de-asserts phy_mac_phystatus.
12. Controller de-asserts mac_phy_asyncpowerchangeack.

**L1 Substates Exit (Locally Initiated)**

1. Any of the normal L1 exit conditions in “L1-PM/L1-ASPM Exit” on page 278 are met
2. Controller asserts mac_phy_pclkreq_n[1].
3. CLKREQ# output buffer is asserted.
4. Controller transitions the PHY to P1.CPM.
5. PHY asserts phy_mac_phystatus for P1.1 (or P1.2).
6. Controller asserts mac_phy_asyncpowerchangeack.
7. PHY de-asserts phy_mac_phystatus.
8. Controller de-asserts mac_phy_asyncpowerchangeack.
9. Controller transitions the PHY to P1 and de-asserts pm_sel_aux_clk to turn on core_clk.
10. PHY asserts phy_mac_phystatus for P1 entry and CLK_RST de-asserts aux_clk_active.
11. Controller transitions the PHY to P0 in the usual way.

**L1 Substates Exit (Remotely Initiated)**

1. The remote link partner asserts CLKREQ#.
2. Controller input clkreq_in_n asserts.
3. Controller asserts mac_phy_pclkreq_n[1].
4. Controller transitions the PHY to P1.CPM.
5. PHY asserts phy_mac_phystatus for P1.1 or (P1.2).
6. Controller asserts mac_phy_asyncpowerchangeack.
7. PHY de-asserts phy_mac_phystatus.
8. Controller de-asserts mac_phy_asyncpowerchangeack.

9. Controller transitions the PHY to P1 and de-asserts pm_sel_aux_clk to turn on core_clk.
10. PHY asserts phy_mac_phystatus for P1 entry and CLK_RST de-asserts aux_clk_active.
11. Controller transitions the PHY to P0 in the usual way.

**L1 Substates Software Control**

When the controller enters L1, the target L1 substate depends on several programming bits:

- PM Control/Status Register
  - USP: The current D-state
  - DSP: The DLLP type that is used by USP to request L1
- L1 Substates Control 1 Register
  - ASPM PM L1.1 Enabled.
  - ASPM PM L1.2 Enabled.
  - PCI PM L1.1 Enabled.
  - PCI PM L1.2 Enabled.

After the USP controller enters L1, it uses the D-state of the device to determine if L1 is entered in ASPM mode or PCI-PM mode. After the DSP controller enters L1, it uses the USPs DLLP L1 request type to determine if L1 is entered in ASPM mode or PCI-PM mode. Table 104.36 and Table 104.37 (below) show the target L1 substate as a function of the relevant programming bits.

**Table 104.36 Target L1 Substate as a Function of Software Controls (USP)**

| D-State | ASPM PM L1.1 Enabled | ASPM PM L1.2 Enabled | Reported LTR >= L1.2 Threshold | PCI PM L1.1 Enabled | PCI PM L1.2 Enabled | Target L1 Substate |
|---|---|---|---|---|---|---|
| !D0 | - | - | - | 0 | 0 | L1 |
| !D0 | - | - | - | 1 | - | L1.1 |
| !D0 | - | - | - | - | 1 | L1.2 |
| D0 | 0 | 0 | - | - | - | L1 |
| D0 | 1 | 0 | - | - | - | L1.1 |
| D0 | 0 | 1 | 0 | - | - | L1 |
| D0 | 1 | 1 | 0 | - | - | L1.1 |
| D0 | - | 1 | 1 | - | - | L1.2 |

**Table 104.37 Target L1 Substate as a Function of Software Controls (DSP)**

| DLLP Received | ASPM PM L1.1 Enabled | ASPM PM L1.2 Enabled | Reported LTR >= L1.2 Threshold | PCI PM L1.1 Enabled | PCI PM L1.2 Enabled | Target L1 Substate |
|---|---|---|---|---|---|---|
| PM_Enter_L1 | - | - | - | 0 | 0 | L1 |
| | - | - | - | 1 | 0 | L1.1 |
| | - | - | - | - | 1 | L1.2 |
| PM_Active_State_Request_L1 | 0 | 0 | - | - | - | L1 |
| | 1 | 0 | - | - | - | L1.1 |
| | 0 | 1 | 0 | - | - | L1 |
| | 1 | 1 | 0 | - | - | L1.1 |
| | - | 1 | 1 | - | - | L1.2 |

The Reported LTR is the maximum of the snoop/no-snoop latency values embedded in LTR messages transmitted by the upstream ports or received by the downstream port. The controller stores these values in the port logic LTR Latency Register (PRTLGC86). When the requirement bit in the message is 0, the latency value is considered infinite (that is, the check with the threshold always pass).

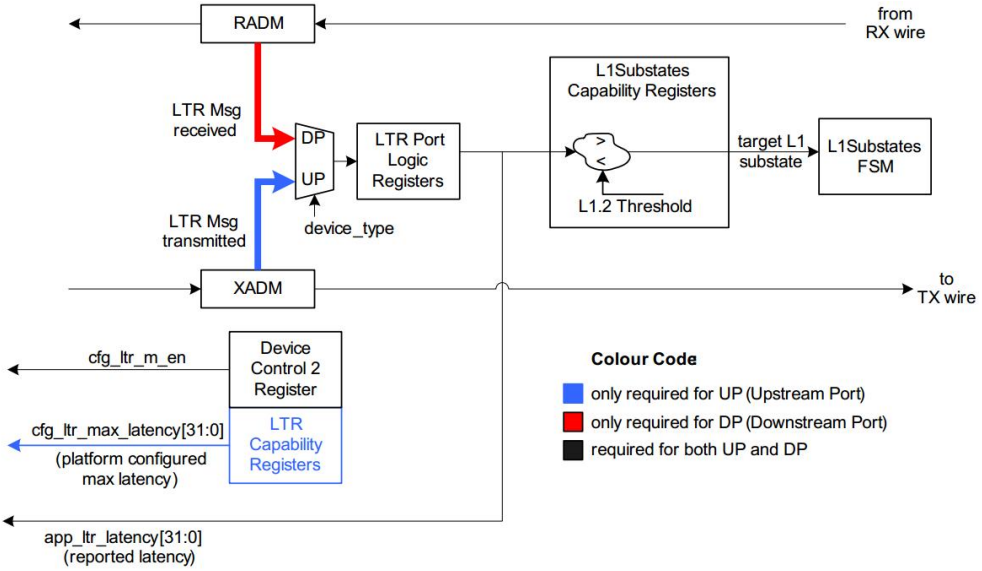

**Figure 104.36 Role of LTR in L1 Substates.**

### (b) L1 Exit Latency

This section provides a breakdown of the L1 exit latency when CX_L1_SUBSTATES_ENABLE is enabled for L1 substates or L1 Clock PM.

**Table 104.38 L1 Substates and L1 Clock PM Exit Latency Component Values**

| | A | B | C | D | E |
|---|---|---|---|---|---|
| Event in Figure 104.38 | CLKREQ# -> mac_phy_p | mac_phy_powerdown -> phy_mac_phystatus (pipe_clk_ stable) | pipe_clk stable -> mac_phy_powe | mac_phy_powerdown -> phy_mac_phystatus & LTSSM change | Recovery -> L0 |

| | owerdown | | rdown | | |
|---|---|---|---|---|---|
| Description | 0 | Time requires to produce a stable pipe_clk | Includes time to switch aux_clk back to pipe_clk and ungating of core_clk. | Time required after pipe_clk is stable to power up circuit for P0 | - |
| Values when exiting L1.1 | 0 | 400ns to reactivate REFCLK + 15us | Estimate: 3aux_clk cycles (slow freq) + 3 core_clk cycles | Time to P0, ~ 2us | Time to execute Recovery |
| Values when exiting L1.2 | 0 | T_power_on to reactivate REFCLK + 15us | | | T_common mode (~55us) + time to execute Recovery |

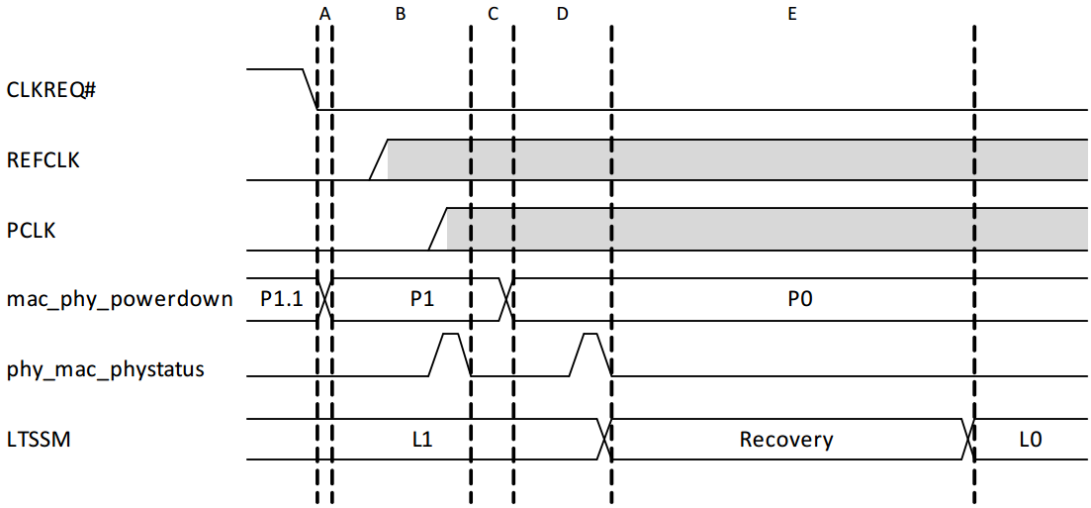

**Figure 104.38 L1 Exit Latency Components**

### (3) L0s Entry and Exit Conditions

This section discusses the L0s link state. The following topics are discussed:

■ “Overview”

■ “L0s Entry”

■ “L0s Exit”**Overview**

L0s is a low-power state enabled by ASPM. ASPM controls entry into L0s for the transmitter. The remote device controls entry into L0s for the receiver.

**L0s Entry**

All of these condition must be met:

- ASPM L0s is enabled through the ASPM Control field in the Link Control register.
- L0s entry conditions as defined in Section 5.4.1.1.1, “Entry into the L0s State” of the *PCI Express Base Specification, Revision 4.0, Version 1.0*, exist for a duration of time (determined by the cfg_l0s_entr_latency_timer field in PRTLGC3).
- No higher stage of power-down requested.

**L0s Exit**

Any of these condition can be met:

- A DLLP or TLP is pending to be sent.
- L1 entry conditions as defined in Section 5.4.1.2.1, “Entry into the L1 State” of the *PCI Express Base Specification, Revision 4.0, Version 1.0* are satisfied.
- PCIe link partner requests to enter into link recovery.

### (4) L1 Operation (Non-substates)

The following topics are discussed:

■ “L1 (ASPM/PM) Entry and Exit Conditions”

■ “L1 Clock PM (L1 with REFCLK Removal/PLL Off) Overview”

■ “L1 Clock PM (L1 with REFCLK Removal/PLL Off); Entry and Exit Conditions”

#### (a) L1 (ASPM/PM) Entry and Exit Conditions

**L1-ASPM Overview**

The L1-ASPM entry negotiation handshake uses PM_Active_State_Request_L1 DLLPs, PM_Request_Ack DLLPs, and PM_Active_State_Nak MSG TLPs. There are three scenarios that cause the controller to enter L1 under ASPM conditions.

**L1-ASPM Entry (Scenario 1): L1 Idle Timeout in L0s**

The controller enters L1-ASPM when all of these conditions are met in the USP:

- ASPM L1 and L0s are enabled through the ASPM Control field in the Link Control register.
- The cfg_l1_entr_wo_rl0s field of PRTLGC3 is set to ‘0’ and the link state is L0s for both link partners, or the cfg_l1_entr_wo_rl0s field of PRTLGC3 is set to ‘1’.
- L1 entry conditions as defined in Section 5.4.1.2.1, “Entry into the L1 State” of the *PCI Express Base Specification, Revision 4.0, Version 1.0*, exist for a duration of time (determined by the cfg_l1_entr_latency_timer field in PRTLGC3).
- No higher stage of power-down requested.
- Your USP application is not asserting the app_xfer_pending input.
- There are no in-progress transactions1 in the controller such as:
  - Rx queue P/NP Request TLPs.

- Rx queue CPL TLPs.
- Outstanding/expected wire completions.
- Outstanding/expected application (at the AXI master interface when present) completions.

- There are no pending requests at the AXI slave interface, that is, slv_a*valid must be 0.
- There are no pending DMA transfers.

**L1-ASPM Entry (Scenario 2): L1 Idle Timeout In L0**

The controller enters L1-ASPM when all of these conditions are met in the USP:

- ASPM L1 is enabled and L0s is not enabled through the ASPM Control field in the Link Control register.
- Link state is L0.
- L1 entry conditions as defined in Section 5.4.1.2.1, “Entry into the L1 State” of the *PCI Express Base Specification, Revision 4.0, Version 1.0*, exist for a duration of time (determined by the cfg_l1_entr_latency_timer field in PRTLGC3).
- No higher stage of power down-requested.
- Your USP application is not asserting the app_xfer_pending input.
- There are no in-progress transactions in the controller such as:
  - Rx queue P/NP Request TLPs.
  - Rx queue CPL TLPs.
  - Outstanding/expected wire completions.
  - Outstanding/expected application (at the AXI master interface when present) completions.
- There are no pending requests at the AXI slave interface, that is, slv_a*valid must be 0.
- There are no pending DMA transfers.

**L1-ASPM Entry (Scenario 3): Application Controlled (USP only)**

The controller enters L1-ASPM when all of these conditions are met in the USP:

- ASPM L1 is enabled through the ASPM Control field in the Link Control register.
- Your application logic pulses the app_req_entr_l1 input.
- Your USP application is not asserting the app_xfer_pending input.
- There are no in-progress transactions1 in the controller such as:
  - Rx queue P/NP Request TLPs.
  - Rx queue CPL TLPs.
  - Outstanding/expected wire completions.
  - Outstanding/expected application (at the AXI master interface when present) completions.

- There are no pending requests at the AXI slave interface, that is, slv_a*valid must be 0.
- There are no pending DMA transfers.

**L1-PM Entry**

The power management state of a link is determined by the D-state of the USP. When you change the device state of the USP to D1 or $D3_{hot}$ by writing to the PMCAP1F*i*, the controller must initiate a link state transition to L1. The USP of a non-ARI multi-function device must not initiate a link state transition to L1 until all of its functions have been programmed to a non-D0 D-state. L1 state is a bi-directional link low-power state. Both link partners must negotiate to go this state. The L1-PM negotiation handshake uses the following DLLPs:

- PM_Enter_L1.
- PM_Request_Ack.

All of these condition must be met:

- L1 entry conditions are satisfied as defined in Section 5.3.2.1, “Entry into the L1 State” of the *PCI Express Base Specification, Revision 4.0, Version 1.0*.

**Note**: An USP application asserting the app_xfer_pending input does not prevent L1-PM entry, but causes immediate exit from L1-PM.

**L1-PM/L1-ASPM Exit**

The controller exits L1-PM/L1-ASPM if any of these conditions is met:

- A DLLP or TLP is pending to be sent.
- Your application asserts the app_req_exit_l1 input.
- Link partner is requesting exit from L1.
- Your application asserts the app_xfer_pending input.
- Your application asserts the apps_pm_xmt_pme input. When the USP is programmed with capability to support PME; it sends a PME message to the RC which calls the PM software to transition the USP to the D0 state. Therefore, you should only use apps_pm_xmt_pme for L1-PM exit.
- PM software (RC) requests a higher stage of power-down by writing to the PMCAP1F*i* in the USP.
- Your application (USP) requests transmission of VDM, MSI, or LTR message.
- Your application is requesting to send traffic by asserting client0_tlp_hv (non-AXI)
- Your application enables a DMA read or write channel, or DMA controller is requesting data.
- Your application (DSP) initiates link disable, or link retrain (by setting cfg_link_dis or cfg_link_retrain field in EXPCAP4Fi to 1).
- Your application (DSP) initiates hot reset by either:
  - setting cfg_plreg_reset field in PRTLGC4 to 1, or
  - setting cfg_2nd_reset field in PCICONF15F*i* to 1, or
  - toggling app_init_rst
- Your application (DSP) requests transmission of Unlock message.

- Your application requests a speed change (by setting cfg_directed_speed_change field in PRTLGC21 to 1).
- Your application requests link width change (by setting cfg_pl_multilane_control[6] field in PRTLGC59 is set to 1).
- Any activity in the RADM, as indicated by radm_idle being set to 1'b0.
- Clearing r_radm_clk_gating_en field in PRTLGC52 register.

***Note:** The CDM space is accessible in L1, but some CDM register bits do not produce the desired results. Writing to CDM register bits which trigger LTSSM state transitions in L1 does not have the desired effect because the LTSSM clock is not running in L1. radm_idle is set to 1'b0 if AERCAP6F*i*.ECE is set to 1'b1 during L1.

****Caution:**
**DMA Doorbell L1**
- Any DMA register can be accessed in L1 because the DMA registers are clocked on aux_clk_g.
- When core_clk is removed in L1 substates or L1 clock power management, aux_clk_g is used.

**DMA Doorbell L1 Exit**
- Doorbelling any DMA read/write channel triggers L1 exit.
- Writing to other DMA registers does not trigger L1 exit.

### (b) L1 Clock PM (L1 with REFCLK Removal/PLL Off) Overview

This feature allows you to shut down the PLL and the reference clock during standard (non-substates) L1. Table 104.39 lists the inputs and outputs that are considered for L1 Clock PM.

**Table 104.39 Inputs and Outputs to Consider for L1 Clock PM**

| CX_L1_SUBSTATES_ENABLE | CX_PIPE_VER | I/O SIGNALS |
|---|---|---|
| 0 | 0 | clk_req_n<br>phy_clk_req_n |
| | 1 | clk_req_n<br>mac_phy_powerdown[3:0] = CX_PIPE43_P1CPM_ENCODING<br>phy_mac_phystatus |
| 1 | 0 | mac_phy_pclkreq_n[0]<br>phy_mac_pclkack_n |
| | 1 | mac_phy_pclkreq_n[0]<br>mac_phy_powerdown[3:0]= CX_PIPE43_P1CPM_ENCODING<br>phy_mac_phystatus |

For PIPE 4.3 (CX_PIPE_VER =1),

- The controller and PHY use mac_phy_powerdown[3:0] to indicate the PHY power state.
- You can specify the power-down encodings using the CX_PIPE43_P1CPM_ENCODING parameter.

- You can specify P1.CPM entry sequence using the CX_PIPE43_P0_P1CPM parameter.

For an USP, host software uses the Enable Clock Power Management bit in the Link Control register to enable this feature. For a DSP, this register bit is hard coded to '0' and cannot be used to control this behavior. Your application can use the app_clk_pm_en input to dynamically control whether to execute L1 with or without Clock PM. The CLKREQ# signal is not directly controlled by the controller.

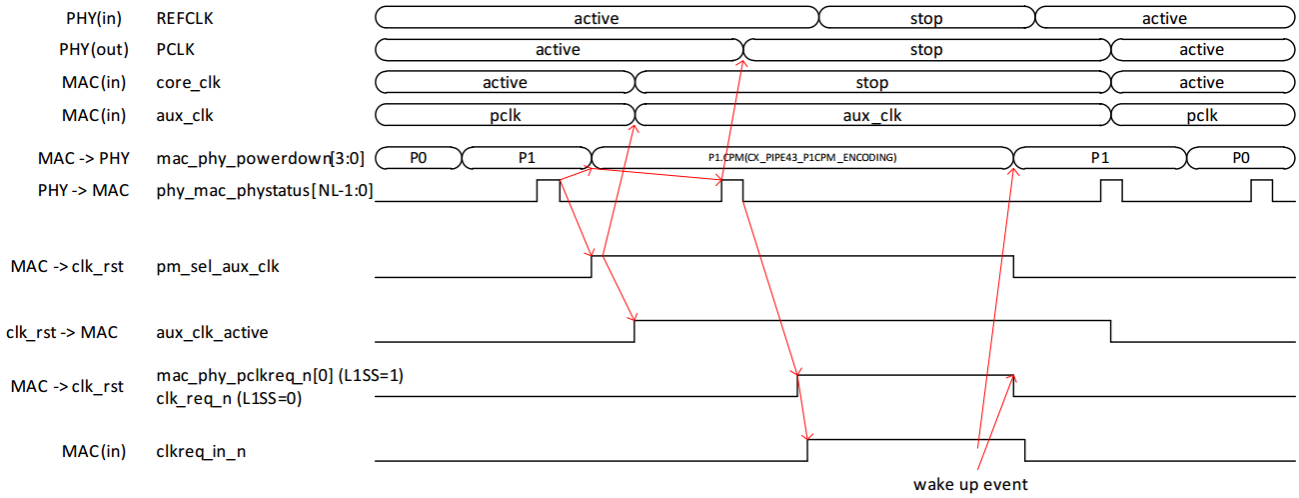

**Figure 104.39 PIPE 4.3 L1 CPM Operation (CX_PIPE43_P0_P1CPM=0)**

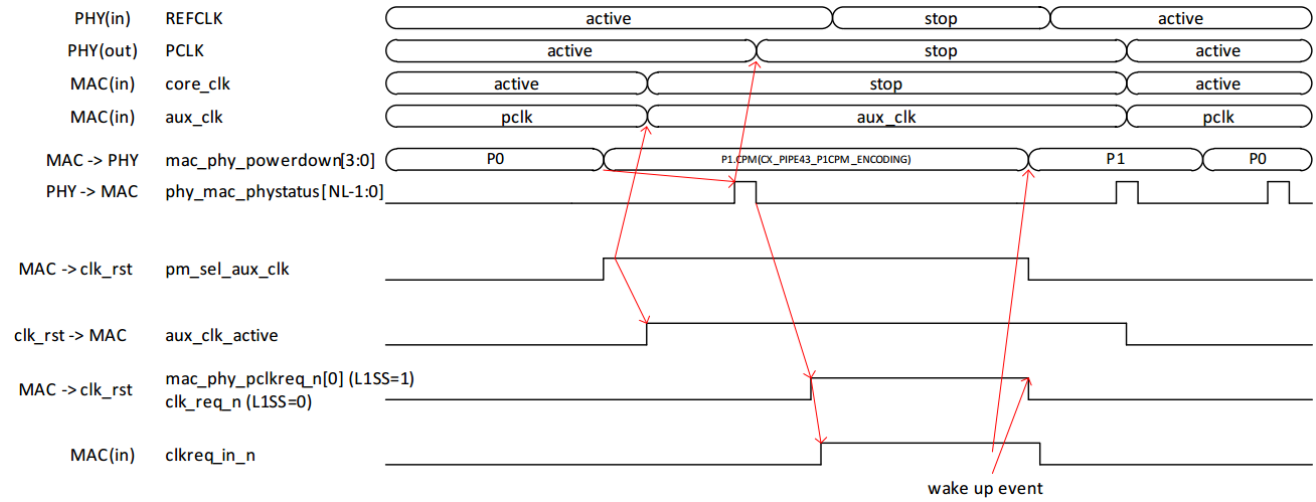

**Figure 104.40 PIPE 4.3 L1 CPM Operation (CX_PIPE43_P0_P1CPM=1)**

### (c) L1 Clock PM (L1 with REFCLK Removal/PLL Off); Entry and Exit Conditions

To enable the controller (upstream port only) to execute L1 with Clock PM:

- The Support Clock Power Management bit in the Link Capabilities register must be set. The default value of this register is controlled by the DEFAULT_CLK_PM_CAP parameter. For downstream ports it is hardcoded to 0, for upstream ports it can be accessed through the DBI.
- The Enable Clock Power Management bit in the Link Control register must be set.
- You must set the app_clk_pm_en input to 1. The controller only samples app_clk_pm_en when L1 is entered.

L1 with Clock PM and L1 substates work orthogonal to each other. L1 with Clock PM uses the mac_phy_pclkreq_n[0] signaling, and L1 substates uses the mac_phy_pclkreq_n[1]signaling. However, L1 substates takes precedence over Clock PM within the cores PM state machine. This means that when the entry conditions for any L1 substate are satisfied then the controller's LTSSM executes the corresponding L1 substate protocol.

For details on L1 exit latency, see “L1-PM/L1-ASPM Exit”.

### (5) L2 and L3 Power Down Entry and Exit Conditions (USP)

This section discusses the L2 and L3 link states. The following topics are discussed:

- “Overview”
- “L2/L3 Entry”
- “L2/L3 Exit”

**Overview**

L2 entry is initiated(1) after the RC calls power management software to initiate the removal of power and clocks. USPs of devices in D0, D1 and $D3_{hot}$ must respond to the receipt of a PME_Turn_Off MSG TLP by transmitting a PME_TO_Ack MSG TLP. The device must then request a link transition to L2_Ready. L2_Ready is a bi-directional link power down state. If your application is not ready to be shut-down, it must keep the app_ready_entr_l23 input de-asserted. This causes the controller to delay sending the PM_Enter_L23 DLLP and thereby stalling the negotiation handshake that uses the following DLLPs:

- PM_Enter_L23.
- PM_Request_Ack

When your application is eventually ready for transitioning to $D3_{cold}$, that is, loss of main power and reference clock, L2_Ready is entered and the downstream device begins preparation for the power and clock removal. After main power has been removed, the link transitions to L2 if Vaux is provided, or it transitions to L3 if no Vaux is provided.

***Note: PCIe does not support L3.**

**L2 Entry**

All of these condition must be met:

- PME_Turn_Off/PME_TO_Ack handshake has been completed.
- Your USP application is ready to be turned off; app_ready_entr_l23 =1.
- After sending the PME_TO_Ack, the USP initiates the L2 Ready transition protocol by sending the PM_Enter_L23 DLLP. The RC responds with the PM_Request_Ack.

Note:
When PCIEPWRMNGSTS0.smlh_ltssm_state is set to '6'h0D' (RCVRY_LOCK) and PCIEPWRMNGSTS1.pm_master_state is set to '5'h18' (Wait for PM DLLP flush), the application should trigger the perst_n (warm reset)

**L2 Exit**

Any of these condition can be met:

- When the USP is programmed(2) with capability to support PME, your application can assert the apps_pm_xmt_pme input to request the controller to wakeup. The USP then sends a PM_PME MSG TLP to the RC which calls the PM software to transition the USP out of the D3 state.
- Device is programmed with capability to support PME and your application requests the controller to wakeup by triggering a native hot-plug event.
- Link partner is requesting exit from L2/L3.

The controller directs the PHY to generate beacon signaling when a PCIe device initiates a wake-up event.

Note :

1. In preparation for removing the main power source, your RC application asserts the apps_pm_xmt_turnoff input which causes the RC to broadcast the PME_Turn_Off MSG TLP to all USPs.

2. pm_pme_en bit is set in PMCAP1Fi, and the cfg_pme_support RT bit is set in PMCAP0Fi for the corresponding D-state for which the function is currently in.

PCIE controller is stuck in L2.IDLE during L2 exit by Electrical Idle.
Note #1:
Set the P2NOBEACON_ENABLE field of the PRTLGC60 register to '1'.
Note #2:
Always use warm reset (perst_n) to exit L2 state.
Note #3:
Upstream port can use WAKE# to exit L2 state.
System Usage note: Beacon is not available as a method for L2 exit.

### 104.3.15 Data Protection

This section discusses how the controller maintains the integrity of the link using different methods at different points.

**(1) Overview**

PCIEC RAS consists of three fundamental components:

- Reliable protocol architecture involving LCRC, ACK/NAK handshake, and Replay mechanisms.
- Internal device-level Datapath and RAM protection (RAS DP) of data, header, and RAM control signals from application I/F to LCRC extraction/generation points.
- Debug, Error Injection, and Statistic gathering (RAS DES).

**(2) RAS Data Protection (DP)**

- For the parts of the PCIEC outside of LCRC protection, PCIEC has the RAS DP feature consisting of:
- RAM Protection (ECC on data and Parity on address)
- An ECC checksum is calculated and added to data that is written to the RAM. When the data is read from the RAM, then the PCIEC recalculates the ECC and compares it against the value read from RAM. RAM ECC protection is provided for all of the RAMs in the PCIEC, except for the RAS-DES RAM. ECC corrects single-bit errors and reports (without correction) multi-bit errors.
- Datapath Protection (Parity)
- For Tx traffic, PCIEC adds parity protection codes to AXI bus address and data.
- For Rx traffic, PCIEC checks the protection codes on AXI bus address and data.

**(3) Uncorrectable Error Handling**

Upon detection of first Uncorrectable error (RAM and Datapath/Interface Protection), depending on value of cfg_rasdp_linkdown_en field of the VSE2CAP10, the PCIEC takes one of the two actions:

- Forces the PCIe link to go down (cfg_rasdp_linkdown_en =1), or
- Enters RASDP Error Mode (cfg_rasdp_linkdown_en =0)

**(a) PCIe Link Down**

- If the PCIEC is configured to cause the link to go down upon detection of an Uncorrectable error, the controller resets and resumes normal operation.

**(b) RASDP Error Mode**

On entering RASDP error mode, the PCIEC sets

slv_rasdp_error_mode/mstr_rasdp_error_mode.

Wire access to CDM registers is suspended to prevent corruption of the register configuration space.

TLP handling in RAS DP Error mode:

- Rx TLP Handling
  - Rx Errored TLPs are Forwarded to AXI bus.
  - Subsequent Rx TLPs not Guaranteed to be Correct; you Must Discard all TLPs.
- Tx TLP Handling for Dual lane link
  - Bad TLP is Nullified (EDB Inserted and LCRC Inverted) and Transmitted.
  - Subsequent TLPs are Nullified and Transmitted.
  - In-progress Replay is Nullified and Transmitted.
  - Subsequent Replays are Silently Dropped.
- Tx TLP Handling for Quad Lane link
  - Bad TLP is Silently Dropped.
  - Subsequent TLPs are Silently Dropped.
  - In-progress Replay is Nullified and Transmitted.
  - Subsequent Replays are Silently Dropped.

Credits accuracy is not retained under uncorrectable error conditions.

Error Logging:

- Uncorrectable Error (2-bit ECC and all parity errors.) is Logged
- Uncorrectable Internal Error Reported (AER)

**(4) Correctable Error Handling**

The PCIEC takes the following action to handle correctable (RAM and Datapath/Interface Protection) errors:

- Correctable Error(1-bit ECC errors) is Logged
- Correctable Internal Error Reported (AER)
- TLP is Modified/Corrected
- Errors Reported When Detected (Immediately)
- Error Correction Enable/Disable Control (Per TX/RX Direction and Per-Layer)
- If the PCIEC is capable of single bit error correction, disabling ECC error correction does not change the nature of the errors and their reporting. A single-bit error is reported as a correctable error although correction might be disabled.

**(5) RAS Debug, Error Injection, and Statistics (DES)**

**(a) Debug**

To facilitate system level debugging the PCIEC provides the following features:

- General Diagnostic Support (Legacy Internal Probe Points).
- Silicon Debug Support (Control and Status of PIPE, Deskew, Ack/Nak, Reversal, FC, EQ, LTSSM, Replay)

**(b) Error Injection**

The PCIEC provides support to inject the following types of errors:

- CRC Error
- Sequence Number Error

- DLLP Error
- Symbol DataK Mask Error or Sync Header Error
- FC Credit Update Error
- TLP Duplicate/Nullify Error
- Specific TLP Error

**(c) Statistics**

To facilitate collection of statistics the PCIEC provides the following features:

- Time Based Analysis (RX/TX data throughput and time spent in each low-power LTSSM state)
- Event counters (Error and Non-Error)

### 104.3.16 Error Handling

This section describes handling of the errors detected by this module.

#### (1) Error Types

This module classifies detected errors into four types: three types defined in the PCI Express standard (correctable errors, non-fatal errors, and fatal errors), and DMA controller error. It reports each type of error through the corresponding interrupt. About Error Types classification, refer to 104.3.17.

#### (a) Correctable Error

Correctable errors are defined as the type of errors from which recovery is possible through the PCI Express protocol. Recovery from the errors is performed by hardware.

When the conditions described later are satisfied, occurrence of a correctable error is signaled by the intreq_pci*m*_corerr interrupt. (m = 0)

#### (b) Non-Fatal Error

Non-fatal errors are defined as the type of errors from which recovery is impossible through the PCI Express protocol but which is not fatal. After this error, a single packet is discarded but the subsequent data communication can be continued. In most cases, error processing such as retransmission of the discarded packet is needed.

When the conditions described later are satisfied, occurrence of a non-fatal error is signaled by the intreq_pci*m*_nonfaterr interrupt. (m = 0)

#### (c) Fatal Error

Fatal errors are defined as the type of errors from which recovery is impossible through the PCI Express protocol and which is fatal. Specifically, the errors that require resetting the communication path or other appropriate processing fall into this type. In most cases, PCIEC must be initialized.

When the conditions described later are satisfied, occurrence of a fatal error is signaled by the intreq_pci*m*_faterr interrupt. (m = 0)

#### (d) DMA Controller Error

DMA controller Errors are defined that the DMA fails to complete the transfer, or an error occurs during the transfer. After this error, issuing new requests are stopped and the DMA channel is placed in a halted state.

When the conditions described later are satisfied, occurrence of a fatal error is signaled by the intreq_pci*m*_dma interrupt. (m = 0)

#### (2) Priority of Errors (in A Single Packet)

Upon detecting multiple errors during reception of a single packet, PCIEC reports only one error that it determines as the most important according to the following priority among errors. About Errors, refer to Table 104.40.

(High Priority)

Uncorrectable Internal Error

Receiver Overflow

Flow Control Protocol Error

Malformed TLP

ECRC Check Failed

Unsupported request (UR), Completer Abort (CA) or unexpected completion

Poisoned TLP received

(Low Priority)

### (3) Error Factor

#### (a) Correctable Error

Correctable errors are defined as the type of errors from which recovery is possible without loss of transfer data through hardware processing such as automatic retransmission request.

If a correctable error occurs, the EXPCAP2F*i*[16].CEDTCD and any bit of register AERCAP4F*i* is set to 1. If a correctable error occurs when the EXPCAP2F*i*[0].CERPE bit is 1 and the corresponding bit of register AERCAP5F*i* is 0 in Endpoint mode, the ERR_COR message is transmitted to the Root Port to notify occurrence of an error. Both Root Port mode and End Port mode, the intreq_pci*m*_corerr interrupt is generated if PRTLGC80[4]. masked_safety_int[PCIE_CORR_INDEX] is 1.

In Root Port mode, if the ERR_COR message is received from an Endpoint when all of the PCICONF15F*i*[17].SERRE, EXPCAP2F*i*[0].CERPE, and EXPCAP7F*i*[0].SERRCEE bits are 1, the intreq_pci*m*_sub interrupt is generated. (*m* = *0*, *i* = 0, 1)

PCIE controller begins to exit the LTSSM state L0 to Recovery.Lock due to receiving TS1 Ordered Sets from the remote partner, while operating in the 4s mode at Gen1 or Gen2 data rate. If a Skip Ordered Set, with a Skip symbol removed is received, it may disrupt the deskew logic to cause an unexpected deskew alignment error (RAS D.E.S register), bad TLP or bad DLLP(correctable errors).
Not any needed, as the controller recovers itself.

The following errors are classified as correctable errors.

**(a-1) Receiver Error**

8b/10b or 128b/130b decode error

Disparity error

Elastic buffer overflow

Elastic buffer underflow

**(a-2) BAD TLP**

LCRC error

Sequence number error

**(a-3) BAD DLLP**

16-bit CRC error

**(a-4) Replay Timeout**

Ack/Nak timeout

**(a-5) Replay Num Rollover**

Replay Num rollover

**(a-6) RAM 1-bit ECC Errors**

RAM Protection ECC 1-bit errors.

**(a-7) Header Log Overflow**

Multiple Error Header Log overflow.

**(b) Non-Fatal Error**

A non-fatal error cannot be corrected through hardware control and one packet of data will be lost. Therefore, recovery processing by software, such as retransmission processing, is needed.

If a non-fatal error occurs, the EXPCAP2F*i*[17].NFEDTCD bit and the corresponding bit inside of register AERCAP1F*i* is set to 1. If a non-fatal error occurs when PCICONF1F*i* [8].SERRE is 1, the PCICONF1F*i* [30].SSE bit is set to 1. If a non-fatal error occurs when the corresponding bit in register AERCAP2F*i* is 0, the EXPCAP2F*i*[1].NFERPE bit or PCICONF1F*i* [8].SERRE bit is 1 in Endpoint mode, the ERR_NONFATAL message is transmitted to the Root Port to notify occurrence of an error. Both Root Port mode and End Port mode, the intreq_pci*m*_nonfaterr interrupt is generated if PRTLGC80 [3].masked_safety_int[PCIE_UNCORR_INDEX] is 1. However, if the error source is an unsupported request (described later), this module does not send the message or generate an interrupt when the conditions described later are satisfied.

In Root Port mode, if the ERR_NONFATAL message is received, PCICONF7F*i* [30].RSE is set to 1. If the ERR_NONFATAL message is received when the PCICONF15F*i*[17].SERRE and PCICONF1F*i*[8].SERRE bits are 1, the PCICONF1F*i*[30].SSE bit is set to 1. If the ERR_NONFATAL message is received from an Endpoint when the PCICONF15F*i*[17].SERRE bit is 1, the EXPCAP2F*i*[1].NFERPE or PCICONF1F*i*[8].SERRE bit is 1, and the EXPCAP7F*i*[1].SERRNFEE bit is 1, the intreq_pci*m*_sub interrupt is generated. However, if the error source is an unsupported request (described later), this module does not generate an interrupt when the conditions described later are satisfied. In addition, if the non-fatal error comes under the advisory non-fatal error cases described later, separately defined processing is performed. (*m* = *0*, *i* = 0, 1)

The following errors are classified as non-fatal errors.

**(b-1) Poisoned TLP Reception**

If a packet with the Poisoned attribute is written, it is handled as a non-fatal error.

This module does not transfer a write request of a packet from the PCI Express side to the internal bus side if the packet has the Poisoned attribute. If a request with the Poisoned attribute is received, the packet is discarded.

If the completion responding to the request issued by this module has the Poisoned attribute, the data in the completion is not transferred to the internal bus side.

If ConfigrationWrite Type0, I/O Write, or MSI has the Poisoned attribute, it is handled also as an unsupported request.

**(b-2) Unsupported Request (UR) Reception**

The following requests are handled as unsupported requests.

- Access to the area other than the PCI address area specified with BAR
- Reception of memory/IO request in Root Port mode when PCICONF1F*i*[2].BME = 0
- Access to memory space when PCICONF1F*i*[1].MSE = 0
- Access to IO space when PCICONF1F*i*[0].IOSE = 0
- Reception of a message with an undefined message code
- Reception of MsgD with message code Msg
- Reception of a message to be received only by an Endpoint in Root Port mode
- Reception of a message to be received only by a Root/Switch in Endpoint mode
- Reception of TLP other than configuration access and message in the Non-D0 state
- Access to a configuration register not implemented
- Reception of a Type1 Configuration Request

- Reception of a Configuration Request in Root Port mode
- Reception of a MRdLk request

If an unsupported request is received, the EXPCAP2F*i*[19].URDTCD bit is set to 1.

If an unsupported request is received when both the EXPCAP2F*i*[3].URRPE and PCICONF1F*i*[8].SERRE bits are 0, neither transmission of a message nor generation of an interrupt is performed.

If an unsupported request is received, the packet is discarded.

**(b-3) Completer Abort (CA)**

If an error occurs on the internal bus when the packet is transferred from the PCI Express to the internal bus, this module considers it as a Completer Abort and performs error handling. When the packet received from the PCI Express is a Non-Posted request, PCIEC returns a completion with the Completer Abort (CA)– Completion Status thus setting the PCICONF1F*i*[27].STA bit to 1.

If the packet received by PCIEC from the PCI Express side violates the PCI Express standard or is considered to be damaged, it is handled as an unsupported request or malformed TLP, not as a Completer Abort.

**(b-4) Unexpected Completion Reception**

If the completion not corresponding to the request issued by PCIEC is received, it is considered as an unexpected completion and error handling is performed.

Reception of an unexpected completion falls into the advisory non-fatal error cases described later.

**(b-5) ECRC Check Failed**

If the packet received by PCIEC from the PCI Express side violates ECRC check, it is considered as ECRC Check Failed. When the packet received from the PCI Express is a Non-Posted request, PCIEC returns a completion with the Completer Abort (CA)– Completion Status thus setting the PCICONF1F*i*[27].STA bit to 1.

**(c) Fatal Error**

Fatal errors are defined as the type of errors from which recovery is impossible through hardware and which usually require system-level error recovery processing such as initialization of the PCI Express.

If a fatal error occurs, the EXPCAP2F*i*[18].FEDTCD and the corresponding bit in register AERCAP1F*i* is set to 1. If a fatal error occurs when the PCICONF1F*i*[8].SERRE bit is 1, the PCICONF1F*i*[30].SSE bit is set to 1. If a fatal error occurs when the corresponding bit in register AERCAP2F*i* is 0, the EXPCAP2F*i*[2].FERPE or PCICONF1F*i*[8].SERRE bit is 1, in Endpoint mode the ERR_FATAL message is transmitted to the Root Port to notify occurrence of an error. Both Root Port mode and End Port mode, the intreq_pci*m*_faterr interrupt is generated if PRTLGC80[3].masked_safety_int[PCIE_UNCORR_INDEX] is 1.

In Root Port mode, if the ERR_FATAL message is received, PCICONF7F*i*[30].RSE is set to 1. If the ERR_FATAL message is received when both of the PCICONF15F*i*[17].SERRE and PCICONF1F*i*[8].SERRE bits are 1, the PCICONF1F*i*[30].SSE bit is set to 1. If the ERR_FATAL message is received from an Endpoint when the PCICONF15F*i*[17].SERRE bit is 1, the EXPCAP2F*i*[2].FERPE or PCICONF1F*i*[8].SERRE bit is 1, and the EXPCAP7Fi[2].SERRFEE bit is 1, the intreq_pci*m*_sub interrupt is generated. (*m* = *0*, *i* = 0, 1)

The following errors are classified as fatal errors.

(c-1) Data Link Layer Protocol Error
(c-2) Reception of malformed TLP
(c-3) Receiver Overflow
(c-4) Flow Control Protocol Error
(c-5) RAM 2-bit ECC errors

(c-6) CDM Register Check Error
(c-7) Tx Interface Progression Detection Error

The following packets are considered as malformed TLPs, which cause a fatal error when received. These packets are discarded when received.

- Reception of a packet with data size exceeding the Max Payload Size
- Reception of a packet with data of different length from the length specified in the size field
- Reception of a TLP with TD field in header = 0 and with the digest field
- Reception of a TLP with TD field in header = 1 and without the digest field
- Reception of a power management message of non TC0
- Reception of an error signal message of non TC0
- Reception of an unlock message of non TC0
- Reception of a Set_Slot_Power_Limit message of non TC0
- Reception of a Set_Slot_Power_Limit message without data
- Reception of a completion with data of different size from the size specified in the Length field
- Reception of a completion with data size exceeding the Max Payload Size
- Reception of a TLP of undefined type or fmt
- Reception of a TLP of the unassigned TC
- Reception of an IO request of TC!=0, Attr[1:0]!=0, Length[9:0]!=1, or Last DWBE[3:0]!=0
- Reception of a configuration request of TC!=0, Attr[1:0]!=0, Length[9:0]!=1, or Last DWBE[3:0]!=0
- Reception of a memory request with illegal DWBE
- Reception of a memory request crossing a 4-Kbyte boundary

**(d) DMA Controller Error**

DMA controller errors are defined that the DMA fails to complete the transfer, or an error occurs during the transfer.

PCIEC can signal the following events as the DMA controller errors by setting the corresponding registers. See 54.17 for more information.

For DMA Read transfer:

- Application Write Error Detected
- Unsupported Request (UR)
- Completer Abort (CA)
- Completion Timeout
- Data Poisoning
- Linked List Element Fetch Error Detected

For DMA Write transfer:

- Application Read Error Detected
- Linked List Element Fetch Error Detected

If any DMA controller error occurs, the intreq_pci*m*_dma interrupt is generated.

**(e) Advisory Non-Fatal Error Case**

The PCI Express standard prescribes that some of non-fatal errors should not be processed when the applicable packet is received because the errors should be judged in terms of cause and significance by the packet transmission source, software, or system. These non-fatal errors are called advisory non-fatal error

cases, which include the cases described in the following sections. If such a case is detected, general non-fatal error processing is not performed but processing prescribed individually is performed instead.

**(e-1) Return of Completion with Unsupported Request/Completer Abort Status**

If a completion with unsupported request/Completer Abort status is returned, PCIEC does not perform non-fatal error processing defined in the PCI Express standard. PCIEC records occurrence of an error in EXPCAP2F*i*[16].CEDTCD, the corresponding AERCAP1F*i* bit, and generates the ERR_COR message and the intreq_pci*m*_corerr interrupt if the corresponding bit set to 1.

**(e-2) Completion Timeout**

If a completion timeout occurs, PCIEC performs non-fatal error processing (recovery from software) defined in the PCI Express standard, does not handle this case as an Advisory Non-Fatal Error.

**(e-3) Reception of Unexpected Completion**

If this module receives an unexpected completion, it does not perform non-fatal error processing defined in the PCI Express standard. PCIEC records occurrence of an error in EXPCAP2F*i*[16].CEDTCD, the corresponding AERCAP1F*i* bits/AERCAP4F*i* bits, and generates the ERR_COR message and the intreq_pci*m*_corerr interrupt if the corresponding bit set to 1.

**(e-4) Reception of Unsupported Request/Completer Abort Completion**

If this module receives a completion of unsupported request/Completer Abort, it does not perform non-fatal error processing defined in the PCI Express standard. PCIEC records occurrence of an error in EXPCAP2F*i*[16].CEDTCD, the corresponding AERCAP1F*i* bits/ERCAP4F*i* bits, and generates the intreq_pci*m*_corerr interrupt if the corresponding bit set to 1.

**(e-5) Reception of Poisoned TLP**

According to the PCI Express standard, the case in which a Poisoned TLP is received and reception is continued is also defined as an advisory non-fatal error case; however, an advisory non-fatal error of such a case does not occur with this module since PCIEC prohibits continuation of Poisoned data processing. Although the cases related to the intermediate receiver are also defined by the standard, the corresponding processing is not performed since PCIEC not operate as an intermediate receiver.

### 104.3.17 Interrupts

Table 104.40 shows the interrupt signals of this module, definition, and the conditions under which interrupts are generated. The interrupt signals are synchronized with the internal bus clock(S0D4_HSCφ).

**Table 104.40 List of Interrupt Signals**

| Name | Definition | Conditions of Generation | Related Registers |
|---|---|---|---|
| intreq_pci*m*_corerr | PCI Express Correctable Error interrupt | Occurrence of a correctable error<br>• Receiver Error<br>• Bad DLLP<br>• Bad TLP<br>• Replay Timer Timeout<br>• RAM 1-bit ECC errors<br>• Header Log Overflow | • PCIEERRSTS0[4] |
| intreq_pci*m*_nonfaterr | PCI Express Uncorrectable Error interrupt | Occurrence of an uncorrectable (fatal & non-fatal) error<br>• Reception of Malformed TLP<br>• Data Link Layer Protocol Error<br>• Receiver Overflow<br>• Flow Control Protocol Error<br>• RAM 2-bit ECC errors<br>• CDM Register Check Error<br>• Tx Interface Progression Detection Error<br>• Unsupported request<br>• Poisoned TLP<br>• ECRC Check Failed<br>• Completion Timeout<br>• Completer Abort<br>• Unexpected Completion | • PCIEERRSTS0[5] |
| intreq_pci*m*_faterr | PCI Express Uncorrectable Error interrupt | Same as intreq_pci*m*_nonfaterr | • PCIEERRSTS0[5] |
| intreq_pci*m*_lperr | PCI Express error message reception interrupt | Reception of an ERR message from link partner.<br>• RC Error Interrupt is received.<br>• RC Error MSI is received.<br>• System Error (RC only) is received. | • PCIEINTSTS0[28:27]<br>• PCIEINTSTS0[30:29]<br>• PCIEERRSTS0[10:9] |

| Name | Definition | Conditions of Generation | Related Registers |
|---|---|---|---|
| intreq_pci*m*_sub | PCI Express message reception interrupt | Reception of a message<br>• PM_PME is received.<br>• Unlock message is received.<br>• LTR is received.<br>• PME Turnoff is received.<br>• PME_TO_Ack is received.<br>• ERR_FATAL message is received.<br>• ERR_NONFATAL message is received.<br>• ERR_COR message is received.<br>Indicate LTSSM status:<br>• Data link layer is up.<br>• PHY link is up<br>Caused by Power Management Event (PME):<br>• MSI caused by PME<br>• Interrupt caused by PME | • PCIEMSGRCPSTS[4]<br>• PCIEMSGRCPSTS[8]<br>• PCIEMSGRCPSTS[0]<br>• PCIEMSGRCPSTS[6]<br>• PCIEMSGRCPSTS[5]<br>• PCIEMSGRCPSTS[3]<br>• PCIEMSGRCPSTS[2]<br>• PCIEMSGRCPSTS[1]<br>• PCIEINTSTS0[7]<br>• PCIEINTSTS0[6]<br>• PCIEINTSTS0[13:12]<br>• PCIEINTSTS0[11:10] |
| intreq_pci*m*_sub | PCI Express link bandwidth change interrupt | Following conditions are true<br>• MSICAP0Fi[16]=1 and EXPCAP4Fi[14]=1 and EXPCAP4Fi[10]=1<br>• PCICONF1Fi[10]=0 and EXPCAP4Fi[10]=1 and EXPCAP4Fi[30]=1<br>• MSICAP0Fi[16]=1 and EXPCAP4Fi[15]=1 and EXPCAP4Fi[11]=1<br>• PCICONF1Fi[10]=0 and EXPCAP4Fi[11]=1 and EXPCAP4Fi[31]=1 | • PCIEINTSTS0[23]<br>• PCIEINTSTS0[22]<br>• PCIEINTSTS0[21]<br>• PCIEINTSTS0[20] |
| intreq_pci*m*_sub | PCI Express reset status interrupt | Change of the following status<br>• Link has gone down or Controller received a hot-reset request.<br>• Same condition as above and after all pending AXI transfers have completed.<br>• Application request downstream port to start Link hot reset.<br>• FLR | • PCIERSTSTS[2]<br>• PCIERSTSTS[1]<br>• PCIERSTSTS[0]<br>• PCIERSTSTS[5:4] |
| intreq_pci*m*_sub | PCI Express-IP power management interrupt | Detection of PM status<br>• Wake Up from power management unit. | • PCIEPWRMNGSTS0[9] |

| Name | Definition | Conditions of Generation | Related Registers |
|---|---|---|---|
| intreq_pci*m*_sub | PCI Express IP Hot-plug logic interrupt | Detection of hot-plug events<br>• INTx interrupt mode.<br>• PME mode.<br>• MSI hot-plug events. | • PCIEINTSTS0[19:18]<br>• PCIEINTSTS0[17:16]<br>• PCIEINTSTS0[15:14] |
| intreq_pci*m*_sub | MSI | MSI Detected | • PCIEINTSTS0[26] |
| intreq_pci*m*_sub | Legacy interrupt | PCI Legacy Interrupts<br>• Assert_INTx is received (radm_int*i*_asserted) .<br>• Deassert_INTx is received radm_int*i*_deasserted ( *i* = a,b,c,d). | • PCIEINTXSTS[0:3]<br>• PCIEINTXSTS[4:7] |

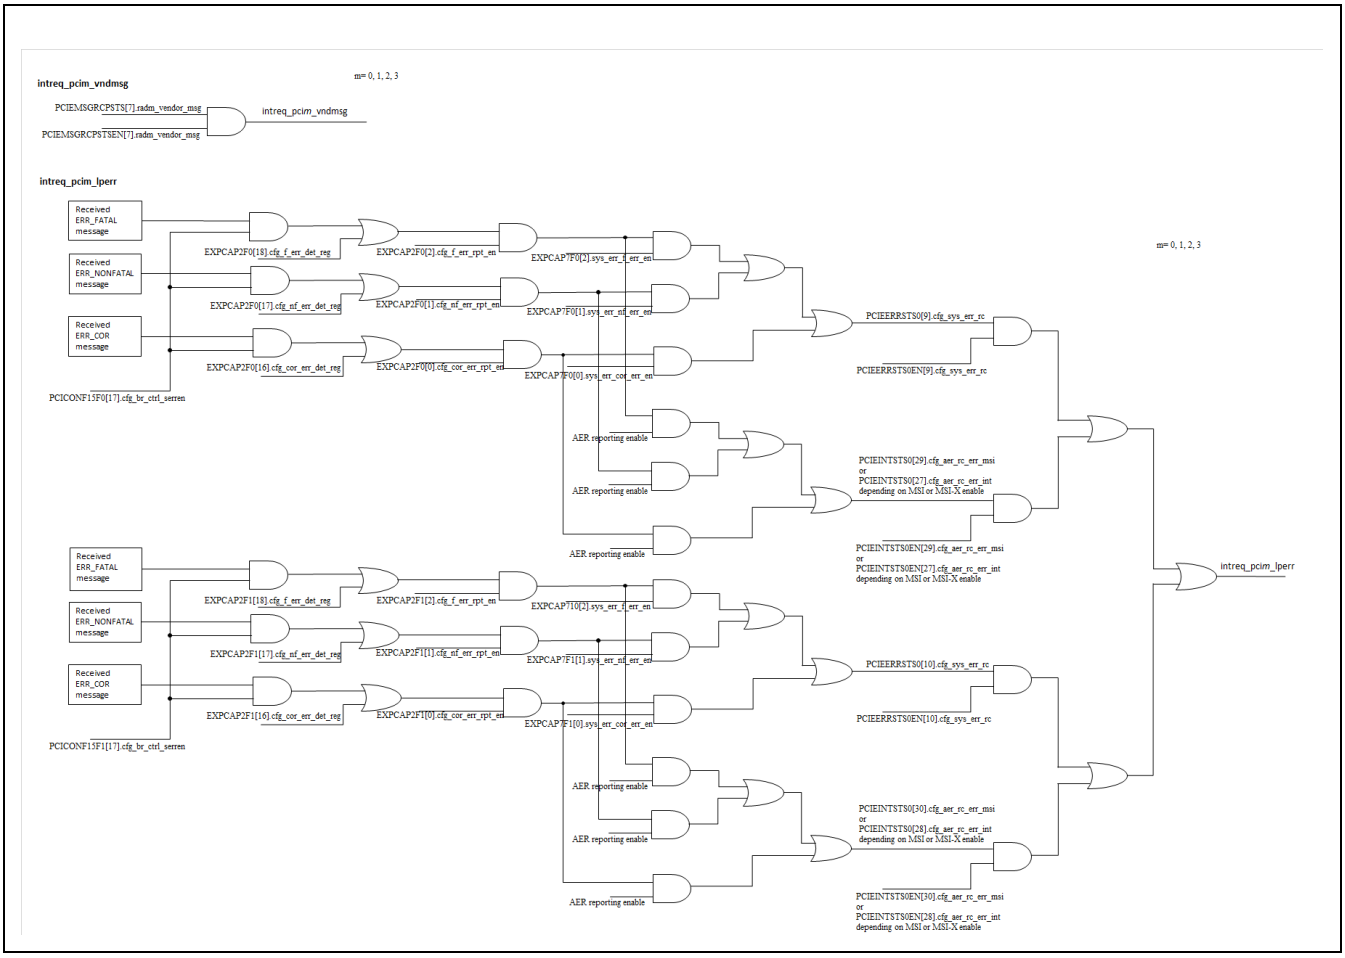

**Figure 104.44 Interrupts Involving Multiple Registers (4)**

### 104.3.18 Messages and MSI

PCIEC supports transmission and reception of the messages and MSI (Message Signaled Interrupt) defined in the PCI Express standard. The messages allow interrupt signaling, power management, error information notification. The MSI is used instead of INTx to signal interrupts. The following sections describe transmission and reception of the messages and MSI.

#### (1) Overview of Messages

PCIEC has the three types of message transmission and reception method.

The first type is automatically message transmission and receptions (Figure 104.45 (a) and Figure 104.46 (a)). The second type is message transmission and receptions by writing and reading the registers of PCIEC (Figure 104.45 (b) and Figure 104.46 (b)). The third types is message transmission and receptions by ATU conversion and received by reading the registers of PCIEC (Figure 104.45 (c) and Figure 104.46 (c)).

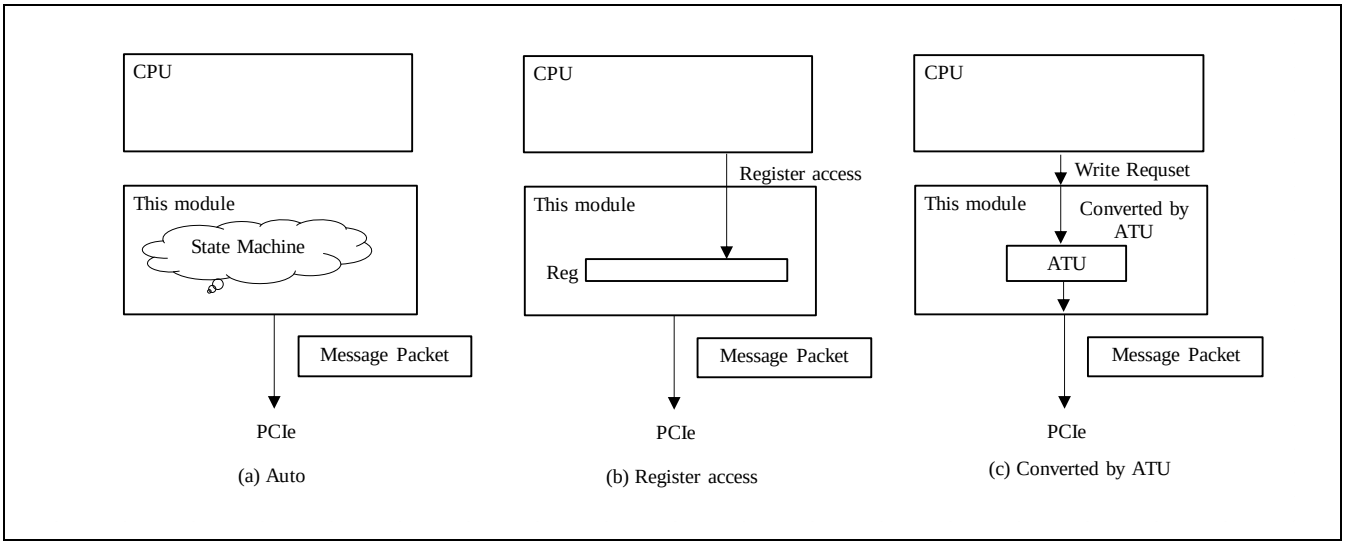

**Figure 104.45 Message Transmission Methods**

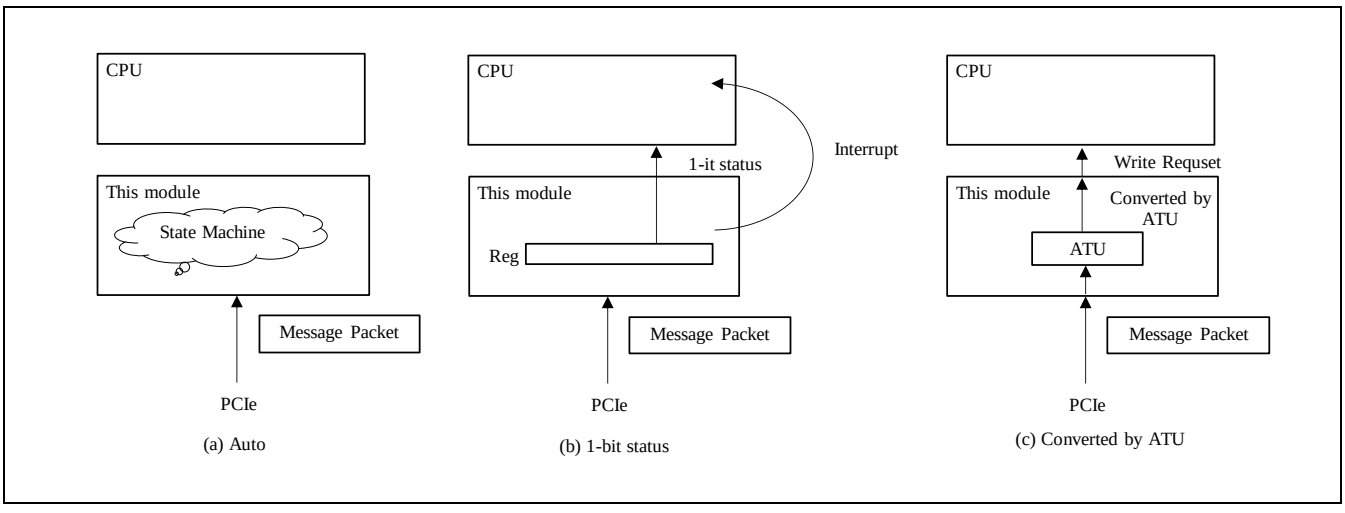

**Figure 104.46 Message Reception Methods**

### (2) Message Transmission

Messages can be transmitted by either of the following three methods.

#### (a) Automatic Message Transmission By Hardware

PCIEC automatically sends a necessary message when an error occurs, LTR clear event occur and PTM event occurs. A part of PM related messages (PME_TO_Ack) is also automatically sent. The following messages are automatically sent.

- ERR_COR: When transmission of the correctable error message is enabled, PCIEC is automatically sent if a correctable error occurs.
- ERR_NONFATAL: When transmission of the non-fatal error message is enabled, PCIEC is automatically sent if a non-fatal error occurs.
- ERR_FATAL: When transmission of the fatal error message is enabled, PCIEC is automatically sent if a fatal error occurs.
- PME_TO_Ack: When PME_Turn_Off message are received by EPs, PME_TO_Ack is automatically sent as response.
- Latency Tolerance Reporting (LTR) clear message: PCIEC automatically sends LTR message with the Requirement bits set to 0 for both Snoop and No-Snoop latencies (LTR clear message) when:
  - A function is directed to a non-D0 state through a write to PMCAP1F*n*[1:0]. Power State, and the LTR mechanism is active since the last DL_Down to DL_Up

  or
  - The LTR mechanism is disabled by clearing EXPCAP10[10].ltr_m_en_r. This field is cleared though a CFG write or function level reset (FLR).
  - By setting cfg_disable_ltr_clr_msg field of the PRTLGC58 register to 1, the automatic generation of the LTR clear message in the above situations can be disabled.

- PTM Request/Response/ResponseD: When PTMCAP2F0[0]. cfg_ptm_enable is set, PCIEC is automatically sent.

#### (b) Initiation of Message Transmission By Writing Through Software

PCIEC sends the PM related message, Vendor_Defined message type0. To send these messages, access the following registers.

- Power management message transmission (PME_* message transmission): Writing 1 to the bits corresponding to the messages in the power management message transmission control register allows transmission of the messages given below: PME_TOFF, and PM_PME.
- LTR message can be generated by writing to PCIELTRMSGCTRL0[0].app_ltr_msg_req to 1. Only use for application where the LTR is changing slowly or static.
- Set_Slot_Power_Limit message, triggered by writing to the Slot Capabilities (EXPCAP5F*i*) register through the DBI, or when LTSSM enters L0.
- Error signaling from the application (Msg). The controller generates error signaling message in response to application requests on the app_err* signal.

#### (c) Initiation of Message Transmission By ATU Conversion

PCIEC sends the LTR request message by ATU conversion. The PM related message, Vendor_Defined message type0 and INTx interrupt message can be transmitted by using this method. To send these message, program the ATU register and issue Write Request from internal bus(AXI). See 54.3.5 for more detail.

### (3) Message Reception

In PCIEC, reception of some messages is automatically handled by hardware. For the message reception processes not performed through hardware, refer to the status and process reception through software. Note that the messages except Vendor_Defined Message are required by the PCI Express standard to be transmitted and received with TC0. If such a message is received with the other TC, the PCIEC considers it as a malformed TLP (fatal error) thus performing error processing automatically.

#### (a) Automatic Message Reception By Hardware

A DSP must automatically send a Set_Slot_Power_Limit message when it enters L0, so the message is sent

and is received by the port itself.

- Set_Slot_Power_Limit

#### (b) Set 1-bit Status and Generating Interrupt

The module hardware detects reception of the following messages but does not automatically process them. Reception of these messages must be checked and processed by software as described below.

- PM_PME: when this message is received, PCIEMSGRCPSTS[4].radm_pm_pme is set. And corresponding enable bit PCIEMSGRCPSTSEN[4].radm_pm_pme is set. The intreq_pci*m*_sub is generated.
- Vendor_Defined Type0: when this message is received, PCIEMSGRCPSTS[7].radm_vendor_msg is set. And corresponding enable bit PCIEMSGRCPSTSEN[7].radm_vendor_msg is set. The intreq_pci*m*_vndmsg is generated.
- LTR request: when this message is received PCIEMSGRCPSTS[0].radm_msg_ltr is set. And corresponding enable bit PCIEMSGRCPSTSEN[0].radm_msg_ltr is set. The intreq_pci*m*_sub is generated.
- Assert_INTx (x is A to D): When this message is received in Root Port mode, PCIEINTXSTS[0,1,2,3].radm_intx_asserted are set (x = a,b,c,d). And the corresponding enable bit PCIEINTXSTSEN[0,1,2,3].radm_intx_asserted are set (x = a,b,c,d). The intreq_pci*m*_sub interrupt is generated. When received in Endpoint mode, this message is considered as a malformed TLP and error processing is performed.
- Deassert_INTx (x is A to D): When this message is received in Root Port mode, PCIEINTXSTS[4,5,6,7].radm_intx_dasserted are set (x = a,b,c,d) are set. And the corresponding enable bit PCIEINTXSTSEN[4,5,6,7].radm_intx_dasserted are set (x = a,b,c,d). The intreq_pci*m*_sub interrupt is generated. When received in Endpoint mode, this message is considered as a malformed TLP and error processing is performed.
- ERR_COR: When this message is received, the appropriate value is set to the configuration register to indicate reception of a correctable error PCIEMSGRCPSTS[1].radm_correctable_err and the corresponding enable bit PCIEMSGRCPSTSEN[1].radm_correctable_err is set. The intreq_pci*m*_sub interrupt is generated.
- ERR_NONFATAL: When this message is received, the appropriate value is set to the configuration register to indicate reception of a correctable error PCIEMSGRCPSTS[2].radm_nonfatal_err and the corresponding enable bit PCIEMSGRCPSTSEN[2].radm_nonfatal_err is set. The corresponding bit the intreq_pci*m*_sub interrupt is generated.
- ERR_FATAL: When this message is received, the appropriate value is set to the configuration register to indicate reception of a correctable error PCIEMSGRCPSTS[3].radm_fatal_err and the corresponding enable bit PCIEMSGRCPSTSEN[3].radm_fatal_err is set. The corresponding bit the intreq_pci*m*_sub interrupt is generated.

STATUS bits are defined for each specified message and 1 is set to the bit correcsponding to the received when a message is received. If the corresponding bit in the ENABLE and STATUS are set to 1, an interrupt will be generated.

**(c) Converted By ATU**

PCIEC converts the received message to Write Request (MEM or IO) and pass to internal bus (AXI) by ATU conversion. This method can be used for message cannot generated by software. All error-free MSG requests are decoded internally, signaled to the application logic..

**(4) Overview of MSI**

This section describes the MSI interrupt.

PCIEC supports MSI interrupt. Whether the PCI Express system should use INTx or MSI interrupts is determined by the Root Port during a configuration cycle. When PCIEC is to be used as a Root Port, whether INTx or MSI interrupt is used should be determined during a configuration cycle, and the results of the determination must be set in the configuration register.

When PCIEC is used as a Root Port, a maximum of 32 interrupt vectors can be used as MSI interrupts.

PCIEC supports both Per Vector Masking and the transmission of 64-bit address messages MSI.

### (5) MSI Transmission

MSI can be transmitted only in Endpoint mode. Figure 104.47 shows an MSI transmission flow.

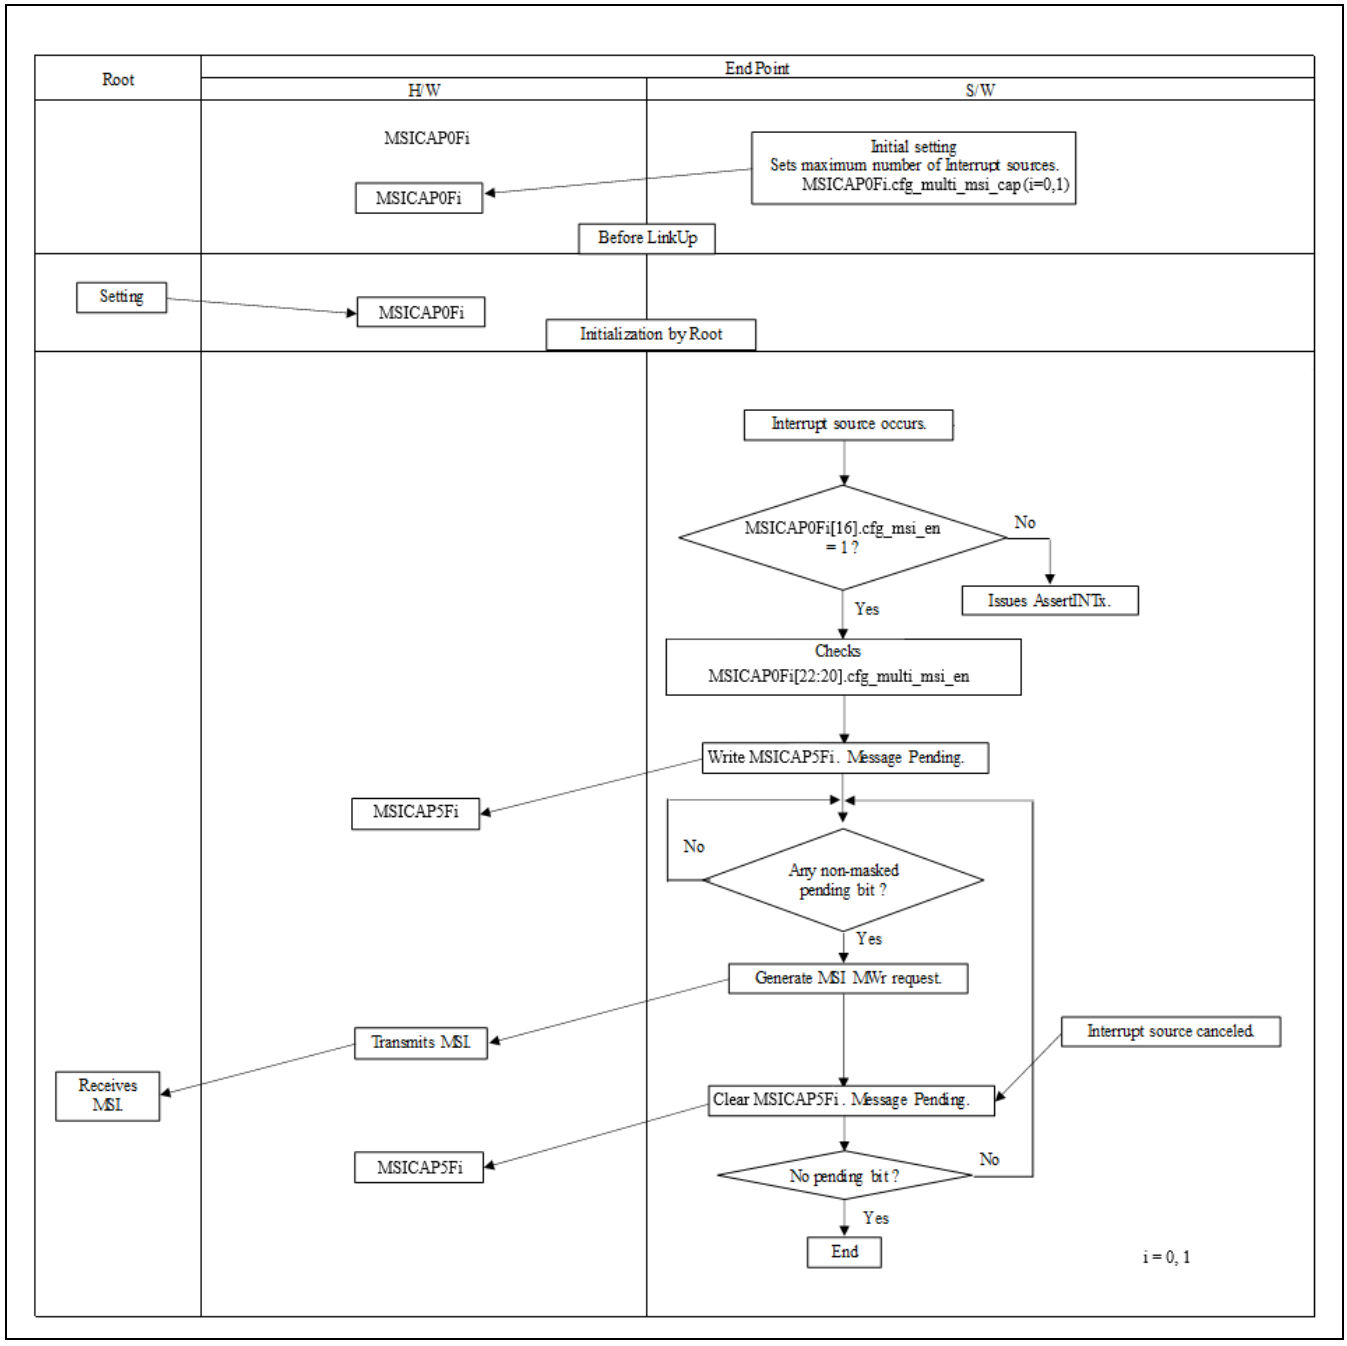

**Figure 104.47 MSI Transmission**

### (6) MSI Reception

MSI can be received only in Root Port mode. The following describes a MSI reception flow.

#### (a) Overview of MSI Reception

When PCIEC is used as a Root Port, whether INTx or MSI interrupts are used should be determined during a configuration cycle. If MSI interrupts are selected, PCIEC has MSI reception module to detect and terminate inbound MSI requests. Rather than propagating MSI MWr TLPs onto the AXI bus through the master interface, the MSI packets are captured, terminated in the AXI bridge, and an interrupt is signaled locally through intreq_pci*m*_sub. This interrupt remains asserted when any MSI interrupt is pending. It is only de-asserted when there is no MSI interrupt pending. PCIEC also can pass the MSI MWr request TLPs to the AXI bus by deactivating MSI reception module.

MSI reception module features are:

- Provides support for up to eight EPs. Each supported EP has a set of interrupt enable(PRTLGC27+3**i*), mask (PRTLGC28+3**i*), and status registers (PRTLGC29+3**i*).
- A maximum of 32 interrupts are supported per EP.

#### (b) Setting for MSI Reception Module

If MSI reception module is activated, the following setting should be performed.

Flow-1) The host CPU configures the MSI capabilities of all endpoints through CFG requests.

— Program the MSI Data Register (MSICAP3F*i* in the MSI capability) as follows to allow the MSI reception module to decode the interrupt source. Table 104.41 shows MSI Data Register Programming format.

**Table 104.41 MSI Data Register Programming**

| Bit | 15:8 | 7:5 | 4:0 |
|---|---|---|---|
| Description | Not Used | EP Number:<br>Allows each EP to be identified within the system. For example, EP#5 is programmed with B'101. | Interrupt Vector Number:<br>Identifies the interrupt source within each EP.<br>Programmed to B'00000.<br>Set by MSI generation logic to identify each interrupt source in real time.<br>Supports up to 32 Vectors. |

—

Flow-2) Program the MSI Capability Lower 32 Bits Address Register (MSICAP1F*i*) of every EP with one common MSI address.

Flow-3) The host CPU configures the MSI reception module regiseters through APB bus.

— Program the MSI reception module registers PRTLGC25 and PRTLGC26 with the same value as in MSICAP1F*i*.

— Read the MSI capability of each EP to determine the number of vectors enabled in each EP and uses this information to program the MSI reception module's interrupt enable register (PRTLGC27+3**i*) which allows up to 32 MSI interrupt vectors to be enabled for a given EP. (*i* = 0, 1, 2, 3, 4, 5, 6, 7)

— The host CPU should program EPs Interrupt Enable register in the MSI reception module appropriately according to the Multiple Message Enable field in an EPs MSI capability structure. For example, when the Multiple Message Enable is 3B'100 for EP#0 (it mean 16 interrupt vectors enabled), the host CPU should program PRTLGC27 with H'0000_FFFF.

#### (c) Processing of Detected Interrupts

The MSI controller decodes the MSI MWr data payload to determine which EP sent the MSI and to which interrupt vector it corresponds. When the decoded interrupt vector is enabled and not masked, then PCIEC sets the corresponding bit in PRTLGC29+3**i* and asserts intreq_pci*m*_sub. This signal remains asserted until the host CPU clears the status bit by writing 1 to the status bit. Writing 0 has no effect. When the decoded interrupt vector is enabled but is masked, then PCIEC sets the corresponding bit in interrupt status register but

it does not assert intreq_pci*m*_sub. This masking is local to the MSI reception module and is not part of Per Vector Masking (PVM) in any of the EPs. When no interrupt have been enabled in any of PRTLGC29+3*i*, then all MSI detection is disabled and valid MSI MWr request TLPs are not terminated in the bridge but are passed to the AXI bus. (*m* = 0, *i* = 0 to 7)

### 104.3.19 Compliance Test

Test compliance according to the PCI Express standard.

### 104.3.20 Precision Time Measurement (PTM)

Precision Time Measurement (PTM) enables precise coordination of events across multiple components with independent local time clocks. Ordinarily, such precise coordination would be difficult given that individual time clocks have differing notions of the value and rate of change of time. To work around this limitation, PTM enables components to calculate the relationship between their local times and a shared PTM Master Time: an independent time domain associated with a PTM Root.

The controller supports the optional PTM feature (CX_PTM_ENABLE =1) as defined in Section 6.22, Precision Time Measurement (PTM) Mechanism of the PCI Express Base Specification, Revision 4.0, Version 1.0. This enables the coordination of timing information across multiple devices with independent local time-bases.

The PTM synchronization is initiated from a downstream requester (USP) to an upstream responder (DSP).

The controller handles the entire timestamp update process without software intervention. Each current (t#n) and previous timestamp (t#n-1) value as well as other context information (clock) can be read from the VSEC registers (PTMRQCAP*/PTMRSCAP*) by software.

**Transmit and Receive Latencies**

A key operational goal of PTM is to stamp the time at which a message is transmitted from the physical boundary of the PCIe device. The Tx latency is the time that it takes a message to travel from the boundary of the controller to the boundary of the PCIe device. It is added to the time at which the message left the controller. The Rx latency is the time that it takes a message to travel from the boundary of the PCIe device to the boundary of the controller. It is subtracted from the time at which the message reaches the controller. The Latency registers may be written to at any time with a more accurate value if required.

For example:

- t1, t3 = Local PTM Clock time when message leaves controller + PTMRQCAP19F*i*.PTM_REQ_TX_LATENCY

- t2, t4 = Local PTM Clock time when message received by controller - PTMRQCAP20F*i*.PTM_REQ_RX_LATENCY

**Note:** The Tx latency includes all delays from the moment timestamp is captured, to the time the message reaches the port pins. The Rx latency includes all delays from the time the message reaches the port pins, to the time the timestamp is captured. These delays depend on the characteristics of the PHY used, skew on the link, and deviation between the reference clocks of the two ports. There may be a dependency on link width and the current link speed also.

The average latencies for all speeds and link widths may be used for Tx and Rx latency calculation. For best accuracy the Tx and Rx latency values should be updated whenever the link parameters change.

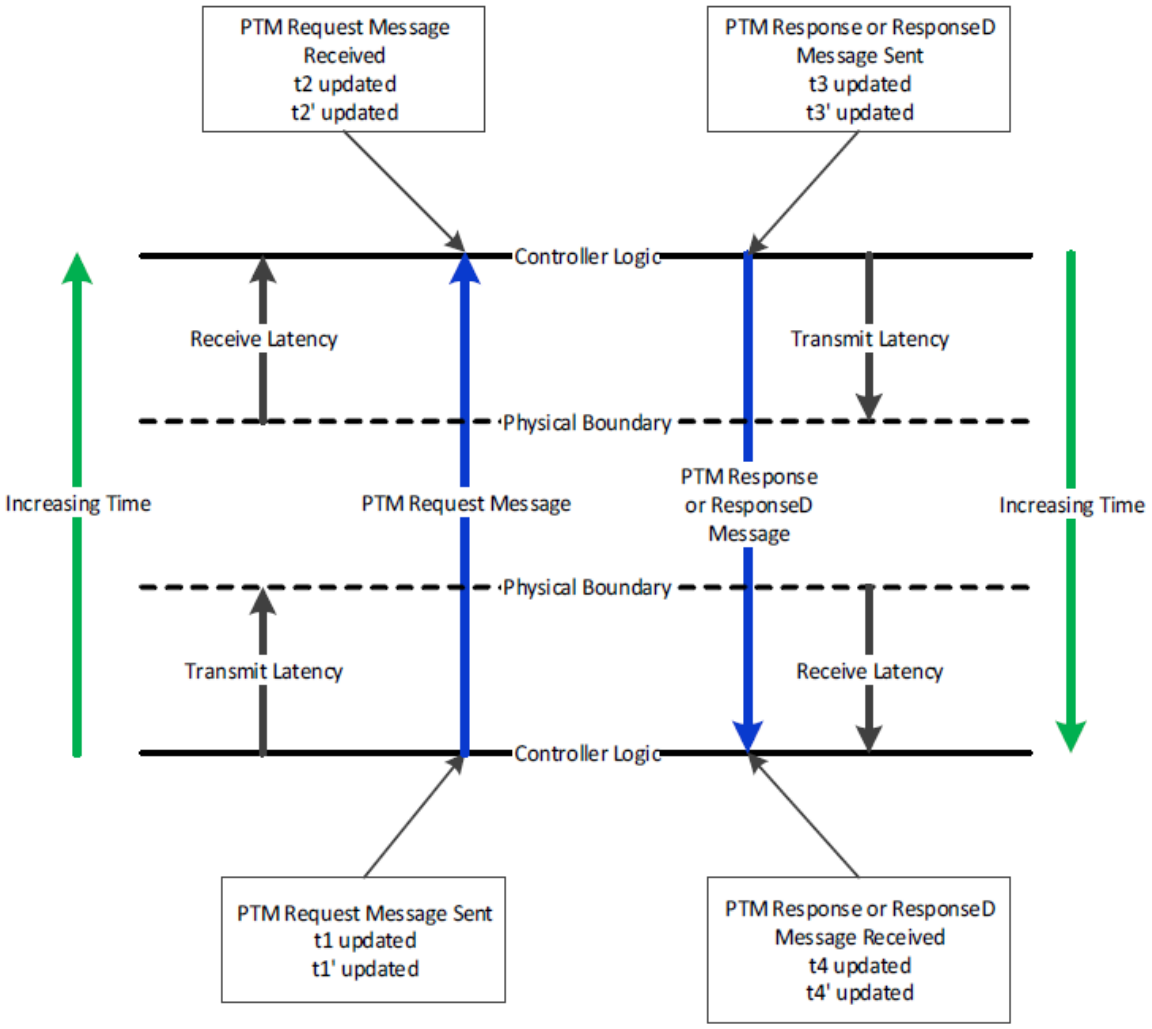

Figure 104.48 Tx and Rx Latencies

**PTM Timers**

The controller implements 1us and 100us timers as per the requirements of the PCI Express Base Specification,

Revision 4.0, Version 1.0. The controller also implements a 10 ms timer which is used for automatic update of PTM context by the Requester.

The controller implements 1us, 100us, and 10ms (used to invalidate local context) timers as per the requirements of the PCI Express Base Specification, Revision 4.0, Version 1.0. The 10 ms timer is also used for automatic update of PTM context by the Requester (USP).

### (1) Requester (USP) Features

■ Integrated hardware for scheduling of requests to start PTM dialogs

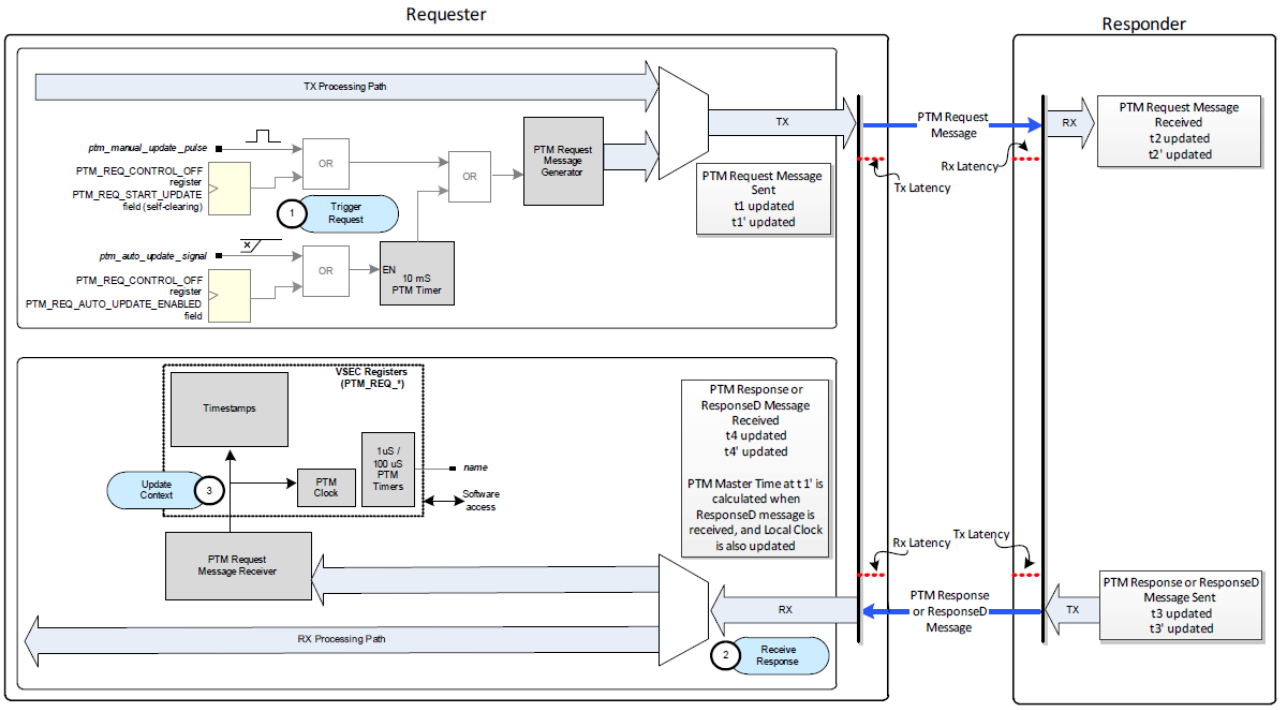

Figure 104.49 PTM Requester (USP)

■ Requester automatically updates PTM context (starting dialogs) when enabled using any or all of:

❑ Automatic trigger every 10ms (can be enabled through top-level pin or through a register)

❑ Manual trigger through top-level pin

❑ Manual trigger through a register write

■ Local PTM Clock

❑ Runs on core_clk, counts time in non-integer nanosecond, and its minimum granularity is defined by the core_clk frequency

❑ Auto-updated on PTM context refresh

❑ Can also be updated by software

❑ Can be read by software

❑ Available through top-level port

■ Context automatically invalidated when core_clk stops, or runs at the wrong frequency (for example, in L1 substates or when the link speed is changing), or when PTM is disabled by clearing the PTM_ENABLE bit in the PTMCAP2F0 register.

■ Context information stored in PTM Requester VSEC (PTMRQCAP*); one instance shared across all functions)

❑ Provides access to timestamps of most recent context refresh

❑ Provides notification when context is valid

❑ Programmable Tx and Rx latency values

### (2) Responder (DSP) Features

■ Integrated hardware for scheduling of PTM responses to dialog requests when context is valid

■ Timestamp generation when PTM Messages are detected

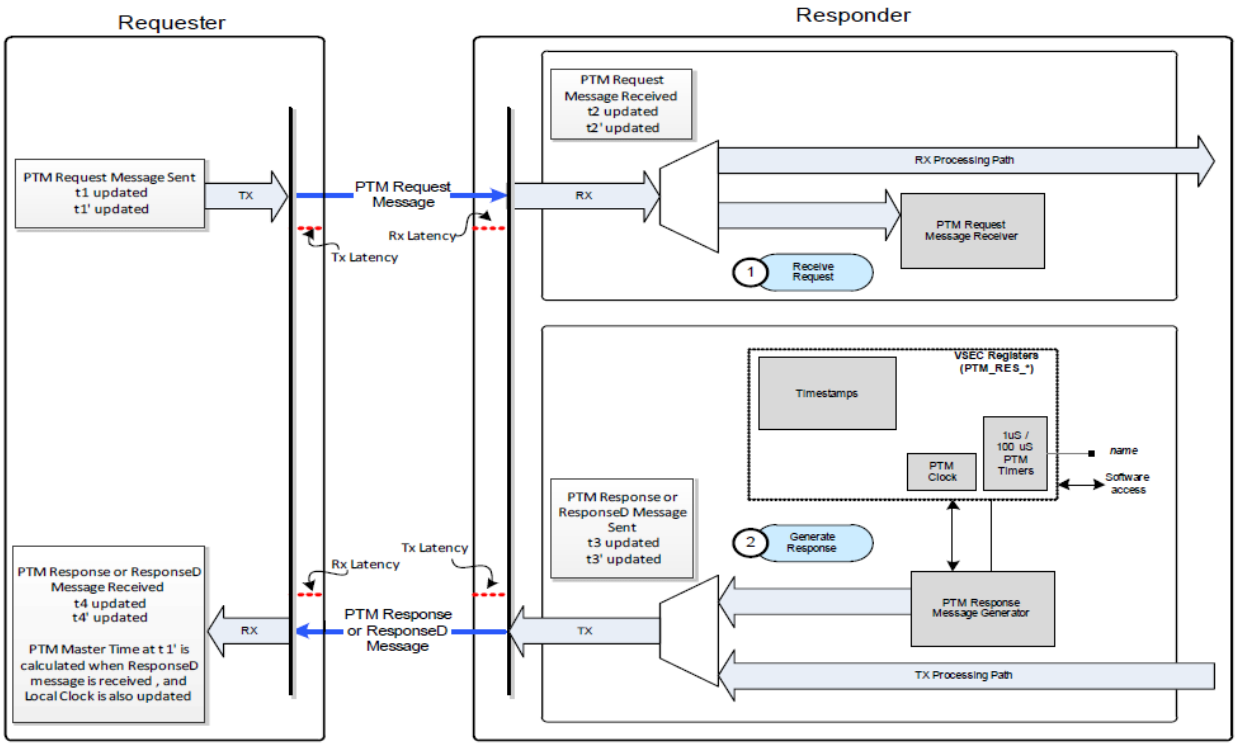

Figure 104.50 PTM Responder (DSP)

■ Local PTM Clock

❑ if CX_PTM_EXTERNAL_MASTER_TIME =1 an external master time can be used to set the clock value

Note: The external master time is latched when ptm_external_master_strobe signal is set to 1.

❑ Can also be updated by software

❑ Can be read by software

❑ Available through top-level port

■ Context automatically invalidated when core_clk stops, or runs at the wrong frequency (for example, in L1 substates or when the link speed is changing), or when PTM is disabled by clearing the PTM_ENABLE bit in the PTMCAP2F0 register. When the controller asserts ptm_responder_ rdy_to_validate signal, your application can re-validate the context by either,

❑ [CX_PTM_EXTERNAL_MASTER_TIME =1]: Updating the local PTM clock using the ptm_external_

master_time and ptm_external_master_strobe signals, which automatically asserts the ptm_context_valid signal.

❑ [DBI Access]: Updating the local PTM clock by writing to PTMRSCAP4F0 and PTMRSCAP5F0 registers, and then setting the PTM_RES_CCONTEXT_VALID field of PTMRSCAP2F0 to 1, which automatically asserts ptm_context_valid signal.

■ Root Support

❑ Ideally a PTM root behaves like a responder with permanently valid context. However,

- If the PTM root enters low power modes or changes link frequency, PTM context is invalidated (indicated by ptm_context_valid =0).

- Following PTM context invalidation, the application must re-validate PTM context, by using either the PTM master time interface signals or the PTM responder VSEC registers, as described in the previous list item.

❑ PTM messages must not contain TLP prefixes

■ Context information stored in PTM Responder VSEC (PTMRSCAP*)

❑ Provides access to timestamps of most recent context refresh

❑ Provides notification when context is valid

❑ Programmable Tx and Rx latency values.

### (3) Local PTM Clock Scaling

PTM clock scaling feature allows the local PTM clock to increment a programmable non-integer nanosecond amount in each controller clock period. This allows the PTM local time to remain coherent if there is a frequency deviation between PTM Requester and Responder. PTM clock scaling also allows the controller to use PTM when the clock period is a non-integer nanosecond multiple, for example when running at CCIX ESM data rates.

**PTM Requester**

To enable this feature set the PTM_REQ_SCALED_CLOCK_T_EN field of PTM_REQ_SCALED_CLOCK_T_OFF register to ‘1’ (this bit can be set only when ptm_context_valid is set). You can set a 24-bit value

consisting of an 8-bit integral part (nanoseconds) and 16-bit fractional part (1/216 nanoseconds) using

PTM_REQ_SCALED_CLOCK_T_INT and PTM_REQ_SCALED_CLOCK_T_FRAC fields of the

PTM_REQ_SCALED_CLOCK_T_OFF register, which represents the scaled local PTM clock period.

The clock scaling procedure is as follows:

■ Following the second and subsequent assertions of the ptm_clock_updated output signal, while

ptm_context_valid remains asserted, your application may read the PTM Requester Clock Correction

register (PTM_REQ_CLOCK_CORR_LSB_OFF).

■ If the correction is below a threshold expected by your the application, your application may calculate

a scaled local PTM clock period value, based on the current default clock period value, the

programmed auto-update interval, and the contents of the PTM Clock Correction register (PTM_REQ_-

CLOCK_CORR_LSB_OFF).

■ Your application may write the scaled PTM clock period to PTM Requester's Scaled PTM Clock Period

register (PTM_REQ_SCALED_CLOCK_T_OFF), which represents the scaled local PTM clock period. This

should happen as quickly as possible after the ptm_clock_updated pulse to avoid error accumulation.

**PTM Responder**

For the PTM Responder, your application fully controls PTM local clock updates. If the external master

clock runs from the same source clock as the PCIe controller, clock scaling is not needed. However, for applications where the external master and PCIe controller run on unrelated clock sources, it may be necessary to scale the local PTM clock period.

To enable this feature set the PTM_RES_SCALED_CLOCK_T_EN field of PTM_RES_SCALED_CLOCK_T_OFF register to '1' (this bit can only be set when ptm_context_valid is set). You can set a 24-bit value consisting of an 8-bit integral part (nanoseconds) and 16-bit fractional part ($1/2^{16}$ nanoseconds) using PTM_RES_SCALED_CLOCK_T_INT and PTM_RES_SCALED_CLOCK_T_FRAC fields of the PTM_RES_SCALED_CLOCK_T_OFF register, which represents the scaled local PTM clock period. The clock scaling procedure is as follows:

- Your application initializes the PTM Responder with a known time from an external master.
- The PTM Responder counts local PTM time using the Nominal PTM Clock Period, which your application can read from the PTM_RES_NOM_CLOCK_T_OFF register.
- Your application waits for a known time and reads the local PTM clock value again.
- Your application calculates the scaled PTM clock period using the deviation between the external master clock and the local PTM clock, and writes the scaled PTM clock period to PTM Responder's Scaled PTM Clock Period register (PTM_RES_SCALED_CLOCK_T_OFF), which represents the scaled local PTM clock period.

If the PTM context becomes invalid your application must reiterate the steps listed above.

### 104.3.21 Master interfaces of AXI

Based on the BDF information, the OSID is generated using the CNVIDn register as a conversion table. When comparing the BDF information, bits with 1 set in the CNVIDMSKn register are compared as don't cares. If none of the BDF information matches, assign the value of the CNVOSIDCTRL register as the OSID.

### 104.3.22 BAR Settings

The BAR settings for this product are shown below:

- BAR0:64-bit Resizable Memory BAR(default size:256MByte), Target_1
- BAR1:- (BAR1 cannot be used because BAR0 is set to 64bit.)
- BAR2:64-bit Resizable Memory BAR(default size:256MByte), Target_1
- BAR3:- (BAR3 cannot be used because BAR2 is set to 64bit.)
- BAR4:32-bit Fixed Mask I/O BAR 256Byte, Target_1
- BAR5: 32-bit Resizable Memory BAR(default size:1MByte), Target_0

Set the size of Resizable BAR in the following registers.
RESBAR_CTRL_REG_0_REG_F*i*.RESBAR_CTRL_REG_BAR_SIZE
RESBAR_CTRL_REG_2_REG_F*i*.RESBAR_CTRL_REG_BAR_SIZE
RESBAR_CTRL_REG_5_REG_F*i*.RESBAR_CTRL_REG_BAR_SIZE

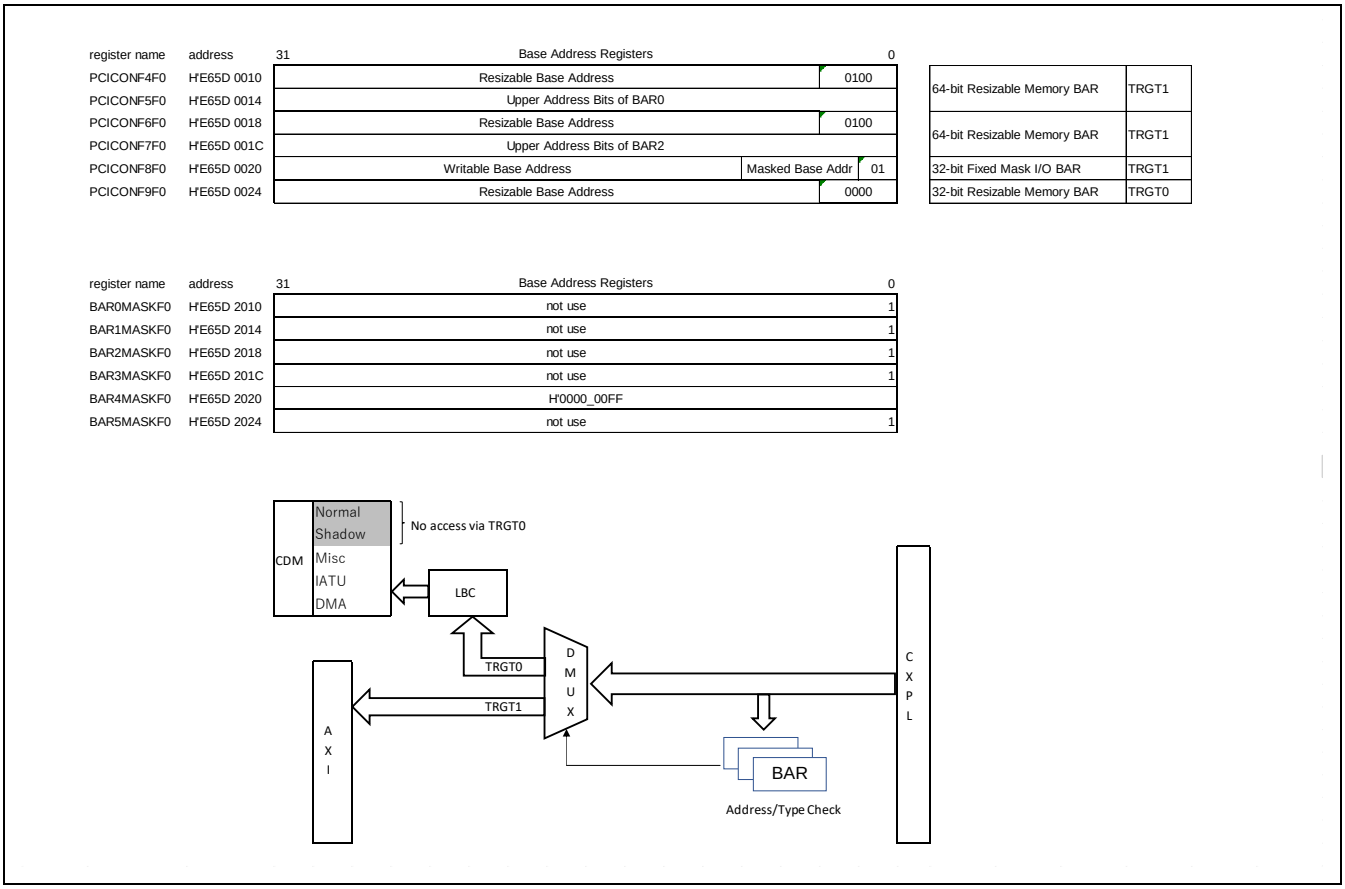

**Figure 104.51 Example Base Address Register Configuration**

### 104.3.23 FLR Signal Interface Timing

The PCI Express Base Specification requires the entire reset process to be completed within 100ms. The controller requires (4* 256 * core_clk) to reset the function. Figure 104.52 shows the timing flow for FLR of physical function x (PFx).

1. The host software writes to the Initiate FLR bit of PFx using a CfgWr request. It cannot use a local DBI write. The controller asserts the PCIERSTSTS.cfg_flr_pf_active[x] in response.
2. Your application terminates TLP transmission from PFxs application logic. During this time, your receive application logic should not halt the receive interface for TLPs directed to PFx.
3. When your application has stopped/reset the PFx application logic, set the PCIERSTCTRL3.app_flr_pf_done[x].
4. When the controller detects 1 on PCIERSTCTRL3.app_flr_pf_done[x], it initiates FLR of PFx.
5. When the reset is complete, the controller de-asserts PCIERSTSTS.cfg_flr_pf_active[x].

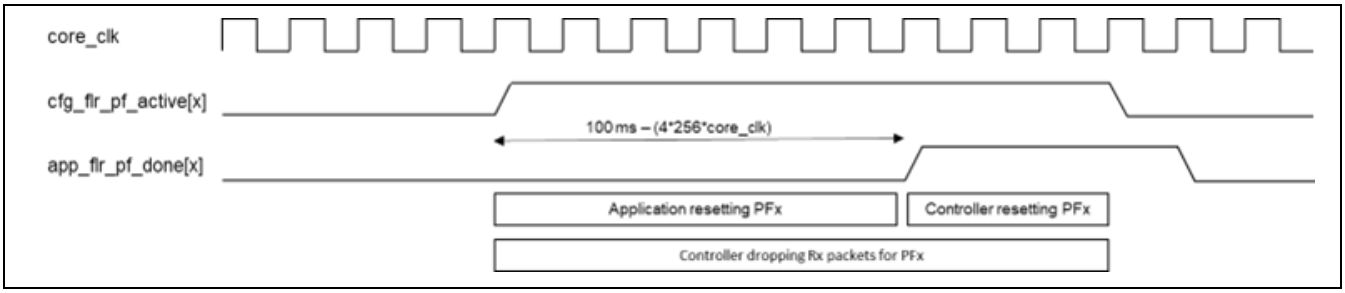

**Figure 104.52 FLR Timing Flow**

### 104.3.24 MSI-X by INTC

The PCIe controller recognizes the MSI/MSI-X interrupt from the AWADDR(AXI write address) of the PCIe/AXI 16 or 32bit Single Write transaction from each VF(Virtual Function) of EP(End Point).
In the case of the MSI/MSI-X interrupt, the PCIe controller overwrite the BDF(RequesterID) in WDATA[47:32] of AXI bus and notifies the INTC in AXI bus.
The INTC allocates the interrupt to the appropriate virtual OS from the BDF which received.

Address judgment method:

AXIINTCCONT.intc_enable & ((AWADDR[31:12],AWADDR[11:3]&AXIINTCCONT.intc_mask) == AXIINTCADDR.intc_address[31:3])

0: Normal Access
1: The MSI/MSI-X interrupt Access

## 104.4 Usage Notes

### 104.4.1 Write/Read Attributes of Configuration Registers

Although the registers in the configuration space have the register attributes defined by the PCI Express standard, these registers have different attributes when accessed by the internal bus. This section shows the attributes required for control.

**Table 104.42 Write/Read Attributes**

| Attributes of PCI Express Registers | Description | Attributes of PCIEC Registers | Example |
|---|---|---|---|
| HWInit | Hardware initialized bit. Initialized by hardware or software. | R for fields initialized by hardware. | EXPCAP0F*i*[24].SLTIMP (*i* = 0, 1) |
| | | RW for fields initialized by software. | EXPCAP3F*i*[31:24].Port Number (*i* = 0, 1) |
| RO | Read-only bit. Cannot be modified by software. | R for fields initialized by hardware. | PCICONF0F*i*[31:16].Device ID (*i* = 0, 1) |
| | | RW for fields initialized by software. | EXPCAP0F*i*[23:20].Device Port Type (*i* = 0, 1) |
| RW | Read/Write bit. Can be modified by software. | RW | PCICONF1F*i*[2].BME (*i* = 0, 1) |
| RW1C | Read-only status bit. Writing 1 clears the bit. Writing 0 has no effect. | RW1C | PCICONF1F*i*[24].MDPE (*i* = 0, 1) |
| ROS | Sticky-read-only bit. Cannot be modified by software.<br>Not initialized by hot reset. | Applies to no PCIEC registers. | — |
| RWS | Sticky-read write bit. Can be modified by software.<br>Not initialized by hot reset. | RWS | EXPCAP2F*i*[10].AUXPPME (*i* = 0, 1) |
| RW1CS | Sticky-read-only status bit. Writing 1 clears the bit. Writing 0 has no effect.<br>Not initialized by hot reset. | RW1CS | PMCAP1F*i*[15].PMEST (*i* = 0, 1) |
| RsvdP | Reserved bit. Read-only.<br>May be used as a RW bit in the future.<br>Reading the bit returns 0. | R | EXPCAP4F*i*[13:12] (*i* = 0, 1) |
| RsvdZ | Reserved bit. Read-only.<br>May be used as a RW1C bit in the future.<br>Reading the bit returns 0. | R | EXPCAP2F*i*[31:22] (*i* = 0, 1) |

The following shows which PCI Configuration Capability is supported by PCIEC.

| | | Offset | | Capability | Spec Requirements | Root Port Type01 | Endpoint Type00 |
|---|---|---|---|---|---|---|---|
| PCI Configuration Space | PCI3.0 Compatible Configuration Space | H'000<br>H'03F | | PCI Compatible Configuration Registers | Required | √ | √ |
| | | H'040 | | PCI Power Management Capability Structure | Required | √ | √ |
| | | | | MSI Capability Structure | Required if an interrupt resource is required | x | √ |
| | | | | PCI Express Capability Structure | Required | √ | √ |
| | | H'0FF | | | | | |

### 104.4.2 Notes on Accessing Configuration Registers

- In Endpoint mode, writing to the configuration registers of this IP is prohibited except at initialization.
- ”PCI RW” in the column header of the table in the description section of each register indicates the attribute of configuration access from the PCI Express bus in Endpoint mode; it is invalid in Root Port mode. For the registers with the same attribute shared in Endpoint mode and Root Port, “—“ is indicated.
- Since the Endpoint configuration space may be accessed by the peer Root Port, it should be set appropriately. The registers implemented according to the Root Port configuration space are not accessed by Endpoint. Therefore, in Root Port mode, the user should appropriately set the registers. For details on register setting, refer to description of each register.

### 104.4.3 Power Management States

Do not stop inputting the reference clock signal in the power management states (L0s/L1/L2). Transition to the power management states (L0s/L1/L2) is made from L0.

The reference clock signal is stopped by PCIE*m*_CLKREQ_N (m = 0)in the power management states (L1 PM Substates). Transition to the power management states (L1 PM Substates) is made from L0.

### 104.4.4 Root Port Signaled Target Abort

When a function other than Function 0 in a Multi-function Device sends a request to the Root Port and the Root Port replies with Completion (CPL) whose status is Completer Abort (CA), the Signaled Target Abort in the Secondary Status Register is mistakenly generated with respect to the Requester ID rather than the Completer ID. Since the Root Port is a single function device where it only contains Function 0, a problem will occur if the Requester ID presents a function other than 0.

To make sure the problem does not occur, the Signaled Target Abort should be asserted with respect to the Function 0 and the Completer ID should be checked rather than the Requester ID.

### 104.4.5 Access DMA Configuration Registers

Feature Usage Note:

Ensure driver software does not generate TLPs with TPH/PH set when accessing DMA configuration registers.

### 104.4.6 Master Data Parity Error and Signaled System Error

・The controller does not correctly set the Master Data Parity Error field when the application reports a Poisoned TLP completion received error through PCIETXCNTRL1. app_err_bus[7].
・The controller sets the Signaled System Error register field to '1' for all PFs. It is only susceptible to the defect when a non-function-specific fatal or non-fatal error is detected.

Host Software Overhead

Instead of using the legacy error reporting method (The Master Data Parity Error), use the Advanced Error Reporting (AER) feature.

### 104.4.7 PM_PME message in L1 sub-state

The PCIe specification defines that the PM_PME messages must be retransmitted every 100ms +50%/-5%.
The PCIe controller does not meet this requirement when the link is in the L1 sub-state.
Note, Assert PCIEPWRMNGCTRL.app_xfer_pending when a PME message is triggered to exit L1 substate.
And de-assert PCIEPWRMNGCTRL.app_xfer_pending only after PCIEPWRMNGSTS1.pm_status is clear.

### 104.4.8 Usage notes for MRRS (Max Read Request Size)

Please set "Max Read Request Size" to 128 bytes or 256 bytes.
If "Max Read Request Size" is set to anything other than the above, the transferred data will not match the expected value.
[Target register]
PCI Express Capability Register 2 function i (EXPCAP2Fi) i = 0, 1 Register
bit14 to 12: Max Read Request Size

### 104.4.9 Usage notes for DMA transfer address

In DMA transfer, if the address is not 32byte aligned, it will not match the expected value.
To ensure correct transfer data, please set either A or B below:

A: The data size of a DMA transfer must be 480 bytes or less.
Non-Linked List Mode:
[Target register]
DMA Capabilities Registers [38+i*16] (DMACAP[38+i*16]) (i = 0 to 7) DMA_TRANSFER_SIZE (for write)
DMA Capabilities Registers [46+i*16] (DMACAP[46+i*16]) (i = 0 to 7) DMA_TRANSFER_SIZE (for read)

Linked List Mode:
Set "Transfer size" to 480 bytes or less, in the Linked List Descriptor in Local Memory.
For more details see Section 104.3.9 DMA Transfer (4) Linked List Mode.

B: Both the source address and destination address must be 32 bytes aligned.
Non-Linked List Mode:
[Target register]

DMA Capabilities Registers [39+i*16] (DMACAP[39+i*16]) (i = 0 to 7) SRC_ADDR_REG_LOW (for write)
DMA Capabilities Registers [41+i*16] (DMACAP[41+i*16]) (i = 0 to 7) DST_ADDR_REG_LOW (for write)
DMA Capabilities Registers [47+i*16] (DMACAP[47+i*16]) (i = 0 to 7) SRC_ADDR_REG_LOW (for read)
DMA Capabilities Registers [49+i*16] (DMACAP[49+i*16]) (i = 0 to 7) DST_ADDR_REG_LOW (for read)

Linked List Mode:
Set "SAR Low" and "DAR Low" to 32 bytes aligned address, in the Linked List Descriptor in Local Memory.
For more details see Section 104.3.9 DMA Transfer (4) Linked List Mode.

### 104.4.10 PCIE_CAP_LINK_TRAINING Register note

When LTSSM is in L1 state and software enables the RTRNLK field, the controller sets the EXPCAP4Fi register field after a delay.
System Usage Note:
Firmware to monitor both 'LTSSM' states on smlh_ltssm_state field of PCIEPWRMNGSTS0 and RTRNLK field of EXPCAP4Fi register bit and interrupt software when RTRNLK field of EXPCAP4Fi register bit is asserted before LTSSM enters recovery state and till it exits recovery state.

### 104.4.11 The L1 Exit Timer note

The L1 exit timer in L1.Idle expires in less than 100ms when GEN3_ZRXDC_NONCOMPL register field is set to one and L1 Substate/CPM is disabled.
System Usage Note:
Program the ECLKPM field in the EXPCAP4Fi register to '1'.

### 104.4.12 FLR Leads to Missing AXI Subordinate Responses in Multi-Function Devices When Operating in 5-Bit Tag Mode

System Usage Note:
When completing an FLR, stop AXI subordinate traffic to all functions and not only the one(s) being reset and wait for all outstanding requests to complete; after the FLR is complete, set the extended tag enable bit to 0 on the function(s) that was (were) reset before resuming AXI subordinate traffic and re-enabling HDMA channels (if present). If the HDMA is enabled, wait for any pending transaction to complete, and then disable all channels.

### 104.4.13 Incorrect Tag Generation in the Controller After Updating Extended Tag Requester Enable

System Usage Note:
After programming the ETAGE field of the EXPCAP2Fi register, issue AXI slave tags Non-Posted requests making sure only one request is outstanding at any given time; this flushes out any duplicate tags. The number of available tags after this procedure might be less than 32.

### 104.4.14 The Controller Drops TLP with ECRC Error when ECRC Check is Disabled

Feature Usage Note:
Program the ECRC check enable bit (ECRC_CHECK_EN) of the Advanced Error Capabilities and Control Register (AERCAP6Fi) to '0' before link-up.

## 104.5 Safety Mechanisms

PCIEC has no logics for FuSa into itself.

PCIEC applies End-to-End and SRAM ECC Protection as chip FuSa policy.

# 105. Serial Communication Interface with FIFO(SCIF)

## 105.1 Overview

This LSI has serial communication interfaces with FIFO buffers (SCIF) that handles asynchronous communication and clock synchronous serial communication. The SCIF has two 16-stage FIFO buffers separately for transmission and reception, which enables fast, efficient, and uninterrupted communication. The following table lists the functions of each interface.

The presence of the SCKn, RTSm#, and CTSm# pins depends on the product or channel. The synchronous mode and mode control functions are supported in the interface channel which has the pins related to these functions.

n = 0, 1, 3, 4
m = 0, 1, 3, 4

**Table 105.1 Channel Information**

| Name | Function | Pin | Base Address | Remarks |
|---|---|---|---|---|
| SCIF-0 | Asynchronous mode (modem control is enabled)<br>Clock synchronous mode | RX0, TX0, SCK0, RTS0#, and CTS0# | H'E6E6 0000 | Transmission/reception clock can be supplied externally from SCK0 pin. |
| | Asynchronous mode<br>Clock synchronous mode | RX0, TX0 and SCK0 | | |
| SCIF-1 | Asynchronous mode (modem control is enabled)<br>Clock synchronous mode | RX1, TX1, SCK1, RTS1#, and CTS1# | H'E6E6 8000 | Transmission/reception clock can be supplied externally from SCK1 pin. |
| | Asynchronous mode<br>Clock synchronous mode | RX1, TX1 and SCK1 | | |
| SCIF-3 | Asynchronous mode (modem control is enabled)<br>Clock synchronous mode | RX3, TX3, SCK3, RTS3#, and CTS3# | H'E6C5 0000 | Transmission/reception clock can be supplied externally from SCK3 pin. |
| | Asynchronous mode<br>Clock synchronous mode | RX3, TX3 and SCK3 | | |
| SCIF-4 | Asynchronous mode (modem control is enabled)<br>Clock synchronous mode | RX4, TX4, SCK4, RTS4#, and CTS4# | H'E6C4 0000 | Transmission/reception clock can be supplied externally from SCK4 pin. |
| | Asynchronous mode<br>Clock synchronous mode | RX4, TX4 and SCK4 | | |

### 105.1.1 Features

The SCIF has the following features.

- Asynchronous serial communication mode

  The SCIF performs serial data communication based on a character-by-character asynchronous system. This feature enables serial data communication with standard asynchronous communication chips that support Universal Asynchronous Receiver/Transmitter (UART) or Asynchronous Communication Interface Adapter (ACIA). There is a choice of eight serial data transfer formats.

  — Data length: 7 or 8 bits
  — Stop bit length: 1 or 2 bits
  — Parity: Even/odd/none
  — Receive error detection: Parity, framing, and overrun errors
  — Break detection:

    A break is detected when a framing error lasts for more than 1 frame length at Space 0 (low level).

    When a framing error occurs, a break can also be detected by reading the RX pin level directly from the serial port register (SCSPTR).
- Clock synchronous serial communication mode

  The SCIF performs serial data communication synchronized with a clock. This feature enables serial data communication with other LSIs that support synchronous communication. There is a single serial data communication format for clock synchronous serial communication.

  — Data length: 8 bits
  — Receive error detection: Overrun errors
- Full-duplex communication capability

  The SCIF has an independent transmitter and receiver that enable simultaneous transmission and reception. The transmitter and receiver both have a 16-stage FIFO buffer structure, enabling continuous serial data transmission and reception.
- On-chip baud rate generator, enabling any bit rate to be selected

  The SCIF enables choice of a clock source for transmission/reception: a clock from the on-chip baud rate generator based on the internal clock or an external clock.
- Eight interrupt sources

  The SCIF has eight types of interrupt sources – receive-data-ready, receive-FIFO-data-full, break, transmit-FIFO-data-empty, transmit-end, receive-error, overrun-error and time-out and enables any of them to be requested independently.
- DMA data transfer

  When the transmit FIFO register is empty or the receive FIFO register has received data, issuing a DMA transfer request activates the DMA controller (DMAC) to execute a data transfer.
- The amount of data in the transmit/receive FIFO registers and the number of receive errors in receive data in the receive FIFO register are available.
- In asynchronous mode, a receive data ready (DR) or a timeout error (TO) can be detected during reception.

### 105.1.2 Block Diagram

Figure 105.1 shows the SCIF block diagram.

SCKi = SASYNCPERD1φ

### 105.1.3 External Pins

Table 105.2 shows the SCIF pin configuration. Pin functions can differ with the interface number. Other functions are also multiplexed on the same pins, so the multiplexed pin settings may restrict usage of the pins.

**Table 105.2 Pin Configuration**

| Name | Abbreviation | I/O | Function |
|---|---|---|---|
| Serial clock pin | SCK | I/O | Synchronous clock I/O |
| Receive data pin | RX | Input | Receive data input |
| Transmit data pin | TX | Output | Transmit data output |
| Modem control pin | CTS# | I/O | Transmission enabled |
| Modem control pin | RTS# | I/O | Transmission request |
| Baud rate generation clock pin* | SCIF_CLK | Input | Clock for input to the baud rate generator for the external clock |

These pins are made to function as serial pins by setting up SCIF operation using bit C/A# in SCSMR, bits TE, RE, CKE[1:0] in SCSCR, and bit MCE in SCFCR. SCSPTR of the SCIF can be used to handle the transmission and detection of break states.

Note: ch0/1/3 can use SCIF_CLK pin, ch4 can use SCIF_CLK2 pin.

### 105.1.4 Register Configuration

(include Safety Mechanism related registers)

Table 105.3 shows the registers in the SCIF.

**Table 105.3 Register Configuration**

| | Abbreviation | R/W | Offset from Base Address | Initial Value | Size |
|---|---|---|---|---|---|
| Serial mode register | SCSMR | R/W | H'00 | H'0000 | 16 |
| Bit rate register | SCBRR | R/W | H'04 | H'FF | 8 |
| Serial control register | SCSCR | R/W | H'08 | H'0000 | 16 |
| Transmit FIFO data register | SCFTDR | —/WB | H'0C | Undefined | 8 |
| Serial status register | SCFSR | R/WC0*1 | H'10 | H'0060 | 16 |
| Receive FIFO data register | SCFRDR | R | H'14 | Undefined | 8 |
| FIFO control register | SCFCR | R/W | H'18 | H'0000 | 16 |
| FIFO data count register | SCFDR | R | H'1C | H'0000 | 16 |
| Serial port register | SCSPTR | R/W | H'20 | H'00XX*3 | 16 |
| Line status register | SCLSR | R/WC0*2 | H'24 | H'0000 | 16 |
| Frequency division register | DL | R/W | H'30 | H'0000 | 16 |
| Clock Select register | CKS | R/W | H'34 | H'0000 | 16 |

Notes: 1. Only 0 can be written to bits 7 to 4, 1, and 0 to clear the flags. Bits 15 to 8, 3, and 2 are read-only bits and cannot be modified.
2. Only 0 can be written to bits 2 and 0 to clear the flags. Bits 15 to 3, and 1 are read-only bits and cannot be modified.
3. The initial values of SCSPTR bits 6, 4, 2, and 0 are undefined.

The table below lists the registers used in asynchronous mode, asynchronous mode with modem control, and clock synchronous mode. When setting up the registers, set the bits related to unsupported modes in each interface to their initial values. Otherwise, the SCIF may malfunction. Do not write to any registers other than listed below. Operations cannot be guaranteed if writing is attempted. Values read from registers other than listed below are undefined.

**Table 105.4 Register Settings in Each Mode**

| Bit | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| SCFRDR | — | — | — | — | — | — | — | — | * | * | * | * | * | * | * | * |
| SCFTDR | — | — | — | — | — | — | — | — | * | * | * | * | * | * | * | * |
| SCSMR | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | C | A | A | A | A | 0 | * | * |
| SCSCR | 0 | 0 | 0 | 0 | * | 0 | 0 | 0 | * | * | * | * | * | A | * | * |
| SCFSR | A | A | A | A | A | A | A | A | A | * | * | A | A | A | * | A |
| SCBRR | — | — | — | — | — | — | — | — | * | * | * | * | * | * | * | * |
| SCFCR | 0 | 0 | 0 | 0 | 0 | M | M | M | * | * | * | * | M | * | * | M |
| SCFDR | 0 | 0 | 0 | * | * | * | * | * | 0 | 0 | 0 | * | * | * | * | * |
| SCSPTR | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | M | M | M | M | C | C | * | * |
| SCLSR | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | A | 0 | * |
| DL | * | * | * | * | * | * | * | * | * | * | * | * | * | * | * | * |
| CKS | * | * | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

[Legend]
* : Used in any mode.
A : Used in asynchronous mode.
M : Used in asynchronous mode (modem control is enabled) (in addition to A).
C : Used in clock synchronous mode.
0 : Reserved (the write value should always be 0.)
— : Undefined

### 105.1.5 Connected Module

Table 105.5 shows the connected modules to the SCIF.

**Table 105.5 Connected modules**

| Module name | Connected module name | Function of connected module |
|---|---|---|
| SCIF | AP-System Core | Access the Register |
| | CPG | Output Clocks |
| | PFC | Select External pins |
| | Module Standby | Control to stop clocks |
| | Software Reset | Execute software reset |
| | INTC | Control to interrupt |
| | SYS-DMAC | Control Direct Memory Access |

## 105.2 Register Description

(include Safety Mechanism related register description)

### 105.2.1 Receive Shift Register (SCRSR)

SCRSR is a register that receives serial data.

The SCIF sets serial data input to the SCRSR from the RX pin in the order received, starting with the LSB (bit 0), and converts it to parallel data. When one byte of data has been received, it is transferred to the receive FIFO data register SCFRDR, automatically.

SCRSR cannot be read from and written to by the CPU.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| | | | | | | | | |
| Initial value: | — | — | — | — | — | — | — | — |
| R/W: | — | — | — | — | — | — | — | — |

### 105.2.2 Receive FIFO Data Register (SCFRDR)

SCFRDR is a 16-stage FIFO register that stores received serial data.

When the SCIF has received one byte of serial data, it transfers the received data from the receive shift register (SCRSR) to SCFRDR for storage, and reception is thus completed. SCRSR is then ready for reception, and is capable of receiving up to 16 consecutive bytes of data before SCFRDR is full.

SCFRDR is a read-only register and cannot be modified by the CPU. Note that the read value will be undefined while there is no receive data in SCFRDR. When SCFRDR is full of receive data, subsequent serial data is lost.

SCFRDR is read as an undefined value after a power-on reset.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| | | | | | | | | |
| Initial value: | — | — | — | — | — | — | — | — |
| R/W: | R | R | R | R | R | R | R | R |

### 105.2.3 Transmit Shift Register (SCTSR)

SCTSR is a register that transmits serial data.

To perform serial data transmission, the SCIF first transfers transmit data from the transmit FIFO data register (SCFTDR) to SCTSR, then sends the data to the TX pin starting with the LSB (bit 0). When transmission of one byte is completed, the SCIF transfers the next transmit data from SCFTDR to SCTSR automatically, then starts transmission.

SCTSR cannot be read from and written to directly by the CPU.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| | | | | | | | | |
| Initial value: | — | — | — | — | — | — | — | — |
| R/W: | — | — | — | — | — | — | — | — |

### 105.2.4 Transmit FIFO Data Register (SCFTDR)

SCFTDR is an 8-bit FIFO register of 16 stages that stores data for serial transmission.

If SCTSR is empty after transmit data has been written to SCFTDR, the SCIF transfers the data from SCFTDR to SCTSR and starts serial transmission.

SCFTDR is a write-only register and cannot be read from by the CPU. Writing further data to SCFTDR is no longer possible when it is full (contains 16 bytes of transmit data). Attempts at writing data to the register in this situation are ignored.

SCFTDR is read as an undefined value on a power-on reset.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| | | | | | | | | |
| Initial value: | — | — | — | — | — | — | — | — |
| R/W: | —/WB | —/WB | —/WB | —/WB | —/WB | —/WB | —/WB | —/WB |

### 105.2.5 Serial Mode Register (SCSMR)

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | C/A# | CHR | PE | O/E# | STOP | — | CKS[1:0] | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R/W | R/W | R/W | R/W | R/W | R | R/W | R/W |

SCSMR is a 16-bit register that sets the SCIF's serial transfer format and selects the baud rate generator clock source.

SCSMR can always be read from and written to by the CPU.

SCSMR is initialized to H'0000 by a power-on reset.

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 to 8 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 7 | C/A# | 0 | R/W | Communication Mode<br>Selects asynchronous mode or clock synchronous mode for the SCIF operation.<br>0: Asynchronous mode<br>1: Clock synchronous mode<br>Note: Whether clock synchronous mode can be selected or not depends on the interface. |
| 6 | CHR | 0 | R/W | Character Length<br>Selects 7 or 8 bits for asynchronous mode data length. In clock synchronous mode, the data length is fixed at 8 bits regardless of the CHR bit setting.<br>0: 8 bits<br>1: 7 bits*<br>Note: * When the 7-bit data is selected, the MSB (bit 7) in the transmit FIFO data register (SCFTDR) is not transmitted. |
| 5 | PE | 0 | R/W | Parity Enable<br>Determines whether parity bit is added in transmission or not, and parity bit is checked in reception in asynchronous mode or not. In clock synchronous mode, the parity bit is not added and checked regardless of the PE bit setting.<br>When bit PE is set to 1, the parity (even or odd) specified by bit O/E# is added to transmit data. In reception, the parity bit is checked for the parity (even or odd) specified by bit O/E#.<br>0: Disables parity bit addition and check.<br>1: Enables parity bit addition and check. |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 4 | O/E# | 0 | R/W | Parity Mode<br>Selects either even or odd parity to use in parity addition and check.<br>In asynchronous mode, the O/E# bit setting is valid only when bit PE is set to 1, enabling parity bit addition and check. In clock synchronous mode or when parity addition or check is disabled in asynchronous mode, the O/E# bit setting is invalid.<br>0: Even parity*1<br>1: Odd parity*2<br>Notes: 1. When even parity is set, the parity bit is added in transmission so that the total number of 1-bits in the transmit character plus the parity bit is even. In reception, a check is performed to see if the total number of 1-bits in the receive character plus the parity bit is even.<br>2. When odd parity is set, the parity bit is added in transmission so that the total number of 1-bits in the transmit character plus the parity bit is odd. In reception, a check is performed to see if the total number of 1-bits in the receive character plus the parity bit is odd. |
| 3 | STOP | 0 | R/W | Stop Bit Length<br>Selects 1 bit or 2 bits as the stop bit length in asynchronous mode.<br>The stop bit setting is valid only in asynchronous mode. Since the stop bit is not added in clock synchronous mode, the STOP bit setting is invalid in this mode.<br>In reception, only the first stop bit is checked, regardless of the STOP bit setting. If the second stop bit is 1, it is treated as a stop bit. If it is 0, it is treated as the start bit of the next transmit character.<br>0: 1 stop bit*1<br>1: 2 stop bits*2<br>Notes: 1. In transmission, high level of 1 bit (stop bit) is added to the end of a transmit character before it is sent.<br>2. In transmission, high level of 2 bits (stop bits) are added to the end of a transmit character before it is sent. |
| 2 | — | 0 | R | Reserved<br>This bit is always read as 0. The write value should always be 0. |
| 1, 0 | CKS[1:0] | 00 | R/W | Clock Select 1 and 0<br>These bits select the clock source for the on-chip baud rate generator.<br>The clock source can be selected from PCK, PCK /4, PCK /16, and PCK /64, according to the setting of bits CKS1 and CKS0.<br>00: PCK<br>01: PCK /4<br>10: PCK /16<br>11: PCK /64 |

### 105.2.6 Serial Control Register (SCSCR)

SCSCR is a register that enables or disables transmission/reception by the SCIF, enables or disables interrupt requests, and selects transmission/reception clock source for the SCIF.

SCSCR can always be read from and written to by the CPU.

SCSCR is initialized to H'0000 by a power-on reset.

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | TEIE | — | — | — | TIE | RIE | TE | RE | REIE | TOIE | CKE[1:0] | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R/W | R | R | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 to 12 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 11 | TEIE | 0 | R/W | Transmit End Interrupt Enable<br>When a transmit-end request is enabled by the TIE bit, the TEIE bit selects the source of the transmit end interrupt request from the following:<br>• Setting the TDFE flag in SCFSR<br>Setting the TEND flag in SCFSR<br>0: The transmit FIFO data empty (TDFE) interrupt request is used.<br>1: The transmit end (TEND) interrupt request is used. |
| 10 to 8 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 7 | TIE | 0 | R/W | Transmit Interrupt Enable<br>Enables or disables a transmit-FIFO-data-empty interrupt (TDFE) request when the TEIE bit in SCSCR is pulled 0, if all of the following conditions are satisfied:<br>• Serial transmit data has been transferred from SCFTDR to SCTSR.<br>• The number of data bytes in SCFTDR is equal to or less than the transmit trigger count.<br>• The TDFE flag in SCFSR is set to 1.<br>Enables or disables a transmit-end interrupt (TEND) request when the TEIE bit of SCSCR is set to 1, if both of the following conditions are satisfied:<br>• Transmission was ended because there is no valid data in SCFTDR when the last bit of the transmit character in SCTSR was transmitted.<br>• The TEND flag of SCFSR is set to 1.<br>0: When the TEIE bit is 0, disables transmit-FIFO-data-empty interrupt (TDFE) request.<br>When the TEIE bit is 1, disables transmit-end interrupt (TEND) request.<br>1: When the TEIE bit is 0, enables transmit-FIFO-data-empty interrupt (TDFE) request.<br>When the TEIE bit is 1, enables transmit-end interrupt (TEND) request. |
| 6 | RIE | 0 | R/W | Receive Interrupt Enable<br>Enables or disables a receive-FIFO-data-full interrupt request when the RDF flag in SCFSR is set to 1, a receive-data-ready interrupt request when the DR flag in SCFSR is set to 1, a receive-error interrupt request when the ER flag in SCFSR is set to 1, a break interrupt request when the BRK flag in SCFSR is set to 1, and an overrun error interrupt request when the ORER flag in SCLSR is set to 1.<br>0: Disables receive-FIFO-data-full interrupt (RDF) requests, receive-data-ready interrupt (DR) requests, receive-error interrupt (ER) requests, break interrupt (BRK) requests, and overrun error interrupt (ORER) requests.<br>1: Enables receive-FIFO-data-full interrupt (RDF) requests, receive-data-ready interrupt (DR) requests, receive-error interrupt (ER) requests, break interrupt (BRK) requests, and overrun error interrupt (ORER) requests. |
| 5 | TE | 0 | R/W | Transmit Enable<br>Enables or disables the start of SCIF serial transmission. The SCIF starts serial transmission when transmit data is written to the SCFTDR while TE is 1. Before setting TE to 1, set SCSMR and SCFCR to specify the transmission format and reset the transmit FIFO.<br>0: Disables transmission.<br>1: Enables transmission. |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 4 | RE | 0 | R/W | Receive Enable<br>Enables or disables the start of SCIF serial reception. When RE is 1, the SCIF starts serial reception by detecting a start bit in asynchronous mode or by detecting a synchronization clock input in clock synchronous mode. Before setting RE to 1, set SCSMR and SCFCR to specify the reception format and reset the receive FIFO.<br>0: Disables reception.*<br>1: Enables reception.<br>Note: Even if RE is cleared to 0, the DR, ER, BRK, RDF, FER, PER, TO and ORER flags are not affected, and retain their states. |
| 3 | REIE | 0 | R/W | Receive Error Interrupt Enable<br>Enables or Disables generation of receive-error interrupt (ER) requests, break interrupt (BRK) requests and overrun-error interrupt (ORER) requests.<br>0: Disables receive-error interrupt (ER) requests, break interrupt (BRK) requests and overrun-error interrupt (ORER) requests.*<br>1: Enables receive-error interrupt (ER) requests, break interrupt (BRK) requests and overrun-error interrupt (ORER) requests.<br>Note: * When REIE is 1, ER, BRK or ORER interrupt requests will occur even if RIE is cleared to 0. This setting is used to notify the interrupt controller of ER, BRK, and ORER interrupt requests during DMAC transfer. |
| 2 | TOIE | 0 | R/W | Timeout Interrupt Enable<br>Enables or disables generation of timeout interrupt (TO) requests when the TO flag in SCLSR is set to 1.<br>0: Disables timeout interrupts (TO).<br>1: Enables timeout interrupts (TO). |
| 1, 0 | CKE[1:0] | 00 | R/W | Clock Enable 1 and 0<br>These bits select the SCIF clock source and enables or disables the clock output from the SCK pin.<br>Whether the SCK pin functions as a serial clock output pin or a serial clock input pin is determined by combination of the CKE [1:0] bits settings. To specify synchronization clock output in clock synchronous mode, set C/A# to 1 in SCSMR then set CKE [1:0].<br>See Table 105.6 for the bit settings. |

**Table 105.6 Clock Selection**

| CKE[1:0] | Mode | Clock Source | SCK Pin |
|---|---|---|---|
| 00 | Asynchronous mode | Internal clock (PCK, PCK /4, PCK/16, PCK/64) | The SCK pin is not used.<br>The SCK pin functions as an input pin (Input signals are ignored). (Initial value) |
| | Clock synchronous mode | | The SCK pin outputs the synchronization clock. (Initial value) |
| 01 | Asynchronous mode | | The SCK pin outputs the clock (with a frequency 16 times the bit rate). |
| | Clock synchronous mode | | The SCK pin outputs the synchronization clock. |
| 10 | Asynchronous mode | Baud rate generator output for external clock or SCK | When SC_CLK is selected:<br>The SCK pin is an input pin (Input signals are ignored).<br>Set the SC_CLK frequency so that the frequency of BRGCLK is 16 times the bit rate. |
| | | | When SCK is selected:<br>The SCK pin inputs the clock (with a frequency 16 times the bit rate). |
| | Clock synchronous mode | SCK* | The SCK pin inputs the synchronization clock. |
| 11 | Prohibited | — | — |

Note: * It is not allowed to set synchronous communication using SC_CLK for input.

### 105.2.7 Serial Status Register (SCFSR)

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | PER[3:0] | | | | FER[3:0] | | | | ER | TEND | TDFE | BRK | FER | PER | RDF | DR |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R/WC0 | R/WC0 | R/WC0 | R/WC0 | R | R | R/WC0 | R/WC0 |

SCFSR is a 16-bit register. The lower 8 bits are a status flag that indicates the operating status of the SCIF, and the upper 8 bits indicate the number of reception errors of data in the receive FIFO register.

SCFSR can always be read from and written to by the CPU. However, the flags ER, TEND, TDFE, BRK, RDF, and DR cannot be written by 1. The FER and PER flags are read-only flags and cannot be modified.

SCFSR is initialized to H'0060 by a power-on reset.

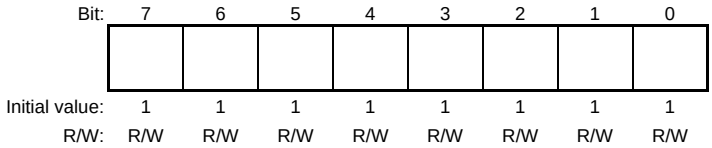
| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 to 12 | PER[3:0] | All 0 | R | Parity Error Count<br>These bits indicate the number of parity errors of receive data stored in the receive FIFO data register (SCFRDR).<br>After the ER is set in SCFSR, the value represented by bits 15 to 12 indicates the number of parity errors. If a parity error occurs in all 16-byte receive data in SCFRDR, PER3 to PER0 are cleared to 0. |
| 11 to 8 | FER[3:0] | All 0 | R | Framing Error Count<br>These bits indicate the number of framing errors of receive data stored in the receive FIFO data register (SCFRDR).<br>After the ER bit is set in SCFSR, the value represented by bits 11 to 8 indicates the number of framing errors. If a framing error occurs in all 16-byte receive data in SCFRDR, FER3 to FER0 are cleared to 0. |
| 7 | ER | 0 | R/WC0 | Receive Error<br>Indicates that a framing error or a parity error has occurred in reception.*1 The ER flag is not affected by an error and retains its previous state when the RE bit is 0 in SCSCR.<br>If a receive error occurs, receive data will be transferred to SCFRDR and reception operation will be continued. Whether there is a receive error in data read from SCFRDR can be determined by the FER and PER bits in SCFSR.<br>0: Indicates that no framing or parity error has occurred in reception.<br>[Clearing conditions]<br>• A power-on reset is executed.<br>• 0 is written to ER.<br>1: Indicates that a framing error or a parity error has occurred in reception.<br>[Setting conditions]<br>• The SCIF checks whether the stop bit at the end of receive data is 1, but the stop bit is 0.*2<br>• The number of 1-bits in receive data plus the parity bit does not match the parity setting (even or odd) specified by the O/E# bit in SCSMR during reception.<br>Note: In the 2-stop-bit mode, only the first stop bit is checked that the value is 1; the second stop bit is not checked. |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 6 | TEND | 1 | R/WC0 | Indicates that transmission has been ended * because there was no valid data in SCFTDR when the last bit of the transmit character was transmitted.<br>0: Indicates that transmission is in progress.<br>[Clearing conditions]<br>• Transmit data is written to SCFTDR, and 0 is written to TEND.<br>• Data is written to SCFTDR by the DMAC.<br>1: Indicates that transmission has been ended.<br>[Setting conditions]<br>• A power-on reset is executed.<br>• The TE bit in SCSCR is 0.<br>• There is no transmit data in SCFTDR when the last bit of a 1-byte serial transmission character is transmitted.<br>Note: When transmit data is written to SCFTDR by the DMAC in clock synchronous mode, the TEND flag may not be cleared. Therefore, if the DMAC is used for transmission in clock synchronous mode, the TEND flag should be read using the following procedure.<br>1. Check that data transfer is completed in the DMAC.<br>2. Read the TEND flag.<br>3. If TEND = 1, clear the TEND flag to 0.<br>4. Read the TEND flag again.<br>5. Use the second read TEND flag. |
| 5 | TDFE | 1 | R/WC0 | Transmit FIFO Data Empty<br>Indicates that the SCIF has transferred data from SCFTDR to SCTSR, the number of data bytes in SCFTDR becomes equal to or less than the transmit trigger count specified by the TTRG1 and TTRG0 bits in SCFCR, and SCFTDR is ready to be written by new transmit data.<br>SCFTDR is a 16-byte FIFO register. The maximum number of bytes that can be written to when TDFE = 1 is “16 – [the transmit trigger count]”. If data exceeding this value is attempted to be written, the data will be ignored. The number of data bytes in SCFTDR is indicated by the upper bits of SCFDR.<br>If the number of data written in SCFTDR is equal to or less than the transmit trigger count, this bit will be set to 1 even if it is cleared to 0 after it is read as 1.<br>0: Indicates that the number of transmit data written to SCFTDR exceeds the transmit trigger count.<br>[Clearing conditions]<br>• Transmit data exceeding the specified transmit trigger count have been written to SCFTDR, and 0 is written to TDFE.<br>• Transmit data exceeding the specified transmit trigger count have been written to SCFTDR by the DMAC.<br>1: Indicates that the number of transmit data in SCFTDR is equal to or less than the transmit trigger count.<br>[Setting conditions]<br>• A power-on reset is executed.<br>• The number of transmit data in SCFTDR is equal to or less than the transmit trigger count after transmission. |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 4 | BRK | 0 | R/WC0 | Break Detect<br>Indicates that a receive data break signal has been detected. If a break signal is detected, receive data (H'00) transfer to SCFRDR is stopped. After the break is canceled and the receive signal returns to 1, the receive data transfer resumes.<br>0: Indicates that no break signal has been received.<br>[Clearing conditions]<br>• A power-on reset is executed.<br>• 0 is written to BRK.<br>1: Indicates that a break signal has been received.<br>[Setting condition]<br>• Data with a framing error is received, followed by the space "0" (low level) for at least one frame length. |
| 3 | FER | 0 | R | Framing Error<br>Indicates that a framing error has been found in the data that is to be read next from SCFRDR in asynchronous mode.<br>0: Indicates that there is no framing error in the receive data that is to be read from SCFRDR.<br>[Clearing conditions]<br>• A power-on reset is executed.<br>• There is no framing error in the data that is to be read next from SCFRDR.<br>1: Indicates that there is a framing error in the receive data that is to be read from SCFRDR.<br>[Setting condition]<br>• There is a framing error in the data that is to be read next from SCFRDR. |
| 2 | PER | 0 | R | Parity Error<br>This bit indicates that a parity error has been found in the data that is to be read next from SCFRDR in asynchronous mode.<br>0: Indicates that there is no parity error in the receive data that is to be read from SCFRDR.<br>[Clearing conditions]<br>• A power-on reset is executed.<br>• There is no parity error in the data that is to be read next from SCFRDR.<br>1: Indicates that there is a parity error in the receive data that is to be read from SCFRDR.<br>[Setting condition]<br>• There is a parity error in the data that is to be read next from SCFRDR. |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 1 | RDF | 0 | R/WC0 | Receive FIFO Data Full<br>Indicates that the received data has been transferred from SCRSR to SCFRDR, and the number of receive data bytes in SCFRDR becomes equal to or more than the receive trigger count specified by the RTRG1 and RTRG0 bits in SCFCR.<br>SCFRDR is a 16-byte FIFO register. When RDF = 1, data equal to or more than the number of receive trigger data bytes can be read. When SCFRDR is empty, SCFRDR is read as an undefined value. The number of receive data bytes in SCFRDR is indicated by the lower bits of SCFDR.<br>If the number of data in SCFRDR is equal to or more than the trigger count, this bit will be set to 1 even if it is cleared to 0. At this time, read receive data until the number of data in SCFRDR is less than the trigger count, read RDF as 1, and then clear RDF.<br>0: Indicates that the number of receive data bytes in SCFRDR is less than the specified receive trigger count.<br>[Clearing conditions]<br>• A power-on reset is executed.<br>• SCFRDR is read until the number of receive data bytes in SCFRDR is less than the receive trigger count, and 0 is written to RDF.<br>• SCFRDR is read by the DMAC until the number of receive data bytes in SCFRDR is less than the receive trigger count.<br>1: Indicates that the number of receive data bytes in SCFRDR is equal to or more than the specified receive trigger count.<br>[Setting condition]<br>• Receive data more than the receive trigger count have been stored in SDFRDR. |
| 0 | DR | 0 | R/WC0 | Receive Data Ready<br>Indicates that the number of data bytes in SCFRDR is less than the receive trigger count and that no further data has been received for at least 15 etu after the stop bit of the data received last in asynchronous mode. This bit is not set in clock synchronous mode.<br>0: Indicates that data is being received or has been successfully received, and there is no receive data in SCFRDR.<br>[Clearing conditions]<br>• A power-on reset is executed.<br>• All the receive data in SCFRDR has been read, and 0 is written to DR.<br>• All the receive data in SCFRDR has been read by the DMAC.<br>1: Indicates that no further receive data has been received.<br>[Setting condition]<br>• The receive FIFO data register (SCFRDR) has the number of data byte that is below the receive trigger number of data bytes and no further data has arrived for at least 15 etu after the stop bit of the data received last.<br>Note: etu: Elementary Time Unit (time for transfer of 1 bit)<br>Equivalent to 1.5 frames with an 8-bit, 1-stop-bit format. |

### 105.2.8 Bit Rate Register (SCBRR)



| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| | | | | | | | | |
| Initial value: | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

SCBRR is an 8-bit register that sets the serial transmission/reception bit rate in accordance with the baud rate generator operating clock selected by the CKS1 and CKS0 bits in SCSMR. This baud rate generator is intended for PCK, PCK/4, PCK/16, and PCK/64. see section 105.3.3, Generation of Internal Clock.

For details on the baud rate generator for external clock, see section 105.3.4, Baud Rate Generator for External Clock (BRG).

SCBRR can always be read from and written to by the CPU except for during transfer.

SCBRR is initialized to H'FF by a power-on reset.

### 105.2.9 FIFO Control Register (SCFCR)

SCFCR is a register that resets data counts and sets the number of trigger data bytes for the transmit and receive FIFO registers. It also has a loopback test enable bit.

SCFCR can always be read from and written to by the CPU except for during transfer.

SCFCR is initialized to H'0000 by a power-on reset.

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | RSTRG[2:0] | | | RTRG[1:0] | | TTRG[1:0] | | MCE | TFRST | RF RST | LOO P |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 to 11 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 10 to 8 | RSTRG[2:0] | 000 | R/W | RTS Output Active Trigger<br>The RTS# signal is high when the number of receive data bytes stored in SCFRDR is equal to or more than the specified trigger number shown below:<br>000: 15<br>001: 1<br>010: 4<br>011: 6<br>100: 8<br>101: 10<br>110: 12<br>111: 14 |
| 7, 6 | RTRG[1:0] | 00 | R/W | Receive FIFO Data Count Trigger<br>These bits specify the number of receive data bytes that makes the RDF (receive data full) flag to be set in SCFSR.<br>The RDF flag is set when the number of receive data bytes in SCFRDR is equal to or more than the specified trigger number shown below: |

| RTRG[1:0] | Asynchronous Mode | Clock Synchronous Mode |
|---|---|---|
| 00 | 1 | 1 |
| 01 | 4 | 2 |
| 10 | 8 | 8 |
| 11 | 14 | 14 |

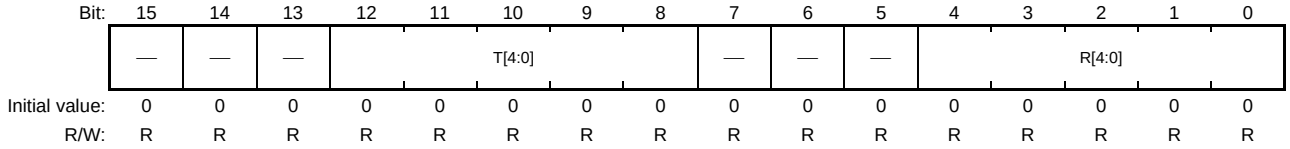
| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 5, 4 | TTRG[1:0] | 00 | R/W | Transmit FIFO Data Count Trigger<br>These bits specify the number of remaining transmit data bytes that makes the transmit FIFO data register empty (TDFE) flag to be set in SCFSR.<br>The TDFE flag is set when the number of transmit data bytes in SCFTDR is equal to or less than the specified trigger count shown below, after transmission:<br>00: 8 (8)<br>01: 4 (12)<br>10: 2 (14)<br>11: 0 (16)<br>Note: Values in parentheses indicate the empty space in SCFTDR in bytes. |
| 3 | MCE | 0 | R/W | Modem Control Enable<br>Enables or disables modem control signals CTS# and RTS#.<br>This bit should always be set to 0 in clock synchronous mode. Whether modem control can be selected or not depends on the interface.<br>0: Disables modem signals.*<br>1: Enables modem signals.<br>Note: CTS# and RTS# control ports. |
| 2 | TFRST | 0 | R/W | Transmit FIFO Data Register Reset<br>Enables or disables a transmit FIFO data register reset that empties the register.<br>0: Disables the reset.*<br>1: Enables the reset.<br>Note: The register is reset by a power-on reset. |
| 1 | RFRST | 0 | R/W | Receive FIFO Data Register Reset<br>Enables or disables a receive FIFO data register reset that empties the register.<br>0: Disables the reset.*<br>1: Enables the reset.<br>Note: The register is reset by a power-on reset. |
| 0 | LOOP | 0 | R/W | Loopback Test<br>Enables or disables the loopback test by internally connecting the transmit output pin (TX) and receive input pin (RX), and the RTS# pin and CTS# pin. If the loopback test is specified, the signal on the RTS# pin is internally conveyed to CTS# pin, and data transmission is automatically suspended when RTS# is asserted.<br>0: Disables the loopback test.<br>1: Enables the loopback test.<br>Even if loopback test is specified by this bit, SCSPTR.RTSDT and SCSPTR.CTSDT bits does not reflect signal on loopback path, because those registers shows signals on RTS#/CTS# pins. |

### 105.2.10 FIFO Data Count Register (SCFDR)

SCFDR is a 16-bit register that indicates the number of data bytes stored in SCFTDR and that in SCFRDR.

The upper 8 bits indicate the number of transmit data bytes in SCFTDR, and the lower 8 bits indicates the number of receive data bytes in SCFRDR.

SCFDR can always be read by the CPU.



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 to 13 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 12 to 8 | T[4:0] | H'00 | R | These bits show the number of data bytes untransmitted and still stored in SCFTDR.<br>H'00 indicates that there is no transmit data in SCFTDR. H'10 indicates that SCFTDR is full of transmit data. |
| 7 to 5 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 4 to 0 | R[4:0] | H'00 | R | These bits show the number of receive data stored in SCFRDR in bytes.<br>H'00 indicates that there is no receive data in SCFRDR. H'10 indicates that SCFRDR is full of receive data. |

### 105.2.11 Serial Port Register (SCSPTR)

SCSPTR controls multiplexed input/output and data on the serial communication interface (SCIF) ports. Bits 1 and 0 control breaks in serial transmission/reception by reading input data from the RX pin and writing output data to the TX pin. Bits 3 and 2 read input data from and write output data to the SCK pin. Bits 5 and 4 read input data from and write output data to the CTS# pin. Bits 7 and 6 read input data from and write output data to the RTS# pin.

SCSPTR is a 16-bit register that can always be read from and written to by the CPU.

All SCSPTR bits except bits 6, 4, 2, and 0 are initialized to 0 by a power-on reset. The values of bits 6, 4, 2, and 0 are undefined.

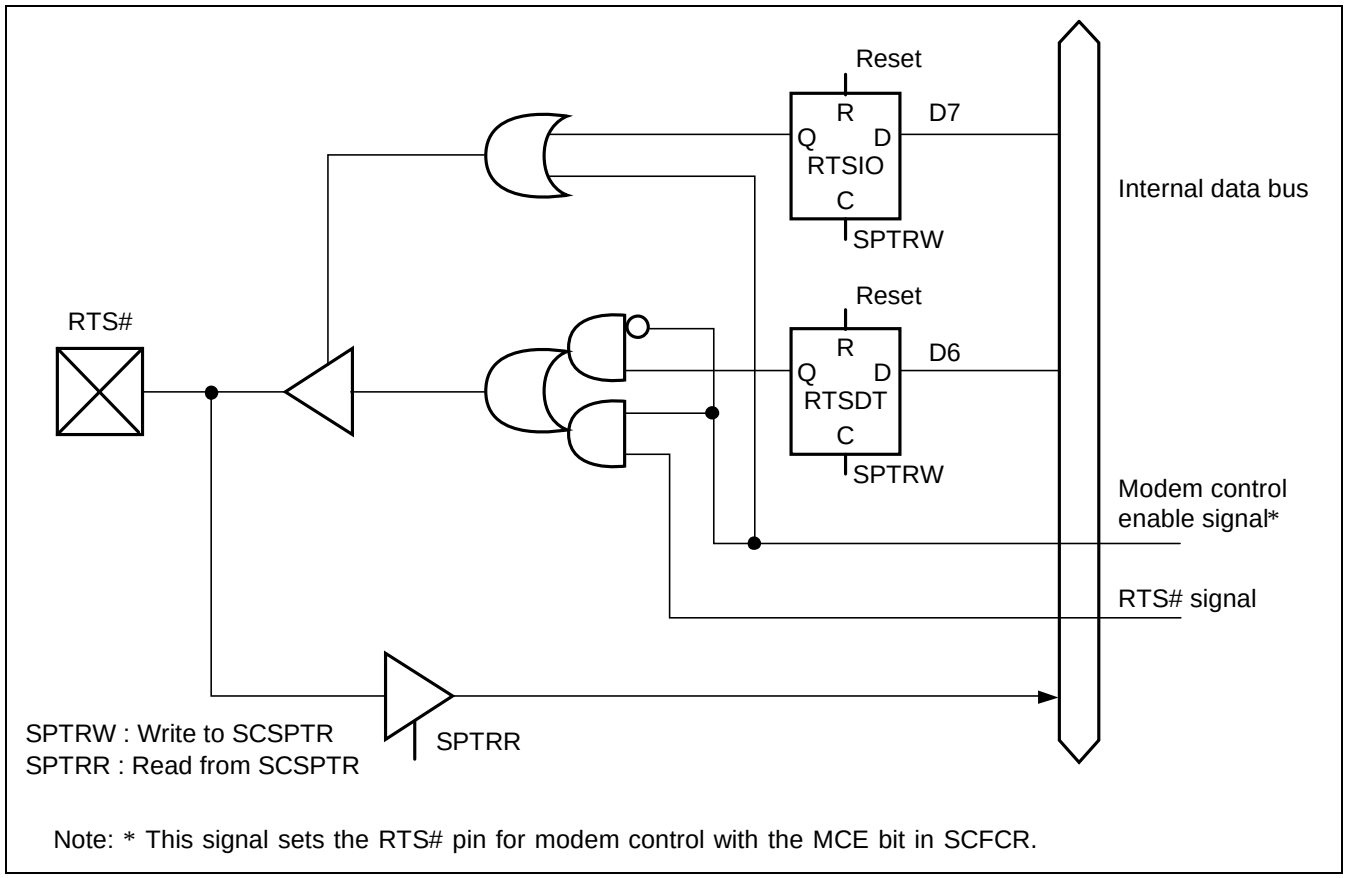
Note: Whether modem control can be selected or not depends on the interface.

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | RTSIO | RTSDT | CTSIO | CTSDT | SCKIO | SCKDT | SPB2IO | SPB2DT |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | — | 0 | — | 0 | — | 0 | — |
| R/W: | R | R | R | R | R | R | R | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 to 8 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 7 | RTSIO | 0 | R/W | Serial Port RTS# Pin Input/output<br>Specifies input or output for the serial port RTS# pin. To actually set the RTS# pin as a port output pin to output the value set by the RTSDT bit, the MCE bit in SCFCR should be cleared to 0.<br>0: Indicates that this bit does not output the value of the RTSDT bit to the RTS# pin.<br>1: Indicates that this bit outputs the value of the RTSDT bit to the RTS# pin. |
| 6 | RTSDT | — | R/W | Serial Port RTS# Pin Data<br>Specifies the input/output data level of the serial port RTS# pin. Whether the pin is set for input or output is determined by the RTSIO bit. When the pin is set for output, the value of the RTSDT bit is output to the RTS# pin. Regardless of the value of the RTSIO bit, the value of the RTS# pin is read from the RTSDT bit.<br>The initial value of this bit is undefined after a power-on reset.<br>0: Indicates that the input/output data is low level.<br>1: Indicates that the input/output data is high level. |
| 5 | CTSIO | 0 | R/W | Serial Port CTS# Pin Input/output<br>Specifies input or output for the serial port CTS# pin. To actually set the CTS# pin as a port output pin to output the value set by the CTSDT bit, the MCE bit in SCFCR should be cleared to 0.<br>0: Indicates that the CTSDT bit value is not output to the CTS# pin.<br>1: Indicates that the CTSDT bit value is output to the CTS# pin. |

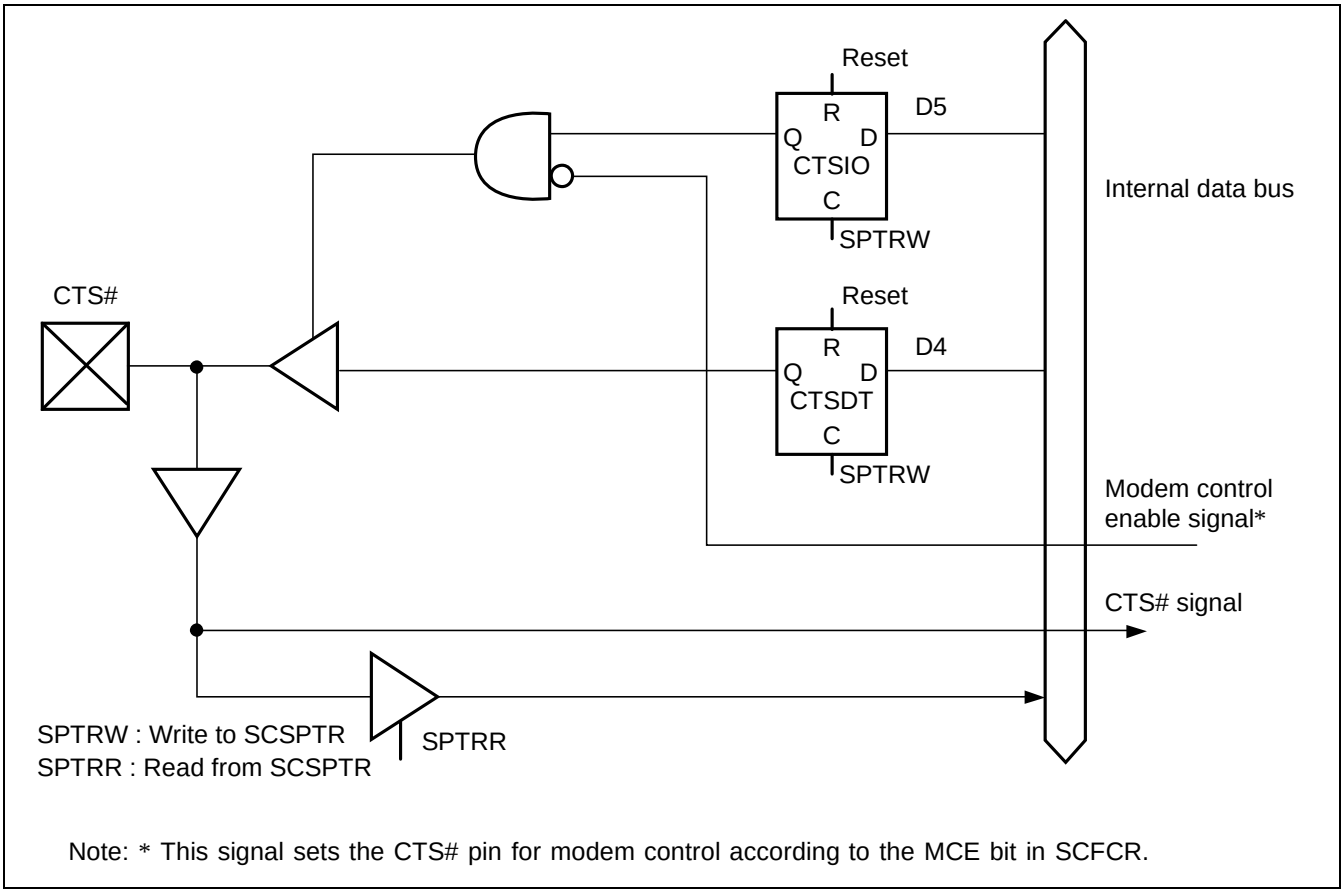
| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 4 | CTSDT | — | R/W | Serial Port CTS# Pin Data<br>Specifies the input/output data level of the serial port CTS# pin. Whether the pin is set for input or output is determined by the CTSIO bit. When the pin is set for output, the value of the CTSDT bit is output to the CTS# pin. Regardless of the value of the CTSIO bit, the value of the CTS# pin is read from the CTSDT bit.<br>The initial value of this bit is undefined after a power-on.<br>0: Indicates that the input/output data is low level.<br>1: Indicates that the input/output data is high level. |
| 3 | SCKIO | 0 | R/W | Serial Port Clock Pin Input/output<br>Specifies input or output for the serial port SCK pin. To actually set the SCK pin as a port output pin to output the value set by the SCKDT bit, the CKE [1:0] bits in SCSCR should be cleared to 0.<br>0: Indicates that the SCKDT bit value is not output to the SCK pin.<br>1: Indicates that the SCKDT bit value is output to the SCK pin. |
| 2 | SCKDT | — | R/W | Serial Port Clock Pin Data<br>Specifies the input/output data level of the serial port SCK pin. Whether the pin is set for input or output is determined by the SCKIO bit. When the pin is set for output, the value of the SCKDT bit is output to the SCK pin. Regardless of the value of the SCKIO bit, the value of the SCK pin is read from the SCKDT bit.<br>The initial value of this bit is undefined after a power-on reset.<br>0: Indicates that the input/output data is low level.<br>1: Indicates that the input/output data is high level. |
| 1 | SPB2IO | 0 | R/W | Serial Port Break Input/Output<br>Specifies the output condition of the serial port TX pin. To actually set the TX pin as a port output pin to output the value set by the SPB2DT bit, the TE bit in SCSCR should be cleared to 0.<br>0: Indicates that the SPB2DT bit value is not output to the TX pin.<br>1: Indicates that the SPB2DT bit value is output to the TX pin. |
| 0 | SPB2DT | — | R/W | Serial Port Break Data<br>Specifies the input level of the serial port RX pin and the output level of the TX pin. The TX pin output conditions are determined by the SPB2IO bit. When the TX pin is set for output, the value of the SPB2DT bit is output to the TX pin. Regardless of the value of the SPB2IO bit, the value of the RX pin is read from the SPB2DT bit.<br>The initial value of this bit is undefined after a power-on reset.<br>0: Indicates that the input/output data is low level.<br>1: Indicates that the input/output data is high level. |

Figure 105.2 to 105.6 show the block diagrams of the SCIF I/O ports.



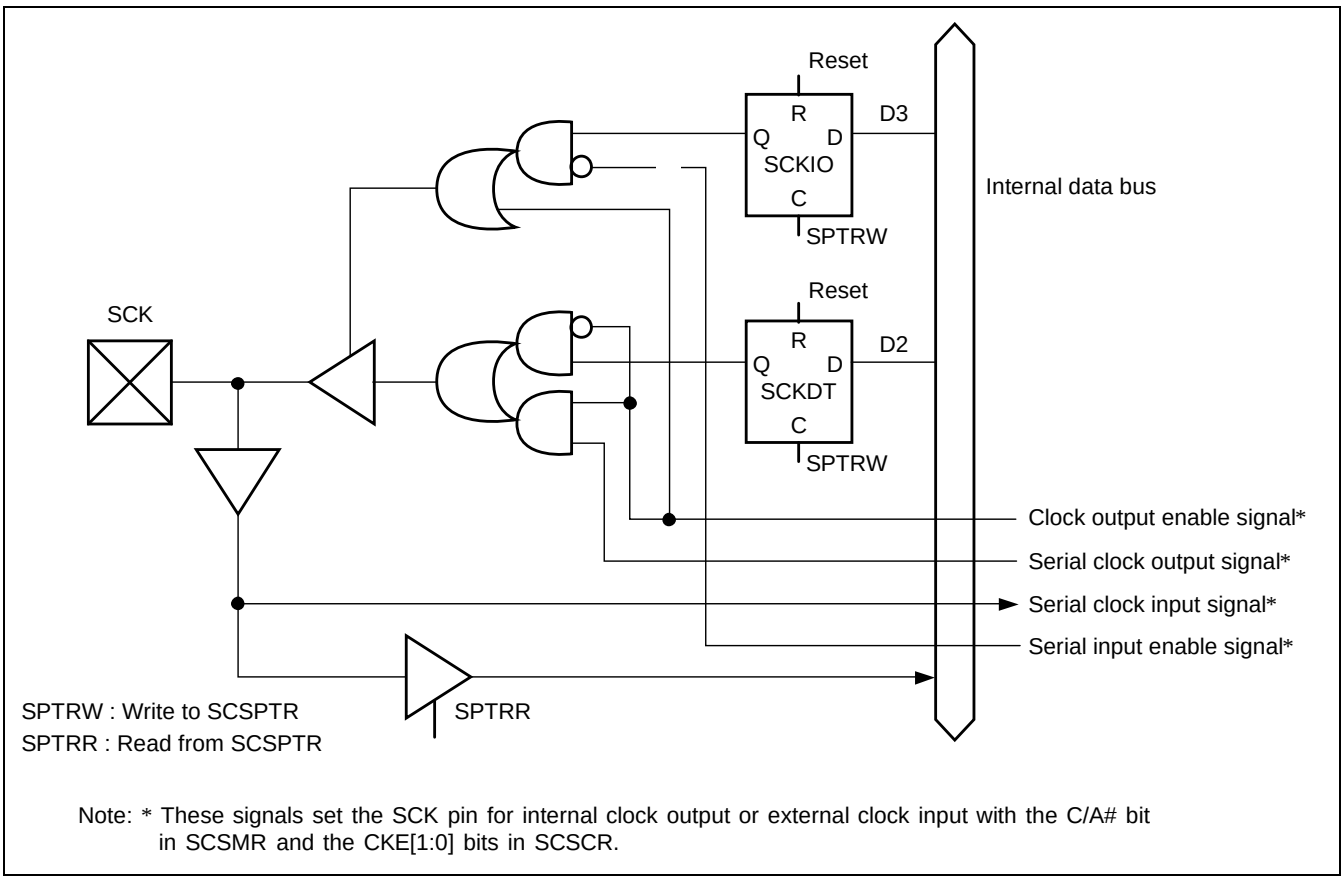
Note: * This signal sets the RTS# pin for modem control with the MCE bit in SCFCR.

**Figure 105.2 RTS# Pin**



Note: * This signal sets the CTS# pin for modem control according to the MCE bit in SCFCR.

**Figure 105.3 CTS# Pin**



Note: * These signals set the SCK pin for internal clock output or external clock input with the C/A# bit in SCSMR and the CKE[1:0] bits in SCSCR.

| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R/WC0 | R | R/WC0 |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 to 3 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 2 | TO | 0 | R/WC0 | Timeout<br>Indicates that the number of data bytes in SCFRDR is less than the receive trigger count, and that no further data has been received for at least 15 etu after the stop bit of the last receive data in asynchronous mode. This bit is not set in clock synchronous mode.<br>0: Indicates that data is being received or has been successfully received and that there is no receive data in SCFRDR.<br>[Clearing conditions]<br>• A power-on reset is executed.<br>• All the receive data in the SCFRDR has been read, and 0 is written to TO.<br>1: Indicates that no further receive data has been received (receive timeout).<br>[Setting condition]<br>• The number of data bytes in SCFRDR is less than the receive trigger count and no further data has been received for at least 15 etu after the stop bit of the last receive data.*<br>Note: etu: Elementary Time Unit (time for transfer of 1 bit)<br>Equivalent to 1.5 frames with an 8-bit, 1-stop-bit format. |
| 1 | — | 0 | R | Reserved<br>This bit is always read as 0. The write value should always be 0. |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 0 | ORER | 0 | R/WC0 | Overrun Error<br>Indicates that an overrun error has occurred in reception and abnormal termination is caused.<br>If an overrun error occurs, the receive data prior to the overrun error is retained in SCFRDR and the data received subsequently is discarded.<br>Any subsequent serial reception is disabled while the ORER flag is 1.<br>To resume data reception after clearing the ORER flag, be sure to first read (or clear) data in the receive FIFO and handle the error, then clear the ORER flag.<br>0: Indicates that data is being received or has been successfully received.<br>[Clearing conditions]<br>• A power-on reset is executed.<br>• 0 is written to ORER.<br>1: Indicates that an overrun error has occurred in reception.<br>[Setting condition]<br>• The next serial reception has been completed while SCFRDR is full of 16-byte data.<br>Note: When bit RE in SCSCR is cleared to 0, the ORER flag is not affected and its previous state is retained. |

### 105.2.13 Frequency Division Register (DL)

This register specifies the value of frequency division for the frequency divided clock generated by the BRG.

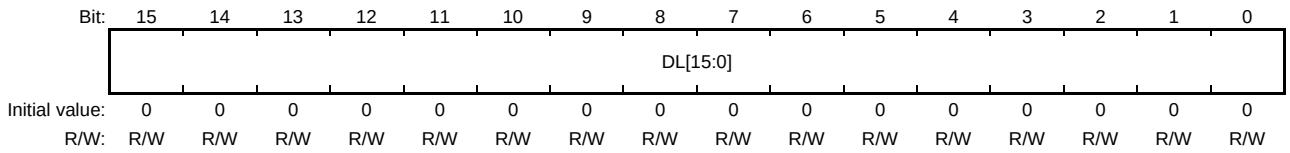
This register supports a 16-bit binary format that allows specifying a value in the rage of 1 to 65535.

Setting all 0s in this register makes the BRG output the frequency divided clock at the low level.

The value of frequency division is given by the following formula:

The value of frequency division = (clock input frequency)/ (required baud rate × 16)

Table 105.9 shows how to use the baud rate generator with a 3.6864-MHz crystal resonator.



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 to 0 | DL[15:0] | All 0 | R/W | Specifies a division value of frequency clock generated in BRG.<br>The value settings enabled in the range of 1 to 65535. |

### 105.2.14 Clock Select Register (CKS)

This register switches the output between the frequency divided clock and specifies a source clock for the external baud rate.

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | CKS | XIN | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 | CKS | 0 | R/W | This bit switches the output between the frequency divided clock (SC_CLK) and external clock (SCK).<br>0: Selects the frequency divided clock.<br>1: Selects the external clock. |
| 14 | XIN | 0 | R/W | Selects the baud rate generator clock source for the external clock between SCIF_CLK and SCKi.<br>0: Selects the external clock (SCIF_CLK).<br>1: Selects the internal clock (SCKi). |
| 13 to 0 | — | All 0 | R | Reserved<br>These bits are always read as 0.<br>Only 0 should be written to these bits. |

## 105.3 Operation

### 105.3.1 Operation in Asynchronous Mode

In asynchronous mode, the SCIF performs serial communication, in which data is transmitted/received in character units using the attached start bit indicating the start of communication and stop bit indicating the end of communication.

Figure 105.7 shows the general format for asynchronous serial communication.

In asynchronous serial communication, the transmission line is usually kept marked (high level). The SCIF monitors the transmission line, and when it finds a space (low level), it regards the space as a start bit and starts serial communication.

One character in serial communication consists of a start bit (low level), followed by transmit/receive data (LSB-first; from the lowest bit), a parity bit (high or low level), and a stop bit (high level).

During reception in asynchronous mode, the SCIF performs synchronization at the falling edge of the start bit. Communication data is acquired at the center of each bit because the SCIF samples data at the eighth pulse of the clock which has a frequency of 16 times the bit rate.

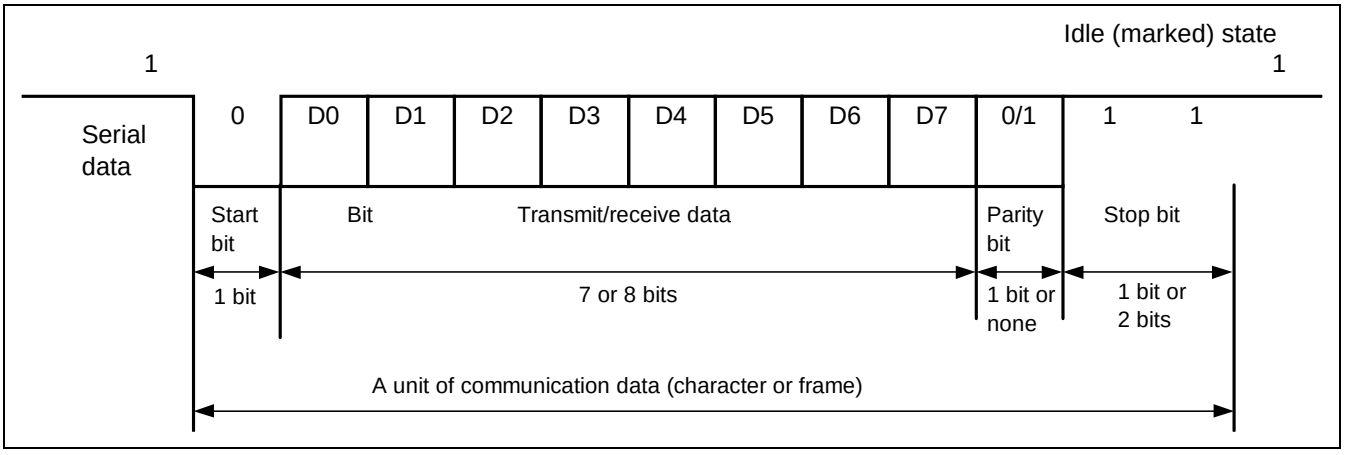


**Figure 105.7 Data Format in Asynchronous Mode (Example of 8-Bit Data with Parity and Two Stop Bits)**

### (1) Transmission/Reception Format

Table 105.7 shows available data transfer formats. The SCIF supports 8 transfer formats, which can be specified by SCSMR.

**Table 105.7 Serial Transmission/Reception Formats (Asynchronous Mode)**

| SCSMR Settings | | | Serial Transmission/Reception Format and Frame Length | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| CHR | PE | STOP | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 |
| 0 | 0 | 0 | S | 8-bit data | | | | | | | | STOP | | |
| | | 1 | S | 8-bit data | | | | | | | | STOP | STOP | |
| | 1 | 0 | S | 8-bit data | | | | | | | | P | STOP | |
| | | 1 | S | 8-bit data | | | | | | | | P | STOP | STOP |
| 1 | 0 | 0 | S | 7-bit data | | | | | | | STOP | | | |
| | | 1 | S | 7-bit data | | | | | | | STOP | STOP | | |
| | 1 | 0 | S | 7-bit data | | | | | | | P | STOP | | |
| | | 1 | S | 7-bit data | | | | | | | P | STOP | STOP | |

[Legend]
S: Start bit
STOP: Stop bit
P: Parity bit

### (2) Clock

The transfer clock can be selected from the following two clocks using the CKE [1:0] bits in SCSCR:

- Internal clock generated by the on-chip baud rate generator
- External clock generated by an external clock baud rate generator

### (3) Data Transmission/Reception

#### (a) Initialization of SCIF (Asynchronous Mode)

Before transmitting/receiving data or changing the operating mode or communication format, the SCIF should be initialized using the sample flowchart for SCIF initialization shown in Figure 105.8.

[Notes]

Clearing the TE bit to 0 initializes SCTSR. However, SCFSR, SCFTDR, and SCFRDR contents are retained even if the TE and RE bits are cleared to 0.

The TE bit should be cleared to 0 after all transmit data has been sent and the TEND flag has been set in SCFSR. The TE bit can be cleared to 0 during transmission, but the data being transmitted will enter the marked state after clearing. In addition, before setting the TE bit to 1 to restart the transmission, set the TFRST bit to 1 in SCFCR to reset SCFTDR.

When an external clock is used, do not stop the clock during operation or initialization. If stopped, the operation will be unreliable. Furthermore, when the baud rate generator for external clock is also to be used, be sure to make settings for it before starting initialization of the SCIF.

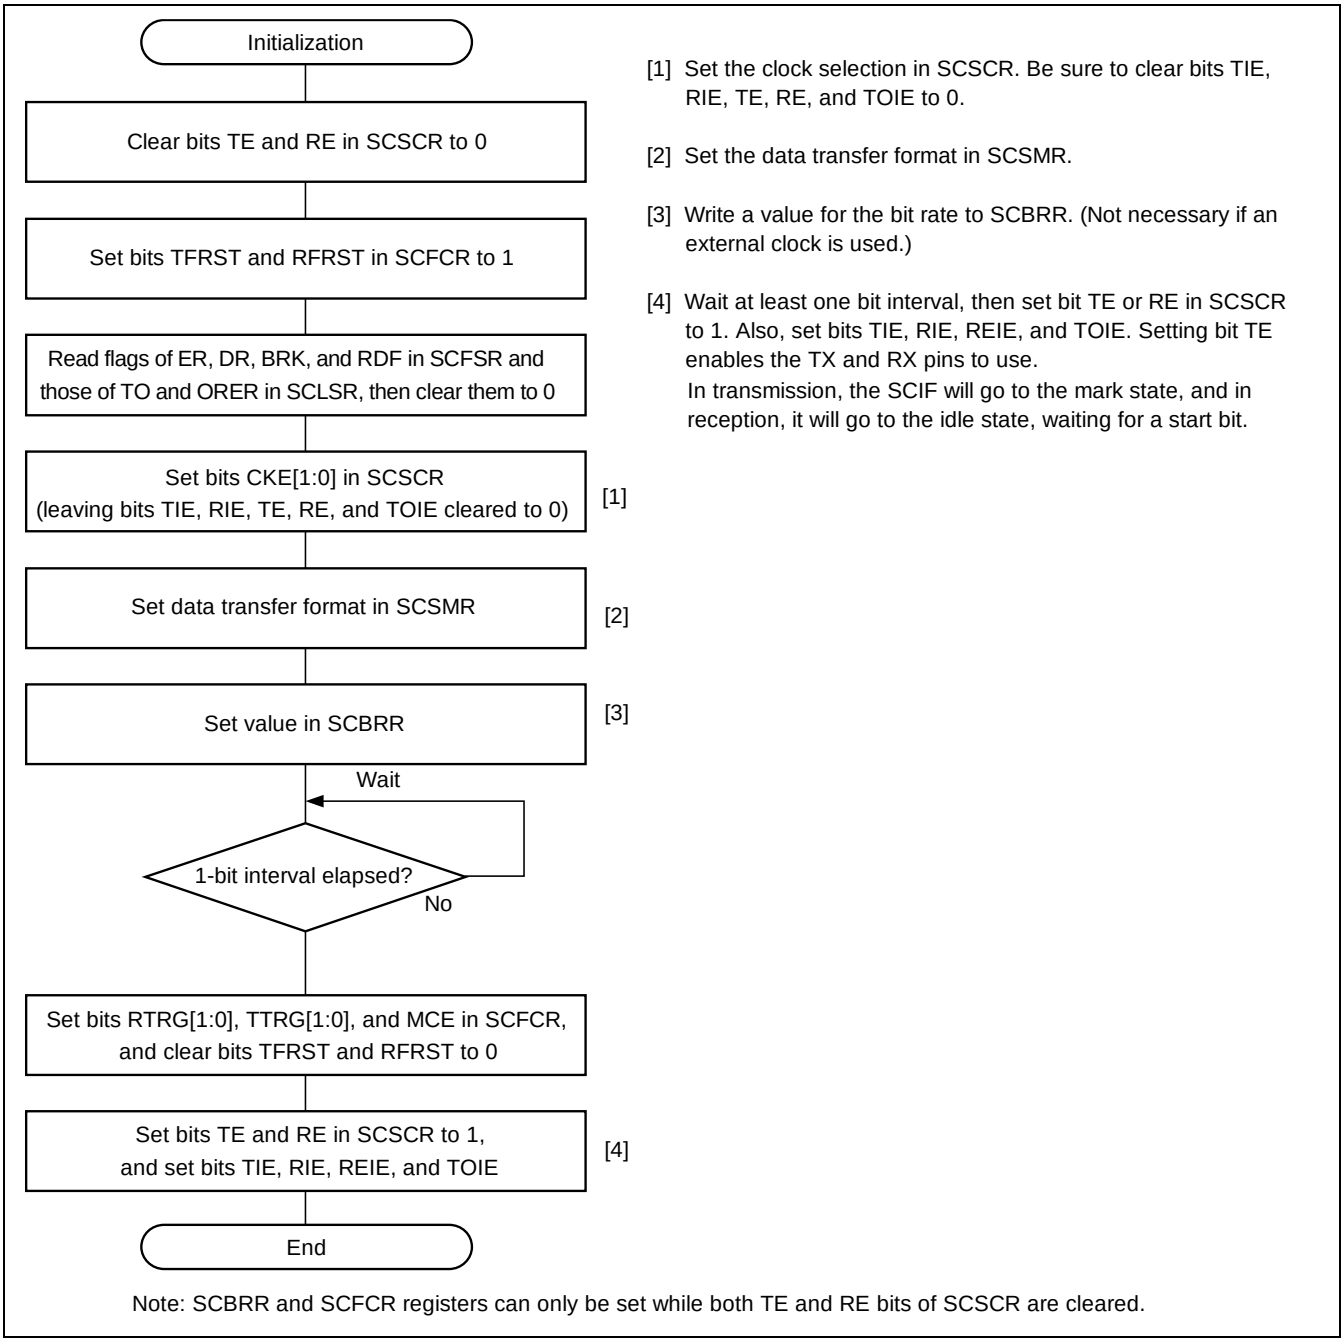

**Figure 105.8 Sample Flowchart for Initializing the SCIF**

**(b) Serial Data Transmission (Asynchronous Mode)**

Figure 105.9 shows a sample flowchart for serial transmission.

After the SCIF transmission operation is enabled, serial data transmission can be performed using the following procedure:

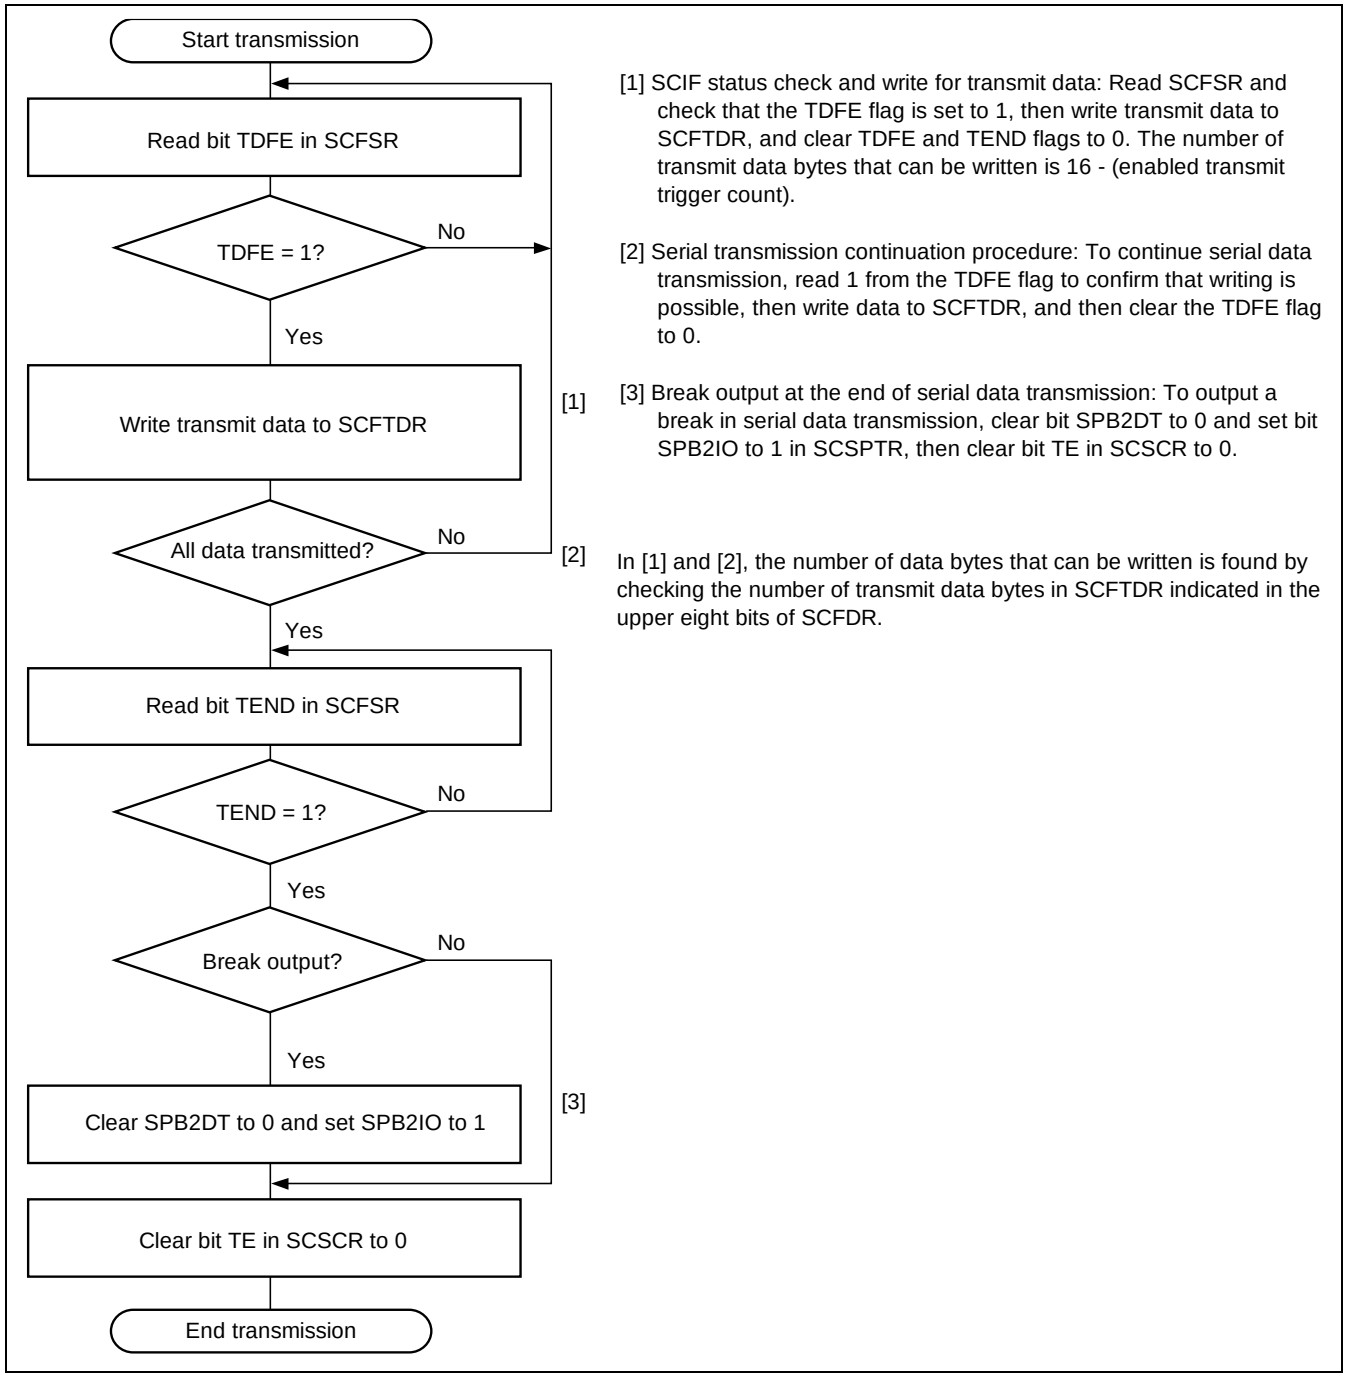

**Figure 105.9 Sample Flowchart for Serial Transmission**

In serial transmission, the SCIF operates as follows:

1. When data is written to SCFTDR, the SCIF transfers the data from SCFTDR to SCTSR and starts transmitting. Confirm that the TDFE flag in SCFSR is set to 1 before writing transmit data to SCFTDR. The number of data bytes that can be written is at least (16- (transmit trigger count)).
2. When data is transferred from SCFTDR to SCTSR and the SCIF starts transmission, consecutive transmission is performed until there is no transmit data left in SCFTDR. When the number of transmit data bytes in SCFTDR is equal to or less than the transmit trigger count specified in SCFCR, the TDFE flag is set. If the TIE and TEIE bits in SCSCR are set to 1 and 0, respectively at this time, a transmit-FIFO-data-empty interrupt (TDFE) request occurs. The serial transmit data is sent from the TX pin in the following order:
   A. Start bit: One 0-bit is output.
   B. Transmit data: 8-bit or 7-bit data is output in LSB-first order.
   C. Parity bit: One parity bit (even or odd parity) is output.
      A format that does not output a parity bit can also be selected.
   D. Stop bit(s): One or two stop bits are output.
   E. Marked state: 1 is output continuously until the start bit that starts the next transmission is sent.
3. The SCIF checks transmit data in SCFTDR when sending the stop bit. If there is data in it, the SCIF transfers the data from SCFTDR to SCTSR, sends the stop bit, and then starts serial transmission of the next frame. If there is no transmit data, the SCIF sets the TEND flag to 1 in SCFSR and sends out the stop bit, and then the marked state is entered to output 1 continuously. At this time, if the TIE and TEIE bits in SCSCR are set to 1, a transmit-end interrupt (TEND) request occurs.

Figure 105.10 shows an example of transmission in asynchronous mode.

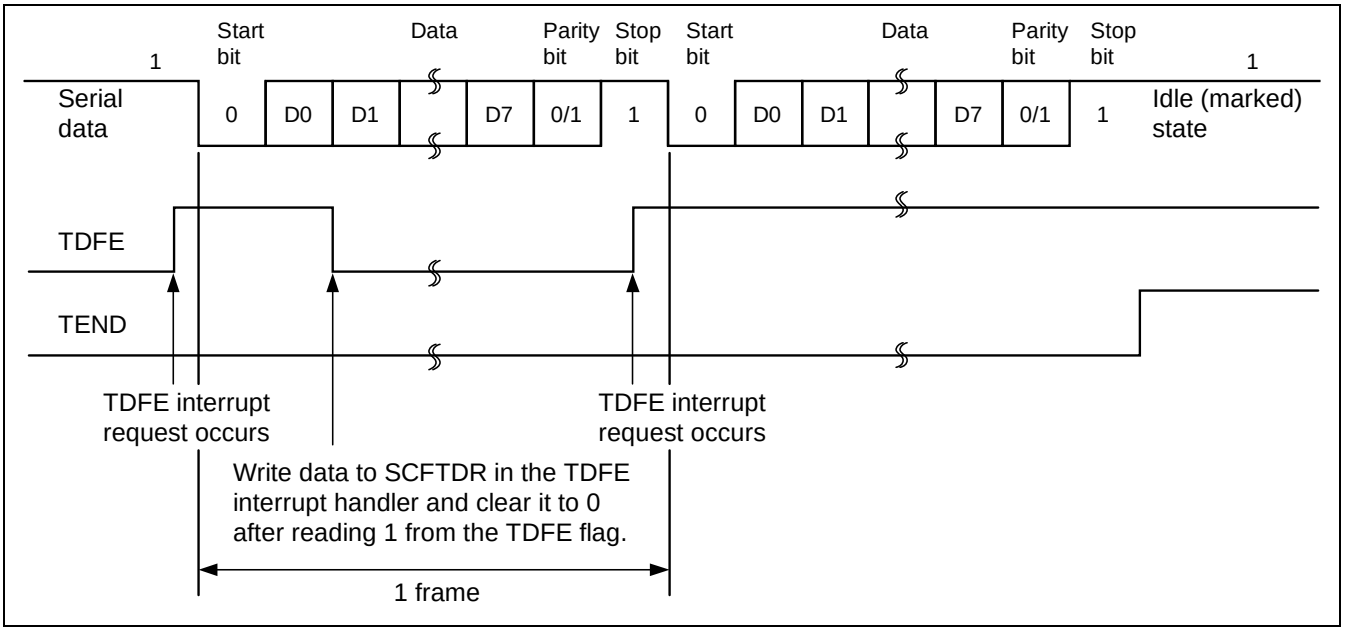

**Figure 105.10 Sample SCIF Transmission Operation (Example of 8-Bit Data with Parity and One Stop Bit)**

4. When modem control is enabled, transmission can be stopped or resumed in accordance with the CTS# input value. When CTS# is set to 1 during transmission, the marked state is entered after one frame of data transmission is ended. Setting CTS# to 0 restarts outputting the next transmit data from the start bit. Figure 105.11 shows an example of the operation with modem control enabled.

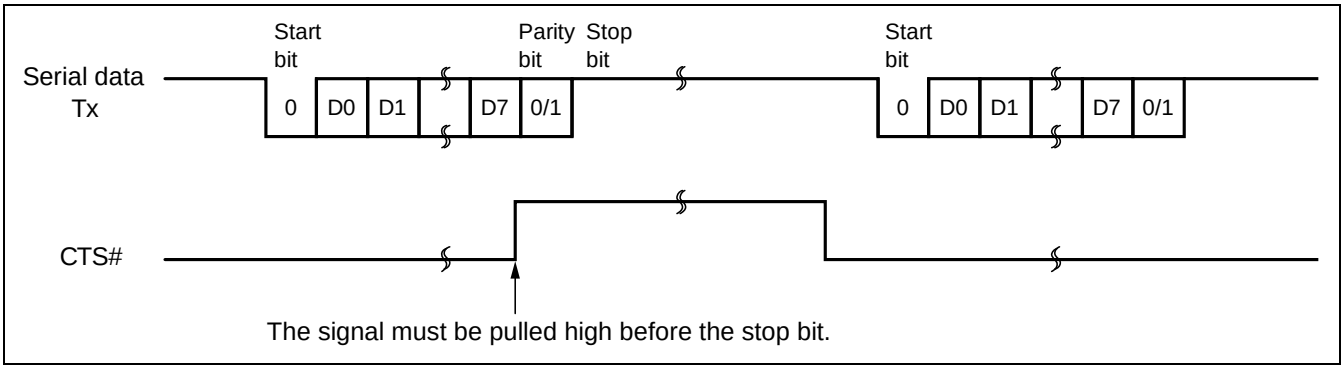

**Figure 105.11 Sample Operation with Modem Control Enabled (CTS#)**

### (c) Serial Data Reception (Asynchronous Mode)

Figure 105.12 and 105.13 show sample flowcharts for serial reception.

After the SCIF reception operation is enabled, serial data reception can be performed using the following procedure:

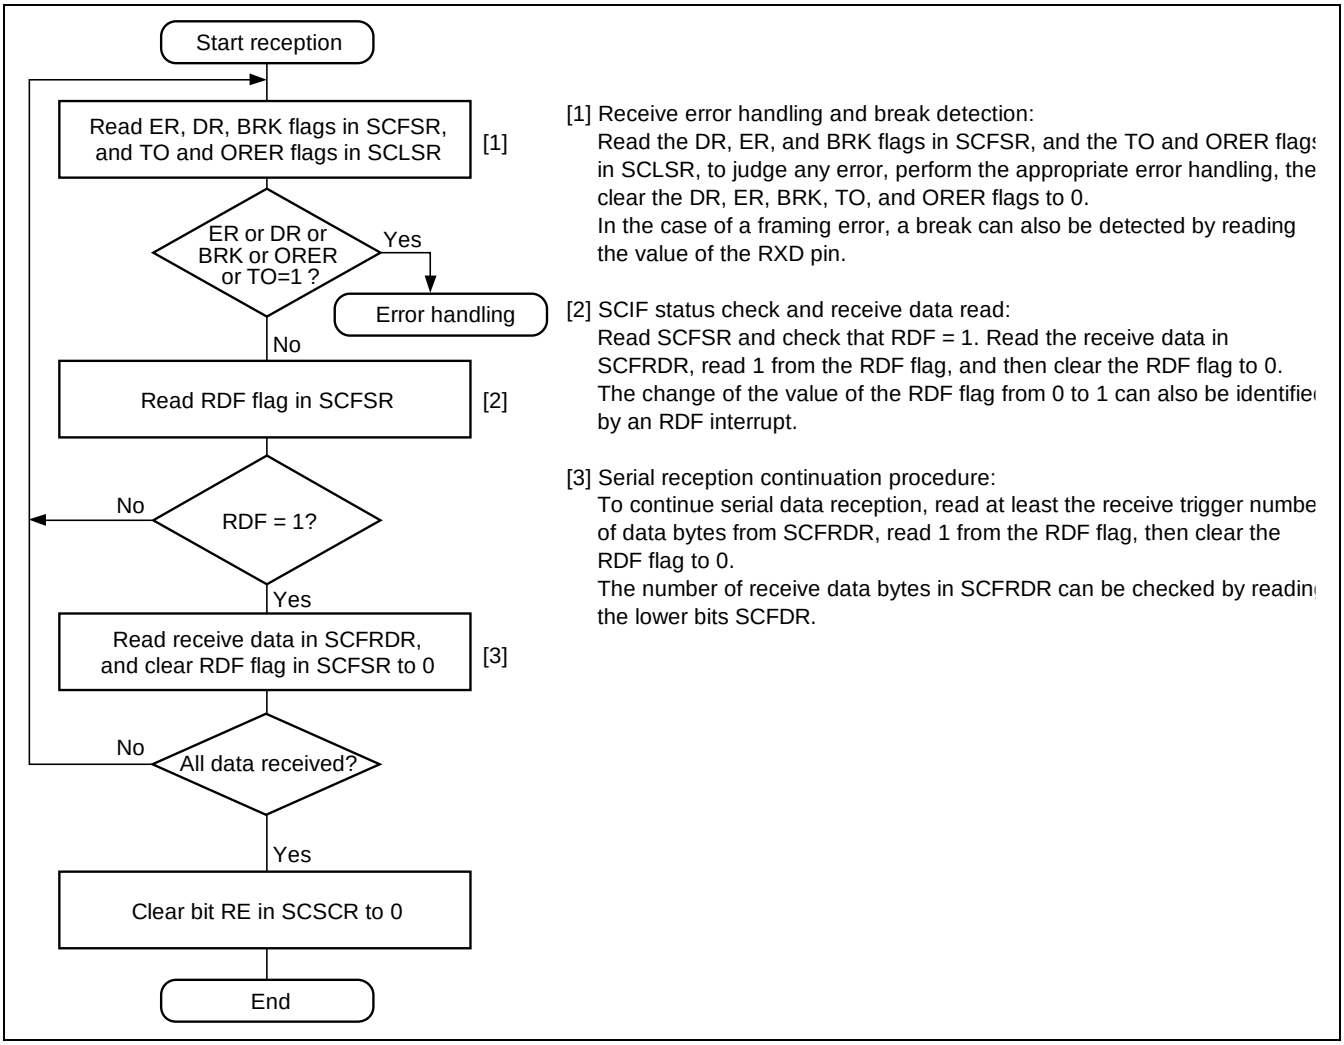

**Figure 105.12 Sample Flowchart for Serial Reception (1)**

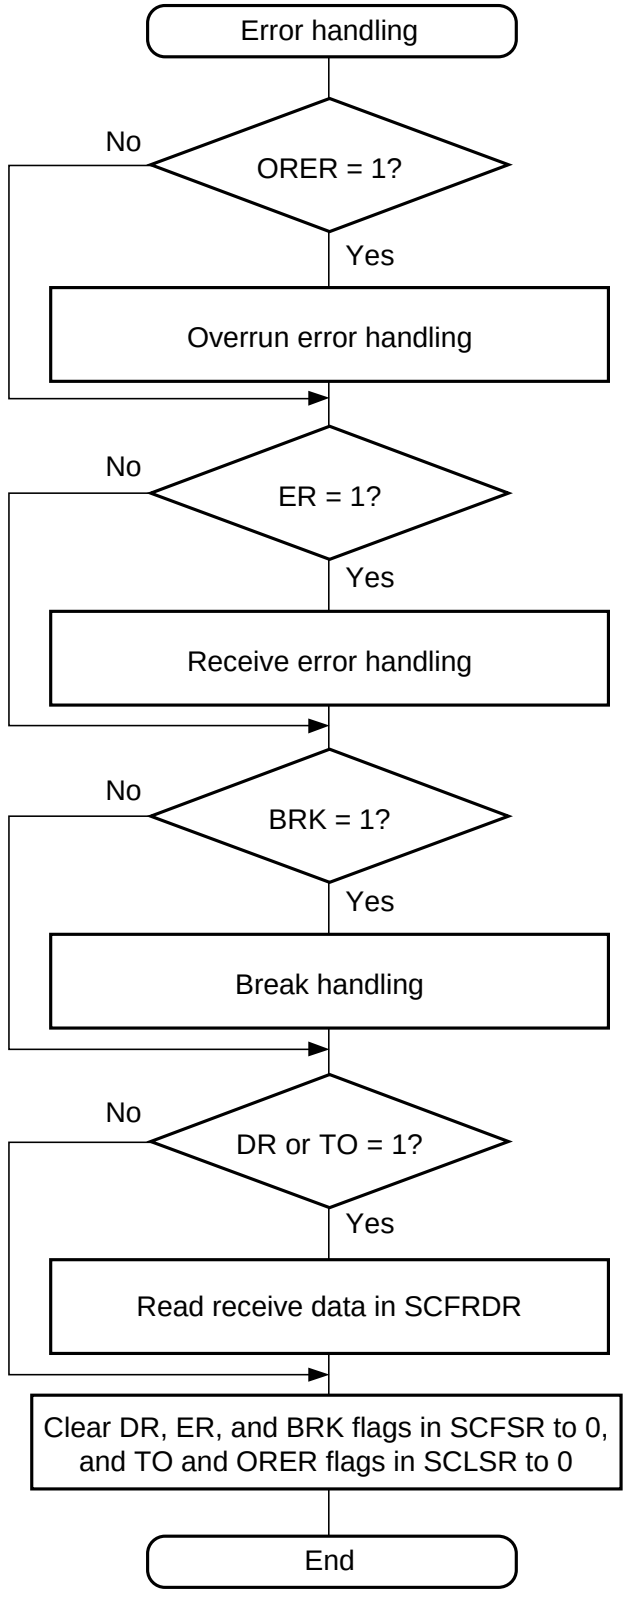

Whether a framing error or parity error has occurred in the receive data that is to be read from SCFRDR can be determined by checking bits FER and PER in SCFSR.

**Figure 105.13 Sample Flowchart for Serial Reception (2)**

In serial reception, the SCIF operates as follows:

1. The SCIF monitors the transmission line, and when detecting the start bit 0, it performs internal synchronization and starts reception.
2. The SCIF stores the received data in SCRSR in LSB-to-MSB order.
3. The SCIF receives the parity bit and stop bit.
   After receiving these bits, the SCIF performs the following checks:
   A. Stop bit: The SCIF checks whether the stop bit is 1.
      If there are two stop bits, it checks only the first stop bit.
   B. Receive data: The SCIF checks that receive data can be transferred from the receive shift register (SCRSR) to SCFRDR.
   C. Overrun error: The SCIF checks that the ORER flag is 0, indicating that no overrun error has occurred.
   D. Break state: The SCIF checks that the BRK flag is 0, indicating that the break state is not set.
   If the SCIF can confirm the conditions of (b), (c), and (d), it stores the receive data in SCFRDR.

   Note: The SCIF continues to receive data even when a parity error or a framing error occurs.

4. If the RDF flag changes to 1 while the RIE bit in SCSCR is 1, a receive-FIFO-data-full interrupt (RDF) request occurs.
   If the DR flag changes to 1 while the RIE bit in SCSCR is 1, a receive-data-ready interrupt (DR) request occurs.
   If the TO flag changes to 1 while the TOIE bit in SCSCR is 1, a timeout interrupt (TO) request occurs.
   If the ER flag changes to 1 while the RIE or REIE bit in SCSCR is 1, a receive-error interrupt (ER) request occurs.
   If the BRK flag changes to 1 while the RIE or REIE bit in SCSCR is 1, a break interrupt (BRK) request occurs.
   If the ORER flag changes to 1 while the RIE or REIE bit in SCSCR is 1, an overrun-error interrupt (ORER) request occurs.

Figure 105.14 shows an example of reception in asynchronous mode.

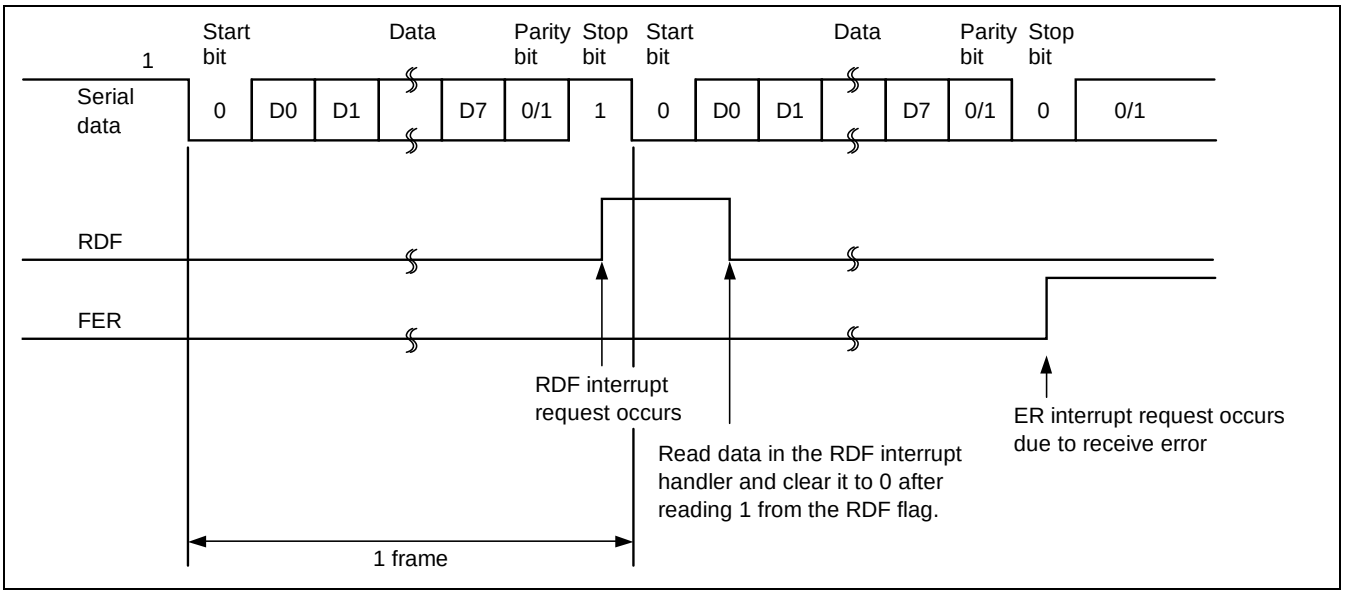

**Figure 105.14 Sample SCIF Receive Operation (Example of 8-Bit Data with Parity and One Stop Bit)**

5. When modem control is enabled, the RTS# signal is output when SCFRDR is empty. When RTS# is 0, data can be received. When RTS# is set to 1, the number of data bytes in SCFRDR is equal to or more than the RTS# output active trigger count.

Figure 105.15 shows an example of the operation with modem control enabled.

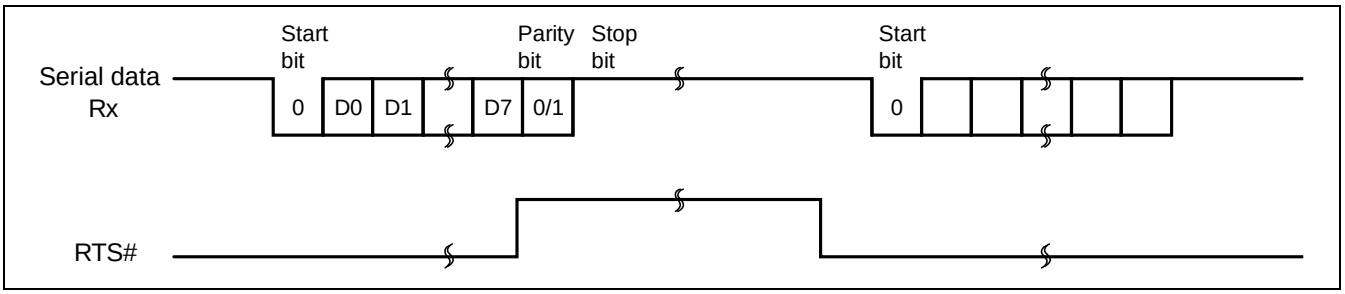

**Figure 105.15 Example of the Operation with Modem Control Enabled (RTS#)**

### 105.3.2 Operation in Clock Synchronous Mode

Clock synchronous mode, in which data is transmitted and received in synchronization with clock pulses, is suitable for fast serial communication.

Figure 105.16 shows the general format for clock synchronous serial communication. In the clock synchronous serial communication, data on the communication line is output between one falling edge of the synchronization clock and the next falling edge. The data decision is done at the rising edge of the clock.

In serial communication, each character is output starting with the LSB and ending with the MSB. After the MSB is output, the communication line retains the state of the last data.

In clock synchronous mode, the SCIF receives data in synchronization with a rising edge of the synchronization clock.

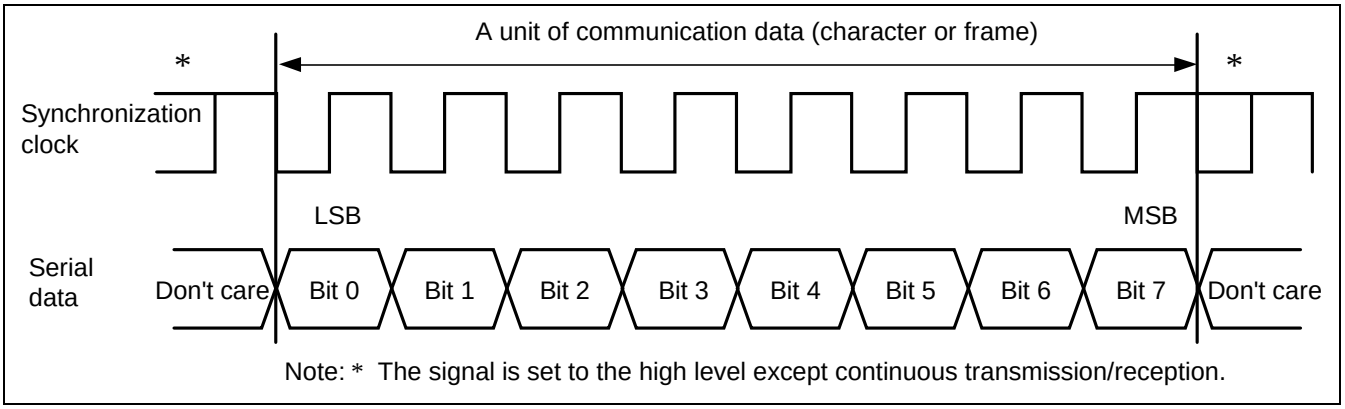

**Figure 105.16 Data Format for Clock Synchronous Communication**

#### (1) Data Transfer Format

The data transfer format is fixed to 8 bits. No parity bit can be added.

#### (2) Clock

The clock can be selected from the following two clocks using the C/A# bit in SCSMR and the CKE [1:0] bits in SCSCR:

- Internal clock generated by the on-chip baud rate generator
- External synchronization clock input at the SCK pin

When the SCIF is operated on an internal clock, the synchronization clock is output from the SCK pin. Eight synchronization clock pulses are output in one-character transfer, and when no transfer is performed the clock is fixed high. When only reception operation is performed, selecting an internal clock outputs clock pulses until the number of data bytes in the receive FIFO reaches the specified receive trigger count, while the RE bit in SCSCR is 1.

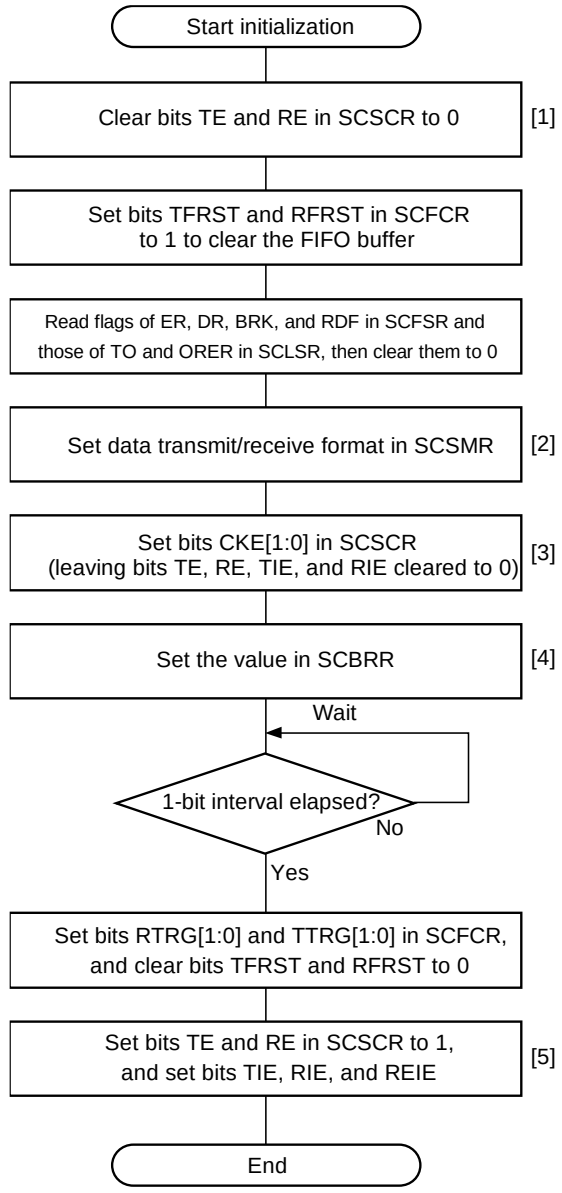
#### (3) Data Transmission/Reception

#### (a) Initialization of SCIF (Synchronous Mode)

Before transmitting/receiving data or changing the operating mode or communication format, the TE and RE bits in SCSCR to 0 and then the SCIF should be initialized using the sample flowchart for SCIF initialization shown in Figure 105.17.

[Note]

Clearing the TE bit to 0 initializes SCTSR. However, clearing the RE bit to 0 does not affect the RDF, PER, FER, and ORER flags and SCFRDR contents.



[1] Leave bits TE and RE cleared to 0 until the initialization almost ends.

[2] Set the data transfer format in SCSMR.

[3] Set bits CKE[1:0].

[4] Write the value of the bit rate to SCBRR. This is not required if an external clock is used. Wait at least one-bit interval after writing the value for the bit rate.

[5] Set bit TE or RE in SCSCR to 1. Also set bits TIE, RIE, and REIE to enable the TX, RX, and SCK pins to use.
In transmission, the TX pin will go to the marked state. In reception in clock synchronous mode with the synchronization clock output (clock master) selected, a clock starts to be output from the SCK pin at this point.

Note: SCBRR and SCFCR registers can only be set while both TE and RE bits of SCSCR are cleared.

**Figure 105.17 Sample Flowchart for SCIF Initialization**

**(b) Serial Data Transmission (Clock Synchronous mode)**

Figure 105.18 shows a sample flowchart for serial transmission.

After the SCIF transmission operation is enabled, serial data transmission can be performed using the following procedure:

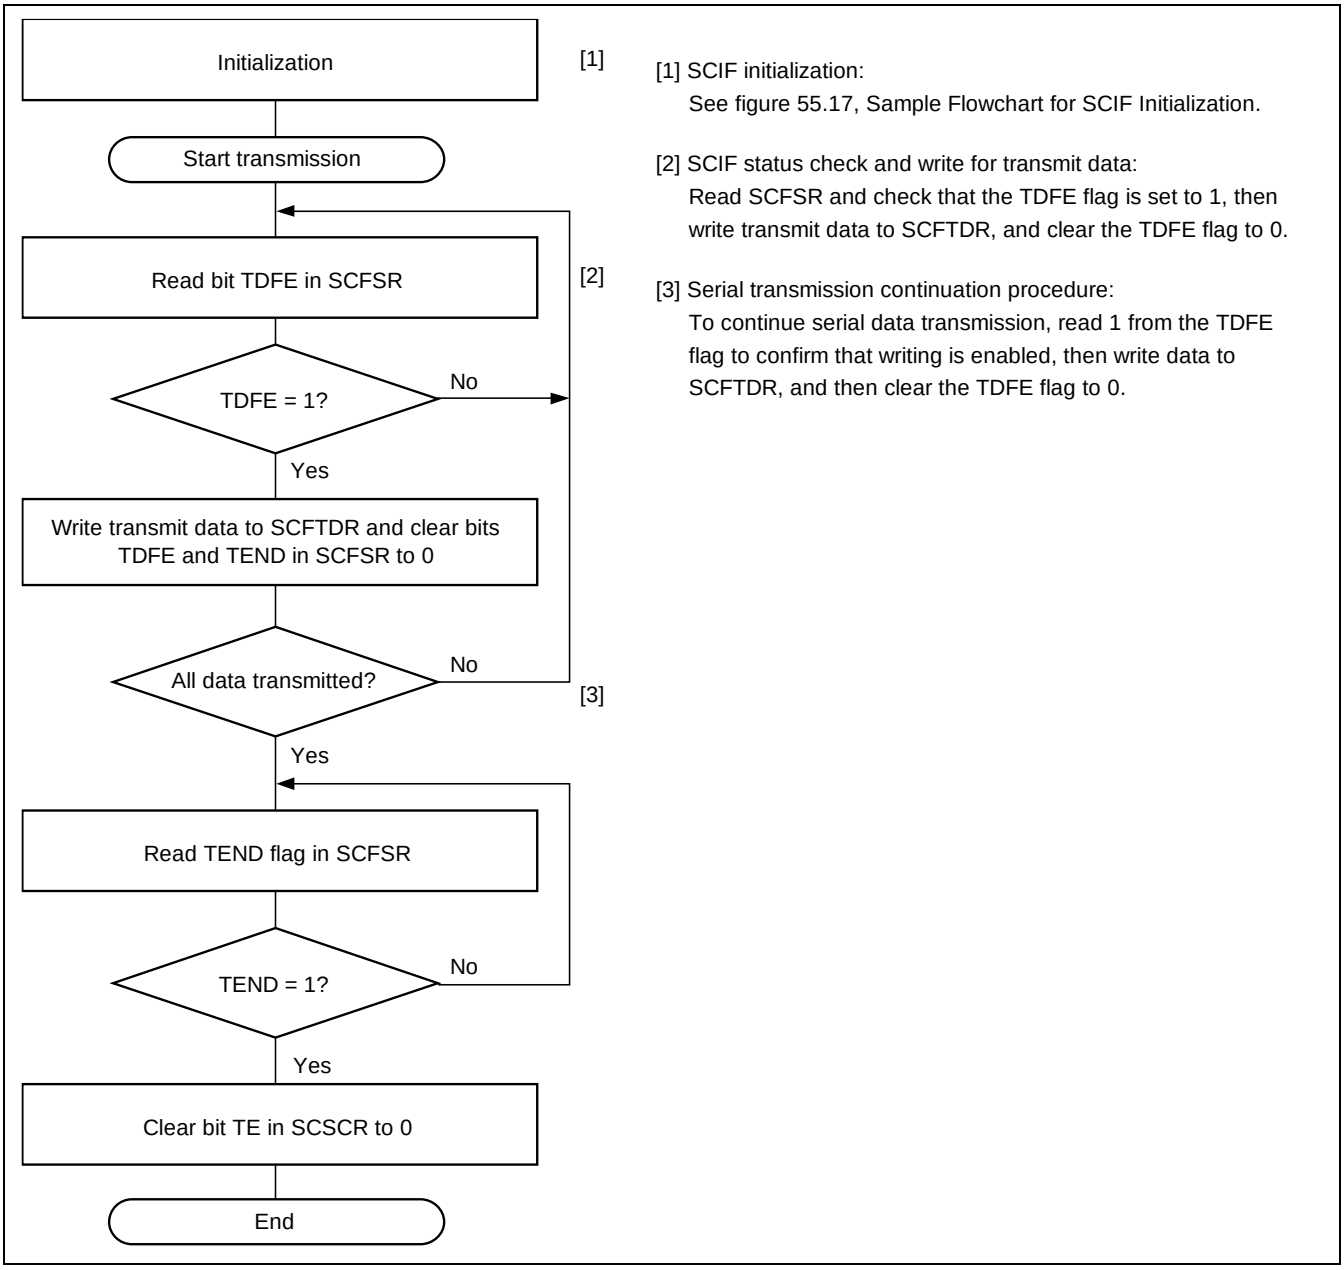


**Figure 105.18 Sample Flowchart for Serial Transmission**

In serial data transmission, the SCIF operates as described below:

1. When data is written to SCFTDR, the SCIF transfers the data from SCFTDR to SCTSR to start transmission. Confirm that the TDFE flag in SCFSR is set to 1 before writing transmit data to SCFTDR. The number of data bytes that can be written is at least (16- (the transmit trigger count)).
2. After the SCIF transfers data from SCFTDR to SCTSR and starts data serial transmission, the SCIF consecutively transmits it until there is no transmit data left in SCFTDR. When the number of transmit data bytes in SCFTDR is equal to or less than the transmit trigger count set in SCFCR, the TDFE flag is set. If the TIE and TEIE bits in SCSCR are set to 1 and 0, respectively at this time, a transmit-FIFO-data-empty interrupt (TDFE) request occurs. When the external clock is selected, data is output in synchronization with the input clock. The serial transmit data is output at the TX pin in the LSB-first order.
3. The SCIF checks transmit data in SCFTDR when sending the last bit. If there is transmit data, the SCIF transfers the data to SCTSR, and starts serial transmission of the next frame. If there is no transmit data left, the TEND flag in SCFSR is set to 1, and the transmit data pin (TX pin) retains its state after the last bit is sent. At this time, if the TIE and TEIE bits in SCSCR are set to 1, a transmit-end interrupt (TEND) request occurs.
4. After serial transmission ends, the SCK pin is fixed high.

Note: In clock synchronous mode, when transmit data is written to SCFTDR by the DMAC, the TEND flag may not be cleared. Therefore, if the DMAC is used for transmission in clock synchronous mode, read the TEND flag in the following method.
   1. Confirm that data transfer is completed in the DMAC.
   2. Read the TEND flag.
   3. Clear the TEND flag to 0 if TEND = 1.
   4. Read the TEND flag again.
   5. Use the second-read TEND flag.

Figure 105.19 shows an example of SCIF serial transmission in clock synchronous mode.

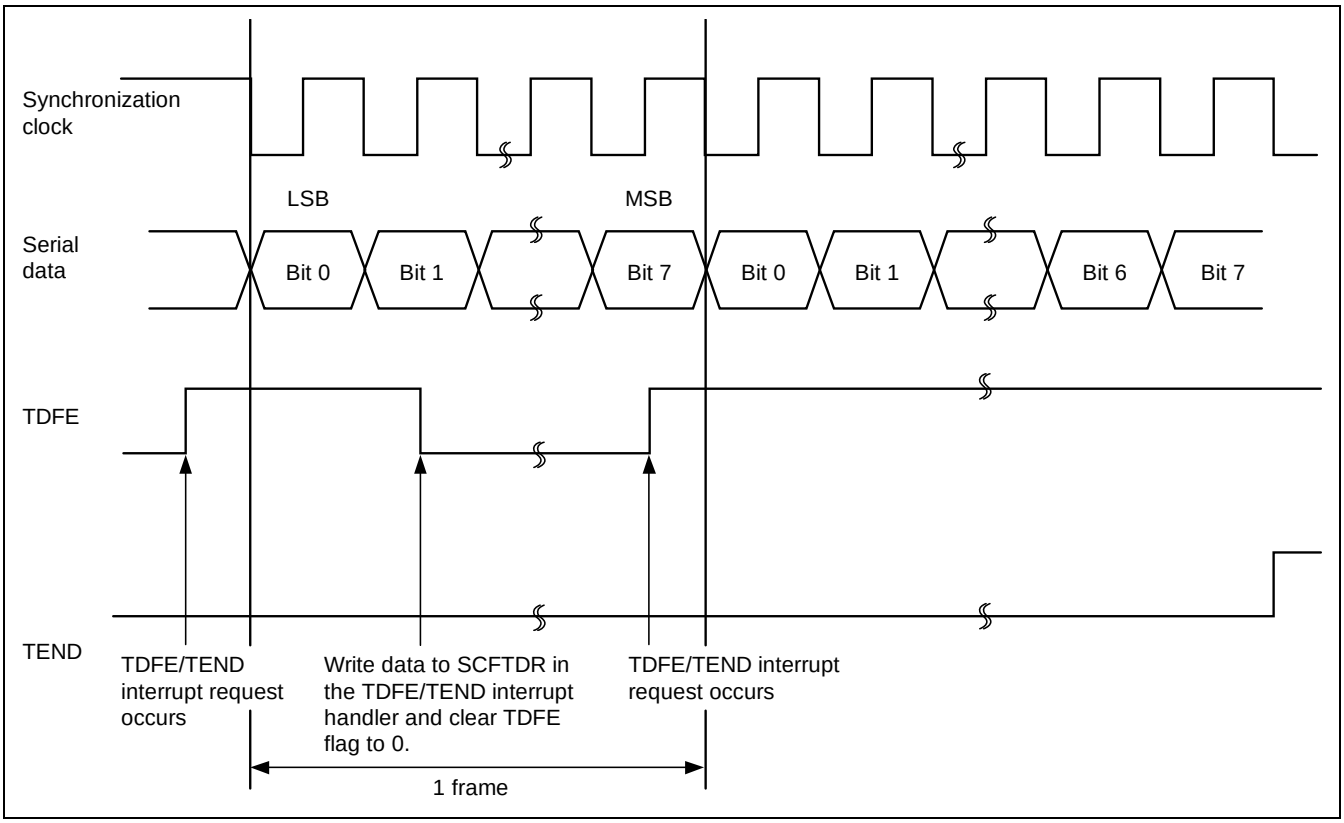

**Figure 105.19 Example of SCIF Serial Transmission in Clock Synchronous Mode**

**(c) Serial Data Reception (Clock Synchronous Mode)**

Figure 105.20 and 105.21 show sample flowcharts for serial reception.

The SCIF reception should be enabled before taking the following steps for serial data transmission.

When switching operating mode from asynchronous mode to clock synchronous mode without initializing the SCIF, check that the ORER, PER3 to PER0, and FER3 to FER0 flags are cleared to 0.

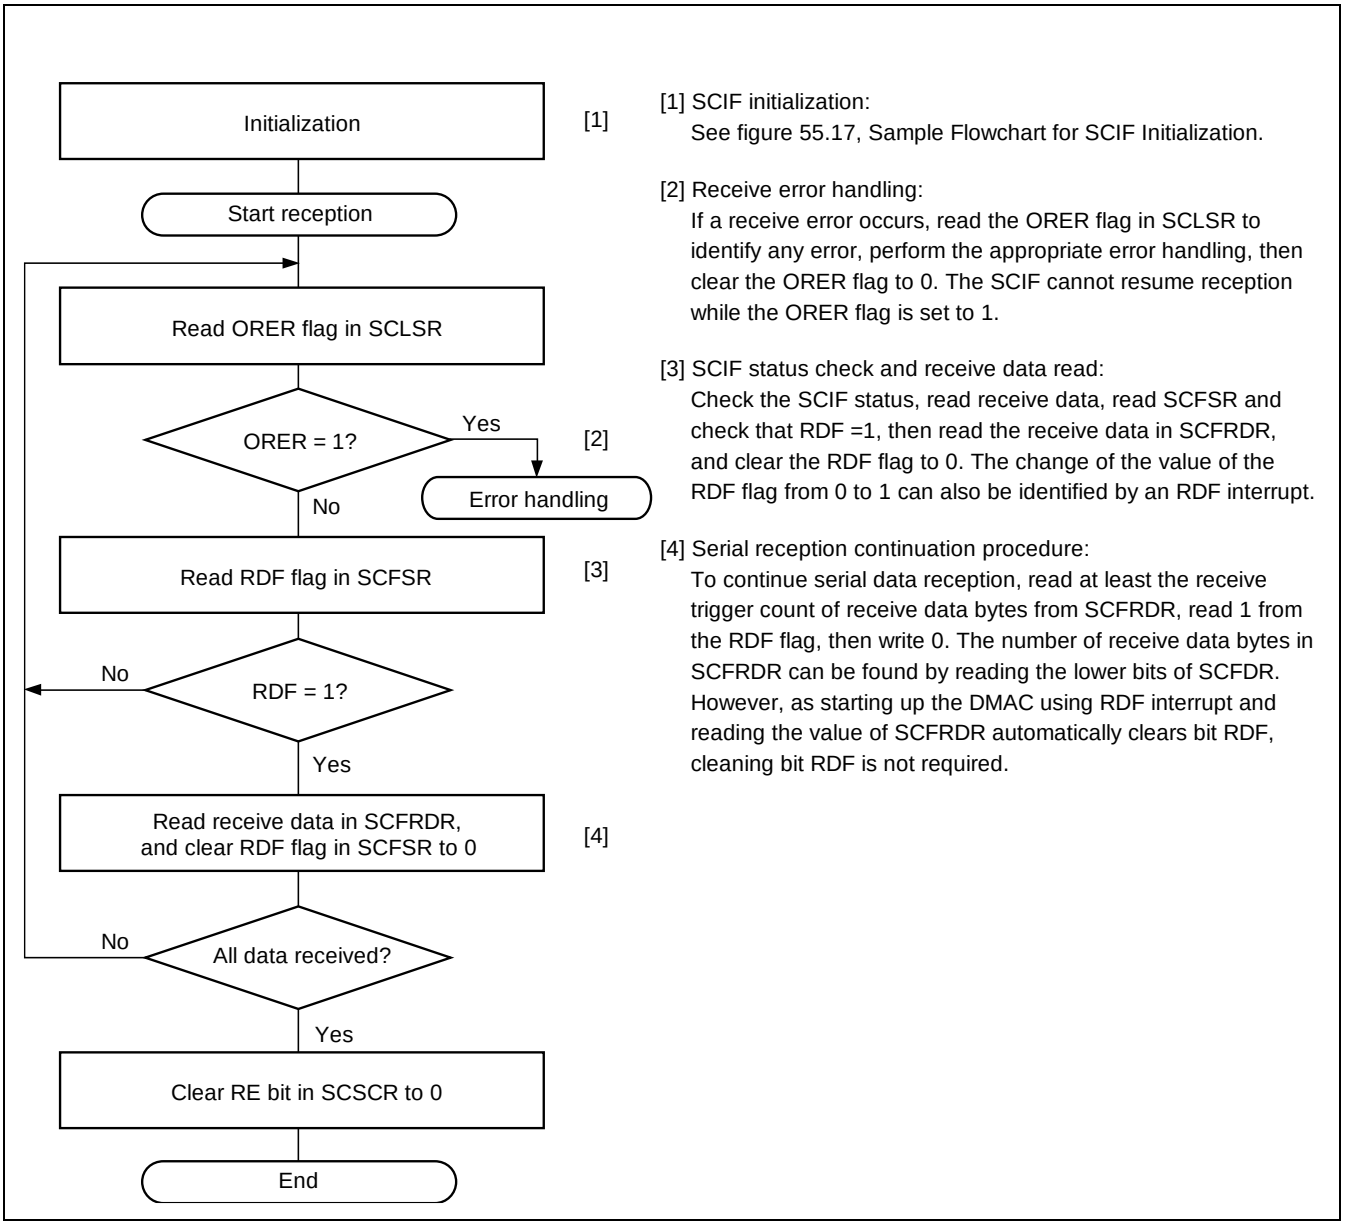

**Figure 105.20 Sample Flowchart for Serial Data Reception**

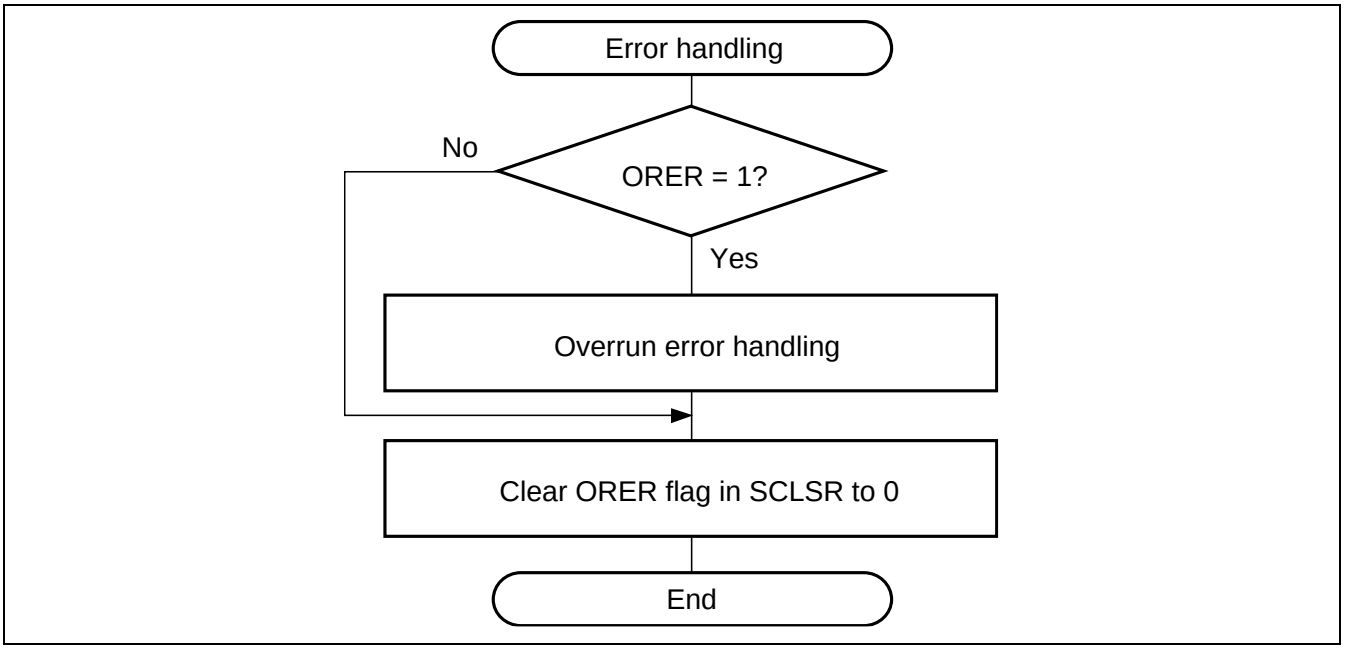

**Figure 105.21 Sample Flowchart for Serial Data Reception**

In serial data reception, the SCIF operates as described below:

1. The SCIF starts receiving data in synchronization with synchronization clock input or output.
2. The SCIF stores receive data in SCRSR in LSB-to-MSB order.
   After receiving the data, the SCIF first checks if the receive data can be transferred from SCRSR to SCFRDR, then starts storing the receive data in SCFRDR.
   If the SCIF detects an overrun error, the SCIF cannot receive subsequent data.
3. If the RDF flag changes to 1 while the RIE bit in SCSCR is 1, a receive-FIFO-data-full interrupt (RDF) request occurs. If the ORER flag changes to 1 while the RIE or REIE bit in SCSCR is 1, a break interrupt (BRI) request occurs.

Figure 105.22 shows an example of SCIF reception in clock synchronous mode.

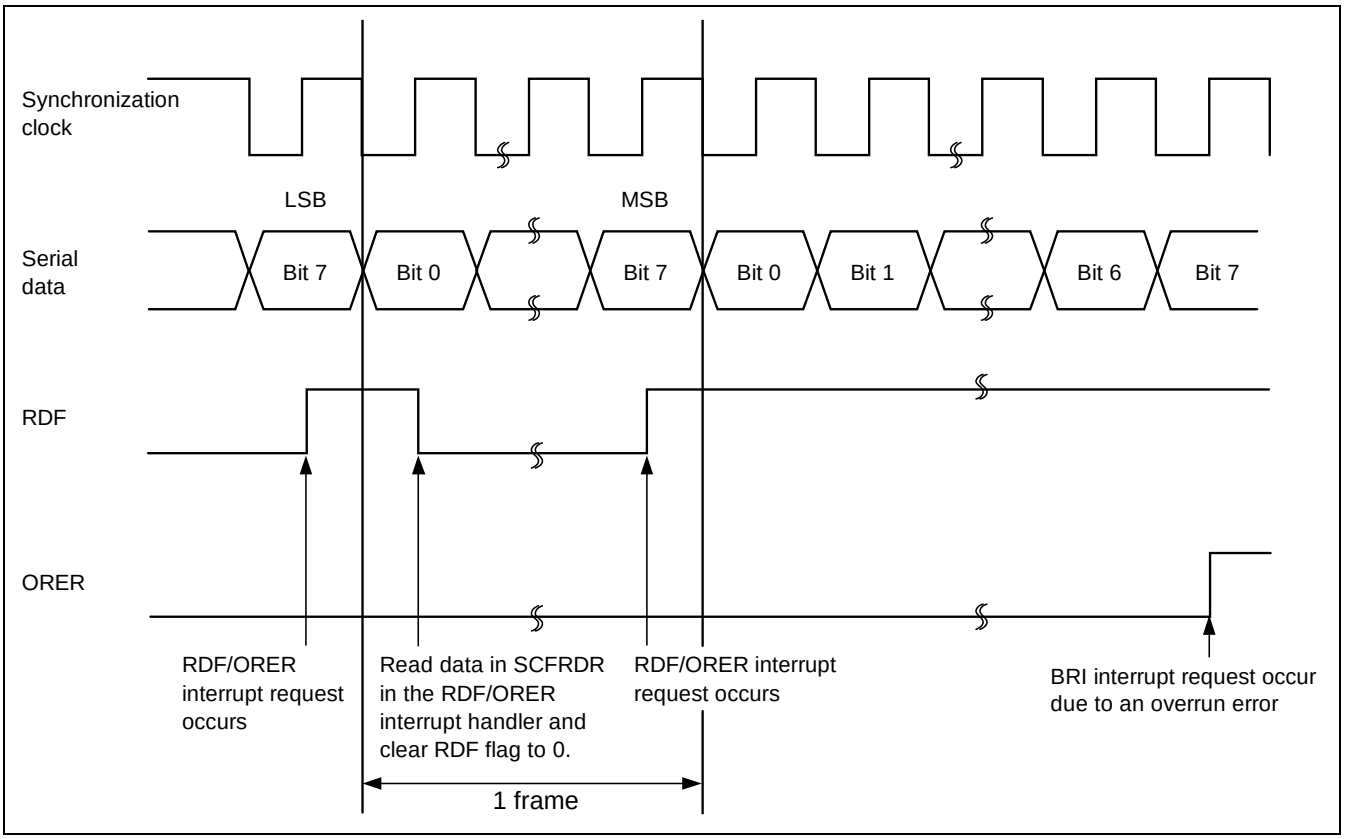

**Figure 105.22 Example of SCIF Reception in Clock Synchronous Mode**

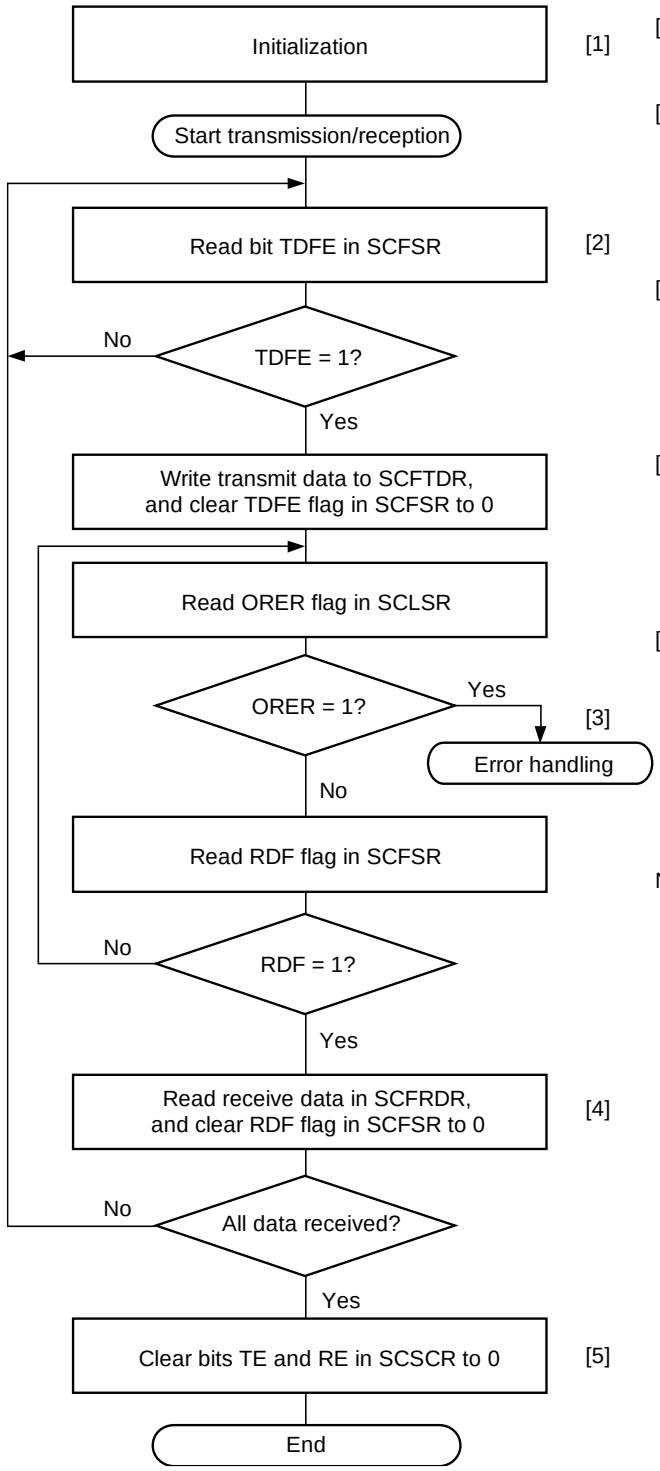
**(d) Simultaneous Serial Data Transmission/Reception (Clock Synchronous Mode)**

Figure 105.23 shows a sample flowchart for simultaneous serial data transmission/reception.

The SCIF transmission and reception should be enabled before taking the following steps for simultaneous serial data transmission/reception.



[1] SCIF initialization:
See figure 55.17, Sample Flowchart for SCIF Initialization.

[2] SCIF status check and write for transmit data:
Read SCFSR and check that the TDFE flag is set to 1, then write transmit data to SCFTDR, and clear the TDFE flag to 0. The change of the value of the TDFE flag from 0 to 1 can also be identified by a TDFE/TEND interrupt.

[3] Receive error handling:
If a receive error occurs, read the ORER flag in SCLSR, perform the appropriate error handling, then clear the ORER flag to 0. The SCIF cannot resume reception while the ORER flag is set to 1.

[4] SCIF status check and read for receive data:
Read SCFSR and check that RDF =1, then read the receive data in SCFRDR, and clear the RDF flag to 0. The change of the value of the RDF flag from 0 to 1 can also be identified by an RDF interrupt.

[5] Serial transmission and reception continuation procedure:
To continue serial data transmission and reception, read RDF flag and SCFRDR, and finish clearing the RDF flag to 0 before receiving the MSB in the current frame.
Similarly, read 1 from the TDFE flag to confirm that writing is enabled before transmitting the MSB in the current frame.
Then write data to SCFTDR and clear the TDFE flag to 0.

Note : When switching from transmission or reception to simultaneous transmission and reception, clear bits TE and RE to 0, and then set them to 1 simultaneously.

**Figure 105.23 Sample Flowchart for Simultaneous Serial Data Transmission/Reception**

### 105.3.3 Generation of Internal Clock

Internal clock generated by the on-chip baud rate generator.
Baud rate is determined by the SCBRR and CKS[1:0] bit in SCSMR.

[Asynchronous mode]

$$N = \frac{PCK}{64 \times 2^{2n-1} \times B} \times 10^6 - 1$$

[Clock synchronous mode]

$$N = \frac{PCK}{8 \times 2^{2n-1} \times B} \times 10^6 - 1$$

B: Bit rate (bit/s)

N: SCBRR setting for the baud rate generator ($0 \leq N \leq 255$) (which satisfies the electrical characteristics)

PCK: Peripheral module operating frequency (MHz)

n: Baud rate generator input clock (n = 0, 1, 2, 3)
(See the Table 105.8 for the relation between n and the clock.)

**Table 105.8 SCSMR Settings**

| n | Clock | SCSMR.CKS[1:0] Setting |
|---|---|---|
| 0 | PCK | 00 |
| 1 | PCK/4 | 01 |
| 2 | PCK/16 | 10 |
| 3 | PCK/64 | 11 |

The bit rate error in asynchronous mode is determined by the following equation:

$$\text{error (\%)} = \left\{ \frac{PCK \times 10^6}{(N+1) \times B \times 64 \times 2^{2n-1}} - 1 \right\} \times 100$$

### 105.3.4 Baud Rate Generator for External Clock (BRG)

#### (1) Overview

The SCIF incorporates a baud rate generator for external clock (abbreviated as BRG, hereafter). The BRG supplies a sampling clock (BRGCLK) to the SCIF core by dividing the external clock SC_CLK (selectable between SCIF_CLK and SCKi) by 1 to 216 – 1. In addition, the BRG switches the output between the external clock SCK and divided clock.

Figure 105.24 shows a block diagram of the BRG.

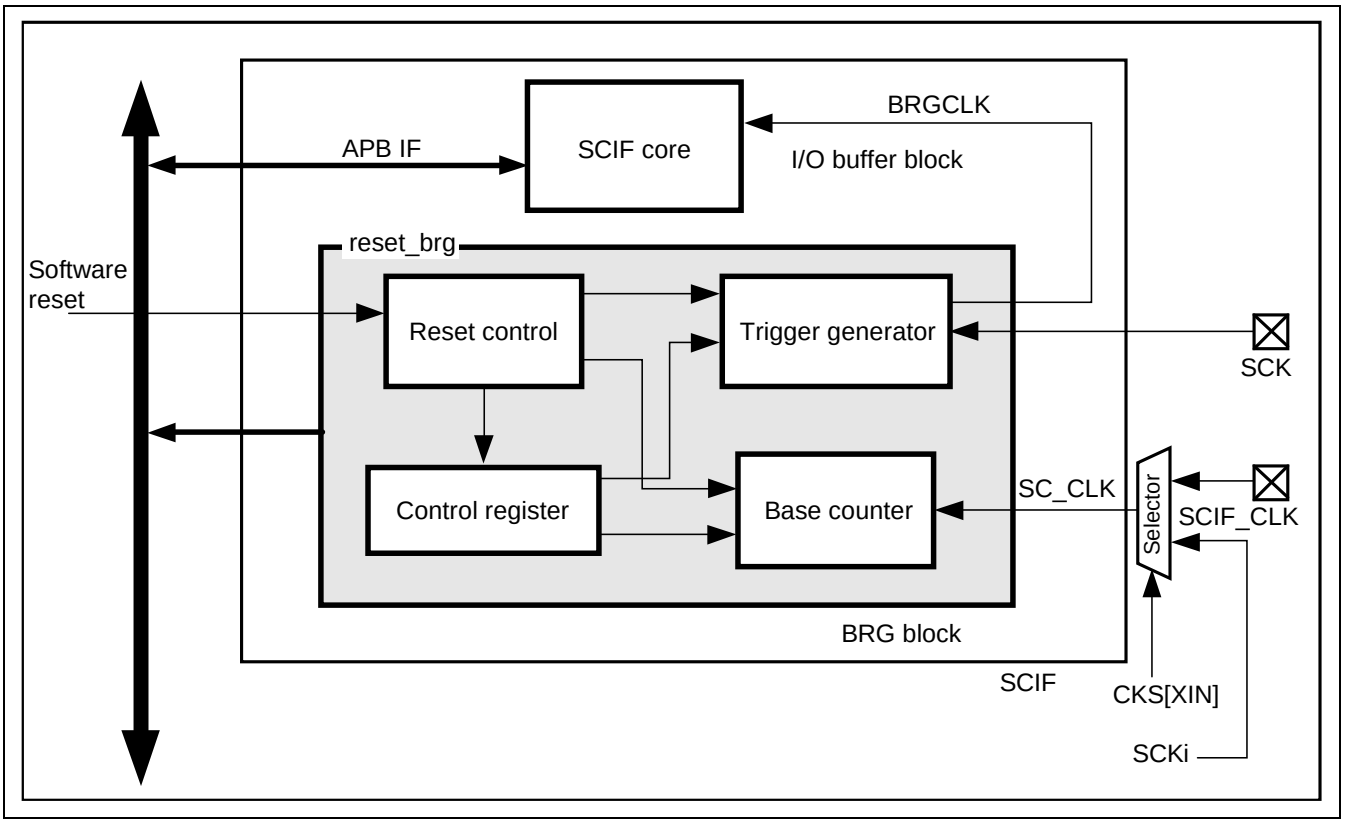


**Figure 105.24 BRG Block Diagram**

(a) Reset Controller:

The reset controller handles resetting the control register, base counter, and trigger generator.

(b) Control Register:

The control register has the frequency division register and clock select register.

(c) Base Counter:

The base counter is a 16-bit CLK synchronization counter that is used to determine the timing for generating a frequency divided clock.

(d) Trigger Generator:

The trigger generator generates rising-edge/falling-edge triggers for a frequency divided clock with the timing according to values of the frequency division register and base counter. The triggers are used to generate the frequency divided clock. In addition, the trigger generator switches the output between the SCK (external clock input) and frequency divided clock.

**(2) Registers**

To set baud rate requires setting to Frequency Division Register (DL) and Clock Select Register (CKS).

**(3) Frequency Division Register (DL)**

To set a division value of frequency requires setting to Frequency Division Register (DL).

Refer to Frequency Division Register (DL).

Table 105.9 shows reference values of Frequency Division Register (DL).

**Table 105.9** Baud Rate (3.6864-MHz clock)

| Baud Rate | Value of Frequency Division | Error Rate (*) |
|---|---|---|
| 50 | 4608 | — |
| 75 | 3072 | — |
| 110 | 2095 | –0.022 |
| 134.5 | 1713 | 0.001 |
| 150 | 1536 | — |
| 300 | 768 | — |
| 600 | 384 | — |
| 1200 | 192 | — |
| 1800 | 128 | — |
| 2000 | 115 | 0.174 |
| 2400 | 96 | — |
| 3600 | 64 | — |
| 4800 | 48 | — |
| 7200 | 32 | — |
| 9600 | 24 | — |
| 14400 | 16 | — |
| 19200 | 12 | — |
| 38400 | 6 | — |
| 76800 | 3 | — |
| 115200 | 2 | — |

Note: —: Indicates that the error rate is 0.

### (4) Clock Select Register (CKS)

To set output between the frequency divided clock and specifies a source clock for the external baud rate requires setting to Clock Select Register (CKS).

Refer to Clock Select Register (CKS).

### (5) Restrictions in BRG

**Notes on Setting Frequency Division Register**

1. For the initial setting of the register after a reset, at least one bit of waiting period is required to secure the clock stabilization time.
   (Example) One bit period when DL = 2

   $3.68\ (\text{MHz}) \times 1/2 \times 1/16 = 0.115\ (\text{MHz}) \rightarrow 8695\ (\text{ns})$

2. For modifying the register value after the setting stated in <1> above, at least one bit of waiting period at the maximum bit rate (DL = '65535') is required.
   The SCIF registers and BRG registers should be set as the following table:

- Asynchronous mode (SC_CLK external input)

| SCIF | | BRG | |
|---|---|---|---|
| **Register Name** | **Setting Value** | **Register Name** | **Setting Value** |
| SCSMR.C/A# | B’0 | CKS | H’0000 |
| SCSCR.CKE[1:0] | B’10 | DL | H’0001 to H’FFFF |

- Asynchronous mode (SCK external input)

| SCIF | | BRG | |
|---|---|---|---|
| **Register Name** | **Setting Value** | **Register Name** | **Setting Value** |
| SCSMR.C/A# | B’0 | CKS | H’8000 |
| SCSCR.CKE[1:0] | B’10 | DL | Don’t care |

- Clock synchronous mode (external input)

| SCIF | | BRG | |
|---|---|---|---|
| **Register Name** | **Setting Value** | **Register Name** | **Setting Value** |
| SCSMR.C/A# | B’1 | CKS | H’8000 |
| SCSCR.CKE[1:0] | B’10 | DL | Don’t care |

- Asynchronous mode (SC_CLK internal input)

| SCIF | | BRG | |
|---|---|---|---|
| **Register Name** | **Setting Value** | **Register Name** | **Setting Value** |
| SCSMR.C/A# | B’0 | CKS | H’4000 |
| SCSCR.CKE[1:0] | B’10 | DL | H’0001 to H’FFFF |

3. The register settings for the baud rate generator for external clock should be made before starting initialization of the SCIF.

### 105.3.5 SCIF Interrupt Sources and the DMAC

If the DMAC is used for transmission/reception, set and enable the DMAC before setting the SCIF.

**Transmission Interrupts and DMA Transfer:**

If the TDFE/TEND flag in SCFSR is set to 1 when the TDFE/TEND interrupt is enabled by the TIE bit, a TDFE/TEND interrupt request and a transmit-FIFO-data-empty DMA transfer request will occur. If the TDFE/TEND flag is set to 1 when TDFE/TEND interrupt is disabled by the TIE bit, only the transmit-FIFO-data-empty DMA transfer request will occur. (A transmit-FIFO-data-empty DMA transfer request is generated when the TDFE flag is set while TEIE is 0, or when the TEND flag is set while TEIE is 1. DMA transfer requests are not affected by the TEIE bit.)

When TDFE/TEND interrupt requests are enabled, the interrupt requests are cleared by the DMAC regardless of the interrupt handling program.

**Reception Interrupts and DMA Transfer:**

If the RDF/DR flag in SCFSR is set to 1 when RDF/DR interrupt is enabled by the RIE bit, an RDF/DR interrupt request occurs. If the RDF/DR flag is set to 1, a receive-FIFO-data-full DMA transfer request occurs. If the RDF/DR flag is set to 1 when RDF/DR interrupt is disabled by the RIE bit, and only a receive-FIFO-data-full DMA transfer request occurs and DMAC can be activated to perform data transfer.

Setting the RIE bit in SCSCR to 0 and the REIE it to 1 generates the ER/BRK/ORER interrupt requests without generating RDF/DR interrupt requests. When the BRK flag in SCFSR or the ORER flag in SCLSR is set to 1, BRK/ORER interrupt requests occur.

If the TO flag is set to 1 in SCLSR when TO interrupts are enabled by the TOIE bit, TO interrupt requests occur.

DR/TO interrupt requests generated by setting the DR or TO flag to 1 or receive-FIFO-data-full DMA transfer requests occur only in asynchronous mode.

When DR/TO interrupt requests are enabled to be issued, interrupt requests generated by the DR flag are cleared by the DMAC regardless of the interrupt handling program, however, those generated by the TO flag are not cleared by the DMAC. Therefore, the TO flag interrupt requests need to be cleared with the interrupt handling program. (The DR and TO flags are set at the same time, but cleared separately.)

**Table 105.10 SCIF Interrupt Sources**

| Interrupt Source | DMAC Activation | Priority on Reset Release |
|---|---|---|
| Interrupts generated by receive error flag (ER) | Disabled | High |
| Interrupts generated by receive-FIFO-data-full (RDF), receive-data-ready (DR) or timeout (TO) * | Enabled | ↕ |
| Interrupts generated by break (BRK) or overrun error (ORER) | Disabled | |
| Interrupts generated by transmit FIFO data empty (TDFE) | Enabled | Low |

Note: * RXI interrupts by means of the DR or TO flag are available only in asynchronous mode.

## 105.4 Usage Notes

### 105.4.1 Break Detection and Operation

Break signals can also be detected by reading the RX pin value directly when a framing error (FER) is detected. In the break state, the input values from the RX pin are all 0s. So, the parity error flag (PER) may be set after the FER flag is set to 1.

Although the SCIF stops receive data transfer to SCFRDR after detecting a break, it continues data reception.

### 105.4.2 Sending a Break Signal

The input/output condition and level of the TX pin are determined by the SPB2IO and SPB2DT bits in SCSPTR. This enables to send a break signal.

The pin does not function as the TX pin from the initialization of the serial transmitter to setting of the TE bit (enabling transmission). In this period, the marked state is substituted by the value of the SPB2DT bit. Therefore, the SPB2IO and SPB2DT bits should be set to 1 (designating output and high level) beforehand.

To send a break signal during serial transmission, clear the SPB2DT bit to 0 (low level), and then clear the TE bit to 0 (halting transmission). When the TE bit is cleared, the transmitter is initialized regardless of the current transmission state, and the TX pin outputs 0.

### 105.4.3 Data Sampling Timing and Reception Margin in Asynchronous Mode

In asynchronous mode, the SCIF operates on the base clock with a frequency 16 times the bit rate.

In reception, the SCIF performs the internal synchronization by sampling the fall edge of the start bit using the base clock. In addition, the SCIF takes receive data at the rising edge of the eighth pulse on the base clock.

Figure 105.25 shows the timing of this operation.

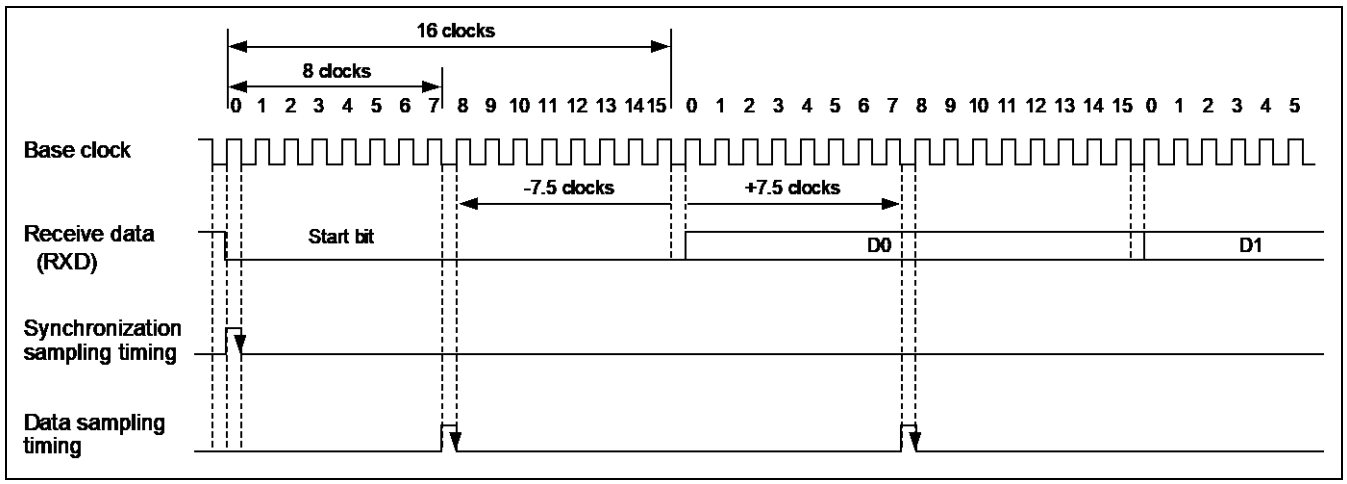

**Figure 105.25 Timing Chart of Receive Data Sampling**

The reception margin in asynchronous mode is given by formula (1).

$$M = \left| (0.5 - \frac{1}{2N}) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F) \right| \times 100\% \quad \text{..... Expression (1)}$$

M: Receive margin (%)

N: Ratio of bit rate to clock (N = 16)

D: Clock duty (D = 0 to 1.0)

L: Frame length (L = 9 to 12)

F: Absolute value of clock frequency deviation

Assuming F = 0 and D = 0.5 for expression (1), the reception margin obtained with expression (2) is 46.875% as shown below:

Assuming D = 0.5 and F = 0

M = (0.5 − 1/ (2 × 16)) × 100%

= 46.875% ……expression (2)

This is a theoretical value. A reasonable margin allowed in system designs is 20% to 30%.

### 105.4.4 Reception Margin and Baud Rate Error

The value of 46.875% obtained by the above expression (2) indicates the reception margin when the baud rate error is 0 (F = 0). If there is no error in the reception and transmission baud rates, reception is possible even with misalignment of approx. 1/2 bit. If there is an error in the reception and transmission baud rates, the errors are accumulated up to the stop bit reception, which reduces the reception margin. The allowable baud rate error can be obtained by modifying the F in expression (1). When D= 0.5:

F = {(15/32 − M)/ (L − 0.5)} × 100 (%)……expression (3)

By using expression (3), the relationship between the allowable error and reception margin with the frame length = 12 can be summarized as follows:

| Allowed Error (%) | Reception Margin (%) |
|---|---|
| 4.07 | 0 |
| 3.64 | 5 |
| 3.20 | 10 |
| 2.33 | 20 |
| 1.46 | 30 |

## 105.5 Safety Mechanisms

SCIF module has no mechanism of FuSa.

# 106. High Speed Serial Communication Interface with FIFO (HSCIF)

## 106.1 Overview

The fourth generation R-Car series products have a high speed serial communication interface with built-in FIFO buffers (high-speed serial communication interface with FIFO: HSCIF) that handles asynchronous communication. The HSCIF has two 128-stage FIFO buffers separately for transmission and reception, which enables fast, efficient, and uninterrupted communication. R-Car V4M has 4 channels of HSCIF. All functions of each channel are same.

### 106.1.1 Features

The HSCIF has the following features.

- Asynchronous serial communication mode

  The HSCIF performs serial data communication based on a character-by-character asynchronous system. This feature enables serial data communication with standard asynchronous communication chips that support universal asynchronous receiver/transmitter (UART) or asynchronous communication interface adapter (ACIA). There is a choice of eight serial data transfer formats.
  - Data length: 7 or 8 bits
  - Stop bit length: 1 or 2 bits
  - Parity: Even/odd/none
  - Receive error detection: Parity, framing, and overrun errors
  - Break detection:

    A break is detected when a framing error lasts for more than 1 frame length at space 0 (low level).

    When a framing error occurs, a break can also be detected by reading the HRX pin level directly from the serial port register (HSSPTR).
  - Sampling rate: Variable (integer number from 8 to 32)
- Capable of full-duplex communication

  The HSCIF has an independent transmitter and receiver that enable simultaneous transmission and reception. The transmitter and receiver both have a 128-stage FIFO buffer structure, enabling continuous serial data transmission and reception.
- On-chip baud rate generator, enabling any bit rate to be selected

  The HSCIF enables choice of a clock source for transmission/reception: a clock from the on-chip baud rate generator based on the internal clock or an external clock.
- Eight interrupt sources

  The HSCIF has eight types of interrupt sources: receive-data-ready, receive-FIFO-data-full, break detection, transmit-FIFO-data-empty, transmit-end, receive-error, overrun-error and time-out, and enables any of them to be requested independently.
- DMA data transfer

  When the transmit FIFO register is empty or the receive FIFO register has received data, issuing a DMA transfer request activates the DMA controller (DMAC) to execute a data transfer.
- Modem control functions (HRTS# and HCTS#) are stored.
- The amount of data in the transmit/receive FIFO registers and the number of receive errors in receive data in the receive FIFO register are available.

A receive data ready (DR) or a timeout error (TO) can be detected during reception.

### 106.1.2 Block Diagram

Figure 106.1 shows the HSCIF block diagram.

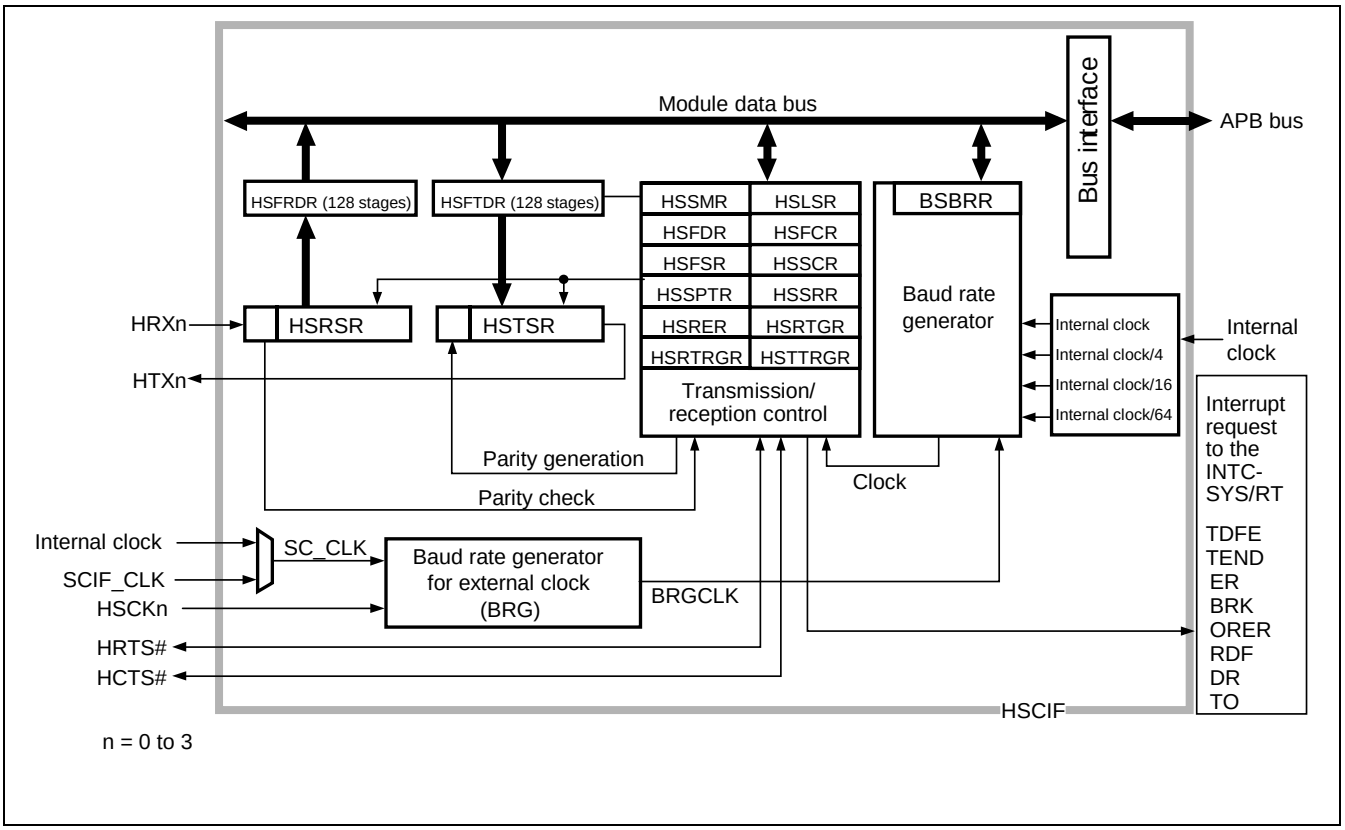

**Figure 106.1 HSCIF Block Diagram**

[Legend]

HSRSR: Receive shift register
HSFRDR: Receive FIFO data register
HSTSR: Transmit shift register
HSFTDR: Transmit FIFO data register

Note: These pins are made to function as serial pins by setting up HSCIF operation using bits TE, RE, CKE[1:0] in HSSCR, and bit MCE in HSFCR. HSSPTR of the HSCIF can be used to handle the transmission and detection of break states.

### 106.1.4 Register Configuration

(include Safety Mechanism related registers)

Table 106.2 shows the registers in the HSCIF. Do not write to any addresses other than listed below. Operations cannot be guaranteed if writing is attempted. Values read from addresses other than those listed below are undefined.

**Table 106.2 Register Configuration**

| Register Name | Abbreviation | R/W | Value after Reset | Offset From Base Address | Access Size |
|---|---|---|---|---|---|
| Serial mode register | HSSMR | R/W | H'0000 | H'00 | 16 |
| Bit rate register | HSBRR | R/W | H'FF | H'04 | 8 |
| Serial control register | HSSCR | R/W | H'0000 | H'08 | 16 |
| Transmit FIFO data register | HSFTDR | —/WB | Undefined | H'0C | 8 |
| Serial status register | HSFSR | R/WC0*1 | H'0060 | H'10 | 16 |
| Receive FIFO data register | HSFRDR | R | Undefined | H'14 | 8 |
| FIFO control register | HSFCR | R/W | H'0000 | H'18 | 16 |
| FIFO data count register | HSFDR | R | H'0000 | H'1C | 16 |
| Serial port register | HSSPTR | R/W | Undefined*3 | H'20 | 16 |
| Line status register | HSLSR | R/WC0*2 | H'0000 | H'24 | 16 |
| Frequency division register | DL | R/W | H'00 | H'30 | 16 |
| Clock select register | CKS | R/W | H'00 | H'34 | 16 |
| Sampling rate register | HSSRR | R/W | H'000F | H'40 | 16 |
| Serial error register | HSRER | R | H'0000 | H'44 | 16 |
| RTS output active trigger register | HSRTGR | R/W | H'000F | H'50 | 16 |
| Receive FIFO data count trigger register | HSRTRGR | R/W | H'0001 | H'54 | 16 |
| Transmit FIFO data count trigger register | HSTTRGR | R/W | H'0008 | H'58 | 16 |

Notes: 1. Only 0 can be written to clear the flags. Bits 15 to 8, 3, and 2 are read-only bits and cannot be modified.
2. Only 0 can be written to clear the flags. Bits 15 to 3, and 1 are read-only bits and cannot be modified.
3. The initial values of HSSPTR bits 6, 4, 2, and 0 are undefined.

| Channel No. | Base Address |
|---|---|
| 0 | H'E654 0000 |
| 1 | H'E655 0000 |
| 2 | H'E656 0000 |
| 3 | H'E66A 0000 |

## 106.2 Register Description

(include Safety Mechanism related register description)

### 106.2.1 Receive Shift Register (HSRSR)

HSRSR is a register that receives serial data.

The HSCIF sets serial data input to the HSRSR from the HRX pin in the order received, starting with the LSB (bit 0), and converts it to parallel data. When one byte of data has been received, it is transferred to the receive FIFO register HSFRDR, automatically.

HSRSR cannot be read from and written to by the CPU.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| | | | | | | | | |
| Initial value: | — | — | — | — | — | — | — | — |
| R/W: | — | — | — | — | — | — | — | — |

### 106.2.2 Receive FIFO Data Register (HSFRDR)

HSFRDR is a 128-stage FIFO register that stores received serial data.

When HSCIF has received one byte of serial data, it transfers the received data from the receive shift register (HSRSR) to HSFRDR for storage, and reception is thus completed. HSRSR is then ready for reception, and is capable of receiving up to 128 consecutive bytes of data before HSFRDR is full.

HSFRDR is a read-only register and cannot be modified by the CPU. Note that the read value will be undefined while there is no receive data in HSFRDR. When HSFRDR is full of receive data, subsequent serial data is lost.

HSFRDR is read as an undefined value after a power-on reset.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| | | | | | | | | |
| Initial value: | — | — | — | — | — | — | — | — |
| R/W: | R | R | R | R | R | R | R | R |

### 106.2.3 Transmit Shift Register (HSTSR)

HSTSR is a register that transmits serial data.

To perform serial data transmission, the HSCIF first transfers transmit data from the transmit fifo data register (HSFTDR) to HSTSR, and then sends the data to the HTX pin starting with the LSB (bit 0). When transmission of one byte is completed, the HSCIF transfers the next transmit data from HSFTDR to HSTSR automatically, then starts transmission.

HSTSR cannot be read from and written to directly by the CPU.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| | | | | | | | | |
| Initial value: | — | — | — | — | — | — | — | — |
| R/W: | — | — | — | — | — | — | — | — |

### 106.2.4 Transmit FIFO Data Register (HSFTDR)

HSFTDR is an 8-bit FIFO register of 128 stages that stores data for serial transmission.

If HSTSR is empty after transmit data has been written to HSFTDR, the HSCIF transfers the data from HSFTDR to HSTSR and starts serial transmission.

HSFTDR is a write-only register and cannot be read from by the CPU. Writing further data to HSFTDR is no longer possible when it is full. Attempts at writing data to the register in this situation are ignored.

HSFTDR is read as an undefined value on a power-on reset.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| | | | | | | | | |
| Initial value: | — | — | — | — | — | — | — | — |
| R/W: | —/WB | —/WB | —/WB | —/WB | —/WB | —/WB | —/WB | —/WB |

### 106.2.5 Serial Mode Register (HSSMR)

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | CHR | PE | O/E# | STOP | — | CKS[1:0] | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R/W | R/W | R/W | R/W | R | R/W | R/W |

HSSMR is a 16-bit register that sets the HSCIF's serial transfer format and selects the baud rate generator clock source.

HSSMR can always be read from and written to by the CPU.

HSSMR is initialized to H'0000 by a power-on reset.

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 to 7 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 6 | CHR | 0 | R/W | Character Length<br>Selects 7 or 8 bits for data length. When the 7-bit data is selected, the MSB (bit 7) in the transmit FIFO data register (HSFTDR) is not transmitted.<br>0: 8 bits<br>1: 7 bits |
| 5 | PE | 0 | R/W | Parity Enable<br>Determines whether parity bit is added in transmission or not, and parity bit is checked in reception or not. When bit PE is set to 1, the parity (even or odd) specified by bit O/E# is added to transmit data. In reception, the parity bit is checked for the parity (even or odd) specified by bit O/E#.<br>0: Disables parity bit addition and check.<br>1: Enables parity bit addition and check. |
| 4 | O/E# | 0 | R/W | Parity Mode<br>Selects either even or odd parity to use in parity addition and check.<br>The O/E# bit setting is valid only when bit PE is set to 1, enabling parity bit addition and check.<br>0: Even parity<br>1: Odd parity<br>When even parity is set, the parity bit is added in transmission so that the total number of 1-bit in the transmit character plus the parity bit is even. In reception, a check is performed to see if the total number of 1-bit in the receive character plus the parity bit is even.<br>When odd parity is set, the parity bit is added in transmission so that the total number of 1-bit in the transmit character plus the parity bit is odd. In reception, a check is performed to see if the total number of 1-bit in the receive character plus the parity bit is odd. |
| 3 | STOP | 0 | R/W | Stop Bit Length<br>Selects 1 bit or 2 bits as the stop bit length.<br>In reception, only the first stop bit is checked, regardless of the STOP bit setting. If the second stop bit is 1, it is treated as a stop bit. If it is 0, it is treated as the start bit of the next transmits character.<br>0: 1 stop bit*1<br>1: 2 stop bits*2<br>Notes: 1. In transmission, high level of 1 bit (stop bit) is added to the end of a transmit character before it is sent.<br>2. In transmission, high level of 2 bits (stop bits) are added to the end of a transmit character before it is sent. |
| 2 | — | 0 | R | Reserved<br>This bit is always read as 0. The write value should always be 0. |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 1, 0 | CKS[1:0] | 00 | R/W | Clock Select 1 and 0<br>These bits select the clock source for the on-chip baud rate generator.<br>The clock source can be selected from Internal clock, Internal clock/4, Internal clock/16, and Internal clock/64, according to the setting of bits CKS [1:0].<br>00: Internal clock<br>01: Internal clock/4<br>10: Internal clock/16<br>11: Internal clock/64 |

### 106.2.6 Serial Control Register (HSSCR)

HSSCR is a register that enables or disables transmission/reception by the HSCIF, enables or disables interrupt requests, and selects transmission/reception clock source for the HSCIF.

HSSCR can always be read from and written to by the CPU.

HSSCR is initialized to H'0000 by a power-on reset.

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|

| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R | R | R/W | R | R | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15, 14 | TOT[1:0] | 00 | R/W | Set the time for a data ready (DR) or a timeout (TO) to be set in asynchronous mode.<br>00: 15 etu*<br>01: 31 etu<br>10: 47 etu<br>11: 63 etu<br>Note: * ETU: Elementary Time Unit (time for transfer of one bit) Equivalent to 1.5 frames with an 8-bit, 1-stop-bit format. |
| 13, 12 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 11 | TEIE | 0 | R/W | Transmit End Interrupt Enable<br>When a transmit-end request is enabled by the TIE bit, the TEIE bit selects the source of the transmit end interrupt request from the following:<br>• Setting the TDFE flag in HSFSR<br>• Setting the TEND flag in HSFSR<br>0: The transmit FIFO data empty (TDFE) interrupt request is used.<br>1: The transmit end (TEND) interrupt request is used. |
| 10 to 8 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 7 | TIE | 0 | R/W | Transmit Interrupt Enable<br>Enables or disables a transmit-FIFO-data-empty interrupt (TDFE) request when the TEIE bit in HSSCR is pulled 0, if all of the following conditions are satisfied:<br>• Serial transmit data has been transferred from HSFTDR to HSTSR.<br>• The number of data bytes in HSFTDR is equal to or less than the transmit trigger count.<br>• The TDFE flag in HSFSR is set to 1.<br>Enables or disables a transmit-end interrupt (TEND) request when the TEIE bit of HSSCR is set to 1, if both of the following conditions are satisfied:<br>• Transmission was ended because there is no valid data in HSFTDR when the last bit of the transmit character in HSTSR was transmitted.<br>• The TEND flag of HSFSR is set to 1.<br>0: When the TEIE bit is 0, disables transmit-FIFO-data-empty interrupt (TDFE) request.<br>When the TEIE bit is 1, disables transmit-end interrupt (TEND) request.<br>1: When the TEIE bit is 0, enables transmit-FIFO-data-empty interrupt (TDFE) request.<br>When the TEIE bit is 1, enables transmit-end interrupt (TEND) request. |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 6 | RIE | 0 | R/W | Receive Interrupt Enable<br>Enables or disables a receive-FIFO-data-full interrupt request when the RDF flag in HSFSR is set to 1, a receive-data-ready interrupt request when the DR flag in HSFSR is set to 1, a receive-error interrupt request when the ER flag in HSFSR is set to 1, a break interrupt request when the BRK flag in HSFSR is set to 1, and an overrun error interrupt request when the ORER flag in HSLSR is set to 1.<br>0: Disables receive-FIFO-data-full interrupts (RDF) requests, receive-data-ready interrupt (DR) requests, receive-error interrupt (ER) requests, break interrupt (BRK) requests, and overrun error interrupt (ORER) requests.<br>1: Enables receive-FIFO-data-full interrupt (RDF) requests, receive-data-ready interrupt (DR) requests, receive-error interrupt (ER) requests, break interrupt (BRK) requests, and overrun error interrupt (ORER) requests. |
| 5 | TE | 0 | R/W | Transmit Enable<br>Enables or disables the start of HSCIF serial transmission. The HSCIF starts serial transmission when transmit data is written to the HSFTDR while TE is 1. Before setting TE to 1, set HSSMR and HSFCR to specify the transmission format and reset the transmit FIFO.<br>0: Disables transmission.<br>1: Enables transmission. |
| 4 | RE | 0 | R/W | Receive Enable<br>Enables or disables the start of HSCIF serial reception. When RE is 1, the HSCIF starts serial reception by detecting a start bit. Before setting RE to 1, set HSSMR and HSFCR to specify the reception format and reset the receive FIFO.<br>0: Disables reception.*<br>1: Enables reception.<br>Note: * Even if RE is cleared to 0, the DR, ER, BRK, RDF, FER, PER, TO and ORER flags are not affected, and retain their states. |
| 3 | REIE | 0 | R/W | Receive Error Interrupt Enable<br>Enables or Disables generation of receive-error interrupt (ER) requests, break interrupt (BRK) requests and overrun-error interrupt (ORER) requests.<br>0: Disables receive-error interrupt (ER) requests, break interrupt (BRK) requests and overrun-error interrupt (ORER) requests.*<br>1: Enables receive-error interrupt (ER) requests, break interrupt (BRK) requests and overrun-error interrupt (ORER) requests.<br>Note: * When REIE is 1, ER, BRK or ORER interrupt requests will occur even if RIE is cleared to 0. This setting is used to notify the interrupt controller of ER, BRK, and ORER interrupt requests during DMAC transfer. |
| 2 | TOIE | 0 | R/W | Timeout Interrupt Enable<br>Enables or disables generation of timeout interrupt (TO) requests when the TO flag in HSLSR is set to 1.<br>0: Disables timeout interrupts (TO).<br>1: Enables timeout interrupts (TO). |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 1, 0 | CKE[1:0] | 00 | R/W | Clock Enable 1 and 0<br>See Table 106.3 for the bit settings. |

**Table 106.3 Clock Selection**

| CKE[1] | CKE[0] | Clock Source | HSCK Pin |
|---|---|---|---|
| 0 | 0 | Internal clock (Internal clock, Internal clock/4, Internal clock/16, and Internal clock/64) | The HSCK pin is not used.<br>The HSCK pin functions as an input pin (input signals are ignored). (Initial value) |
| 0 | 1 | Prohibited | — |
| 1 | 0 | Baud rate generator output for external clock or HSCK | When SC_CLK is selected:<br>The HSCK pin is an input pin (input signals are ignored).<br>Set the SC_CLK frequency so that the frequency of BRGCLK is multiplied by the sampling rate. |
| | | | When HSCK is selected:<br>The HSCK pin inputs the clock (with the bit rate multiplied by the sampling rate). |
| | 1 | Prohibited | |

Note: It is not allowed to set synchronous communication using SC_CLK for input.

### 106.2.7 Serial Status Register (HSFSR)

HSFSR is a 16-bit register. The lower 8 bits are status flags that indicate the operating status of the HSCIF, and the upper 8 bits are all reserved.

HSFSR can always be read from and written to by the CPU. However, the flags ER, TEND, TDFE, BRK, RDF, and DR cannot be written by 1. The FER and PER flags are read-only flags and cannot be modified.

HSFSR is initialized to H'0060 by a power-on reset.

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | ER | TEND | TDFE | BRK | FER | PER | RDF | DR |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R/WC0 | R/WC0 | R/WC0 | R/WC0 | R | R | R/WC0 | R/WC0 |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 to 8 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 7 | ER | 0 | R/WC0 | Receive Error<br>Indicates that a framing error or a parity error has occurred in reception. The ER flag is not affected by an error and retains its previous state when the RE bit is 0 in HSSCR.<br>If a receive error occurs, receive data will be transferred to HSFRDR and reception operation will be continued. Whether there is a receive error in data read from HSFRDR can be determined by the FER and PER bits in HSFSR.<br>0: Indicates that no framing or parity error has occurred in reception.<br>[Clearing conditions]<br>• A power-on reset is executed.<br>• 0 is written to ER.<br>1: Indicates that a framing error or a parity error has occurred in reception.<br>[Setting conditions]<br>• The HSCIF checks whether the stop bit at the end of receive data is 1, but the stop bit is 0.*<br>• The number of 1-bit in receive data plus the parity bit does not match the parity setting (even or odd) specified by the O/E# bit in HSSMR during reception.<br>Note: * In the 2-stop-bit mode, only the first stop bit is checked that the value is 1; the second stop bit is not checked. |
| 6 | TEND | 1 | R/WC0 | Transmit End<br>Indicates that transmission has been ended because there was no valid data in HSFTDR when the last bit of the transmit character was transmitted.<br>0: Indicates that transmission is in progress.<br>[Clearing conditions]<br>• Transmit data is written to HSFTDR, and 0 is written to TEND.<br>• Data is written to HSFTDR by the DMAC.<br>1: Indicates that transmission has been ended.<br>[Setting conditions]<br>• A power-on reset is executed.<br>• The TE bit in HSSCR is 0.<br>• There is no transmission data in HSFTDR when the last bit of a 1-byte serial transmission character is transmitted. |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 5 | TDFE | 1 | R/WC0 | Transmit FIFO Data Empty<br>Indicates that the HSCIF has transferred data from HSFTDR to HSTSR, the number of data bytes in HSFTDR becomes equal to or less than the transmit trigger count specified by the HSTTRGR, and HSFTDR is ready to be written by new transmit data.<br>HSFTDR is a 128-byte FIFO register. The maximum number of bytes that can be written to when TDFE = 1 is "128 – [the transmit trigger count]". If data exceeding this value is attempted to be written, the data will be ignored. The number of data bytes in HSFTDR is indicated by the upper bits of HSFDR.<br>If the number of data written in HSFTDR is equal to or less than the transmit trigger count, this bit will be set to 1 even if it is cleared to 0 after it is read as 1.<br>0: Indicates that the number of transmit data written to HSFTDR exceeds the transmit trigger count.<br>[Clearing conditions]<br>• Transmit data exceeding the specified transmit trigger count have been written to HSFTDR, and 0 is written to TDFE.<br>• Transmit data exceeding the specified transmit trigger count have been written to HSFTDR by the DMAC.<br>1: Indicates that the number of transmit data in HSFTDR is equal to or less than the transmit trigger count.<br>[Setting conditions]<br>• A power-on reset is executed.<br>• The number of transmit data in HSFTDR is equal to or less than the transmit trigger count after transmission. |
| 4 | BRK | 0 | R/WC0 | Break Detect<br>Indicates that a receive data break signal has been detected. If a break signal is detected, receive data (H'00) transfer to HSFRDR is stopped. After the break is canceled and the receive signal returns to 1, the receive data transfer resumes.<br>0: Indicates that no break signal has been received.<br>[Clearing conditions]<br>• A power-on reset is executed.<br>• 0 is written to BRK.<br>1: Indicates that a break signal has been received.<br>[Setting condition]<br>• Data with a framing error is received, followed by the space "0" (low level) for at least one frame length. |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 3 | FER | 0 | R | Framing Error<br>Indicates that a framing error has been found in the data that is to be read next from HSFRDR.<br>0: Indicates that there is no framing error in the receive data that is to be read from HSFRDR.<br>[Clearing conditions]<br>• A power-on reset is executed.<br>• There is no framing error in the data that is to be read next from HSFRDR.<br>1: Indicates that there is a framing error in the receive data that is to be read from HSFRDR.<br>[Setting condition]<br>• There is a framing error in the data that is to be read next from HSFRDR. |
| 2 | PER | 0 | R | Parity Error<br>This bit indicates that a parity error has been found in the data that is to be read next from HSFRDR.<br>0: Indicates that there is no parity error in the receive data that is to be read from HSFRDR.<br>[Clearing conditions]<br>• A power-on reset is executed.<br>• There is no parity error in the data that is to be read next from HSFRDR.<br>1: Indicates that there is a parity error in the receive data that is to be read from HSFRDR.<br>[Setting condition]<br>• There is a parity error in the data that is to be read next from HSFRDR. |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 1 | RDF | 0 | R/WC0 | Receive FIFO Data Full<br>Indicates that the received data has been transferred from HSRSR to HSFRDR, and the number of receive data bytes in HSFRDR becomes equal to or more than the receive trigger count specified by the HSRTRGR.<br>HSFRDR is a 128-byte FIFO register. When RDF = 1, data equal to or more than the number of receive trigger data bytes can be read. When HSFRDR is empty, HSFRDR is read as an undefined value. The number of receive data bytes in HSFRDR is indicated by the lower bits of HSFDR.<br>If the number of data in HSFRDR is equal to or more than the trigger count, this bit will be set to 1 even if it is cleared to 0. At this time, read receive data until the number of data in HSFRDR is less than the trigger count, read RDF as 1, and then clear RDF.<br>0: Indicates that the number of receive data bytes in HSFRDR is less than the specified receive trigger count.<br>[Clearing conditions]<br>• A power-on reset is executed.<br>• HSFRDR is read until the number of receive data bytes in HSFRDR is less than the receive trigger count, and 0 is written to RDF.<br>• HSFRDR is read by the DMAC until the number of receive data bytes in HSFRDR is less than the receive trigger count.<br>1: Indicates that the number of receive data bytes in HSFRDR is equal to or more than the specified receive trigger count.<br>[Setting condition]<br>• Receive data more than the receive trigger count have been stored in HSFRDR. |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 0 | DR | 0 | R/WC0 | Receive Data Ready<br>Indicates that the receive FIFO data register (HSFRDR) contains fewer bytes than the trigger number for reception and no further data have arrived over at least the time corresponding to the setting of HSSCR[15:14]* since the stop bit for the byte to have been received.<br>0: Indicates that data is being received or has been successfully received, and there is no receive data in HSFRDR.<br>[Clearing conditions]<br>• A power-on reset is executed.<br>• All the receive data in HSFRDR has been read, and 0 is written to DR.<br>• All the receive data in HSFRDR has been read by the DMAC.<br>1: Indicates that no further receive data has been received.<br>[Setting condition]<br>The receive FIFO data register (HSFRDR) contains fewer bytes than the trigger number for reception and no further data have arrived over at least the time corresponding to the setting of HSSCR[15:14]* since the stop bit for the byte to have been received.<br>Note: * When the setting is 00, the time is 15 etu. This is equivalent to 1.5 frames in an 8-bit, 1-stop-bit format.<br>etu: Elementary Time Unit (time for transfer of one bit) |

### 106.2.8 Bit Rate Register (HSBRR)

HSBRR is an 8-bit register that sets the serial transmission/reception bit rate in accordance with the baud rate generator operating clock selected by the CKS [1:0] bits in HSSMR. This baud rate generator is intended for Internal clock, Internal clock/4, Internal clock/16, and Internal clock/64, see section 106.3.2, Generation of Internal Clock.

For details on the baud rate generator for external clock, see section 106.3.3 Baud Rate Generator for External Clock (BRG).

HSBRR can always be read from and written to by the CPU except for during transfer.

HSBRR is initialized to H'FF by a power-on reset.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|

### 106.2.9 Frequency Division Register (DL)

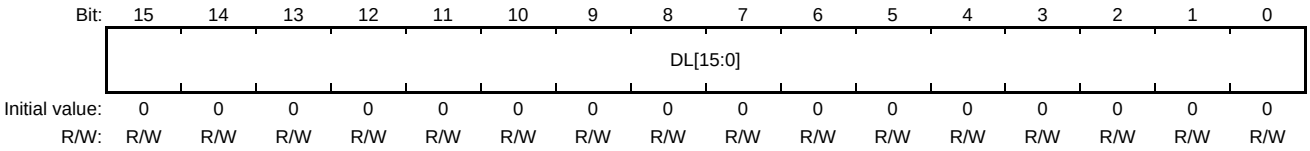
This register specifies the value of frequency division for the frequency divided clock generated by the BRG.

This register supports a 16-bit binary format that allows specifying a value in the range of 1 to 65535.

Setting all 0s in this register makes the BRG output the frequency divided clock at the low level.

The value of frequency division is given by the following formula:

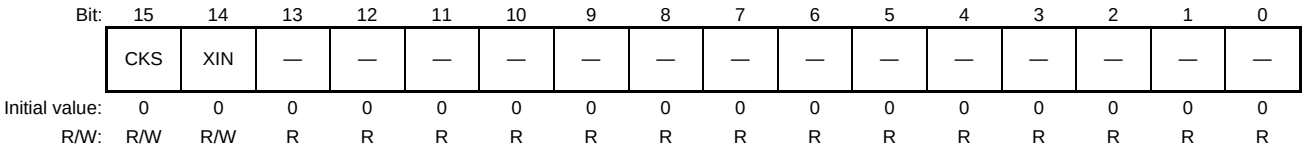
The value of frequency division = (clock input frequency)/ (required baud rate × sampling rate)



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 to 0 | DL[15:0] | All 0 | R/W | Specifies a division value of frequency clock generated in BRG.<br>The setting value is enabled in the range of 1 to 65535. |

### 106.2.10 Clock Select Register (CKS)

This register switches the output between the frequency divided clocks and specifies a source clock for the external baud rate.



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 | CKS | 0 | R/W | This bit switches the output between the frequency divided clock (SC_CLK) and external clock (HSCK).<br>0: Selects the frequency divided clock.<br>1: Selects the external clock. |
| 14 | XIN | 0 | R/W | Selects the baud rate generator clock source for the external clock between SCIF_CLK and Internal clock.<br>0: Selects the external clock (SCIF_CLK).<br>1: Selects the internal clock (Internal clock). |
| 13 to 0 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |

### 106.2.11 FIFO Control Register (HSFCR)

HSFCR is a register that resets data counts for transmit and receive FIFO registers. It also has a modem control and a loopback test enable bit.

HSFCR can always be read from and written to by the CPU except for during transfer.

HSFCR is initialized to H'0000 by a power-on reset.

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | — | MCE | TFRST | RFRST | LOOP |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R/W | R/W | R/W | R/W |

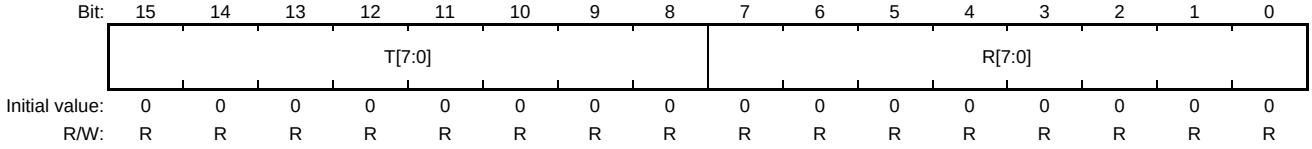
| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 to 4 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 3 | MCE | 0 | R/W | Modem Control Enable<br>Enables or disables modem control signals HCTS# and HRTS#.<br>0: Disables modem signals.*<br>1: Enables modem signals.<br>Note: * HCTS# and HRTS# control ports. |
| 2 | TFRST | 0 | R/W | Transmit FIFO Data Register Reset<br>Enables or disables a transmit FIFO data register reset that empties the register.<br>0: Disables the reset.*<br>1: Enables the reset.<br>Note: * The register is reset by a power-on reset. |
| 1 | RFRST | 0 | R/W | Receive FIFO Data Register Reset<br>Enables or disables a receive FIFO data register (HSFRDR) reset that empties the register.<br>0: Disables the reset.*<br>1: Enables the reset.<br>Note: * The register is reset by a power-on reset. |
| 0 | LOOP | 0 | R/W | Loopback Test<br>Enables or disables the loopback test by internally connecting the transmit output pin (HTX) and receive input pin (HRX), and the HRTS# pin and HCTS# pin.<br>0: Disables the loopback test.<br>1: Enables the loopback test. |

### 106.2.12 FIFO Data Count Register (HSFDR)

HSFDR is a 16-bit register that indicates the number of data bytes stored in HSFTDR and that in HSFRDR.

The upper 8 bits indicate the number of transmit data bytes in HSFTDR, and the lower 8 bits indicates the number of receive data bytes in HSFRDR.

HSFDR can always be read by the CPU.



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 to 8 | T[7:0] | H'00 | R | These bits indicate the number of data bytes un-transmitted and still stored in HSFTDR.<br>H'00 indicates that there is no transmit data in HSFTDR, and H'80 indicates that HSFTDR is full of transmit data. |
| 7 to 0 | R[7:0] | H'00 | R | These bits indicate the number of receive data stored in HSFRDR.<br>H'00 indicates that there is no receive data in HSFRDR, and H'80 indicates that HSFRDR is full of receive data. |

### 106.2.13 Serial Port Register (HSSPTR)

HSSPTR controls multiplexed input/output and data on the high speed serial communication interface (HSCIF) ports. Bits 1 and 0 control breaks in serial transmission/reception by reading input data from the HRX pin and writing output data to the HTX pin. Bits 3 and 2 read input data from and write output data to the HSCK pin. Bits 5 and 4 read input data from and write output data to the HCTS# pin. Bits 7 and 6 read input data from and write output data to the HRTS# pin.

HSSPTR is a 16-bit register that can always be read from and written to by the CPU.

All HSSPTR bits except bits 6, 4, 2, and 0 are initialized to 0 by a power-on reset. The values of bits 6, 4, 2, and 0 are undefined.

Note: Whether modem control can be selected or not depends on the channel.

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | RTSIO | RTSDT | CTSIO | CTSDT | SCKIO | SCKDT | SPB 2IO | SPB 2DT |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | — | 0 | — | 0 | — | 0 | — |
| R/W: | R | R | R | R | R | R | R | R | R/W | R/W | R/W | R/W | R | R | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 to 8 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 7 | RTSIO | 0 | R/W | Serial Port – RTS Port Input/output<br>Specifies input or output for the serial port HRTS# pin. To actually set the HRTS# pin as a port output pin to output the value set by the RTSDT bit, the MCE bit in HSFCR should be cleared to 0.<br>0: Indicates that this bit does not output the value of the RTSDT bit to the HRTS# pin.<br>1: Indicates that this bit outputs the value of the RTSDT bit to the HRTS# pin. |
| 6 | RTSDT | — | R/W* | Serial Port – RTS Port Data<br>Specifies the input/output data level of the serial port HRTS# pin. Whether the pin is set for input or output is determined by the RTSIO bit. When the pin is set for output, the value of the RTSDT bit is output to the HRTS# pin. Regardless of the value of the RTSIO bit, the value of the HRTS# pin is read from the RTSDT bit.<br>The initial value of this bit is undefined after a power-on reset.<br>0: Indicates that the input/output data is low level.<br>1: Indicates that the input/output data is high level. |
| 5 | CTSIO | 0 | R/W | Serial Port – CTS Port Input/output<br>Specifies input or output for the serial port HCTS# pin. To actually set the HCTS# pin as a port output pin to output the value set by the CTSDT bit, the MCE bit in HSFCR should be cleared to 0.<br>0: Indicates that the CTSDT bit value is not output to the HCTS# pin.<br>1: Indicates that the CTSDT bit value is output to the HCTS# pin. |
| 4 | CTSDT | — | R/W* | Serial Port – CTS Port Data<br>Specifies the input/output data level of the serial port HCTS# pin. Whether the pin is set for input or output is determined by the CTSIO bit. When the pin is set for output, the value of the CTSDT bit is output to the HCTS# pin. Regardless of the value of the CTSIO bit, the value of the HCTS# pin is read from the CTSDT bit.<br>The initial value of this bit is undefined after a power-on reset.<br>0: Indicates that the input/output data is low level.<br>1: Indicates that the input/output data is high level. |
| 3 | SCKIO | 0 | R | Serial Port – Clock Port Input |
| 2 | SCKDT | — | R | Serial Port – Clock Port Data<br>The initial value of this bit is undefined after a power-on reset. |
| 1 | SPB2IO | 0 | R/W | Serial Port – Break Input/output<br>Specifies the output condition of the serial port HTX pin. To actually set the HTX pin as a port output pin to output the value set by the SPB2DT bit, the TE bit in HSSCR should be cleared to 0.<br>0: Indicates that the SPB2DT bit value is not output to the HTX pin.<br>1: Indicates that the SPB2DT bit value is output to the HTX pin. |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 0 | SPB2DT | — | R/W* | Serial Port – Break Data<br>Specifies the input level of the serial port HRX pin and the output level of the HTX pin. The HTX pin output conditions are determined by the SPB2IO bit. When the HTX pin is set for output, the value of the SPB2DT bit is output to the HTX pin. Regardless of the value of the SPB2IO bit, the value of the HRX pin is read from the SPB2DT bit.<br>The initial value of this bit is undefined after a power-on reset.<br>0: Indicates that the input/output data is low level.<br>1: Indicates that the input/output data is high level. |

Note: * The value written to these bits can't be read because the value of the pin is read.

### 106.2.14 Line Status Register (HSLSR)

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | TO | — | ORER |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R/WC0 | R | R/WC0 |

| Bit | Bit Name | Initial Value | R/W | Description |

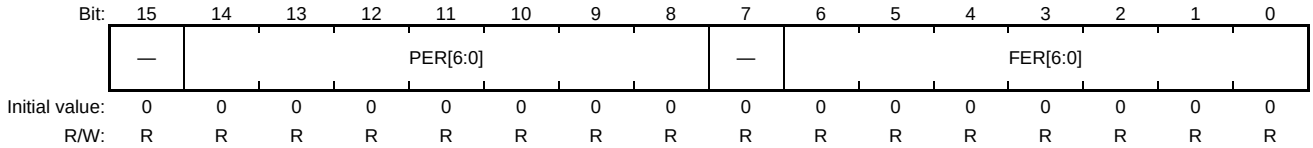
| 15 to 3 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 2 | TO | 0 | R/WC0 | Timeout<br>Indicates that the receive FIFO data register (HSFRDR) contains fewer bytes than the trigger number for reception and no further data have arrived over at least the time corresponding to the setting of HSSCR[15:14]* since the stop bit for the byte to have been received.<br>0: Indicates that data is being received or has been successfully received and that there is no receive data in HSFRDR.<br>[Clearing conditions]<br>• A power-on reset is executed.<br>• All the receive data in the HSFRDR has been read, and 0 is written to TO.<br>1: Indicates that no further receive data has been received (receive timeout).<br>[Setting condition]<br>• The receive FIFO data register (HSFRDR) contains fewer bytes than the trigger number for reception and no further data have arrived over at least the time corresponding to the setting of HSSCR[15:14]* since the stop bit for the byte to have been received.*<br>Note: * When the setting is 00, the time is 15 etu. This is equivalent to 1.5 frames in an 8-bit, 1-stop-bit format.<br>etu: Elementary Time Unit (time for transfer of one bit) |
| 1 | — | 0 | R | Reserved<br>This bit is always read as 0. The write value should always be 0. |
| 0 | ORER | 0 | R/WC0 | Overrun Error<br>Indicates that an overrun error has occurred in reception and abnormal termination is caused.<br>If an overrun error occurs, the receive data prior to the overrun error is retained in HSFRDR and the data received subsequently is discarded.<br>Any subsequent serial reception is disabled while the ORER flag is 1.<br>To resume data reception after clearing the ORER flag, be sure to first read (or clear) data in the receive FIFO and handle the error, then clear the ORER flag.<br>0: Indicates that data is being received or has been successfully received.<br>[Clearing conditions]<br>• A power-on reset is executed.<br>• 0 is written to ORER.<br>1: Indicates that an overrun error has occurred in reception.<br>[Setting condition]<br>• The next serial reception has been completed while HSFRDR is full of 128-byte data.<br>Note: When bit RE in HSSCR is cleared to 0, the ORER flag is not affected and its previous state is retained. |

### 106.2.15 Sampling Rate Register (HSSRR)

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | SRE | SRDE | — | — | SRHP[3:0] | | | | — | — | — | SRCYC[4:0] | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 1 | 1 |
| R/W: | R/W | R/W | R | R | R/W | R/W | R/W | R/W | R | R | R | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 | SRE | 0 | R/W | Sampling Rate Register Enable (SRE)<br>0: Set the SRCYC [4: 0] bits to 15 (initial value).<br>1: Validates the setting of the SRCYC [4:0] bits. |
| 14 | SRDE | 0 | R/W | Sampling Point Register Enable (SRDE)<br>0: Invalidates the setting of the SRHP [3:0] bits and the sampling point will be (S+1)/2 for an odd sampling rate (S) and S/2 for an even sampling rate.<br>1: Validates the setting of the SRHP [3: 0] bits. |
| 13, 12 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 11 to 8 | SRHP[3:0] | 0000 | R/W | Sampling Point Register (SRHP)<br>The sampling point can be moved by setting the SDRE bit to 1 and setting a value in these bits. Normally, the sampling point is the point of S/2 or (S+1)/2 for a sampling rate of S. By setting a signed 4-bit integer in these bits, the sampling point can be shifted by the amount of the specified sampling clock cycles. This will improve the receive margin.<br>When setting a value in these bits, take notice that the sampling point does not become a negative value or it does not exceed the sampling rate. The shifted sampling point must satisfy the setup margin and hold margin. |
| 7 to 5 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 4 to 0 | SRCYC[4:0] | 01111 | R/W | Bits 4 to 0: Sampling Rate Register (SRCYC)<br>Data transfer at a desired sampling rate can be enabled by setting the SRE bit to 1 and setting a value in these bits. Set a value of "S - 1" in these bits for a sampling rate of S. Note that the sampling rate must be from 8 to 32 (a value from 7 to 31 can be set in these bits). Set these bits to 15 (initial value) when the SRE bit is set to 0. |

### 106.2.16 Serial Error Register (HSRER)



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 | — | 0 | R | Reserved<br>This bit is always read as 0. The write value should always be 0. |
| 14 to 8 | PER[6:0] | H'00 | R | Parity Error Count<br>These bits indicate the number of data items in which a parity error occurred in the receive data stored in the receive FIFO data register (HSFRDR).<br>After the ER bit in HSFSR is set, the value in bits 14 to 8 will be the number of data items in which a parity error occurred. If all 128 bytes of receive data in HSFRDR have parity errors, bits PER [6:0] will have the value 0. |
| 7 | — | 0 | R | Reserved<br>This bit is always read as 0. The write value should always be 0. |
| 6 to 0 | FER[6:0] | H'00 | R | Framing Error Count<br>These bits indicate the number of data items in which a framing error occurred in the receive data stored in the receive FIFO data register (HSFRDR).<br>After the ER bit in HSFSR is set, the value in bits 6 to 0 will be the number of data items in which a framing error occurred. If all 128 bytes of receive data in HSFRDR have framing errors, bits<br>FER [6:0] will have the value 0. |

### 106.2.17 RTS Output Active Trigger Register (HSRTGR)

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | RSTRG[6:0] | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 1 | 1 |
| R/W: | R | R | R | R | R | R | R | R | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

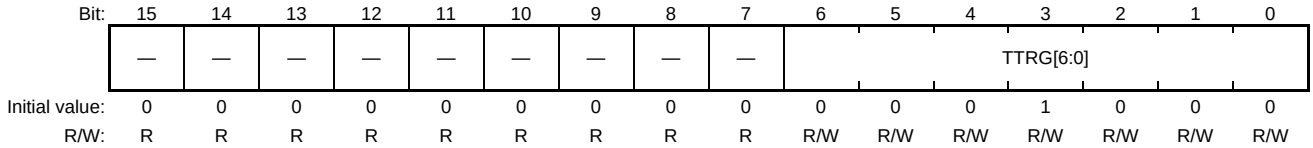
| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 to 7 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 6 to 0 | RSTRG[6:0] | H'0F | R/W | RTS Output Active Trigger Count<br>The HRTS# signal goes high when the number of receive data items stored in the receive FIFO data register (HSFRDR) exceeds the value set in these bits. The initial value is 15. |

### 106.2.18 Receive FIFO Data Count Trigger Register (HSRTRGR)

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | RTRG[6:0] | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 |
| R/W: | R | R | R | R | R | R | R | R | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 to 7 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 6 to 0 | RTRG[6:0] | H'01 | R/W | Receive FIFO Data Count Trigger<br>These bits set the receive data item count at which the receive data full (RDF) flag in the serial status register (HSFSR) is set. The RDF flag is set when the number of receive data items stored in the receive FIFO data register (HSFRDR) equals or exceeds the value set in these bits. The initial value is 1. |

### 106.2.19 Transmit FIFO Data Count Trigger Register (HSTTRGR)



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 to 7 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 6 to 0 | TTRG[6:0] | H'08 | R/W | Transmit FIFO Data Count Trigger<br>These bits set the un-transmitted data item count at which the transmit FIFO data register empty (TDFE) flag in the serial status register (HSFSR) is set. The TDFE flag is set when the number of transmit data items in the transmit FIFO data register (HSFTDR) falls under the value set in these bits due to transmit operations. The initial value is 8. |

## 106.3 Operation

### 106.3.1 Operation in Asynchronous Serial Communication Mode

In asynchronous serial communication mode, the HSCIF performs serial communication, in which data is transmitted or received in character units using the attached start bit indicating the start of communication and stop bit indicating the end of communication.

Figure 106.2 shows the general format for asynchronous serial communication.

In asynchronous serial communication, the transmission line is usually kept marked (high level). The HSCIF monitors the transmission line, and when it finds a space (low level), it regards the space as a start bit and starts serial communication.

One character in serial communication consists of a start bit (low level), followed by transmit/receive data (LSB-first; from the lowest bit), a parity bit (high or low level), and a stop bit (high level).

During reception in asynchronous mode, the HSCIF performs synchronization at the falling edge of the start bit. Transferred data is acquired at the center of each bit because the HSCIF samples on *S/2*th cycles of the clock which has a frequency of S times the bit rate, when the sampling rate as set in the sampling rate register (HSSRR) is S (if the sampling-rate setting is an odd number, the data is sampled on every *(S+1)/2*th pulse).

In addition, when the setting of the SRDE bit makes the setting of the sampling point bits effective, the point where the bits are latched can be intentionally moved from the centers of each bit.

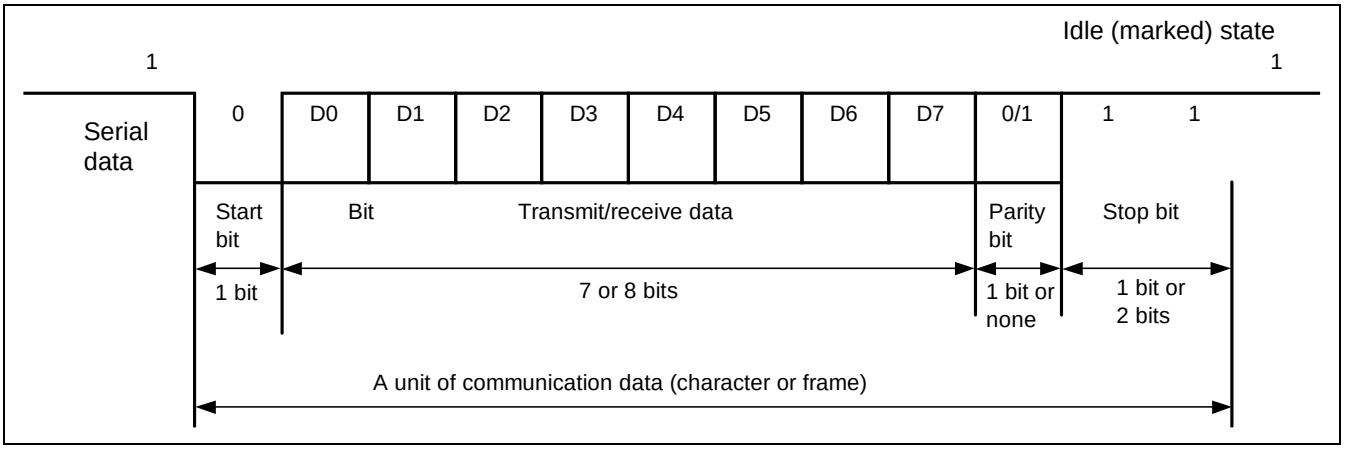


**Figure 106.2 Data Format in Asynchronous Mode (Example of 8-Bit Data with Parity and Two Stop Bits)**

### (1) Transmission/reception format

Table 106.4 shows available data transfer formats. The HSCIF supports 8 transfer formats, which can be specified by HSSMR.

**Table 106.4 Serial Transmission/Reception Formats (Asynchronous Mode)**

| SCSMR settings | | | Serial transmission/reception format and frame length | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| CHR | PE | STOP | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 |
| 0 | 0 | 0 | S | 8-bit data | | | | | | | | STOP | | |
| 0 | 0 | 1 | S | 8-bit data | | | | | | | | STOP | STOP | |
| 0 | 1 | 0 | S | 8-bit data | | | | | | | | P | STOP | |
| 0 | 1 | 1 | S | 8-bit data | | | | | | | | P | STOP | STOP |
| 1 | 0 | 0 | S | 7-bit data | | | | | | | | STOP | | |
| 1 | 0 | 1 | S | 7-bit data | | | | | | | | STOP | STOP | |
| 1 | 1 | 0 | S | 7-bit data | | | | | | | | P | STOP | |
| 1 | 1 | 1 | S | 7-bit data | | | | | | | | P | STOP | STOP |

[Legend]
S : Start bit
STOP : Stop bit
P : Parity bit

### (2) Clock

The transfer clock can be selected from the following two clocks using the CKE[1:0] bits in HSSCR:

- Internal clock generated by the on-chip baud rate generator
- External clock generated by an external clock baud rate generator

### (3) Data transmission/reception

#### (a) Initialization of HSCIF (asynchronous mode)

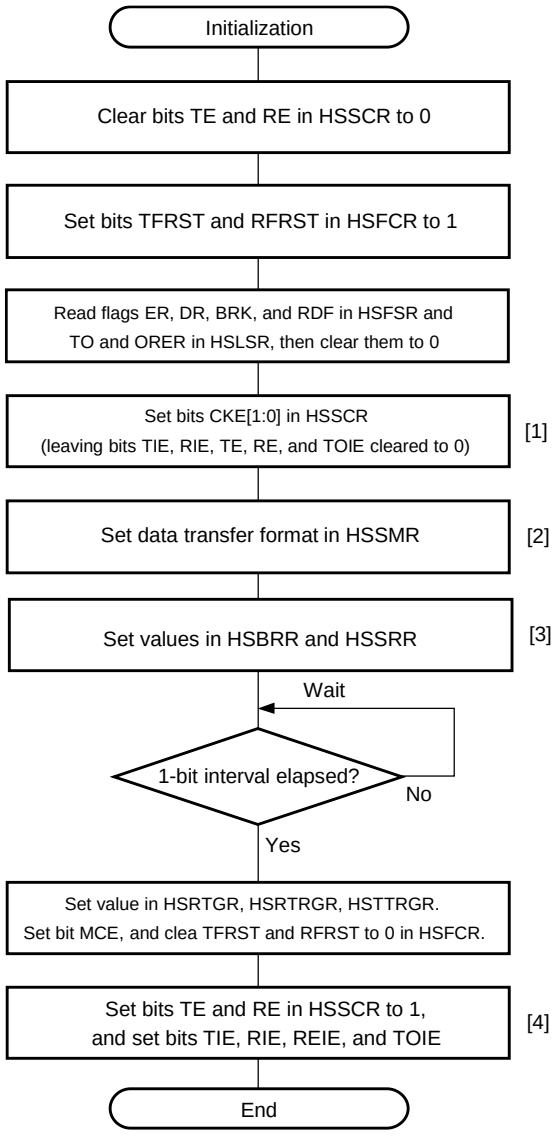
Before transmitting/receiving data or changing the operating mode or communication format, the HSCIF should be initialized using the sample flowchart for HSCIF initialization shown in Figure 106.3.

[Notes]

Clearing the TE bit to 0 initializes HSTSR. However, HSFSR, HSFTDR, and HSFRDR contents are retained even if the TE and RE bits are cleared to 0.

The TE bit should be cleared to 0 after all transmit data has been sent and the TEND flag has been set in HSFSR. The TE bit can be cleared to 0 during transmission, but the data being transmitted will enter the marked state after clearing. In addition, before setting the TE bit to 1 to restart the transmission, set the TFRST bit to 1 in HSFCR to reset HSFTDR.

When an external clock is used, do not stop the clock during operation or initialization. If stopped, the operation will be unreliable. Furthermore, when the baud rate generator for external clock is also to be used, be sure to make settings for it before starting initialization of the HSCIF.



[1] Set the clock selection in HSSCR. Be sure to clear bits TIE, RIE, TE, RE, and TOIE to 0.

[2] Set the data transfer format in HSSMR.

[3] Write a value for the bit rate to HSBRR. (Not necessary if an external clock is used.) Set values for the sampling rate and sampling point to HSSRR.

[4] Wait at least one bit interval, then set bit TE or RE in HSSCR to 1. Also, set bits TIE, RIE, REIE, and TOIE. Setting bit TE enables the HTX and HRX pins to use.
In transmission, the HSCIF will go to the mark state, and in reception, it will go to the idle state, waiting for a start bit.

Note: HSBRR and HSFCR registers can only be set while both TE and RE bits of HSSCR are cleared.

**Figure 106.3 Sample Flowcharts for Initializing the HSCIF**

**(b) Serial data transmission (asynchronous mode)**

Figure 106.4 shows a sample flowchart for serial transmission.

After the HSCIF transmission operation is enabled, serial data transmission can be performed using the following procedure:

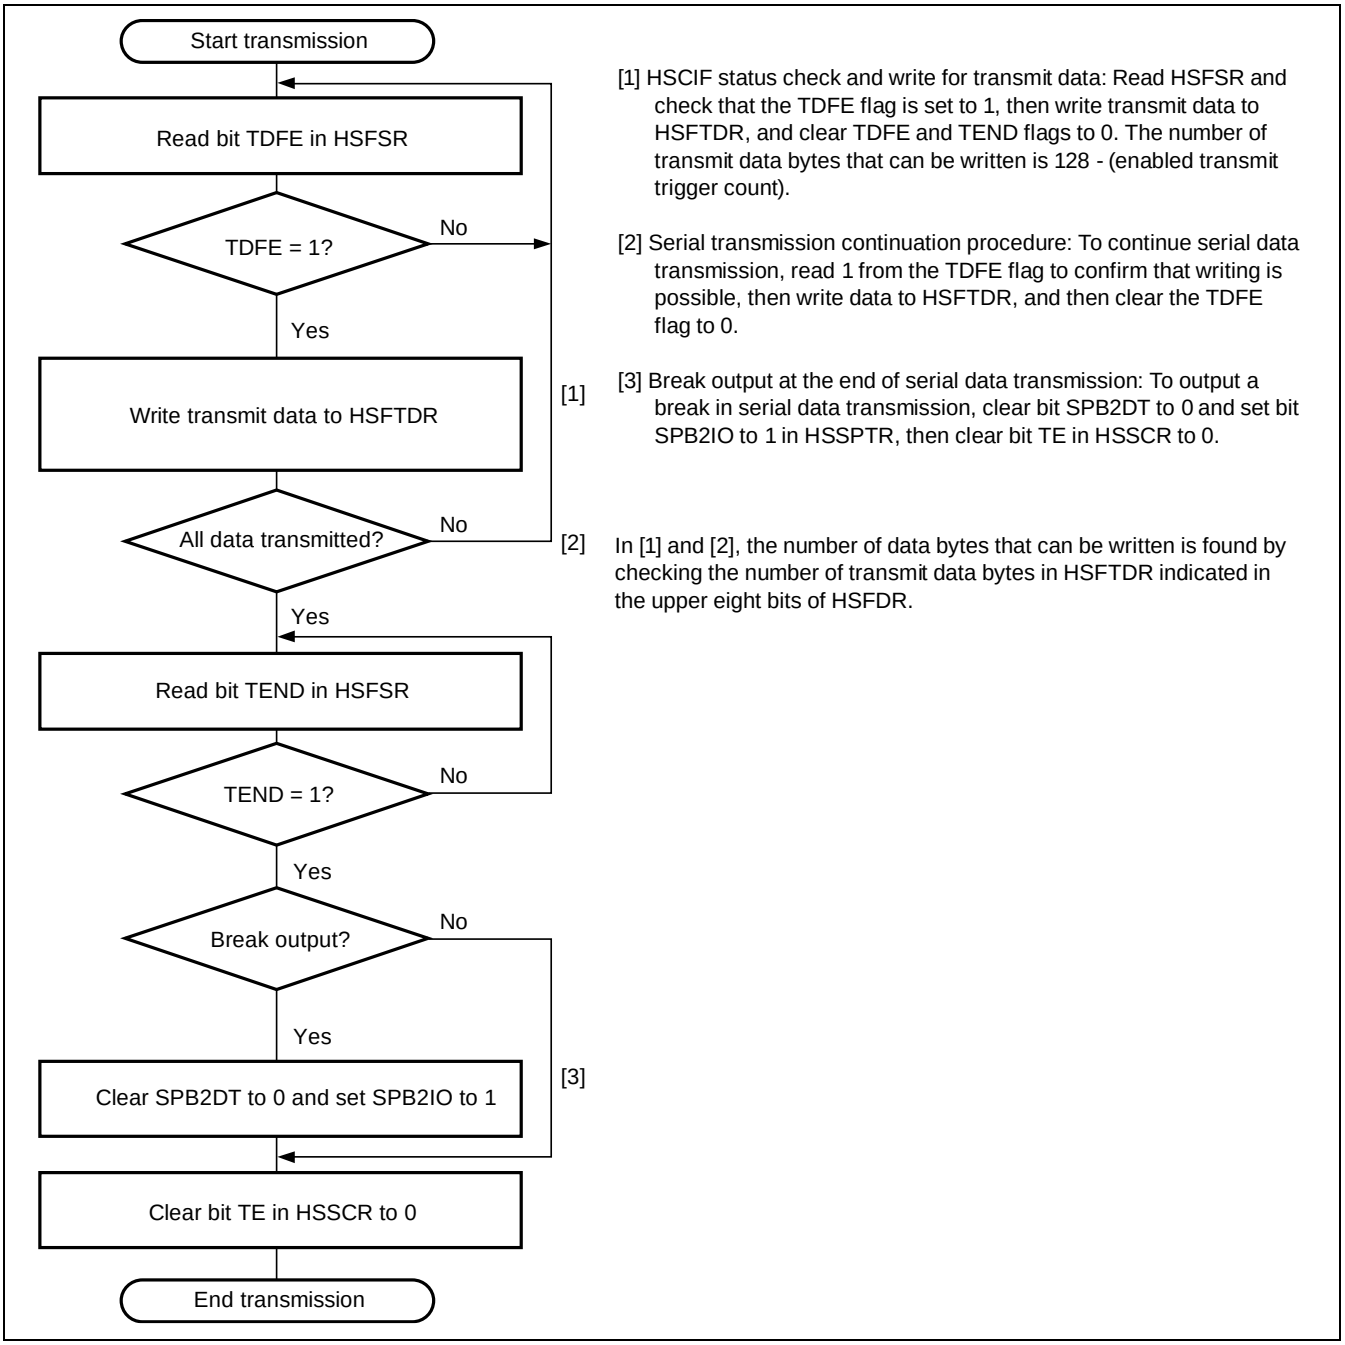


**Figure 106.4 Sample Flowcharts for Serial Transmission**

In serial transmission, the HSCIF operates as follows:

1. When data is written to HSFTDR, the HSCIF transfers the data from HSFTDR to HSTSR and starts transmitting. Confirm that the TDFE flag in HSFSR is set to 1 before writing transmit data to HSFTDR. The number of data bytes that can be written is at least 128 - (transmit trigger count).

2. When data is transferred from HSFTDR to HSTSR and the HSCIF starts transmission, consecutive transmission is performed until there is no transmit data left in HSFTDR. When the number of transmit data bytes in HSFTDR is equal to or less than the transmit trigger count specified in HSTTRGR, the TDFE flag is set. If the TIE and TEIE bits in HSSCR are set to 1 and 0, respectively at this time, a transmit-FIFO-data-empty interrupt (TDFE) request occurs. The serial transmit data is sent from the HTX pin in the following order:
   A. Start bit: One 0-bit is output.
   B. Transmit data: 8-bit or 7-bit data is output in LSB-first order.
   C. Parity bit: One parity bit (even or odd parity) is output.
      A format that does not output a parity bit can also be selected.
   D. Stop bit(s): One or two stop bits are output.
   E. Marked state: 1 is output continuously until the start bit that starts the next transmission is sent.
3. The HSCIF checks transmit data in HSFTDR when sending the stop bit. If there is data in it, the HSCIF transfers the data from HSFTDR to HSTSR, sends the stop bit, and then starts serial transmission of the next frame. If there is no transmit data, the HSCIF sets the TEND flag to 1 in HSFSR and sends out the stop bit, and then the marked state is entered to output 1 continuously. At this time, if the TIE and TEIE bits in HSSCR are set to 1, a transmit-end interrupt (TEND) request occurs.

Figure 106.5 shows an example of transmission in asynchronous mode.

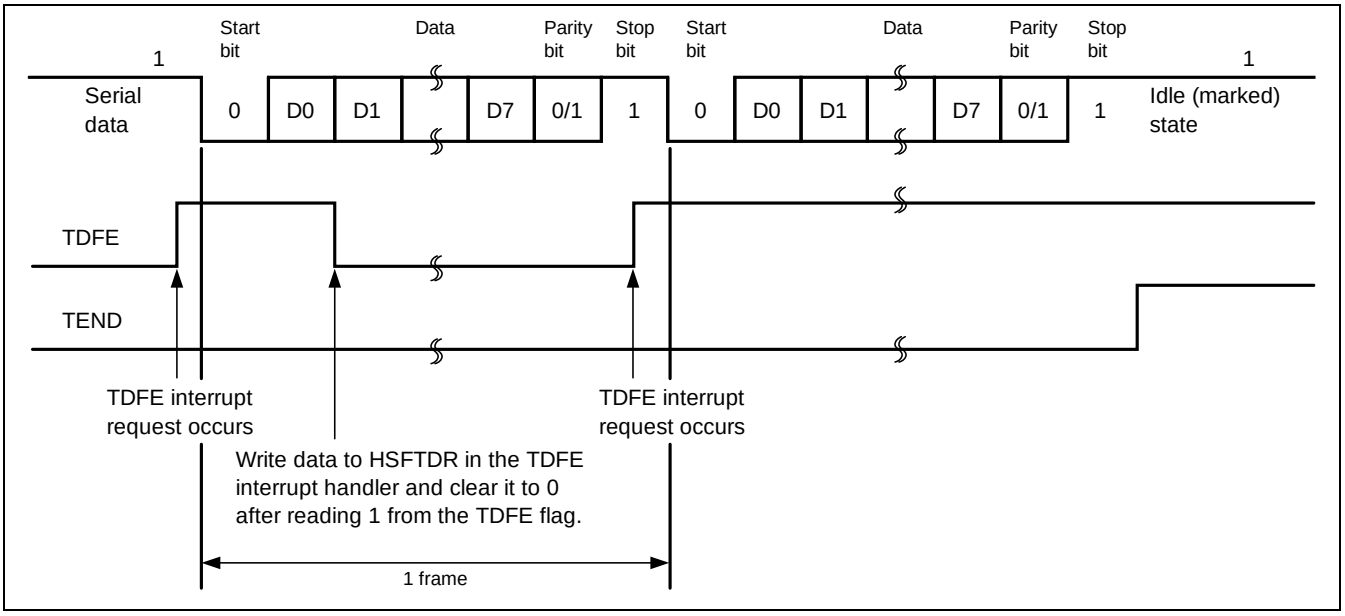

**Figure 106.5 Sample HSCIF Transmission Operation (Example of 8-Bit Data with Parity and One Stop Bit)**

4. When modem control is enabled, transmission can be stopped or resumed in accordance with the HCTS# input value. When HCTS# is set to 1 during transmission, the marked state is entered after one frame of data transmission is ended. Setting HCTS# to 0 restarts outputting the next transmit data from the start bit. Figure 106.6 shows an example of the operation with modem control enabled.

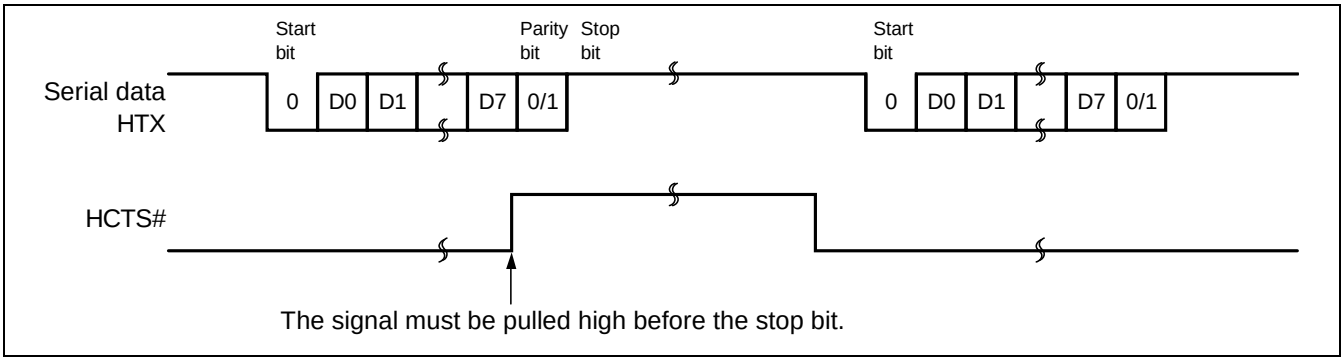

**Figure 106.6 Sample Operation with Modem Control Enabled (HCTS#)**

### (c) Serial data reception (asynchronous mode)

Figure 106.7 and Figure 106.8 show sample flowcharts for serial reception.

After the HSCIF reception operation is enabled, serial data reception can be performed using the following procedure:

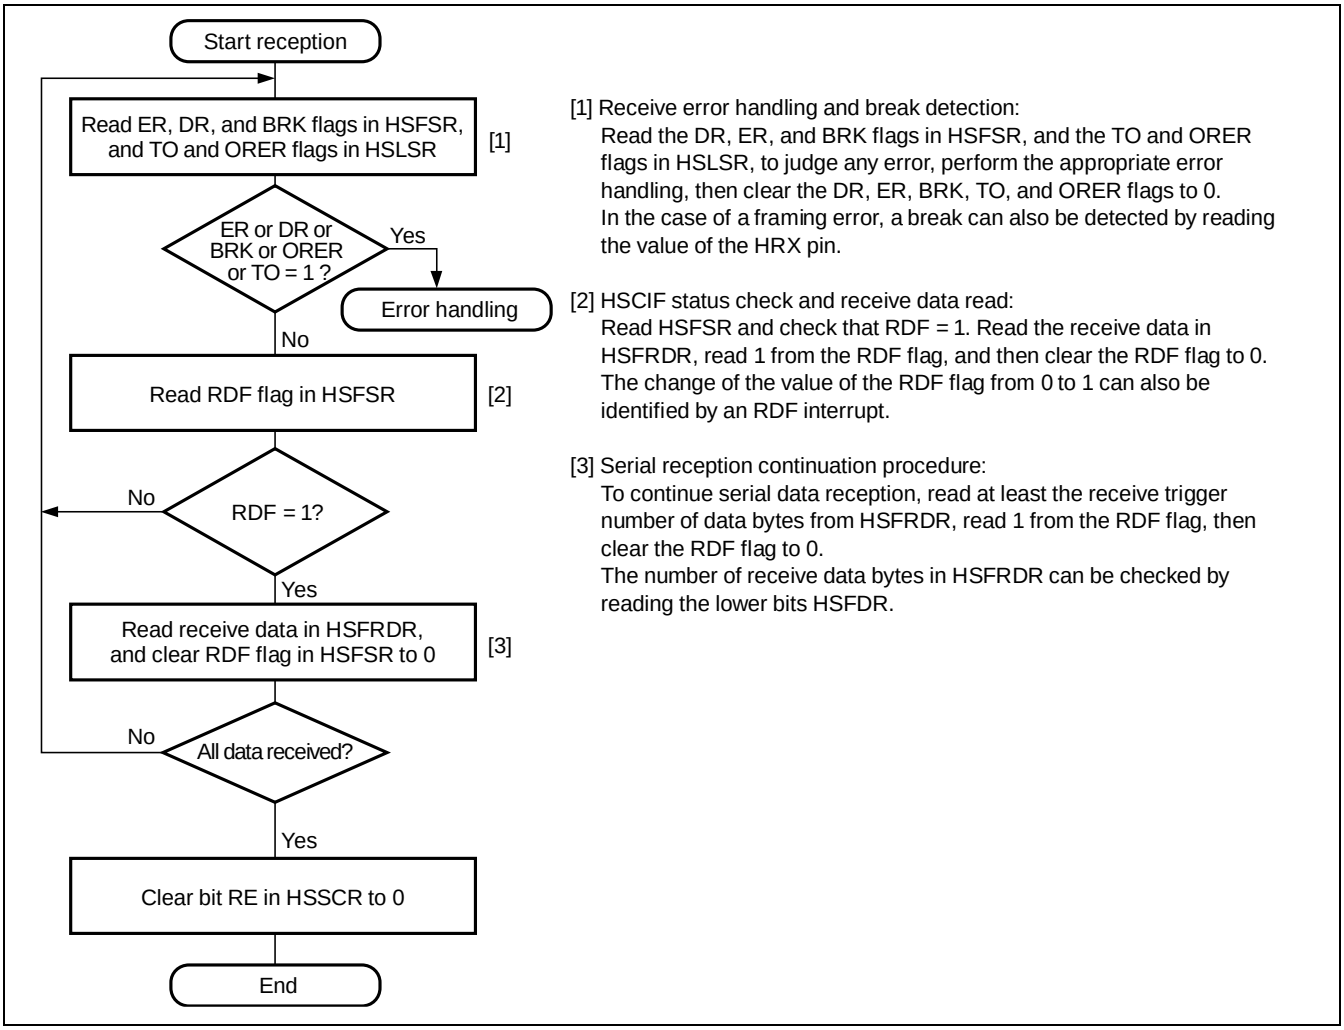

**Figure 106.7 Sample Flowcharts for Serial Reception (1)**

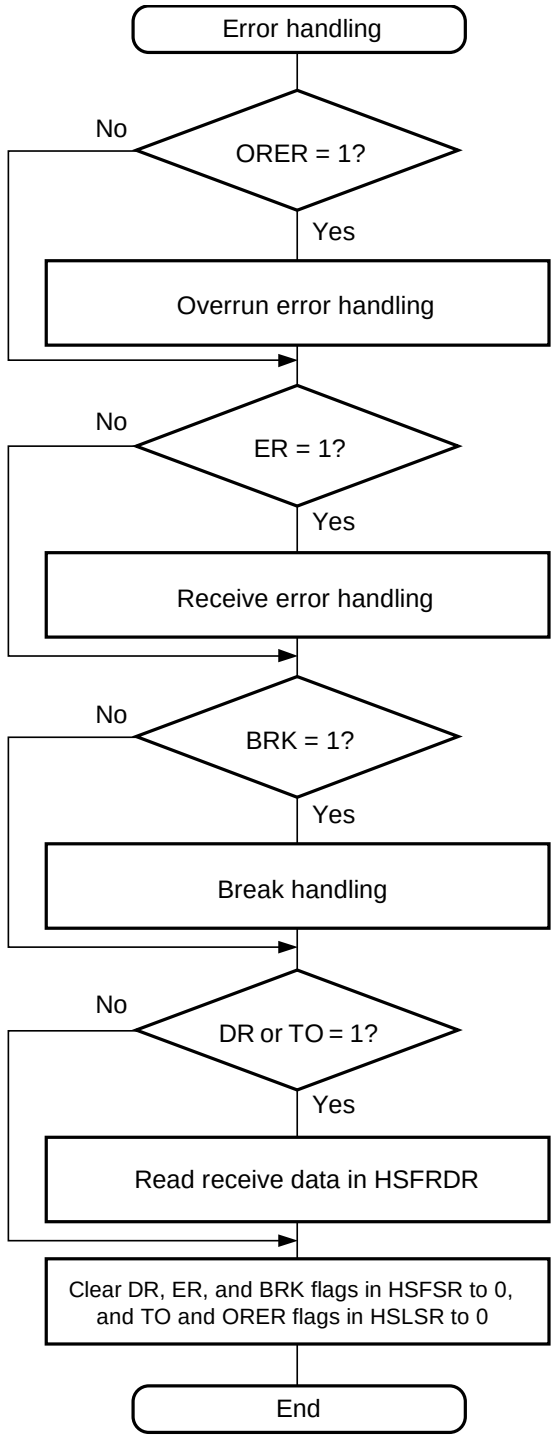

Whether a framing error or parity error has occurred in the receive data that is to be read from HSFRDR can be determined by checking bits FER and PER in HSRER.

**Figure 106.8 Sample Flowcharts for Serial Reception (2)**

In serial reception, the HSCIF operates as follows:

1. The HSCIF monitors the transmission line, and when detecting the start bit 0, it performs internal synchronization and starts reception.
2. The HSCIF stores the received data in HSRSR in LSB-to-MSB order.
3. The HSCIF receives the parity bit and stop bit.
   After receiving these bits, the HSCIF performs the following checks:

A. Stop bit: The HSCIF checks whether the stop bit is 1.
   If there are two stop bits, it checks only the first stop bit.
B. Receive data: The HSCIF checks that receive data can be transferred from the receive shift register (HSRSR) to HSFRDR.
C. Overrun error: The HSCIF checks that the ORER flag is 0, indicating that no overrun error has occurred.
D. Break state: The HSCIF checks that the BRK flag is 0, indicating that the break state is not set.

If the HSCIF can confirm the conditions of (b), (c), and (d), it stores the receive data in HSFRDR.

Note: The HSCIF continues to receive data even when a parity error or a framing error occurs.

4. If the RDF flag changes to 1 while the RIE bit in HSSCR is 1, a receive-FIFO-data-full interrupt (RDF) request occurs.
   If the DR flag changes to 1 while the RIE bit in HSSCR is 1, a receive-data-ready interrupt (DR) request occurs.
   If the TO flag changes to 1 while the TOIE bit in HSSCR is 1, a timeout interrupt (TO) request occurs.
   If the ER flag changes to 1 while the RIE or REIE bit in HSSCR is 1, a receive-error interrupt (ER) request occurs.
   If the BRK flag changes to 1 while the RIE or REIE bit in HSSCR is 1, a break interrupt (BRK) request occurs.
   If the ORER flag changes to 1 while the RIE or REIE bit in HSSCR is 1, an overrun-error interrupt (ORER) request occurs.

Figure 106.9 shows an example of reception in asynchronous mode.

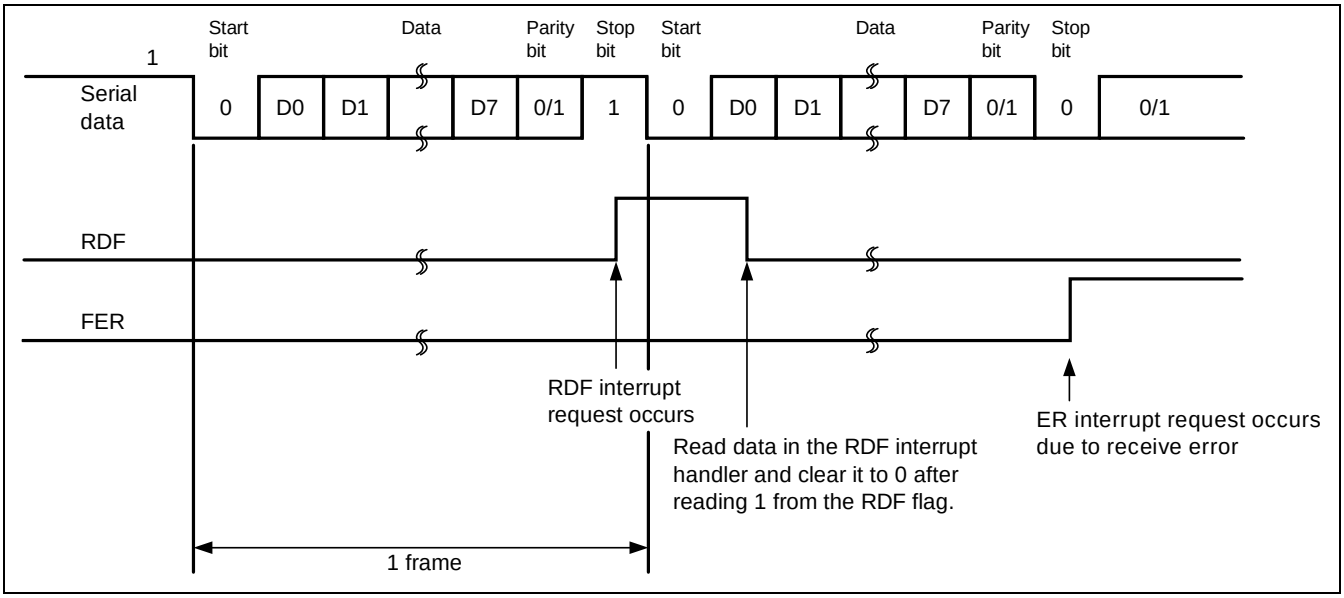

**Figure 106.9 Sample HSCIF Receive Operation (Example of 8-Bit Data with Parity and One Stop Bit)**

5. When modem control is enabled, the HRTS# signal is output when HSFRDR is empty. When HRTS# is 0, data can be received. When HRTS# is set to 1, the number of data bytes in HSFRDR is equal to or more than the RTS output active trigger count (HSRTGR.RSTRG).

Figure 106.10 shows an example of the operation with modem control enabled.

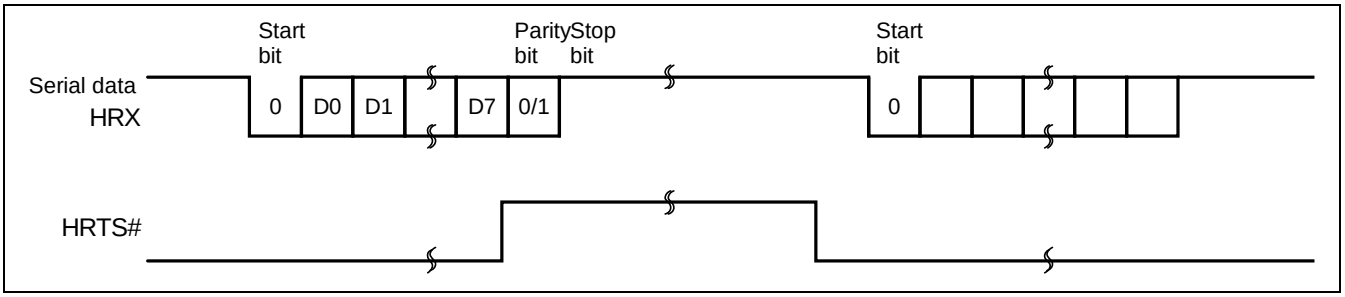

**Figure 106.10 Example of the Operation with Modem Control Enabled (HRTS#)**

### 106.3.2 Generation of Internal Clock

Internal clock is generated by the on-chip baud rate generator.
Baud rate is determined by the HSBRR and CKS[1:0] bit in HSSMR.

[Asynchronous mode]

$$N = \frac{\text{Internal clock}}{Sr \times 2^{2n+1} \times B} \times 10^6 - 1$$

B: Bit rate (bit/s)

N: HSBRR setting for the baud rate generator ($0 \leq N \leq 255$) (which satisfies the electrical characteristics)

Internal clock: AXI bus clock operating frequency (MHz)

n: Baud rate generator input clock (n = 0, 1, 2, 3)
(See the Table 106.5 for the relation between n and the clock.)

Sr: Sampling rate (8 to 32)

**Table 106.5 HSSMR Settings**

| | Baud Rate Generator | HSSMR Setting | |
|---|---|---|---|
| **n** | **Input Clock** | **CKS[1]** | **CKS[0]** |
| 0 | Internal clock | 0 | 0 |
| 1 | Internal clock/4 | 0 | 1 |
| 2 | Internal clock/16 | 1 | 0 |
| 3 | Internal clock/64 | 1 | 1 |

The bit rate error in asynchronous mode is determined by the following equation:

$$\text{error (\%)} = \left\{ \frac{\text{Internal clock} \times 10^6}{(N+1) \times B \times Sr \times 2^{2n+1}} - 1 \right\} \times 100$$

### 106.3.3 Baud Rate Generator for External Clock (BRG)

#### (1) Overview

The HSCIF incorporates a baud rate generator for external clock (abbreviated as BRG, hereafter). The BRG supplies a sampling clock (BRGCLK) to the HSCIF core by dividing the external clock SC_CLK (selectable between SCIF_CLK and Internal clock) by 1 to 216 – 1. In addition, the BRG switches the output between the external clock HSCK and divided clock.

Figure 106.11 shows a block diagram of the BRG.

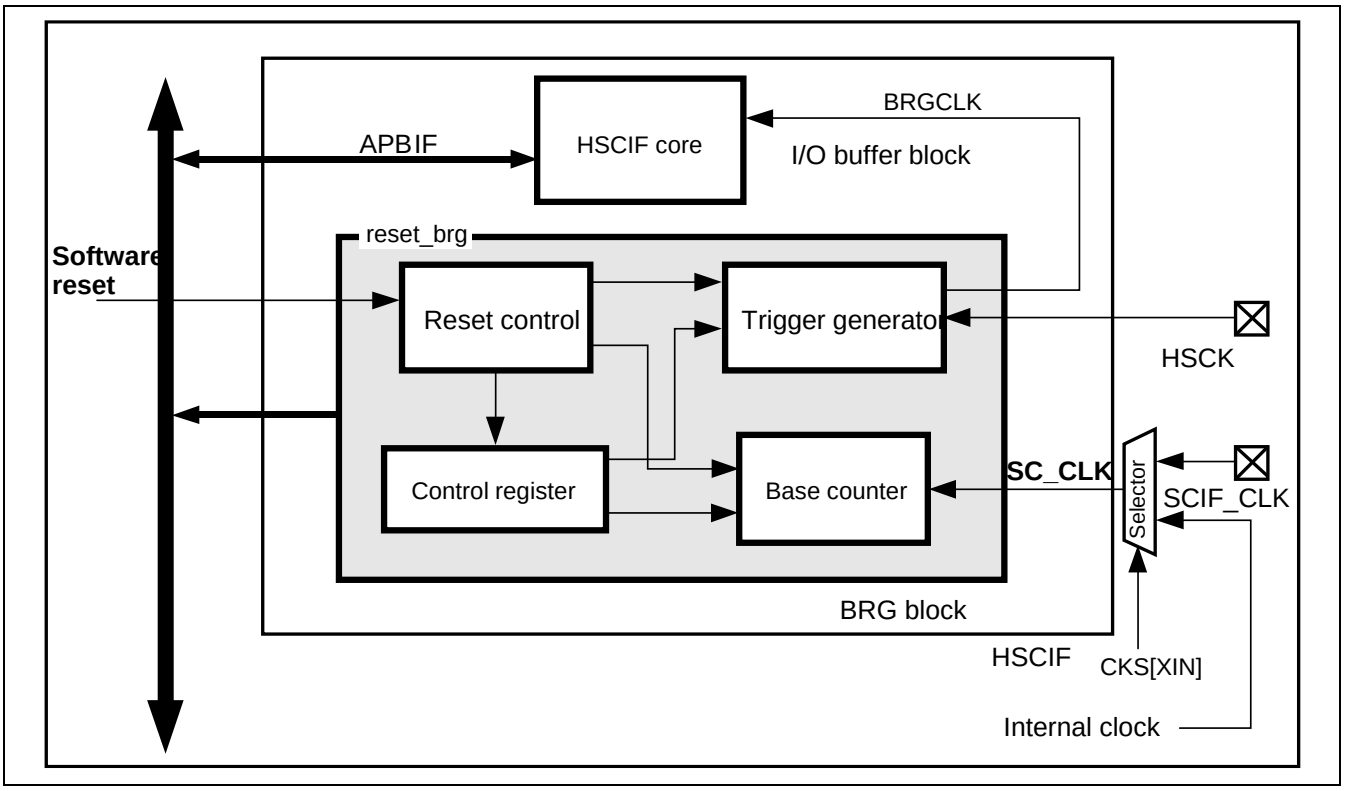

**Figure 106.11 BRG Block Diagram**

(a) Reset controller:

The reset controller handles resetting the control register, base counter, and trigger generator.

(b) Control register:

The control register has the frequency division register and clock select register.

(c) Base counter:

The base counter is a 16-bit CLK synchronization counter that is used to determine the timing for generating a frequency divided clock.

(d) Trigger generator:

The trigger generator generates rising-edge/falling-edge triggers for a frequency divided clock with the timing according to values of the frequency division register and base counter. The triggers are used to generate the frequency divided clock. In addition, the trigger generator switches the output between the HSCK (external clock input) and frequency divided clock.

#### (2) Registers

To set baud rate requires setting to Frequency Division Register(DL) and Clock Select Register(CKS)

### (3) Frequency Division Register (DL)

To set a division value of frequency requires setting to Frequency-Division-Register(DL).

Refer to Frequency-Division-Register(DL).

Table 106.6 shows reference values of Frequency-Division-Register(DL).

Table 106.6 and Table 106.7 show how to use the baud rate generator with a3.6864-MHz crystal resonator, and a 26-MHz crystal resonator.

**Table 106.6 Baud Rate (3.6864-MHz clock)**

| Baud Rate | Value of Frequency Division | Error Rate (*) |
|---|---|---|
| 50 | 4608 | — |
| 75 | 3072 | — |
| 110 | 2095 | –0.022 |
| 134.5 | 1713 | 0.001 |
| 150 | 1536 | — |
| 300 | 768 | — |
| 600 | 384 | — |
| 1200 | 192 | — |
| 1800 | 128 | — |
| 2000 | 115 | 0.174 |
| 2400 | 96 | — |
| 3600 | 64 | — |
| 4800 | 48 | — |
| 7200 | 32 | — |
| 9600 | 24 | — |
| 14400 | 16 | — |
| 19200 | 12 | — |
| 38400 | 6 | — |
| 76800 | 3 | — |
| 115200 | 2 | — |

Note: —: Indicates that the error rate is 0.

**Table 106.7 Baud Rate (26-MHz clock)**

| Baud Rate | Value of Frequency Division | Sampling Rate | Error Rate* |
|---|---|---|---|
| 9600 | 129 | 21 | 0.025 |
| 19200 | 52 | 26 | -0.160 |
| 38400 | 26 | 26 | -0.160 |
| 57600 | 15 | 30 | -0.309 |
| 115200 | 9 | 25 | -0.309 |
| 230400 | 4 | 28 | -0.756 |
| 460800 | 2 | 28 | -0.756 |
| 921600 | 1 | 28 | -0.756 |
| 1843200 | 1 | 14 | -0.756 |
| 3250000 | 1 | 8 | — |

Note: * "—" Indicates that the error rate is 0.

### (4) Clock Select Register (CKS)

To set output between the frequency divided clock and specifies a source clock for the external baud rate requires setting to Clock Select Register (CKS).

Refer to Clock Select Register (CKS).

### (5) Restrictions in BRG

#### (a) Notes on setting frequency division register

1. For the initial setting of the register after a reset, at least one bit of waiting period is required to secure the clock stabilization time.

   (Example) One bit period when DL = 2

   3.68 (MHz) × 1/2 × 1/16 = 0.115 (MHz) → 8695 (ns)

2. For modifying the register value after the setting stated in <1> above, at least one bit of waiting period at the maximum bit rate (DL = '65535') is required.

   The HSCIF registers and BRG registers should be set as the following table:

- Asynchronous mode (SC_CLK external input)

| HSCIF | | BRG | |
|---|---|---|---|
| **Register Name** | **Setting Value** | **Register Name** | **Setting Value** |
| HSSCR.CKE[1:0] | B'10 | CKS | H'0000 |
| | | DL | H'1 to H'FFFF |

- Asynchronous mode (HSCK external input)

| HSCIF | | BRG | |
|---|---|---|---|
| **Register Name** | **Setting Value** | **Register Name** | **Setting Value** |
| HSSCR.CKE[1:0] | B'10 | CKS | H'8000 |
| | | DL | Don't care |

- Asynchronous mode (SC_CLK internal input)

| HSCIF | | BRG | |
|---|---|---|---|
| **Register Name** | **Setting Value** | **Register Name** | **Setting Value** |
| HSSCR.CKE[1:0] | B'10 | CKS | H'4000 |
| | | DL | H'1 to H'FFFF |

3. The register settings for the baud rate generator for external clock should be made before starting initialization of the HSCIF.

### 106.3.4 HSCIF Interrupt Sources and the DMAC

If the DMAC is used for transmission/reception, set and enable the DMAC before setting the HSCIF.

**Transmission interrupts and DMA transfer:**

If the TDFE/TEND flag in HSFSR is set to 1 when the TDFE/TEND interrupt is enabled by the TIE bit, a TDFE/TEND interrupt request and a transmit-FIFO-data-empty DMA transfer request will occur. If the TDFE/TEND flag is set to 1 when TDFE/TEND interrupt is disabled by the TIE bit, only the transmit-FIFO-data-empty DMA transfer request will occur. (A transmit-FIFO-data-empty DMA transfer request is generated when the TDFE flag is set while TEIE is 0, or when the TEND flag is set while TEIE is 1. DMA transfer requests are not affected by the TEIE bit.)

When TDFE/TEND interrupt requests are enabled, the interrupt requests are cleared by the DMAC regardless of the interrupt handling program.

**Reception interrupts and DMA transfer:**

If the RDF/DR flag in HSFSR is set to 1 when RDF/DR interrupt is enabled by the RIE bit, an RDF/DR interrupt request occurs. If the RDF/DR flag is set to 1, a receive-FIFO-data-full DMA transfer request occurs. If the RDF/DR flag is set to 1 when RDF/DR interrupt is disabled by the RIE bit, and only a receive-FIFO-data-full DMA transfer request occurs and DMAC can be activated to perform data transfer.

Setting the RIE bit in HSSCR to 0 and the REIE bit to 1 generates the ER/BRK/ORER interrupt requests without generating RDF/DR interrupt requests. When the BRK flag in HSFSR or the ORER flag in HSLSR is set to 1, BRK/ORER interrupt requests occur.

If the TO flag is set to 1 in HSLSR when TO interrupts are enabled by the TOIE bit, TO interrupt requests occur.

When DR/TO interrupt requests are enabled to be issued, interrupt requests generated by the DR flag are cleared by the DMAC regardless of the interrupt handling program, however, those generated by the TO flag are not cleared by the DMAC. Therefore, the TO flag interrupt requests need to be cleared with the interrupt handling program. (The DR and TO flags are set at the same time, but cleared separately.)

**Table 106.8 HSCIF Interrupt Sources**

| Interrupt Source | DMAC Activation |
|---|---|
| Interrupts generated by receive error flag (ER) | Disabled |
| Interrupts generated by receive-FIFO-data-full (RDF), receive-data-ready (DR) or timeout (TO) | Enabled |
| Interrupts generated by break (BRK) or overrun error (ORER) | Disabled |
| Interrupts generated by transmit FIFO data empty (TDFE) | Enabled |

## 106.4 Usage Notes

### (1) Break detection and operation

Break signals can also be detected by reading the HRX pin value directly when a framing error (FER) is detected. In the break state, the input values from the HRX pin are all 0s. So, the parity error flag (PER) may be set after the FER flag is set to 1.

Although the HSCIF stops receive data transfer to HSFRDR after detecting a break, it continues data reception.

### (2) Sending a break signal

The input/output condition and level of the HTX pin are determined by the SPB2IO and SPB2DT bits in HSSPTR. This enables to send a break signal.

The pin does not function as the HTX pin from the initialization of the serial transmitter to setting of the TE bit (enabling transmission). In this period, the marked state is substituted by the value of the SPB2DT bit. Therefore, the SPB2IO and SPB2DT bits should be set to 1 (designating output and high level) beforehand.

To send a break signal during serial transmission, clear the SPB2DT bit to 0 (low level), and then clear the TE bit to 0 (halting transmission). When the TE bit is cleared, the transmitter is initialized regardless of the current transmission state, and the HTX pin outputs 0.

### (3) Data sampling timing and reception margin in asynchronous mode

The HSCIF operates on the base clock with a frequency multiplied by the number which is set as a sampling rate for the bit rate.

In reception, the HSCIF performs the internal synchronization by sampling the falling edge of the start bit using the base clock. In addition, the HSCIF takes receive data at the rising edge of the S/2 pulse (when S is an even number) or (S+1)/2 pulse (when S is an odd number) on the base clock when sampling rate is S.

Figure 106.12 shows the timing of this operation when S = 16.

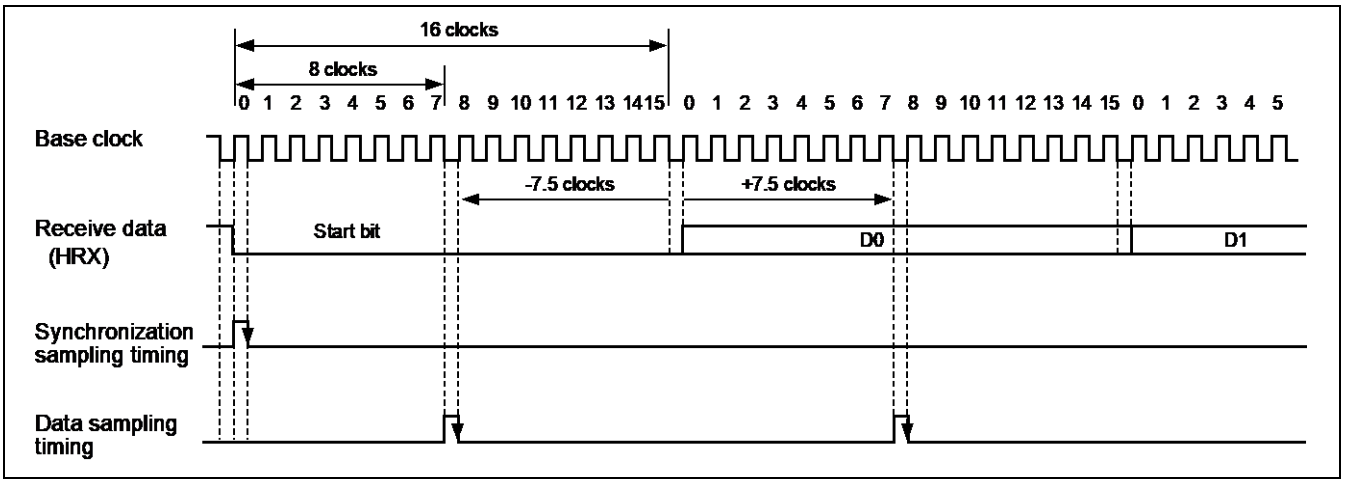

**Figure 106.12 Timing Chart of Receive Data Sampling**

The reception margin in asynchronous mode is given by formula (1).

$$M = \left| (0.5 - \frac{1}{2N}) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F) \right| \times 100\% \quad \cdots\cdots \text{Expression (1)}$$

M: Receive margin (%)

N: Ratio of bit rate to clock (N = sampling rate)

D: Clock duty (D = 0 to 1.0)

L: Frame length (L = 9 to 12)

F: Absolute value of clock frequency deviation

Assuming F = 0, D = 0.5 and sampling rate = 16 for expression (1), the reception margin obtained with expression (2) is 46.875% as shown below:

Assuming D = 0.5 and F = 0

$$M = (0.5 - 1/(2 \times 16)) \times 100\%$$

$$= 46.875\% \ldots\ldots \text{expression (2)}$$

This is a theoretical value. A reasonable margin allowed in system designs is 20% to 30%.

**(4) Reception margin and baud rate error**

The value of 46.875% obtained by the above expression (2) indicates the reception margin when the baud rate error is 0 (F = 0). If there is no error in the reception and transmission baud rates, reception is possible even with misalignment of approx. 1/2 bit. If there is an error in the reception and transmission baud rates, the errors are accumulated up to the stop bit reception, which reduces the reception margin. The allowable baud rate error can be obtained by modifying the F in expression (1). When D = 0.5:

$$F = \{(15/32 - M)/(L - 0.5)\} \times 100\ (\%) \ldots\ldots \text{expression (3)}$$

By using expression (3), the relationship between the allowable error and reception margin with the frame length = 12 can be summarized as follows:

| Allowed Error (%) | Reception Margin (%) |
|---|---|
| 4.07 | 0 |
| 3.64 | 5 |
| 3.20 | 10 |
| 2.33 | 20 |
| 1.46 | 30 |

**(5) Usage method of SRHP bits**

The method for using the SRHP bits in the sampling rate register is described below.

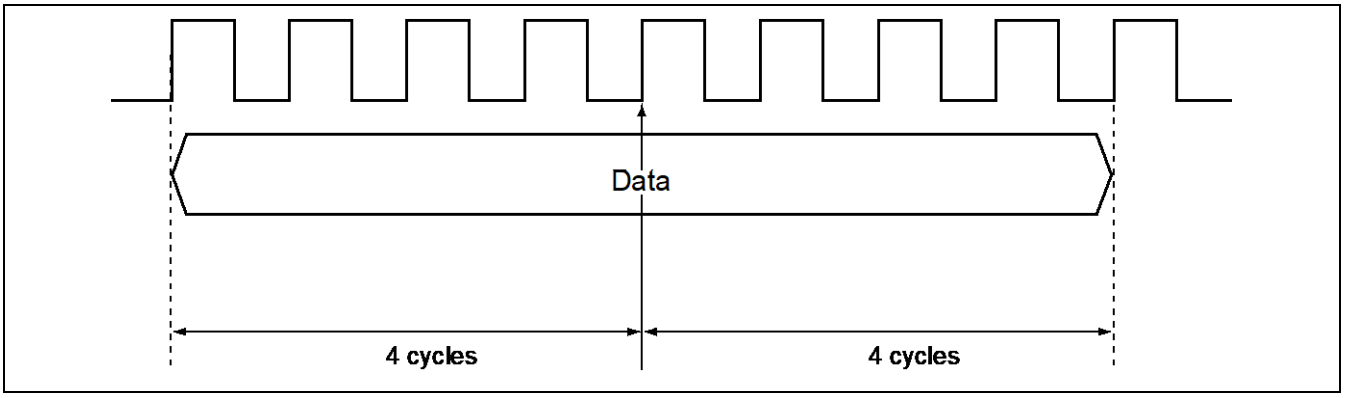

**Figure 106.13 Sampling with Invalid SRHP Bits**

Figure 106.13 shows a sampling example in which the SRHP bits are invalid (sampling rate = 8). In this case, the HSCIF samples data at half of the sampling rate, which is at the rising edge of the fourth pulse of the clock. This allows a setup margin and hold margin of 50% each to be provided.

However, if the ratio between the baud rate and sampling clock is not 1:1, either the setup margin or hold margin is omitted in data reception of a single frame. If the setup margin is omitted, the hold margin increases. On the other hand, if the hold margin is omitted, the setup margin increases. Figure 106.14 and Figure 106.15 show examples.

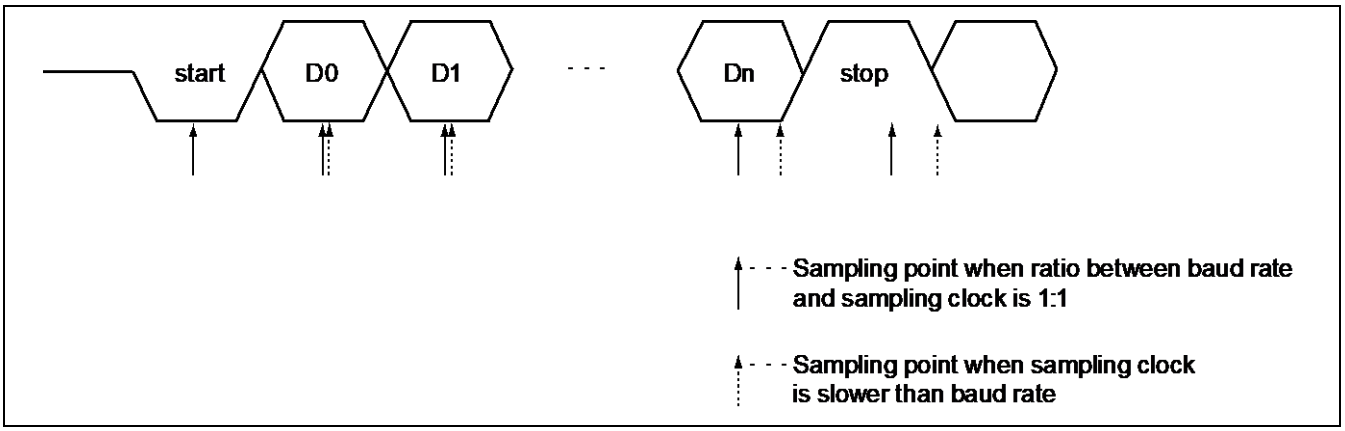

**Figure 106.14 Sampling Point with Sampling Clock Slower Than Baud Rate**

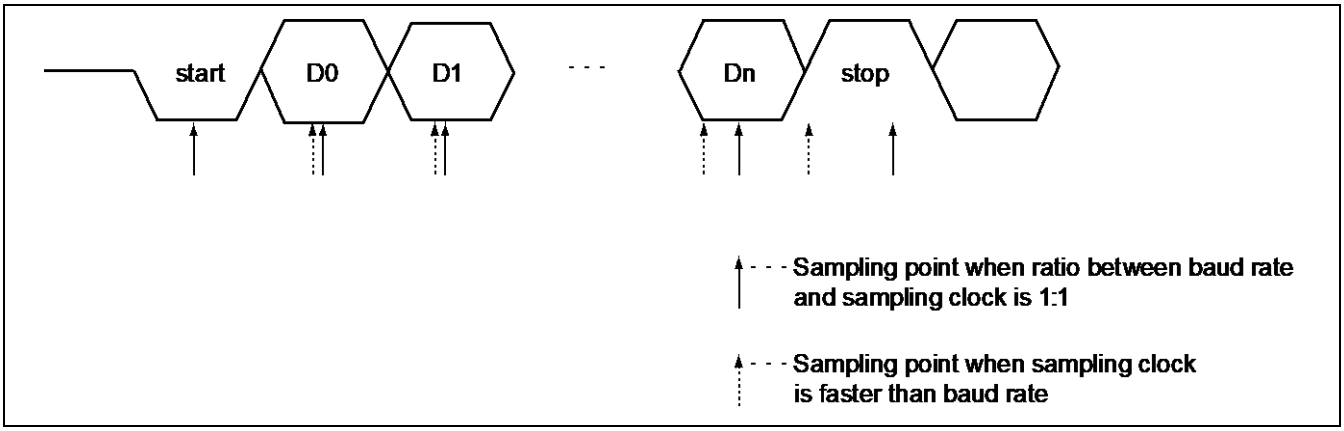

**Figure 106.15 Sampling Point with Sampling Clock Faster Than Baud Rate**

The ratio between the baud rate and sampling clock can be used to determine which margin among the setup margin and hold margin is to be omitted and which is to be increased. Based on this, the margin within a single frame can be increased by intentionally increasing the margin to be omitted in advance. The sampling point can be moved by setting a value in the SRHP bits. Figure 106.16 shows an example.

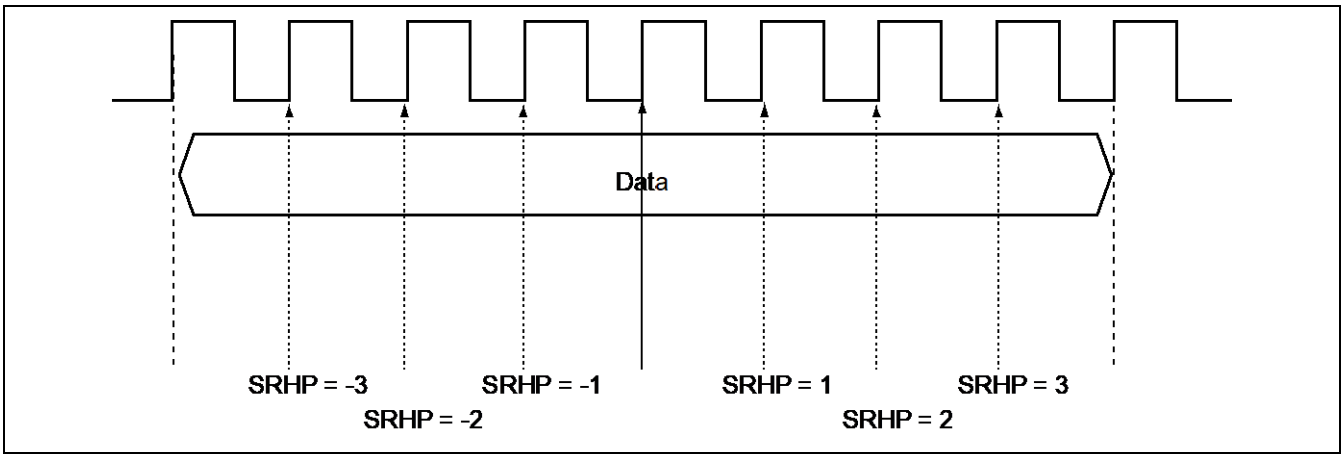

**Figure 106.16 Sampling Point Moved by SRHP Bits**

**(6) Sampling rate and bit rate settings and respective margin**

To set the baud rate in the HSCIF, in addition to setting the clock division ratio, the two registers, bit rate register (HSBRR) and sampling rate register (HSSRR), need to be set. These registers must be set so that the margin calculated by expression (1) in section 106.4 (3) will be a sufficient value.

The bit rate error is small when the value obtained by dividing the divided clock frequency used in the HSCIF with the sampling rate is near the desired baud rate. If there are many combinations of bit rate and sampling rate with the same bit rate error, choosing a combination with a large sampling rate provides a large margin. This is because when the bit rate error is constant in expression (1) in section 106.4 (3), that is, when the "absolute value of clock frequency deviation (F)" is constant, the margin (M) increases in accordance with the sampling rate (N).

If the sampling rate is made larger in a combination of bit rate and sampling rate with different bit rate errors, the bit rate error is increased. Accordingly, the "absolute value of clock frequency deviation (F)" on the right side in expression (1) in section 106.4 (3) gets larger and the margin (M) smaller.

Refer to the following procedure when selecting the sampling rate and bit rate settings.

1. Obtain the bit rate with the smallest bit rate error for sampling rates from 8 to 32.

2. Using expression (1) in section 106.4 (3), calculate the margin for each combination of sampling rate and bit rate which was obtained in step 1.

3. Select the combination with the largest margin among the combinations of sampling rate and bit rate.

## 106.5 Safety Mechanisms

HSCIF module has no mechanism of FuSa.

# 107. I2C Bus Interface (I2C)

## 107.1 Overview

### 107.1.1 Features

Fourth generation R-Car series products have up to four I2C bus interfaces conformant with the Philips Semiconductors (now NXP Semiconductors) I2C bus (Inter-IC bus) specification. However, the configuration of registers that control the I2C bus differs partly from the NXP Semiconductors register configuration. The I2C bus interface has the following features. Note that "module clock (MOD_CLK)" refers to the peripheral module clock in this section.

Module clock is S0D6_PERφ for all channels.

- The I2C interfaces support the I2C bus specification from NXP Semiconductors
- Multi-master compatible
- Seven- or ten-bit address compatible master
- Seven-bit slave address
- Fast mode compatible
- Variable clock frequencies
- DMA transfer support for Master/Slave Transmission Master/Slave Reception.
- Supporting Fast mode+

Figure 107.1 shows a block diagram of the I2C bus interface.

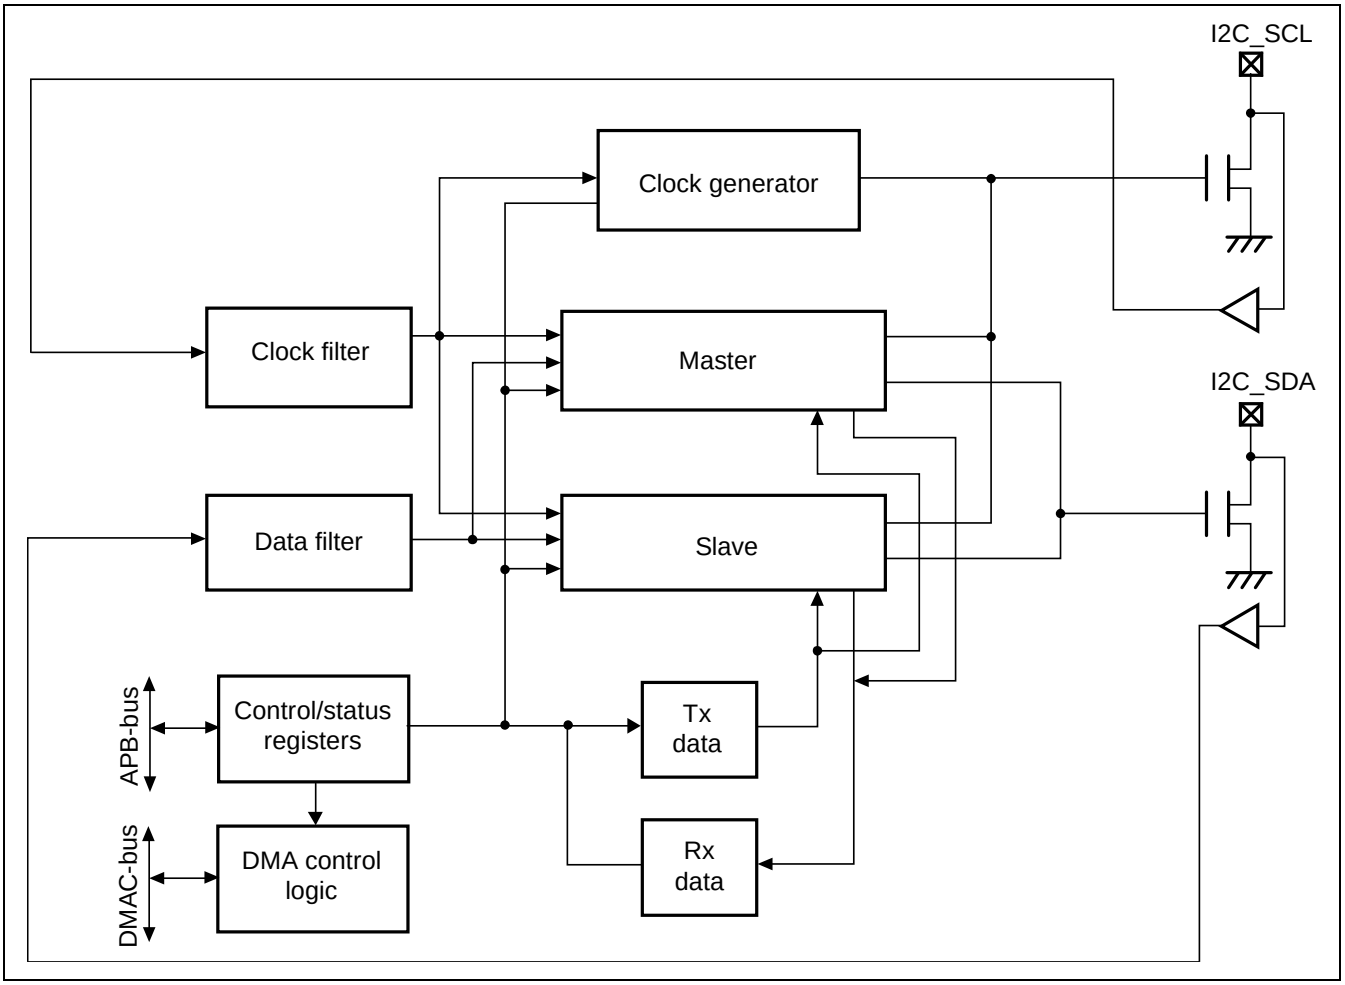

**Figure 107.1 Block Diagram of I2C Bus Interface**

### 107.1.2 External Pins

Table 107.1 lists the pins used in the I2C bus interface.

**Table 107.1 I2C Bus Interface**

| Channel Number | Pin Name | I/O | Function | Output Buffer Type*1 |
|---|---|---|---|---|
| 0 | SCL0 | I/O | SCL: | OD |
| | SDA0 | | I2C serial clock input/output pin | |
| 1 | SCL1 | | SDA: | OD |
| | SDA1 | | I2C serial data input/output pin | |
| 2 | SCL2 | | | OD |
| | SDA2 | | | |
| 3 | SCL3 | | | OD |
| | SDA3 | | | |

Note:1 Output buffer type: "OD" is open drain buffer. OD assigned channel pins are selected 1.8 V I/O or 3.3V I/O by 7.2.7 POWER Condition Control Register (POCn) register. (Not 3.3V tolerant IO cell)

The I2C buffer in this LSI is not compliant with the 5V-input. When turning off the I/O power source of this LSI, turn off the power source of the pull-up resistors connected to the I2C pins.

### 107.1.3 Register Configuration

(include Safety Mechanism related registers)

The base address for each channel of registers of the I2C bus interface is as follows:

- I2C0: H'E650 0000
- I2C1: H'E650 8000
- I2C2: H'E651 0000
- I2C3: H'E66D 0000

Each channel of the I2C bus interface has the registers below.

**Table 107.2 Register Configuration**

| Register Name | Abbreviation | R/W | Offset Address from Base Address | Initial Value | Size |
|---|---|---|---|---|---|
| Slave control register | ICSCR | R/W | H'00 | H'0000 0000 | 32 |
| Master control register | ICMCR | R/W | H'04 | H'0000 0000*3 | 32 |
| Slave status register | ICSSR | R/(W)*1 | H'08 | H'0000 0000 | 32 |
| Master status register | ICMSR | R/(W)*2 | H'0C | H'0000 0000 | 32 |
| Slave interrupt enable register | ICSIER | R/W | H'10 | H'0000 0000 | 32 |
| Master interrupt enable register | ICMIER | R/W | H'14 | H'0000 0000 | 32 |
| Clock control register | ICCCR | R/W | H'18 | H'0000 0000 | 32 |
| Slave address register | ICSAR | R/W | H'1C | H'0000 0000 | 32 |
| Master address register | ICMAR | R/W | H'20 | H'0000 0000 | 32 |
| Receive data register | ICRXD | R | H'24 | H'0000 0000 | 32 |
| Transmit data register | ICTXD | W | H'24 | H'0000 0000 | 32 |
| Clock control register 2 | ICCCR2 | R/W | H'28 | H'0000 0000 | 32 |
| SCL mask control register | ICMPR | R/W | H'2C | H'0000 0000 | 32 |
| SCL high control register | ICHPR | R/W | H'30 | H'0000 0000 | 32 |
| SCL low control register | ICLPR | R/W | H'34 | H'0000 0000 | 32 |
| DMA enable register | ICDMAER | R/W | H'3C | H'0000 0000 | 32 |
| First bit setup cycle register | ICFBSCR | R/W | H'38 | H'0000 0004 | 32 |

Notes: Do not write to any addresses other than listed above. Operations cannot be guaranteed if writing is attempted.
Values read from addresses other than those listed above are undefined.
Although the actual register name and its abbreviation have channel number as a suffix respectively, it is omitted in this section (the number "2" of ICCCR2 is not channel number).
Operation cannot be guaranteed if the register is not accessed as a longword (32bit)

1. Only 0 can be written to bits 4 to 0 to clear the flags.
2. Only 0 can be written to bits 6 to 0 to clear the flags.
3. Bits 30, 29, 22, 21, 14, 13, 6, and 5 are undefined.

## 107.2 Register Description

Registers in the I2C are allocated to and arranged in the address space of the internal bus.

Legend for Register Description

Initial value: Register value after a reset

—: Undefined value

R/W: Readable/writable. The written value can be read.

R/WC0: Readable/writable. Writing 0 initializes the bit. Writing 1 is ignored.

R/WC1: Readable/writable. Writing 1 initializes the bit. Writing 0 is ignored.

R: Read-only. When the bit is reserved, the write value should always be 0. Writing 1 to these bits can cause a malfunction of I2C.

—/W: Write-only. The read value is undefined.

### 107.2.1 Slave Control Register (ICSCR)

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 31 to 8 | □ | All 0 | R | Reserved<br>When these bits are read, bits 31 to 24, 23 to 16, and 15 to 8 reflect the values of bits 7 to 0. The write value should always be 0. |
| 7 to 5 | □ | All 0 | R | Reserved<br>The write value should always be 0. |
| 4 | SCSS | 0 | R/W | Slave Clock Stretch Select<br>This bit is used to select the timing of Clock Stretch.<br>0: Clock Stretch is in front of ACK/NACK<br>1: Clock Stretch is next to ACK/NACK |
| 3 | SDBS | 0 | R/W | Slave Data Buffer Select<br>This bit is used to select the data buffer. Select the single-buffer mode supported in this module.<br>When this bit is set to 1, the single-buffer mode is selected. SCL will be held low from the timing when the receive data register acquires the data packet until the SDR flag is cleared.<br>0: Setting prohibited<br>1: Single-buffer mode |
| 2 | SIE | 0 | R/W | Slave Interface Enable<br>This bit must be set for the slave operation. If this bit is low, the slave interface is reset. |
| 1 | GCAE | 0 | R/W | General Call Acknowledgement Enable<br>When slave devices are to issue an acknowledgement in response to a general call address sent from a master, this bit must be set to 1. |
| 0 | FNA | 0 | R/W | Forced Non Acknowledgement<br>In the slave receive mode, the level of this bit is sent to the transmitting device as the acknowledge signal. This bit is set to 0 during the period that the data packet is being received, and set to 1 on completion of data reception.<br>Forced non acknowledgement is returned to the master during slave reception.<br>When the slave has received the last byte of data in a data packet, the slave communicates with the master by sending a NACK, meaning that the acknowledgement is not driven. The master issues a stop on the bus after receiving a NACK. The setting of this bit does not affect the acknowledgement of the slave address. |

### 107.2.2 Slave Status Register (ICSSR)

Bits 0 to 4 among the status bits in the slave status register are cleared by writing 0 to the respective status bit positions. The individual bits are held 1 until 0 is written to (other than the GCAR and STM bits).

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | GCAR | STM | SSR | SDE | SDT | SDR | SAR |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R/W* | R/W* | R/W* | R/W* | R/W* |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 31 to 8 | — | All 0 | R | Reserved<br>When these bits are read, bits 31 to 24, 23 to 16, and 15 to 8 reflect the values of bits 7 to 0. The write value should always be 0. |
| 7 | — | 0 | R | Reserved<br>The write value should always be 0. |
| 6 | GCAR | 0 | R | General Call Address Received<br>Indicates that the address received from the bus is a general call address (H'00). This status bit does not cause an interrupt.<br>This bit is automatically cleared by hardware when the SIE bit (bit 2 in the slave control register) is set to 0 or when the SSR bit (bit 4 in this register) is set to 1. |
| 5 | STM | 0 | R | Slave Transmit Mode<br>Indicates whether the current slave transmit mode is read or write. When this bit is set to 0, the mode is write (slave reception). When this bit is set to 1, the mode is read (slave transmission). This status bit does not cause an interrupt.<br>This bit is automatically cleared by hardware when the SIE bit (bit 2 in the slave control register) is set to 0 or when the SSR bit (bit 4 in the slave status register) is set to 1. |
| 4 | SSR | 0 | R/W* | Slave Stop Received<br>A stop condition has been output on the bus. This status bit becomes active after the rising edge of SDA during reception of a stop bit. |
| 3 | SDE | 0 | R/W* | Slave Data Empty<br>Indicates that data to be transmitted has been loaded into the shift register. At the start of byte data transmission, the contents of the ICTXD register are loaded into a shift register ready for outputting data on the bus. This status bit indicates that data has been loaded and the ICTXD register is again ready for further data. This status bit becomes active on the falling edge of SCL before reception of the first data bit.<br>- When bit SDE = 1 & bit TSDMAE = 0, the interrupt SDE is issued to CPU, so the transmit data register is to accept further data.<br>- When bit SDE = 1 & bit TSDMAE = 1, enable DMA transfer request to DMAC.<br>During the single-buffer mode, this bit must be reset every time new data has been written to ICTXD. If not, the slave will hold SCL low after the current data transfer has finished to stop the bus.<br>During DMA transmit mode, the SDE bit is also set after data is loaded into the shift register. In this case, this bit is cleared by DMA logic control. This mechanism to assure the continuous data transfer without software control. For the last byte data transmitted, this bit is cleared by software. |
| 2 | SDT | 0 | R/W* | Slave Data Transmitted<br>A byte of data has been transmitted to the bus. This bit becomes active after the falling edge of SCL during reception of the last data bit. |
| 1 | SDR | 0 | R/W* | Slave Data Received<br>A byte of data has been received from the bus and is ready for reading from the receive data register. This bit becomes active after the falling edge of SCL during reception of the last data bit. During the single-buffer mode, this bit must be reset after data has been read from the ICRXD register.<br>- When bit SDR = 1 & bit RSDMAE = 0, the interrupt SDR is issued to CPU, so the transmit data register is to accept further data.<br>- When bit SDR = 1 & bit RSDMAE = 1, enable DMA transfer request to DMAC.<br>When SDBS is set to 1, SCL will be held low from the timing when the receive data register acquires the data packet until the SDR flag is cleared.<br>During DMA receive mode, the SDR bit is also set after data is received into RXD register. In this case, this bit is cleared by DMA logic control. This mechanism to assure the continuous data transfer without software control. |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 0 | SAR | 0 | R/W* | Slave Address Received<br>Indicates that the slave has recognized its own address on the bus (defined by the contents of the slave address register). If the general call acknowledgement enable bit is enabled in the slave control register, then this status bit is also set to 1 even if the address on the bus is a general call address. In this case, the GCAR bit in this register is used to determine whether or not the address is a general call address. The STM bit indicates whether the access is read (high) or write (low). This status becomes active after the falling edge of SCL during reception of the last address bit. The slave holds the SCL signal low from the start of the ACK phase until the software resets this status bit. |

Note: * This bit can be read from or written to. Writing 0 clears this bit to 0 and writing 1 is ignored.

### 107.2.3 Slave Interrupt Enable Register (ICSIER)

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 31 to 8 | — | All 0 | R | Reserved<br>When these bits are read, bits 31 to 24, 23 to 16, and 15 to 8 reflect the values of bits 7 to 0. The write value should always be 0. |
| 7 to 5 | — | All 0 | R | Reserved<br>The write value should always be 0. |
| 4 | SSRE | 0 | R/W | Slave Stop Received Interrupt Enable<br>0: Disables the SSR interrupt.<br>1: Enables the SSR interrupt. |
| 3 | SDEE | 0 | R/W | Slave Data Empty Interrupt Enable<br>0: Disables the SDE interrupt.<br>1: Enables the SDE interrupt. |
| 2 | SDTE | 0 | R/W | Slave Data Transmitted Interrupt Enable<br>0: Disables the SDT interrupt.<br>1: Enables the SDT interrupt. |
| 1 | SDRE | 0 | R/W | Slave Data Received Interrupt Enable<br>0: Disables the SDR interrupt.<br>1: Enables the SDR interrupt. |
| 0 | SARE | 0 | R/W | Slave Address Received Interrupt Enable<br>0: Disables the SAR interrupt.<br>1: Enables the SAR interrupt. |

### 107.2.4 Slave Address Register (ICSAR)

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | SADD0_6 | SADD0_5 | SADD0_4 | SADD0_3 | SADD0_2 | SADD0_1 | SADD0_0 |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 31 to 8 | — | All 0 | R | Reserved<br>When these bits are read, bits 31 to 24, 23 to 16, and 15 to 8 reflect the values of bits 7 to 0. The write value should always be 0. |
| 7 | — | 0 | R | Reserved<br>The write value should always be 0. |
| 6 to 0 | SADD0_6 to SADD0_0 | All 0 | R/W | Slave Address<br>This is the unique 7-bit address allocated to the slave on the I2C bus. The slave interface compares this address with the first seven bits transmitted as the slave address, at the beginning of a data packet transmission. |

### 107.2.5 Master Control Register (ICMCR)

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Initial value: | 0 | — | — | 0 | 0 | 0 | 0 | 0 | 0 | — | — | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | MDBS | FSCL | FSDA | OBPC | MIE | TSBE | FSB | ESG |
| Initial value: | 0 | — | — | 0 | 0 | 0 | 0 | 0 | 0 | — | — | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 31 to 8 | — | All 0, except bits 30, 29, 22, 21, 14, and 13 in which case, initial value is undefined. | R | Reserved<br>When these bits are read, bits 31 to 24, 23 to 16, and 15 to 8 reflect the values of bits 7 to 0. The write value should always be 0. |
| 7 | MDBS | 0 | R/W | Master Data Buffer Select<br>This bit is used to select the data buffer mode. Select the single-buffer mode supported in this module. When this bit is set to 1, the single-buffer mode is selected. SCL will be held low from the timing when the receive data register acquires the data packet until the MDR flag is cleared.<br>0: Setting prohibited<br>1: Single-buffer mode |
| 6 | FSCL | — | R/W | Forced SCL<br>This bit controls the status of the I2C_SCL pin (reading reflects the current status of the I2C_SCL pin). When the OBPC bit is set, this bit directly controls the SCL line on the bus.<br>During a read cycle, the level on this bit (which includes the reset level) will change depending on the level on I2C_SCL since it directly reflects the level on the I2C_SCL. |
| 5 | FSDA | — | R/W | Forced SDA<br>This bit controls the status of the I2C_SDA pin (reading reflects the busy status level on the I2C bus). When the OBPC bit is set, then this bit directly controls the SDA line on the bus.<br>During a read cycle, the level on this bit (which includes the reset level) will show the busy status of the I2C bus (1 for busy; 0 for not busy). |
| 4 | OBPC | 0 | R/W | Override Bus Pin Control<br>When this bit is set to 1, the FSDA and FSCL bits in this register control SDA and SCL directly. |
| 3 | MIE | 0 | R/W | Master Interface Enable<br>When this bit is set to 1, the master interface is enabled.<br>The master interface is disabled when this interface loses in arbitration of bus mastership even MIE bit indicates 1. If 0 is not subsequently written to the bit, the master interface is restored on detection of a STOP condition on the I2C bus. Regarding the state following a loss in arbitration of bus mastership, see the description of the MAL bit in ICMSR. |
| 2 | TSBE | 0 | R/W | Start Byte Transmission Enable<br>The write value for this bit should always be 0. |
| 1 | FSB | 0 | R/W | Forced Stop onto the Bus<br>When this bit is set to 1, the master transmits a STOP condition on the bus at the end of the current transfer. If ESG is also set, the master immediately transmits a START condition and begins transmitting a new data packet. If ESG is not set, the master enters the idle state. |
| 0 | ESG | 0 | R/W | Enable Start Generation<br>When this bit is set to 1, the master starts transmission of a data packet. If the bus is idle when ESG is set, the master transmits a START condition on the bus and then transmits the slave address. If the master is transferring data when ESG is set, at the end of that data byte transfer, the master transmits a repeated START condition before transmitting the slave address. When transmitting a data packet, the software must reset this bit when the slave address has been transmitted, otherwise a repeated START condition is transmitted after every transmission is completed. |

### 107.2.6 Master Status Register (ICMSR)

The status bits (bits 0 to 6) in the master status register are cleared by writing 0 to the respective status bit positions. The individual status bits are held 1 until a reset by writing 0 to the appropriate bit position.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | — | — | MNR | MAL | MST | MDE | MDT | MDR | MAT |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 31 to 8 | — | All 0 | R | Reserved<br>When these bits are read, bits 31 to 24, 23 to 16, and 15 to 8 reflect the values of bits 7 to 0. The write value should always be 0. |
| 7 | — | 0 | R | Reserved<br>The write value should always be 0 |
| 6 | MNR | 0 | R/W* | Master NACK Received<br>When this bit is set to 1, this bit indicates that the master has received a NACK response (the SDA line is high during the acknowledge cycle on the bus) to either an address or data transmission. **<br>To restart the address transmission from idle state on Master, this bit must be cleared. |
| 5 | MAL | 0 | R/W* | Master Arbitration Lost<br>In a multi-master system, when this bit is set to 1, it indicates that the master has lost arbitration to other masters on the bus.<br>At this point, the master interface is disabled then Master enters the idle state again. |
| 4 | MST | 0 | R/W* | Master Stop Transmitted<br>When this bit is set to 1, it indicates that the master has sent a STOP condition on the bus. A STOP condition can be sent either as a result of the setting of the forced stop bit in the control register, or from a NACK being received from a slave during a slave receive data packet. |
| 3 | MDE | 0 | R/W* | Master Data Empty<br>At the start of a byte data transmission, the contents of the transmit data register are loaded into a shift register ready for transmitting on the bus. This status bit becomes active:<br>- When bit MDE = 1, MAT = 0 & bit TMDMAE = 0, the interrupt MDE is issued to CPU, so the transmit data register is to accept further data.<br>- When bit MDE = 1, MAT = 0 & bit TMDMAE = 1, enable DMA transfer request to DMAC.<br>During master transmission, the MDE bit is also set at the same time as the MAT bit is set after transmission of the slave address. In this case, you need to clear the MDE and MAT bits after the ICMCR's ESG bit is cleared. The clearing will restart the data transmission.<br>During DMA transmit mode, the MDE bit is also set after data is loaded into the shift register. In this case, this bit is cleared by DMA logic control. This mechanism to assure the continuous data transfer without software control. For the last byte data transmitted, this bit cleared by software. |
| 2 | MDT | 0 | R/W* | Master Data Transmitted<br>Byte data has been sent to the slave on the bus. This status bit becomes active after the falling edge of SCL during reception of the last data bit. |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 1 | MDR | 0 | R/W* | Master Data Received<br>Byte data has been received from the bus and is in the receive data register. This status bit becomes active after the falling edge of SCL during reception of the last data bit. During single-buffer mode, this status bit must be reset after data has been read from the receive data register.<br>- When bit MDR = 1, MAT = 0 & bit RMDMAE = 0, the interrupt MDR is issued to CPU, so the receive data register is to accept further data.<br>- When bit MDR = 1, MAT = 0 & bit RMDMAE = 1, enable DMA transfer request to DMAC.<br>When MDBS is set to 1, SCL will be held low from the timing when the receive data register acquires the data packet until the MDR flag is cleared.<br>During master reception mode, the MDR bit is also set at the same time as the MAT bit is set after transmission of the slave address. In this case, you must clear the MDR and MAT bits after the ICMCR's ESG bit is cleared. Clearing will start the data reception.<br>During DMA receive mode, the MDR bit is also set after data is received into RXD register. In this case, this bit is cleared by DMA logic control. This mechanism to assure the continuous data transfer without software control. |
| 0 | MAT | 0 | R/W* | Master Address Transmitted<br>The master has been transmitted the slave address byte of a data packet. This bit becomes active after the falling edge of SCL during reception of the ACK bit following transmission of the address. |

Note: * This bit can be read from or written to. Writing 0 clears this bit to 0 and writing 1 is ignored.

Note: ** In the case “ICMCR.ESG = 1”, STOP condition will never sent from Master I/F whenever ICMSR.MNR get asserted.

### 107.2.7 Master Interrupt Enable Register (ICMIER)

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 31 to 9 | — | All 0 | R | Reserved<br>The read value is always 0. The write value should always be 0. |
| 8 to 3 | SCGD | All 0 | R/W | SCL Clock Generation Divider<br>When operation is in master mode, the SCL clock is generated from the internal clock by using SCGD as the ratio. This is also the operating clock in slave-mode operation while SCL is being held low to stop the bus after an overflow has occurred. SCGD must be specified in both master and slave modes. The formula expressing the relationship is:<br>Equation 2: SCL rate calculation<br>SCLfreq = I2Cck/(20 + SCGD × 8 + F[(tICF + tr + IntDelay) × I2Cck])<br>I2Cck: I2C internal clock frequency<br>tICF: I2C SCL falling time (depending on external load)<br>tr: I2C SCL rising time (depending on external load)<br>IntDelay: LSI internal delay corresponds to output buffer type.<br>Open drain buffer: 50 ns (typ.), 110 ns (max.)<br>F[n]: n rounded down to an integer<br>Suggested settings for CDF and SCGD for CPU speeds and the two I2C bus speeds are given in Table 107.3. |
